Dedication

To my wife and children: Through and through, thank you for your love and support—in this project, yes—but much more so in the everyday moments of life. You are all amazing.

To everyone who has made sacrifices to help others in the pandemic—healthcare and other frontline workers, absolutely—but also the everyday individuals who have chosen to make small but consistent sacrifices based on physician recommendations and solid scientific data (e.g., wearing masks and taking the vaccine) in order to protect yourselves and protect others: You are heroes, and individuals like you are the best hope for ending the pandemic anytime soon. Thank you for your selflessness, vision, and endurance.

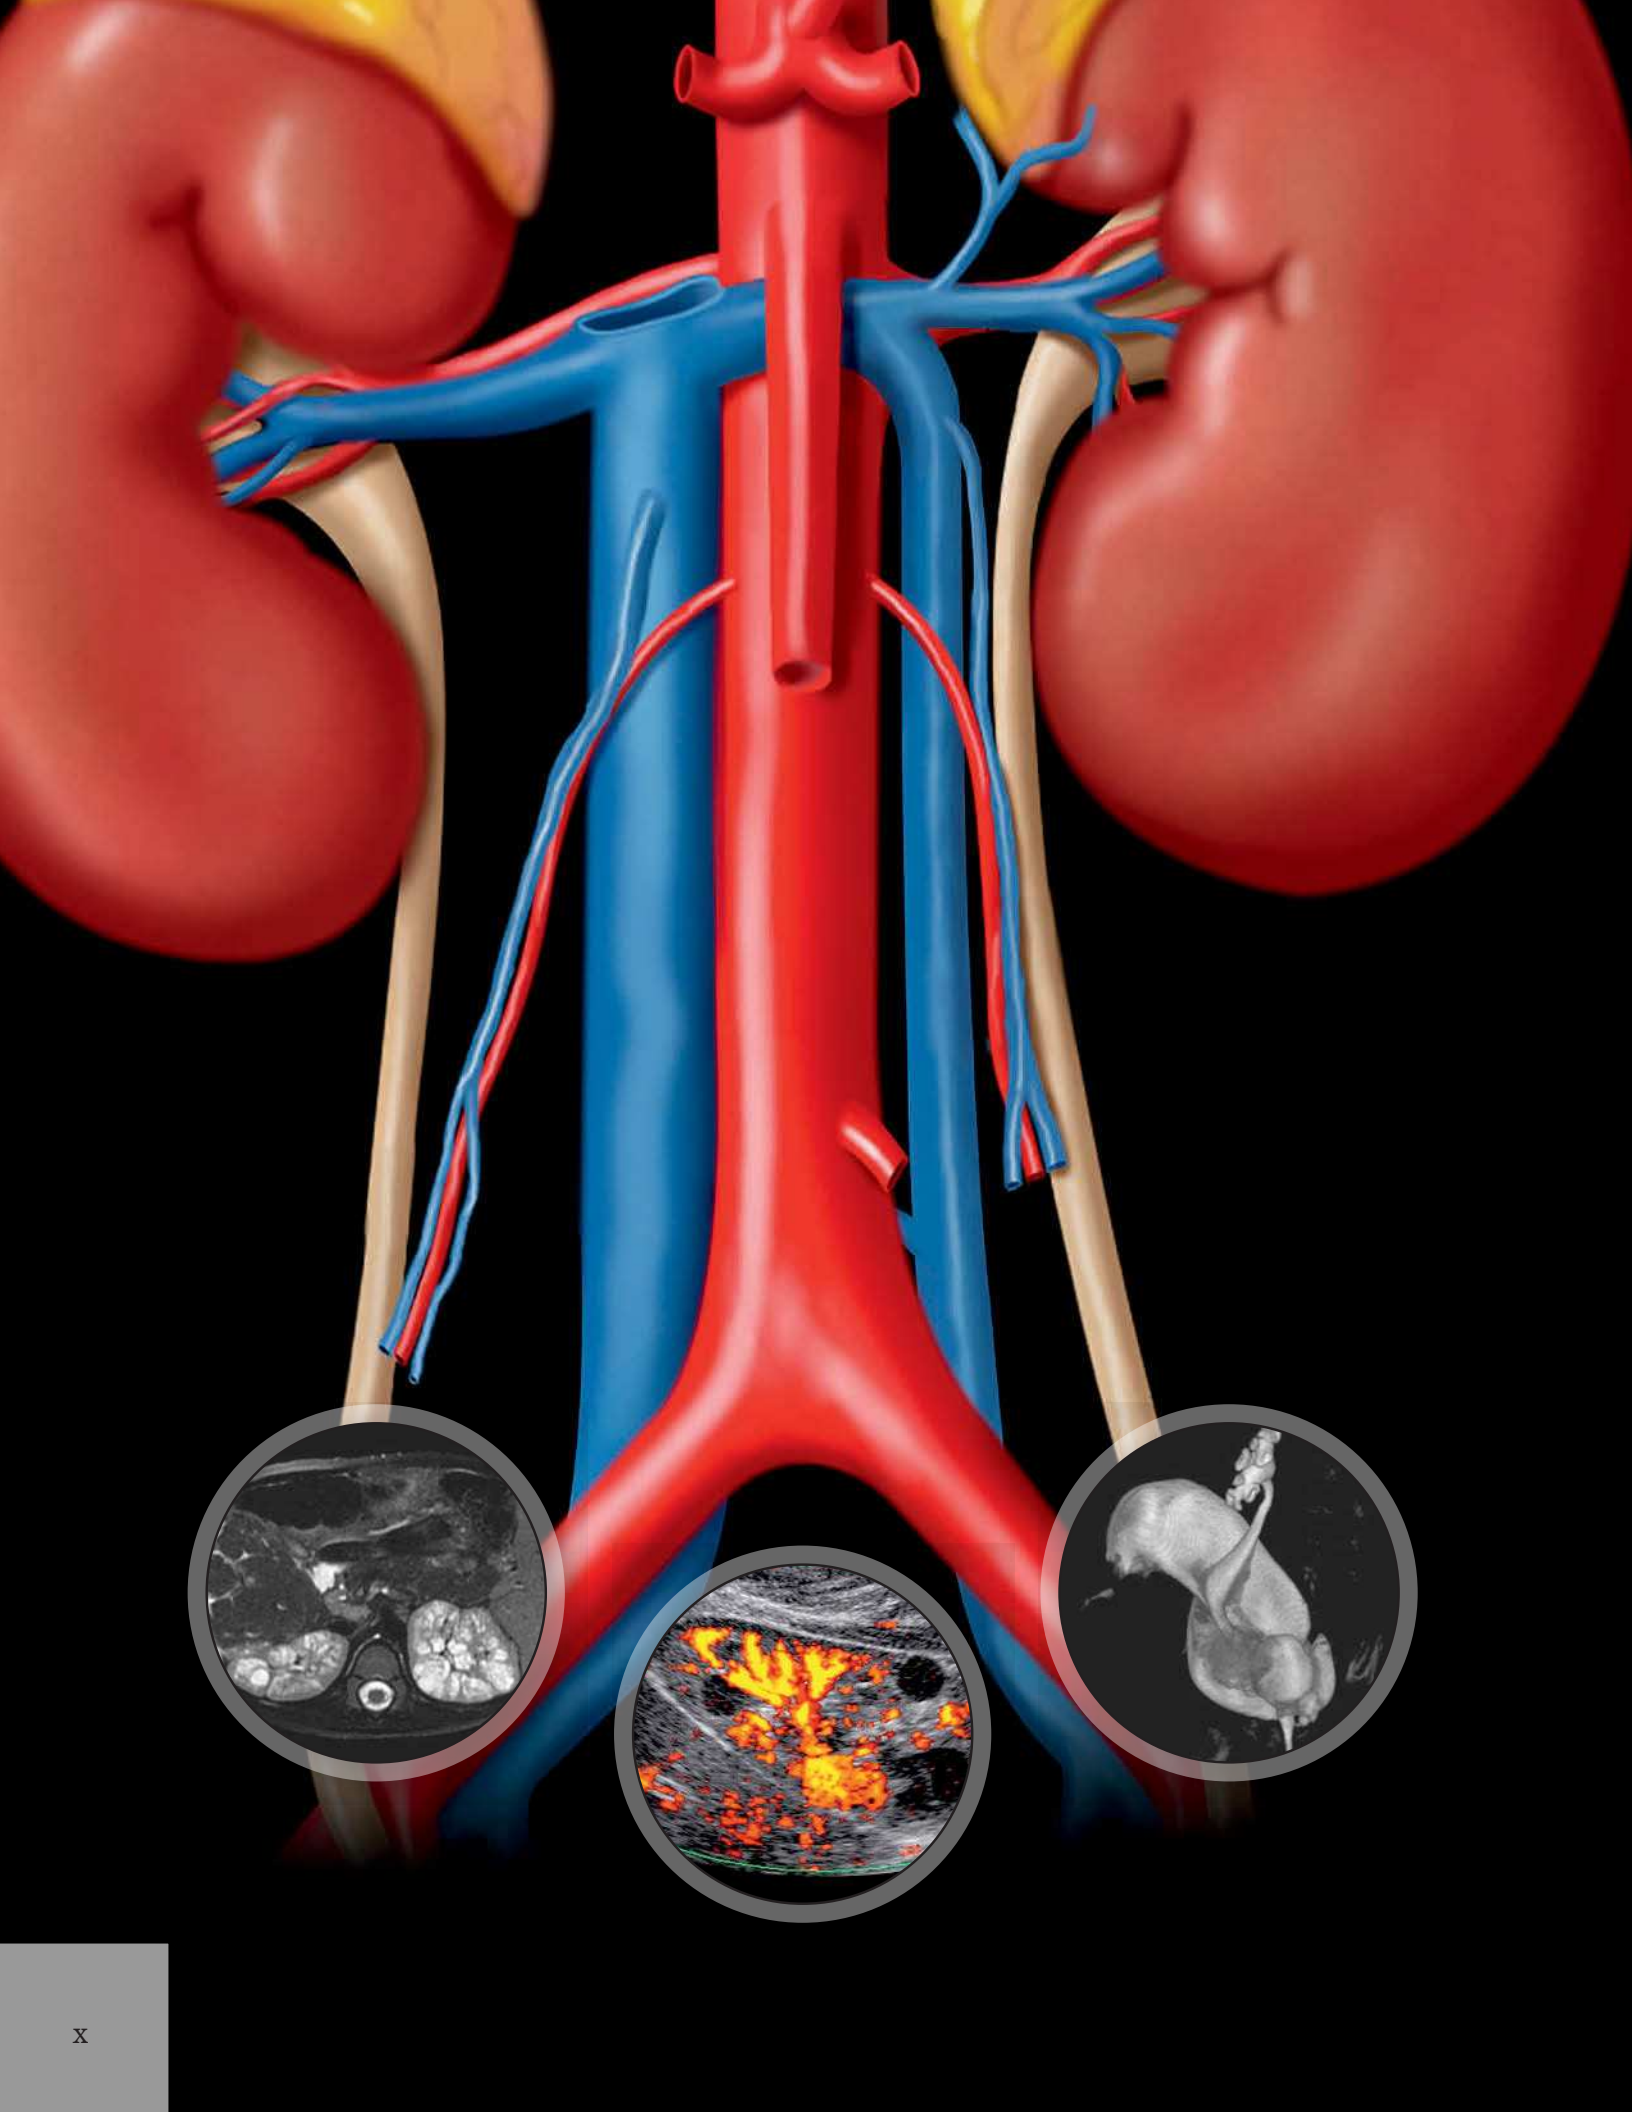
Preface

Welcome to the fourth edition of *Diagnostic Imaging: Pediatrics*. While we have made the expected updates over the third edition of the text (including new images and videos, terminology, disease classifications, and even new chapters), the events of the last 2 years have led to what I hope to be a once-in-a-lifetime occurrence: the opportunity to include a disease that did not exist 5 years ago and of which virtually the entire global population is now aware. I highly doubt that anyone reading this text has been unaffected by the COVID-19 pandemic, directly or indirectly.



So, in that context, I only have a few relevant thoughts.

I hope that each of you is truly *well*. That you've found a consistent way to refresh your soul in this trying time—that you have light, joy, purpose, and engagement—and somehow that wellness spills over into the lives of others—your patients and their families, your colleagues, your family and friends. We all need a little hope and encouragement from each other.

Finally, I must thank all who have worked on this book, especially those who helped carry my burdens when the light was dim. I am greatly indebted to you.

A. Carlson Merrow, Jr., MD, FAAP

TABLE OF CONTENTS

SECTION 1: AIRWAY

4 **Approach to Pediatric Airway**
A. Carlson Merrow, Jr., MD, FAAP

NORMAL DYNAMIC AIRWAY FINDINGS IN INFANTS

6 **Expiratory Buckling of Trachea**
A. Carlson Merrow, Jr., MD, FAAP
7 **Pseudothickening of Retropharyngeal Tissues**
A. Carlson Merrow, Jr., MD, FAAP

NEWBORN AIRWAY OBSTRUCTION

8 **Congenital Nasal Pyriform Aperture Stenosis**
Bernadette L. Koch, MD
10 **Nasolacrimal Duct Mucocele**
Bernadette L. Koch, MD and Surjith Vattoth, MD, FRCR
12 **Choanal Atresia**
Bernadette L. Koch, MD
14 **Lymphatic Malformation, Cervical**
Bernadette L. Koch, MD
16 **Congenital High Airway Obstruction Syndrome**
A. Carlson Merrow, Jr., MD, FAAP
17 **Tracheal Agenesis**
A. Carlson Merrow, Jr., MD, FAAP

INFECTIOUS CAUSES OF AIRWAY COMPROMISE

18 **Epiglottitis**
Michael R. Aquino, MD, MHSc
22 **Croup**
Emily S. Orscheln, MD and A. Carlson Merrow, Jr., MD, FAAP
26 **Bacterial Tracheitis**
A. Carlson Merrow, Jr., MD, FAAP
30 **Retropharyngeal Space Abscess**
Bernadette L. Koch, MD

EXTRINSIC VASCULAR COMPRESSION OF AIRWAY

34 **Double Aortic Arch**
Randy R. Richardson, MD and Mantosh S. Rattan, MD
38 **Pulmonary Sling**
Randy R. Richardson, MD and Mantosh S. Rattan, MD
42 **Innominate Artery Compression Syndrome**
Prakash M. Masand, MD and Randy R. Richardson, MD
44 **Right Arch With Aberrant Left Subclavian Artery**
Randy R. Richardson, MD and Prakash M. Masand, MD

MISCELLANEOUS AIRWAY OBSTRUCTIONS

46 **Infantile Hemangioma, Airway**
Bernadette L. Koch, MD
48 **Tracheobronchomalacia**
Randy R. Richardson, MD and Mantosh S. Rattan, MD

SECTION 2: CHEST

52 **Approach to Pediatric Chest**
Randy R. Richardson, MD and Mantosh S. Rattan, MD

NORMAL DEVELOPMENTAL VARIANTS

56 **Normal Thymus**
Arthur B. Meyers, MD
60 **Palpable Normal Variants of Chest Wall**
A. Carlson Merrow, Jr., MD, FAAP

CONGENITAL LUNG LESIONS

62 **Congenital Pulmonary Airway Malformation**
Hank Baskin, MD
66 **Bronchopulmonary Sequestration**
A. Carlson Merrow, Jr., MD, FAAP
70 **Bronchogenic Cyst**
Emily S. Orscheln, MD and A. Carlson Merrow, Jr., MD, FAAP
74 **Congenital Lobar Overinflation**
Hank Baskin, MD
78 **Bronchial Atresia**
A. Carlson Merrow, Jr., MD, FAAP and Randy R. Richardson, MD

NEONATAL CHEST ISSUES

80 **Esophageal Atresia and Tracheoesophageal Fistula**
Steven J. Kraus, MD
84 **Congenital Diaphragmatic Hernia**
A. Carlson Merrow, Jr., MD, FAAP
88 **Surfactant Deficiency Disease**
Hank Baskin, MD
92 **Neonatal Pneumonia**
Michael R. Aquino, MD, MHSc
94 **Meconium Aspiration Syndrome**
Emily S. Orscheln, MD
96 **Transient Tachypnea of Newborn**
Hank Baskin, MD and Randy R. Richardson, MD
98 **Pulmonary Interstitial Emphysema**
Emily S. Orscheln, MD and A. Carlson Merrow, Jr., MD, FAAP
102 **Neonatal Pneumothorax**
Michael R. Aquino, MD, MHSc

TABLE OF CONTENTS

104 **Chylothorax**
Randy R. Richardson, MD and A. Carlson Merrow, Jr., MD, FAAP
106 **Bronchopulmonary Dysplasia**
Emily S. Orscheln, MD
110 **Umbilical Catheter Positions and Complications**
Emily S. Orscheln, MD and A. Carlson Merrow, Jr., MD, FAAP
112 **Esophageal Intubation**
Michael R. Aquino, MD, MHSc
113 **ECMO Catheters**
Michael R. Aquino, MD, MHSc
114 **PICCs**
Michael R. Aquino, MD, MHSc

CHEST INFECTIONS

116 **Viral Chest Infection**
Michael R. Aquino, MD, MHSc
120 **COVID-19/MIS-C**
Michael R. Aquino, MD, MHSc
124 **Round Pneumonia**
Michael R. Aquino, MD, MHSc
128 **Parapneumonic Effusion and Empyema**
Michael R. Aquino, MD, MHSc
130 **Pneumonia With Cavitary Necrosis**
Michael R. Aquino, MD, MHSc
134 **Fungal Pneumonia in Immunocompromised Children**
Alexander J. Towbin, MD
136 **Papillomatosis**
Alexander J. Towbin, MD

MEDIASTINAL MASSES

140 **Lymphoma**
Alexander J. Towbin, MD
144 **Germ Cell Tumors**
Alexander J. Towbin, MD
148 **Neuroblastoma, Thoracic**
Alexander J. Towbin, MD

PULMONARY MASSES

152 **Pleuropulmonary Blastoma**
Alexander J. Towbin, MD
156 **Pulmonary Arteriovenous Malformation**
Hank Baskin, MD

TRAUMA

158 **Child Abuse, Rib Fractures**
Michael R. Aquino, MD, MHSc
162 **Lung Contusion and Laceration**
Michael R. Aquino, MD, MHSc
166 **Aortic Injury**
Hank Baskin, MD
170 **Pneumomediastinum**
Michael R. Aquino, MD, MHSc

PEDIATRIC INTERSTITIAL LUNG DISEASES

174 **Neuroendocrine Cell Hyperplasia of Infancy**
Mantosh S. Rattan, MD and Randy R. Richardson, MD
176 **Pulmonary Interstitial Glycogenosis**
Randy R. Richardson, MD and Mantosh S. Rattan, MD
178 **Alveolar Growth Abnormality**
Mantosh S. Rattan, MD and Randy R. Richardson, MD
180 **Surfactant Dysfunction Disorders**
Mantosh S. Rattan, MD and Randy R. Richardson, MD
182 **Swyer-James Syndrome**
Hank Baskin, MD
184 **Lymphangioleiomyomatosis**
A. Carlson Merrow, Jr., MD, FAAP
186 **Langerhans Cell Histiocytosis, Pulmonary**
Randy R. Richardson, MD and Mantosh S. Rattan, MD

CHEST WALL ISSUES

188 **Pectus Excavatum**
Mantosh S. Rattan, MD and Randy R. Richardson, MD
190 **Minimally Invasive Pectus Repair Appearance**
Randy R. Richardson, MD and Mantosh S. Rattan, MD
191 **Askin Tumor/Ewing Sarcoma of Chest Wall**
Arthur B. Meyers, MD
192 **Chest Wall Hamartoma**
A. Carlson Merrow, Jr., MD, FAAP

MISCELLANEOUS

194 **Asthma**
Hank Baskin, MD
198 **Bronchial Obstruction**
Hank Baskin, MD
202 **Cystic Fibrosis, Pulmonary**
Randy R. Richardson, MD
206 **Chronic Esophageal Foreign Body**
Randy R. Richardson, MD
208 **Sickle Cell Disease, Acute Chest Syndrome**
Alexander J. Towbin, MD
212 **Kaposiform Lymphangiomatosis**
A. Carlson Merrow, Jr., MD, FAAP
214 **EVALI**
Michael R. Aquino, MD, MHSc

SECTION 3: CARDIAC

218 **Approach to Pediatric Heart**
Randy R. Richardson, MD

CONGENITAL HEART DISEASE

222 **Atrial Septal Defect**
Randy R. Richardson, MD
226 **Ventricular Septal Defect**
Randy R. Richardson, MD
230 **Atrioventricular Septal Defect**
Randy R. Richardson, MD
234 **Patent Ductus Arteriosus**
Randy R. Richardson, MD
238 **Tetralogy of Fallot**
Randy R. Richardson, MD and Ryan A. Moore, MD
242 **Pulmonary Atresia**
Randy R. Richardson, MD
246 **Ebstein Anomaly**
Randy R. Richardson, MD

TABLE OF CONTENTS

250 **D-Transposition of Great Arteries**
Randy R. Richardson, MD
252 **L-Transposition of Great Arteries**
Randy R. Richardson, MD
254 **Tricuspid Atresia**
Randy R. Richardson, MD
256 **Truncus Arteriosus**
Randy R. Richardson, MD
260 **Total Anomalous Pulmonary Venous Return**
Randy R. Richardson, MD
264 **Hypoplastic Left Heart Syndrome**
Ryan A. Moore, MD and Randy R. Richardson, MD
268 **Left Coronary Artery Anomalous Origin**
Randy R. Richardson, MD and Ryan A. Moore, MD
272 **Double-Outlet Right Ventricle**
Randy R. Richardson, MD
274 **Aortic Coarctation**
Randy R. Richardson, MD
278 **Aortic Stenosis**
Randy R. Richardson, MD
282 **Pulmonary Artery Stenosis**
Randy R. Richardson, MD
286 **Scimitar Syndrome**
Randy R. Richardson, MD

SURGICAL PROCEDURES FOR CONGENITAL HEART DISEASE

288 **Glenn Shunt**
Randy R. Richardson, MD and Prakash M. Masand, MD
290 **Fontan Operation**
Randy R. Richardson, MD and Prakash M. Masand, MD
292 **Arterial Switch Procedure**
Randy R. Richardson, MD and Prakash M. Masand, MD
294 **Norwood Procedure**
Randy R. Richardson, MD
296 **Blalock-Taussig Shunt**
Randy R. Richardson, MD and Prakash M. Masand, MD
298 **Amplatzer Occluder Device**
Randy R. Richardson, MD
300 **Sano Shunt**
Randy R. Richardson, MD and Prakash M. Masand, MD

CARDIOMYOPATHIES

302 **Myocarditis**
Randy R. Richardson, MD and Ryan A. Moore, MD
304 **Left Ventricular Noncompaction**
Randy R. Richardson, MD and Ryan A. Moore, MD
306 **Hypertrophic Cardiomyopathy**
Randy R. Richardson, MD and Ryan A. Moore, MD
308 **Duchenne Muscular Dystrophy-Related Cardiomyopathy**
Randy R. Richardson, MD and Ryan A. Moore, MD
310 **Arrhythmogenic Right Ventricular Dysplasia**
Leila Rezai Gharai, MD, John D. Grizzard, MD, and Randy R. Richardson, MD

MISCELLANEOUS

314 **Heterotaxy Syndromes**
Randy R. Richardson, MD and Ryan A. Moore, MD
318 **Rhabdomyoma**
Randy R. Richardson, MD, Ryan A. Moore, MD, and Paula J. Woodward, MD
322 **Kawasaki Disease**
Randy R. Richardson, MD and Ryan A. Moore, MD
326 **Rheumatic Heart Disease**
Randy R. Richardson, MD
328 **Marfan Syndrome**
Randy R. Richardson, MD
330 **Loeys-Dietz Syndrome**
Randy R. Richardson, MD

SECTION 4: GASTROINTESTINAL

334 **Approach to Pediatric Gastrointestinal Tract**
Alexander J. Towbin, MD

NORMAL PEDIATRIC VARIANTS

338 **Normal Variations of Duodenojejunal Junction Position**
Steven J. Kraus, MD
342 **Normal Variations of Cecal Position**
Steven J. Kraus, MD
344 **Age-Related Appearance of Spleen**
Ethan A. Smith, MD

NEONATAL UPPER INTESTINAL OBSTRUCTIONS

346 **Malrotation**
Steven J. Kraus, MD
350 **Midgut Volvulus**
Steven J. Kraus, MD
354 **Duodenal Atresia or Stenosis**
Steven J. Kraus, MD
358 **Duodenal Web**
Steven J. Kraus, MD and A. Carlson Merrow, Jr., MD, FAAP
359 **Pyloric Atresia**
A. Carlson Merrow, Jr., MD, FAAP

NEONATAL LOWER INTESTINAL OBSTRUCTIONS

360 **Jejunoileal Atresia**
Steven J. Kraus, MD
364 **Colonic Atresia**
Steven J. Kraus, MD
365 **Multiple Intestinal Atresias**
A. Carlson Merrow, Jr., MD, FAAP
366 **Meconium Ileus**
Steven J. Kraus, MD
370 **Neonatal Small Left Colon**
A. Carlson Merrow, Jr., MD, FAAP
372 **Hirschsprung Disease**
Steven J. Kraus, MD
376 **Anorectal Malformations**
Steven J. Kraus, MD

TABLE OF CONTENTS

OTHER NEONATAL GASTROINTESTINAL DISORDERS

380 **Meconium Peritonitis**
Steven J. Kraus, MD
384 **Necrotizing Enterocolitis**
Hank Baskin, MD
388 **Spontaneous Intestinal Perforation in Neonates**
Emily S. Orscheln, MD

UPPER GASTROINTESTINAL ABNORMALITIES TYPICALLY SEEN IN INFANTS AND YOUNG CHILDREN

390 **Gastroesophageal Reflux**
Steven J. Kraus, MD
392 **Hypertrophic Pyloric Stenosis**
Sara M. O'Hara, MD, FAAP
396 **Gastric Volvulus**
Michael R. Aquino, MD, MHSc
398 **Ingested Coins**
Michael R. Aquino, MD, MHSc
400 **Ingested Button Batteries**
Michael R. Aquino, MD, MHSc
402 **Ingested Multiple Magnets**
Michael R. Aquino, MD, MHSc

ABNORMALITIES OF ABDOMINAL WALL

404 **Hernias**
Alexander J. Towbin, MD
408 **Omphalocele**
A. Carlson Merrow, Jr., MD, FAAP

Introduction

Anatomically & functionally, the pediatric airway can be divided into upper & lower segments at the glottis (larynx) or large & small airways at the transition from the cartilage-containing bronchi proximally to the distal airways that lack supporting cartilage. The superimposed disease processes may be extrinsic or intrinsic, & they may manifest as acute or chronic airway compromise at a variety of ages. Broad categories of airway compromise include congenital airway obstructions (e.g., choanal atresia), acute infectious etiologies (e.g., croup, epiglottitis), noninfectious intrinsic & extrinsic obstructions (e.g., foreign bodies, vascular rings), & obstructive sleep apnea (e.g., tonsillar hypertrophy, glossoptosis). These general categories of disease are not always distinct with some processes affecting multiple levels or presenting later in childhood despite an underlying congenital issue.

Imaging Modalities

Radiographs

Plain radiographs remain the imaging modality of choice for the initial evaluation of the pediatric airway. Two views (AP & lateral) are obtained to include the airway from the nasal passages & nasopharynx superiorly to the carina inferiorly. It is particularly important in young children to obtain the lateral view during inspiration & with the neck extended to prevent the simulation of pathology by normal tissue redundancy in these patients.

Airway radiographs are helpful in looking for ingested/inhaled foreign bodies (especially those that are radiopaque) & evaluating sites of midline pharyngeal or tracheal narrowing due to inflammation or extrinsic compression. Most extrinsic processes affecting the airway (such as peritonsillar abscesses & nodal conglomerations) will require further characterization with ultrasound or CECT.

Less acute indications for airway radiographs include infants with noisy breathing & older children with snoring (the latter of which could be obtained as a single lateral view of the upper airway).

Fluoroscopy

In the current era, fluoroscopy has a limited role in evaluating the pediatric airway. A commonly encountered circumstance is in the infant where a retropharyngeal space process is suspected clinically &/or radiographically. In this setting, the initial lateral radiograph will sometimes not be obtained with adequate extension &/or inspiration, making the retropharyngeal tissues appear abnormally thickened when they are not. Pulsed fluoroscopic visualization of such an airway during the respiratory cycle will demonstrate, in the lateral view, normal expansion & collapse of the retropharyngeal soft tissue in this age group (if there is no inflammatory change present).

Fluoroscopy may incidentally detect tracheomalacia or other sites of airway collapse in patients with obstructive sleep apnea, though it is not primarily used in the investigation of these entities.

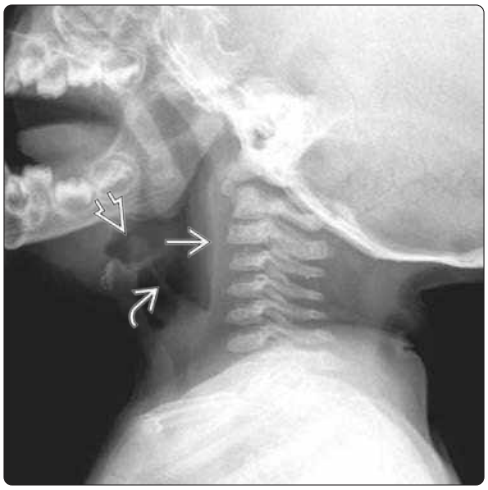
Video swallowing studies (a.k.a. modified barium swallows) are frequently performed (in conjunction with speech pathologists) when aspiration or feeding difficulties are suspected. Another related study is the esophagram. While this exam is typically performed for dysphagia, it may have airway implications if there is a pattern of esophageal compression that suggests a vascular ring.

Computed Tomography

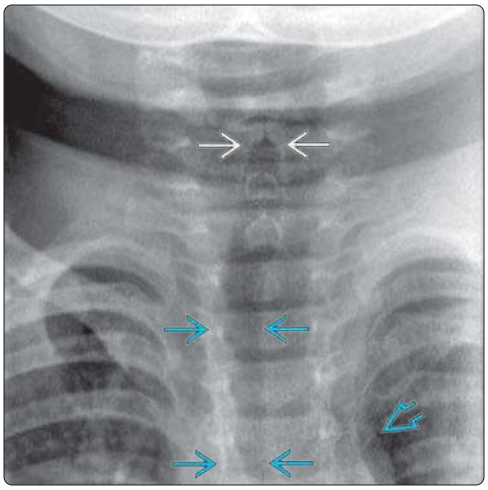
The applications of CT in evaluating the airway have become quite numerous. In the acute setting, CECT may be used to detail drainable abscesses of the retropharynx or peritonsillar tissues. NECT can be used to create virtual bronchoscopic images when there is concern for an aspirated foreign body that is not radiopaque. In the setting of congenital or chronic airway anomalies, CT angiography can be used to look for vascular rings causing compression of the airway (typically during a pulmonary or otolaryngology work-up). Dynamic change in the airway caliber may also be assessed, creating 4D cine images of the airway lumen during the respiratory cycle. Given these applications & its rapid acquisition, CT has taken on a significant role in the work-up of complex airway anomalies.

Magnetic Resonance

While MR has other applications in the neck, MR targeted to the airway is typically limited to the evaluation of recurrent obstructive sleep apnea after tonsillectomy. Its strengths lie in its ability to distinguish the various soft tissue components contributing to intermittent airway obstructions, allowing observation of the supraglottic airway over numerous respiratory cycles & with the application of various interventions during the scan.



The exquisite contrast resolution of MR as compared to CT makes it ideal for evaluating the relationships of slow-flow/high fluid content vascular malformations (e.g., lymphatic &/or venous malformations) to the various segments of the airway as these lesions frequently involve the oral cavity, neck, & mediastinum.



Ultrasound

Traditionally, sonography has rarely been used in the evaluation of the pediatric airway, primarily due to the artifacts associated with gas. While palpable neck masses are well characterized by ultrasound, their depth of extension & exact relationship to the airway are much better visualized by CT or MR. More recently, specific uses of airway ultrasound have been increasingly described, including the assessment of peritonsillar abscesses (using an intraoral probe), laryngeal motion (by otolaryngologists), & endotracheal tube position (during point of care ultrasound by the emergency or ICU physician).

(Left) *Lateral radiograph of the normal pharynx in a young child shows a "thin" & well-defined epiglottis. Note the normal retropharyngeal soft tissue width & thin aryepiglottic folds.* **(Right)** *AP radiograph of a normal airway shows normal angular "shoulders" or lateral convexities in the subglottic region. The remainder of the trachea has a uniform caliber & is slightly shifted to the right by a normal left-sided aortic arch.*

(Left) *Axial CECT of a normal trachea shows a normal round morphology of the tracheal lumen. The posterior wall may flatten slightly with expiration.* **(Right)** *Sagittal T2 MR in a 17-month-old patient with an extensive facial lymphatic malformation shows marked infiltration of the tongue, floor of mouth tissues, & soft palate by the lesion, resulting in complete effacement of the oral cavity, oropharynx, & upper hypopharynx. A tracheostomy is partially visualized.*

(Left) *Axial CECT in a child with lymphoma shows a large mediastinal mass with a flattened appearance of the trachea (typical of extrinsic compression).* **(Right)** *Anterior 3D NECT of the airways shows a round, narrow-caliber distal trachea, typical of complete cartilage rings. There is an isolated right upper lobe bronchus arising from the trachea & leaving a narrowed intermediate left bronchus, which then gives rise to the left main bronchus & a right bridging bronchus.*

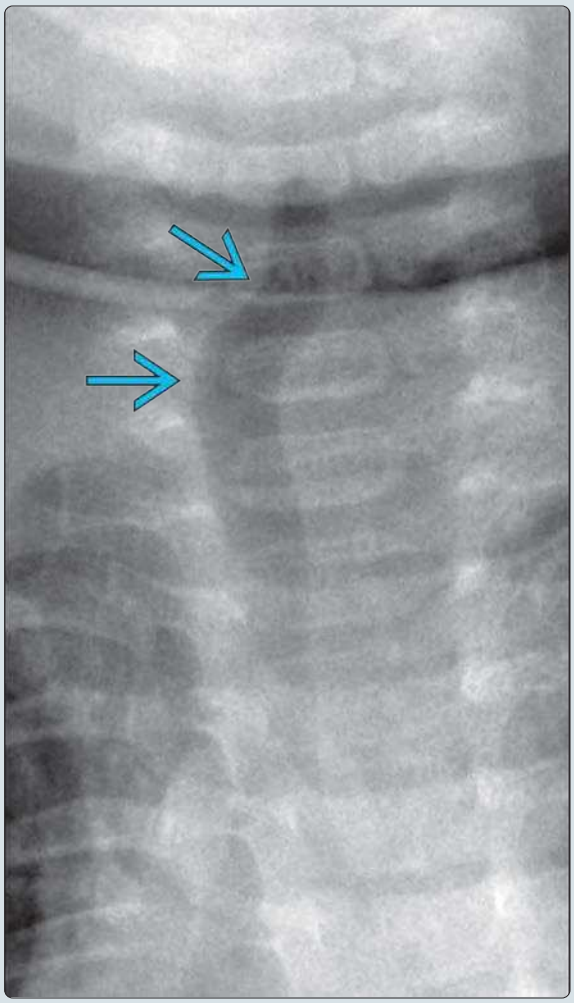
Expiratory Buckling of Trachea

KEY FACTS

TERMINOLOGY

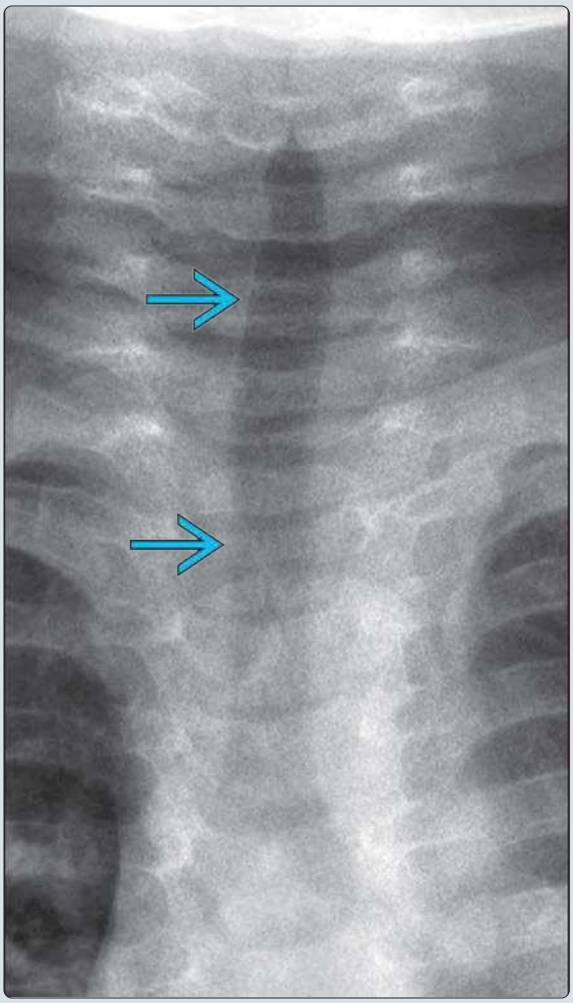
- Intermittent normal change in transverse & craniocaudal configuration of trachea in infants during expiration

IMAGING



- On AP view, trachea is normally straight & of uniform caliber in older children & adults throughout respiratory cycle
- In infants, trachea is normally straight during inspiration but changes with expiration
  - Focal shortening, "crinkle," bend, or curve at/above thoracic inlet without significant caliber change
  - Directed towards right in patients with left aortic arch
    - Buckling toward left suggests right aortic arch
  - Trachea becomes straight again with inspiration
- No need to repeat radiograph

TOP DIFFERENTIAL DIAGNOSES



- Croup: Symmetric narrowing ("steeple") of subglottic trachea in young child with characteristic "barky" cough
- Infantile hemangioma: Persistent asymmetric tracheal narrowing by intraluminal, benign vascular neoplasm
  - Often associated with cutaneous infantile hemangiomas in "beard distribution"
- Tracheomalacia: Abnormal dynamic tracheal collapse in anterior to posterior dimension (not transverse)
  - Static lateral view may show caliber narrowing; dynamic change confirms tracheomalacia rather than stenosis
- Compression by extrinsic mass or aberrant vessel
  - Persistent focal airway narrowing with deviation away from mass/vessel; mass may enlarge mediastinum

CLINICAL ISSUES

- Incidental finding on chest or airway radiographs if morphology & patient age are correct
- Does not cause airway symptoms

AP radiograph of the airway in an 8-month-old patient shows the typical configuration of expiratory tracheal buckling: The trachea at & just above the thoracic inlet demonstrates a focal bend toward the right ⇨ but does not demonstrate narrowing.

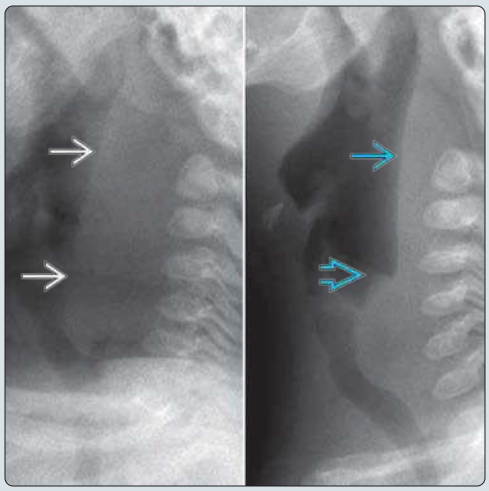
AP radiograph in an 8-month-old patient during inspiration shows a trachea that is relatively straight vertically ⇨.

KEY FACTS

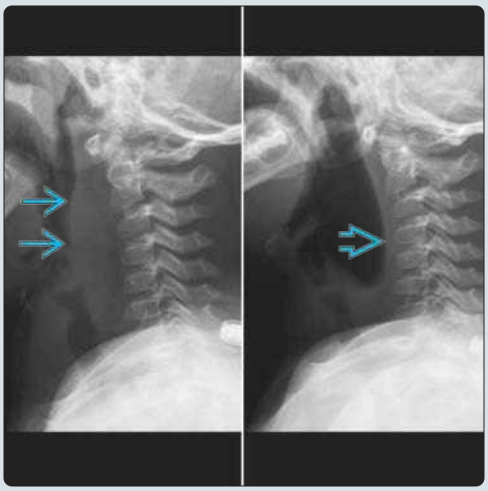
TERMINOLOGY

- Transient thickening of normal retropharyngeal soft tissues of infant on lateral airway radiograph
  - "Swelling" with expiration or poor extension
  - Resolution with inspiration & adequate extension
- Contributing factors to this appearance include
  - Relatively short necks of infants & young children, which lead to poor positioning for airway radiographs
  - Relatively long expiratory component of crying also challenges acquisition during maximal inspiration

IMAGING

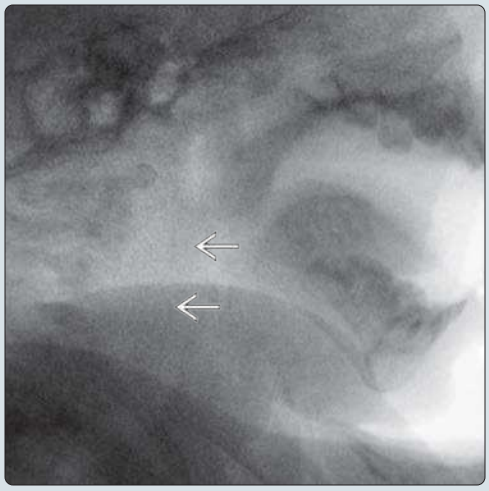


- Generalized thickening/bulging of prevertebral soft tissues
  - ± retention of normal step-off at junction of hypopharynx & cervical esophagus
- Resolves on repeat lateral radiograph with improved inspiratory timing of exposure & ↑ neck extension
- Observation of dynamic airway changes under fluoroscopy can confirm intermittent thickening & resolution
  - Use "last image capture/image hold" for documentation
    - Thickening from expiration will recur during time required for true exposure

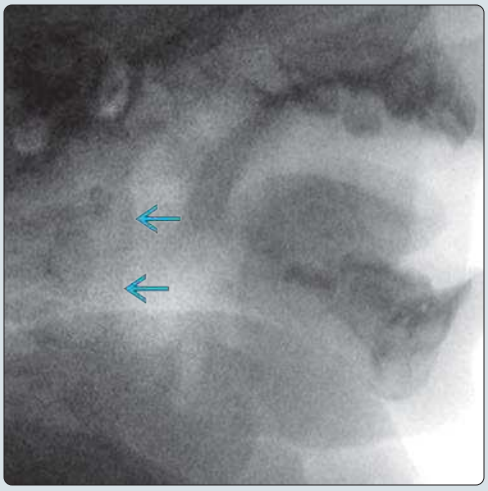


TOP DIFFERENTIAL DIAGNOSES

- Retropharyngeal cellulitis/abscess
  - Convex generalized bulging of prevertebral soft tissues persists despite inspiration & neck extension
  - Often lose normal step-off at hypopharyngeal-esophageal junction
- Cervical spine pathology
  - Trauma, inflammation/infection, or neoplasm → prevertebral soft tissue swelling
  - ± radiographically visible bony abnormality



CLINICAL ISSUES



- Uncommon in children > 2 years of age
- Unlike true pathology, pseudothickening does not cause characteristic signs/symptoms

(Left) *Lateral airway radiographs in an infant show pseudothickening of the prevertebral soft tissues initially ➡ with improved neck extension & inspiratory timing ⇨. Note the normal step-off at the hypopharyngeal-esophageal junction ⇨.* **(Right)** *Lateral radiographs of the neck soft tissues in a 3-year-old with fever & limited neck range of motion show fullness ⇨ & collapse ⇨ of the prevertebral soft tissues during expiration (L) & inspiration (R), respectively.*

(Left) *Lateral fluoroscopic "image hold" in an 11- month-old with stridor & suggested retropharyngeal thickening on preceding radiographs (not shown) demonstrates bulging of the prevertebral soft tissues ➡ during expiration.* **(Right)** *Lateral fluoroscopic "image hold" in the same patient during inspiration shows normal collapse of the prevertebral soft tissues ⇨, confirming pseudothickening on the initial image.*

Congenital Nasal Pyriform Aperture Stenosis

KEY FACTS

TERMINOLOGY

- Congenital nasal pyriform aperture stenosis (CNPAS): Congenital narrowing of anterior bony nasal passageway

IMAGING

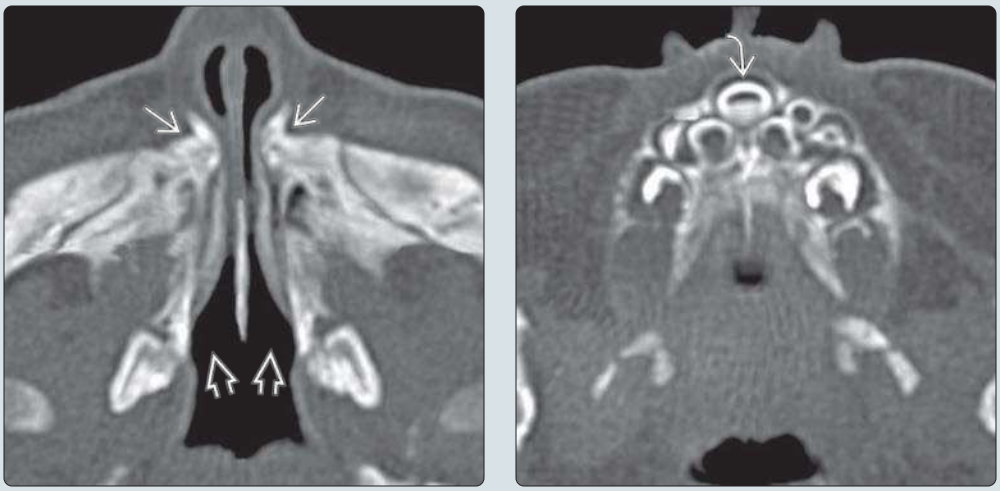
- Best tool: Bone CT in axial & coronal planes
  - Medial deviation of anterior maxillae ± thickening of nasal processes
  - Abnormal maxillary dentition: Solitary median maxillary central incisor (SMMCI) in up to 75%
  - Triangle-shaped palate

TOP DIFFERENTIAL DIAGNOSES

- Nasolacrimal duct mucoceles
  - Intranasal component narrows anterior nasal cavity
- Nasal choanal stenosis/atresia
  - Narrow posterior nasal passage by membrane or bone

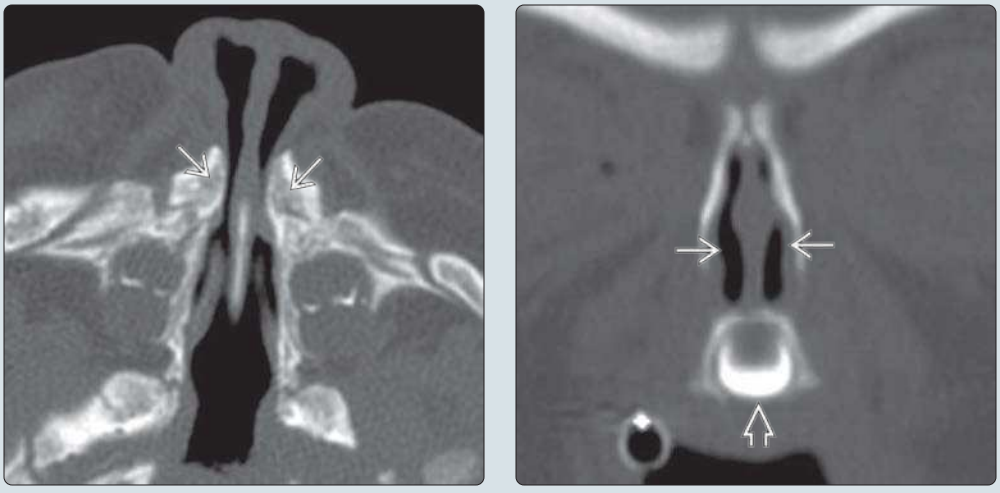
PATHOLOGY

- CNPAS without SMMCI is almost always isolated anomaly
- Solitary maxillary central incisor in 75% of cases
  - Associated with holoprosencephaly



CLINICAL ISSUES

- Respiratory distress in newborn/infant
  - Breathing problems may be triggered by upper respiratory infection
  - Symptoms may be more pronounced with feeding
- Narrow nasal inlet on clinical exam
- CNPAS is 1/5 to 1/3 as common as choanal atresia



DIAGNOSTIC CHECKLIST

- Bone CT is recommended for diagnosis of bony narrowing & dental abnormalities
- Brain MR is recommended in cases of SMMCI to exclude midline brain anomalies

(Left) *Axial bone CT in a newborn shows the typical features of congenital nasal pyriform aperture stenosis (CNPAS). There is overgrowth & medial deviation of the anterior maxillae ➡ with marked narrowing of the anterior nasal passages. There is no associated choanal atresia ➡.* **(Right)** *Axial bone CT at the level of the palate in the same patient shows a classic associated finding in patients with CNPAS, a solitary median maxillary central incisor (SMMCI) or megaincisor ➡.*

(Left) *Axial bone CT in a newborn with respiratory distress demonstrates CNPAS. The anterior & medial aspects of the maxillae are thickened ➡, causing narrowing of the anterior nasal airway.* **(Right)** *Coronal bone CT in the same patient demonstrates the narrowing of the anterior nasal airway bilaterally ➡ with an associated SMMCI ➡.*

TERMINOLOGY

Abbreviations

- Congenital nasal pyriform aperture stenosis (CNPAS)

Definitions

- Congenital narrowing of anterior bony nasal passageway/nasal aperture

IMAGING

General Features

- Best diagnostic clue
  - Medialization & thickening of anterior maxillae with narrowing of nasal airway
- Location
  - Most often bilateral
- Size
  - Pyriform aperture (PA) size in CNPAS
    - PA width < 11 mm in term infant is diagnostic (normal = 13.4-15.6 mm)
    - PA area = 0.2-0.4 cm² (0.7-1.1 cm² is normal)

Imaging Recommendations

- Best imaging tool
  - Bone CT in axial & coronal planes

CT Findings

- Narrowed bony nasal inlet
  - Medial deviation of lateral wall of PA (anterior maxillae) ± thickening of nasal processes
- Triangle-shaped hard palate
  - Bony ridge along oral surface of hard palate on coronal images
- Abnormal maxillary dentition may occur
  - Fused or malaligned central & lateral incisors
  - Solitary median maxillary central incisor (SMMCI) syndrome (in up to 75%)
- Thinning of anterior nasal septum
- Posterior choanae are normal in caliber

DIFFERENTIAL DIAGNOSIS

Nasolacrimal Duct Mucoceles

- Obstruction of distal nasolacrimal ducts → cysts at bilateral inferior meatus → narrow anterior nasal cavity
- Bony aperture is normal

Nasal Choanal Stenosis/Atresia

- Narrow or occluded posterior nasal passage: Membranous, osseous, or mixed
- Anterior nasal passage is normal in caliber

PATHOLOGY

General Features

- Etiology
  - 2 theories of pathogenesis
    - Deficiency of primary palate derived from midline mesodermal tissue
      - Embryologically, medial maxillary swelling forms structures of primary palate, including 4 incisors
      - Mesoderm is thought to have inductive effect on forebrain, hence association of SMMCI syndrome with holoprosencephaly
    - Overgrowth or dysplasia of nasal processes of maxilla
  - CNPAS without SMMCI is almost always isolated anomaly
- Associated abnormalities
  - Upper teeth anomalies
    - SMMCI syndrome (75% of CNPAS cases)
  - Semilobar or alobar holoprosencephaly
  - Endocrine dysfunction: Pituitary-adrenal axis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Respiratory distress, especially with feeding, as infants are obligate nasal breathers
    - Can mimic choanal atresia/stenosis
    - Breathing problems may be triggered by upper respiratory infection further compromising airway
  - Cyanosis
- Other signs/symptoms
  - Nasogastric tube is difficult to pass

Demographics

- Age
  - Newborns or infants in 1st few months of life
- Epidemiology
  - Congenital airway obstruction affects 1 in 5,000 infants
    - Majority are choanal atresia
    - CNPAS is 1/5 to 1/3 as common as choanal atresia
      - 1 in 25,000 live births

Treatment

- May be treated conservatively with special feeding techniques
  - Nasal cavity eventually grows & mild obstruction is relieved
- Surgical intervention in patients with persistent respiratory difficulty & poor weight gain
  - Resection of anteromedial maxilla ± anterior aspect of inferior turbinates & reconstruction of anterior nasal orifice
  - PA width < 5.7 mm in neonate may correlate with need for surgical intervention

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Brain MR is recommended with SMMCI to exclude midline brain anomalies

Nasolacrimal Duct Mucocele

KEY FACTS

TERMINOLOGY

- Synonym: Congenital dacryocystocele

IMAGING

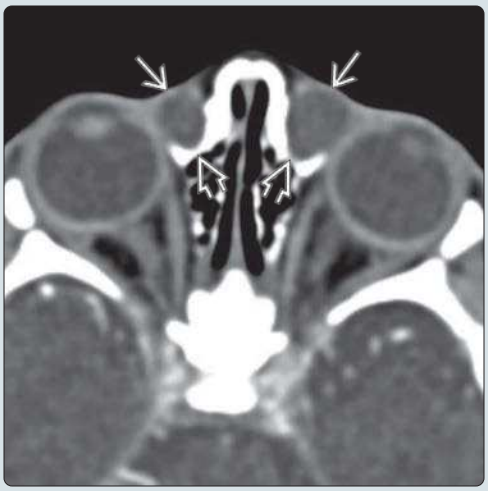
- Well-defined, cystic, medial canthal mass in continuity with enlarged nasolacrimal duct (NLD) in newborn
  - Unilateral or bilateral
- Absent or minimal wall enhancement (unless infected)
- Coronal/sagittal reformatted images show continuity of proximal cyst at lacrimal sac with distal inferior meatus cyst through dilated NLD

TOP DIFFERENTIAL DIAGNOSES

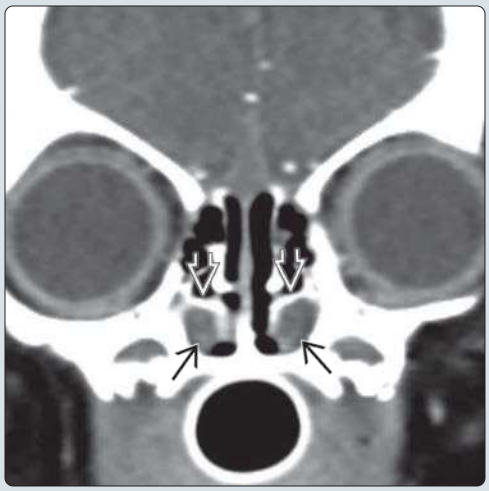
- Orbital dermoid & epidermoid
- Frontoethmoidal (nasoorbital) cephalocele
- Infantile hemangioma
- Acquired dacryocystocele

PATHOLOGY

- Tears & mucus accumulate in NLD with imperforate Hasner membrane (i.e., distal duct obstruction)
- Most common abnormality of infant lacrimal apparatus

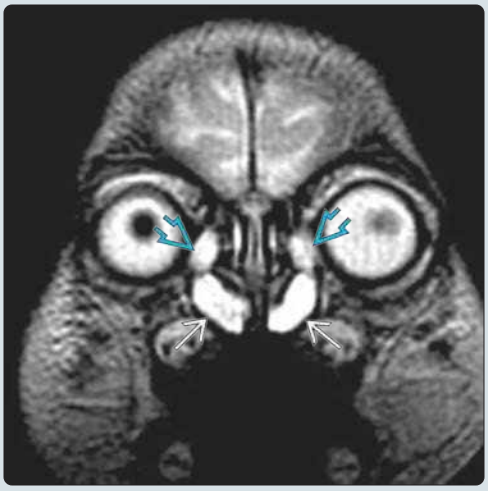


CLINICAL ISSUES

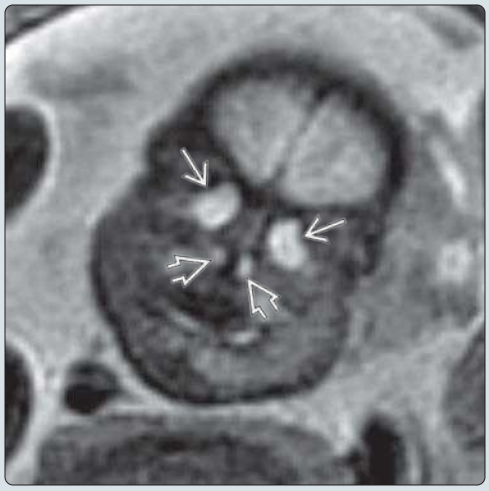


- Proximal cyst: Small, round, bluish, medial canthal mass identified at birth or shortly thereafter; ± cellulitis
- Distal cyst: Nasal airway obstruction with respiratory distress if bilateral (especially during feeding)

DIAGNOSTIC CHECKLIST



- CT or MR evaluates lacrimal apparatus lesion extent
  - Excludes other sinonasal causes of respiratory distress in newborn
- Comment on full extent of lesion from medial canthus to inferior meatus
- Exclude contralateral lesion



(Left) *Axial CECT in a 4-day-old with bluish, bilateral medial orbital swelling & left purulent drainage shows bilateral lacrimal sac enlargement. Note also the bilateral lacrimal sac fossae splaying.* **(Right)** *Coronal CECT in the same patient demonstrates the typical locations of the distal intranasal components of the nasolacrimal duct (NLD) mucoceles in the bilateral inferior meatus inferior to the inferior turbinates.*

(Left) *Coronal T2 MR in an infant shows hyperintense nasolacrimal duct mucoceles extending from the dilated lacrimal sacs proximally to protrude inferomedially from the inferior nasolacrimal ducts.* **(Right)** *Coronal T2 SSFSE MR in a 2nd-trimester fetus demonstrates bilateral lacrimal sac enlargement with distal extension into each inferior meatus, a typical appearance of nasolacrimal duct mucoceles.*

TERMINOLOGY

Synonyms

- Congenital dacryocystocele

Definitions

- Nasolacrimal duct (NLD) mucocele: Cystic dilation of nasolacrimal apparatus secondary to proximal & distal obstruction of NLD
- Canthus: Corner of eye where eyelids meet

IMAGING

General Features

- Best diagnostic clue
  - Well-defined, cystic, medial canthal mass in continuity with enlarged NLD in newborn
- Location
  - From lacrimal sac at medial canthus to distal aspect of NLD at inferior meatus in nasal cavity
  - Unilateral or bilateral

CT Findings

- Hypodense, thin-walled cyst at medial canthus ± bulging cystic component at inferior meatus
  - Cysts communicate through enlarged NLD
- Minimal wall enhancement; if infected, thick rim enhancement ± fluid/debris level & surrounding fat stranding

MR Findings

- T1-hypointense/T2-hyperintense, well-circumscribed mass(es)
- Signal intensity varies with protein content &/or infection
- Minimal wall enhancement normally
- If inflamed/infected → thick rim of enhancement with surrounding poorly defined soft tissue stranding

Ultrasonographic Findings

- Anechoic/hypoechoic round lesion with thin wall & ↑ through transmission at medial canthus

DIFFERENTIAL DIAGNOSIS

Orbital Dermoid & Epidermoid

- Lateral > medial canthus
- Near suture: Frontozygomatic > frontonasal/nasolacrimal
- 50% show fat density/intensity with thin rim enhancement

Frontoethmoidal (Nasoorbital) Cephalocele

- Swelling at inferomedial orbit connected to brain/meninges

Infantile Hemangioma

- Lobulated red (cutaneous) or bluish (subcutaneous) highly vascular benign neoplasm of infants
- Grows rapidly in 1st few weeks-months of life with very gradual spontaneous regression

Acquired Dacryocystocele

- Typically in adults with history of prior regional trauma
  - Other possible history
    - Post inflammatory or neoplastic stenosis
    - Previous NLD injury during Caldwell-Luc, uncinectomy, medial maxillectomy

PATHOLOGY

General Features

- Etiology
  - Tears & mucus accumulate in NLD due to imperforate Hasner membrane at distal duct
  - If bacteria enter distended sac → dacryocystitis ± cellulitis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Small, round, bluish, medial canthal mass identified at or shortly after birth = distended lacrimal sac
  - Nasal airway obstruction & respiratory distress (especially during feeding) with bilateral nasal components
    - Obligate nose breathers during infancy
- Other signs/symptoms
  - Tearing & crusting at medial canthus, preseptal cellulitis, dacryocystitis
  - Small NLD mucoceles may be identified incidentally on brain MR imaging in fetus/infant

Demographics

- Epidemiology
  - Infancy: Typically 4 days to 10 weeks of age

Natural History & Prognosis

- 90% of simple distal NLD obstructions (or congenital dacryostenosis) resolve spontaneously by age 1 year
- Only 50% of those recognized on prenatal MR ultimately have postnatal symptoms
- Intervention before infection to prevent nasal airway obstruction, dacryocystitis, & permanent sequelae

Treatment

- Daily manual massage ± prophylactic antibiotics
  - Manual massage is inappropriate if NLD mucocele is infected or causing airway obstruction
- 10% require probing with irrigation ± silastic stent
- With endonasal component & no response to above → endoscopic resection with marsupialization
- Excellent prognosis with adequate early treatment
- High success rate for nasal endoscopic surgery: Cure (81.5%), improvement (18.5%), unhealed (0%)
- Theoretical risk of nasolacrimal apparatus scarring, amblyopia, & permanent canthal asymmetry if untreated

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Comment on full extent of lesion from medial canthus to inferior meatus, bilaterality, & signs of infection

Choanal Atresia

KEY FACTS

TERMINOLOGY

- Congenital obstruction of posterior nasal aperture(s)

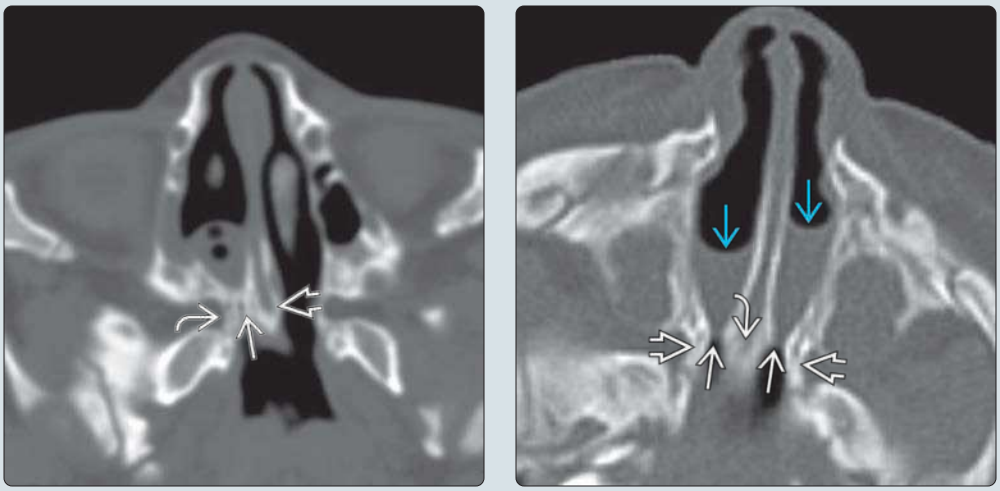
IMAGING

- Unilateral or bilateral osseous narrowing of posterior nasal cavity with complete obstruction by associated membrane &/or bony plate
  - Thickening of vomer
  - Medial bowing of posterior maxilla(e)
  - ± air-fluid level in obstructed nasal cavity
- Unilateral in up to 75% (R > L)
- Bilateral in up to 25%
  - 75% of bilateral cases have other anomalies

TOP DIFFERENTIAL DIAGNOSES

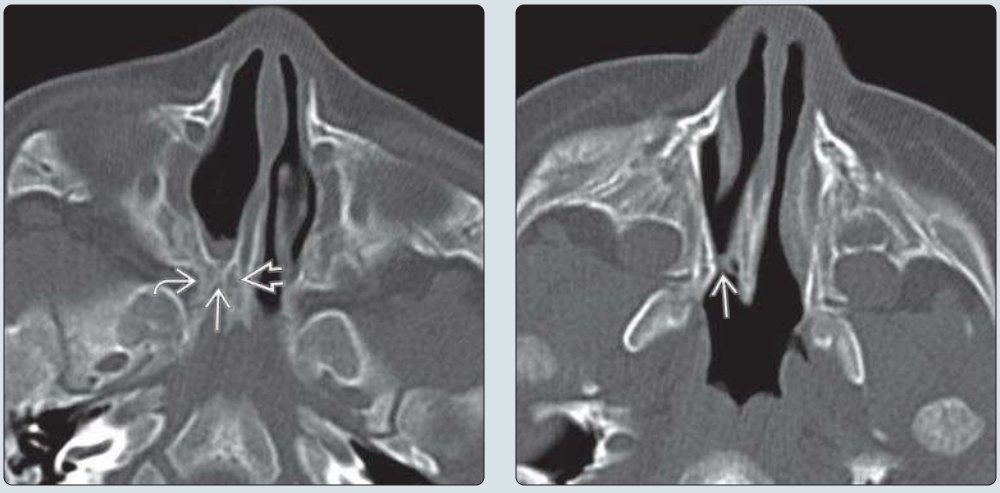
- Choanal stenosis
- Pyriform aperture stenosis
- Nasolacrimal duct mucocele

PATHOLOGY



- Choanal atresia is most common congenital abnormality of nasal cavity
- Choanal atresia types
  - Mixed bony & membranous atresia in up to 70%
  - Purely bony atresia in up to 30%

CLINICAL ISSUES



- Typical presentations include
  - Bilateral choanal atresia: Significant respiratory distress in newborn
    - Due to their physiologic obligate nasal breather status
  - Unilateral choanal atresia: Chronic, purulent unilateral rhinorrhea with mild airway obstruction in older child

DIAGNOSTIC CHECKLIST

- Respiratory distress & suspected nasal obstruction in newborn should be evaluated with thin-section bone CT

(Left) *Axial NECT (in bone windows) through the upper choanae in a child shows a complete osseous right choanal obstruction ➡ secondary to fusion of an enlarged vomer ➡ to the thickened, medially positioned posterior maxilla ➡.* **(Right)** *Axial bone CT in an infant shows significant narrowing of the choanae ➡, medialization of thickened posteromedial maxillae ➡, a wide vomer ➡, small membranes traversing the stenotic choanae, & bilateral nasal cavity air-fluid levels ➡.*

(Left) *Axial bone CT obtained at the upper aspect of the choanae in a 6-week-old with right nasal obstruction demonstrates complete obliteration of the right choana ➡ by the thickened vomer ➡ fused to the thickened posteromedial maxilla ➡.* **(Right)** *Axial bone CT 2 mm more inferior in the same patient shows a stenotic choana & crossing membrane ➡, not an uncommon appearance in patients with mixed atresia with bony (upper) & membranous (lower) components.*

TERMINOLOGY

Definitions

- Congenital obstruction of posterior nasal aperture
  - Choana: Junction of posterior nasal cavity & nasopharynx
  - Choanal atresia: Lack of communication between nasal cavity & nasopharynx

IMAGING

General Features

- Best diagnostic clue
  - Bony narrowing of posterior nasal cavity with membranous &/or osseous obstruction of choana
- Location
  - Unilateral in ~ 75% (R > L), bilateral in ~ 25%
- Size
  - Newborn choanal opening is abnormal if < 0.34 cm wide
  - Newborn vomer is abnormal if > 0.23 cm thick
- Morphology
  - Medial bowing of posterior maxilla (lateral nasal wall) & pterygoid plate
  - Large/thickened vomer
  - Bony narrowing ± soft tissue membrane/plug or bony plate obstructing choana
    - Mixed bony & membranous atresia in up to 70%
    - Purely bony atresia in up to 30%

CT Findings

- Bone CT
  - Choanal narrowing by medially bowed posterior maxilla/pterygoid & thickened vomer
  - Narrow gap between maxilla & vomer is bridged by continuous bony plate or membrane
    - Membranous atresia may be thin/strand-like or thick/plug-like
  - Air-fluid level is frequently present in obstructed nasal passage
    - Nasal cavity may also be filled with soft tissue, hypertrophied inferior turbinates

Imaging Recommendations

- Best imaging tool
  - High-resolution unenhanced bone CT
- Protocol advice
  - Suction secretions from nasal cavity prior to scanning
  - Axial images are angled 5° cephalad to palate
    - If angle is too great, region of choanae at level of skull base creates false appearance of choanal atresia
  - Edge enhancement bone kernel helps delineate bone margins in partially ossified skull base
  - Multiplanar reformations as needed
  - 3D reconstructions may be helpful for clinical decision making & surgical planning

DIFFERENTIAL DIAGNOSIS

Choanal Stenosis

- Posterior nasal airway narrowed (not completely occluded)

Pyriform Aperture Stenosis

- Narrowed anterior inferior nasal passage(s)
- Thickened anteromedial maxilla(e)
- ± single central megaincisor
- Must evaluate brain for holoprosencephaly

Nasolacrimal Duct Mucocele

- Bilobed cystic mass extending from medial orbital nasolacrimal fossa to inferior meatus

PATHOLOGY

General Features

- Associated abnormalities
  - Syndromes are common in bilateral atresia (up to 75%)
    - CHARGE syndrome: **C**oloboma, **h**eart defect, choanal **a**tresia, **r**estricted growth, **g**enitourinary & **e**ar defects
  - Unilateral choanal atresia is more likely to be isolated

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Bilateral choanal atresia: Respiratory distress in newborn
    - Infants normally breathe through nose (obligate nasal breathers) until 6 months of age
    - Aggravated by feeding, relieved by crying
  - Unilateral choanal atresia or stenosis: Chronic, purulent, unilateral rhinorrhea in older child
  - Inability to pass nasogastric tube through nasal cavity beyond 3-4 cm despite aerated lungs on radiograph

Treatment

- Establish oral airway immediately for proper breathing
- Membranous atresia may be perforated upon passage of nasogastric tube
- Surgery will alleviate respiratory symptoms

DIAGNOSTIC CHECKLIST

Consider

- Once airway is established, respiratory distress with suspected nasal obstruction in newborn should be evaluated with thin-section bone CT

Image Interpretation Pearls

- Determine if choanal atresia is unilateral or bilateral
- Look for associated anomalies in head & neck

Reporting Tips

- Describe choanal atresia as
  - Unilateral or bilateral
  - Mixed membranous/bony or purely bony
    - Comment on thickness of atretic bone plate

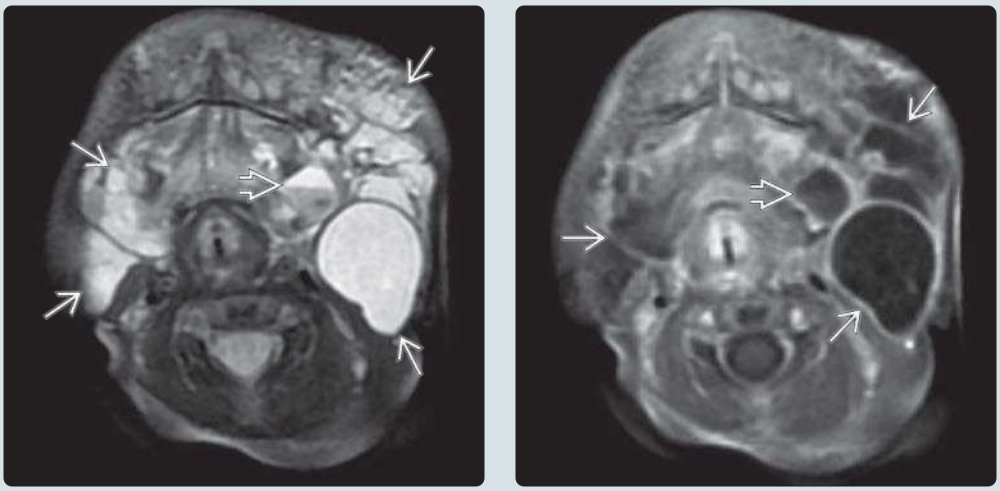
Lymphatic Malformation, Cervical

KEY FACTS

TERMINOLOGY

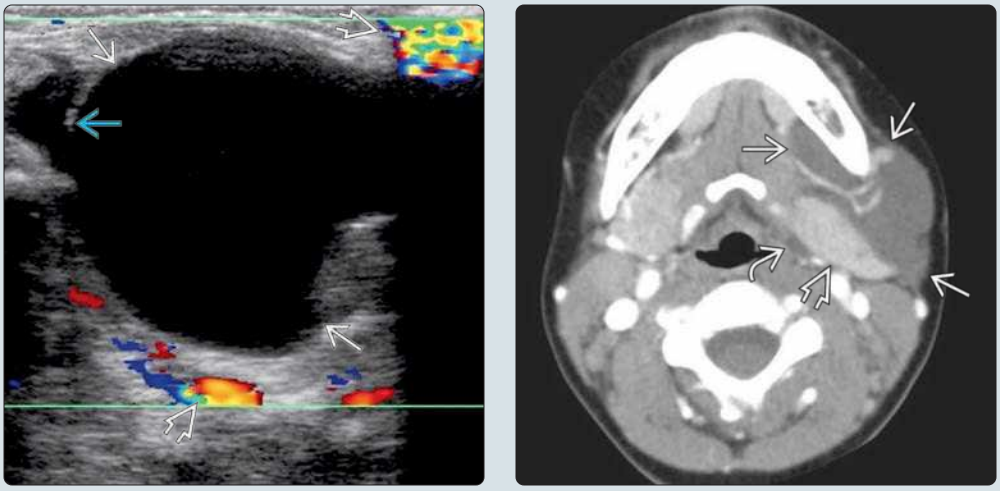
- Lymphatic malformation (LM): Subtype of slow-/low-flow congenital vascular malformation composed of embryonic lymphatic sacs; not neoplastic
- Composed of macrocysts > 1 cm &/or microcysts < 1 cm

IMAGING



- Macrocystic LM: Multiloculated, cystic neck mass with imperceptible wall, thin septations, & fluid-fluid levels
- Microcystic LM: Ill-defined, infiltrative, &/or solid-appearing
- Transspatial, often crosses midline extensively
- Insinuates between vessels & other normal structures
- US: Cysts can show varying degrees of ↑ echogenicity; Doppler shows no significant internal vascularity
- T2 FS/STIR MR: Hyperintense, frequent fluid-fluid levels
  - Best defines extent, relationship to airway & vessels
- T1 FS C+ MR: No significant or minimal rim enhancement
  - Must compare with precontrast T1, as hemorrhage & protein often show hyperintensity

TOP DIFFERENTIAL DIAGNOSES



- 2nd branchial cleft anomaly
- Thyroglossal duct cyst
- Abscess
- Thymic cyst
- Teratoma
- Neurofibroma
- Soft tissue sarcoma

CLINICAL ISSUES

- Nontender, compressible mass
  - Present since birth, grows commensurate with patient
  - May not be clinically apparent until hemorrhage, infection, or hormonal stimulation → rapid ↑ in size
- Depending on size & extent, treatment options primarily include resection, sclerotherapy (for macrocysts), & sirolimus
  - Staged combination therapy is often required

(Left) *Axial T2 FS MR in a 1-week-old infant demonstrates a multiloculated, mixed micro- & macrocystic, transspatial lymphatic malformation (LM) involving the left anterior neck more than the right. A single fluid-fluid level is present in a left-sided submandibular macrocyst, typical of layering blood products.* **(Right)** *Axial T1 C+ FS MR in the same patient shows a typical appearance of an extensive LM. The macrocysts show only mild peripheral enhancement, & the fluid-fluid level is much more difficult to discern.*

(Left) *Transverse color Doppler ultrasound in an infant with a macrocystic LM shows the typical anechoic nature of the dominant cyst with vessels identified adjacent to, but not within, the cyst. Note the thin septation peripherally.* **(Right)** *Axial CECT in a 3-year-old shows a well-defined, hypodense, macrocystic LM in the sublingual & submandibular spaces, moderately flattening the left submandibular gland. There is also minimal extension deep to the left submandibular gland.*

TERMINOLOGY

Definitions

- Lymphatic malformation (LM): Subtype of slow-/low-flow congenital vascular malformation composed of embryonic lymphatic sacs; not neoplastic
  - No communication with normal lymphatics
  - Composed of macrocysts > 1 cm &/or microcysts < 1 cm
- Venolymphatic malformation (VLM): Combined elements of venous malformation & LM

IMAGING

General Features

- Best diagnostic clue
  - Macrocystic LM: Multiloculated, cystic neck mass with imperceptible wall, thin septations, & fluid-fluid levels
  - Microcystic LM: More ill-defined, infiltrative, &/or solid-appearing
  - Crosses tissue planes, insinuating between vessels & other normal structures

Ultrasonographic Findings

- Unilocular vs. septated & multilocular transspatial mass
- Contents are predominantly hypo- or anechoic
  - Separate compartments in multicystic mass can show varying degrees of ↑ echogenicity
    - ± swirling debris &/or layering fluid-debris levels
- No true vascular flow in cysts by Doppler
  - ± flow (from encased normal vessels) in septations

MR Findings

- T1WI
  - Primarily hypointense fluid; hyperintense if prior hemorrhage or high protein content (± fluid-fluid levels)
- T2 FS or STIR
  - High-signal contents with thin, low-signal septa
    - Fluid-fluid levels in multiple cysts are very common
  - When transspatial, often poorly marginated
- T1WI C+ FS
  - No significant enhancement (± subtle rim enhancement)
  - Patchy enhancement suggests venolymphatic malformation (VLM) or microcystic LM

Imaging Recommendations

- Best imaging tool
  - Ultrasound is often diagnostic of superficial components
  - MR is better for defining deep extent & recognizing characteristic fluid-fluid levels
- Protocol advice
  - Fluid-sensitive sequences (T2 FS or STIR) are essential
  - T1 C+ FS is helpful to detect venous malformation component of mixed lesions: Subtraction of precontrast T1 FS improves assessment of true enhancement

DIFFERENTIAL DIAGNOSIS

2nd Branchial Cleft Anomaly

- Ovoid, unilocular cyst at angle of mandible with characteristic displacement pattern

Abscess

- Fluid collection with thick, enhancing, irregular wall
- Adjacent cellulitis > myositis, fasciitis

Teratoma

- Solid & cystic components are typical ± internal vascularity
- Frequently contain Ca^{2+}; tend to be more firm, unilateral, focal, & exophytic compared to LM

Thyroglossal Duct Cyst

- Anterior midline/paramidline unilocular cystic mass
- Anywhere from tongue base to lower anterior neck

Soft Tissue Sarcoma

- Well-defined, typically solid; rarely predominantly cystic

PATHOLOGY

General Features

- Genetics
  - ± association of anterior neck LM with Turner syndrome & trisomies; aneuploidy & high mortality in posterior midline cystic neck masses (cystic hygroma) of early gestation

Microscopic Features

- Immunohistochemical panel of PROX1, D2-40, VEGFR3, CD31, & CD34 antibodies to differentiate LM from other vascular malformations
  - PROX1 & VEGFR3 are most sensitive, specific

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Nontender, soft, compressible mass
  - Present since birth & grows commensurate with patient
    - May not be clinically apparent until hemorrhage, infection, or hormonal stimulation → rapid ↑ in size
  - Larger lesions are detected prenatally
- Other signs/symptoms: LMs may infiltrate upper airway or cause extrinsic compression

Treatment

- Surgical resection &/or percutaneous sclerotherapy
  - Sclerotherapy is primarily for macrocystic disease
  - Extensive disease often requires combined &/or numerous staged procedures
- Intralesional bleomycin injection for microcystic LM
- Medical therapy with sirolimus
- Tracheostomy for significant airway involvement

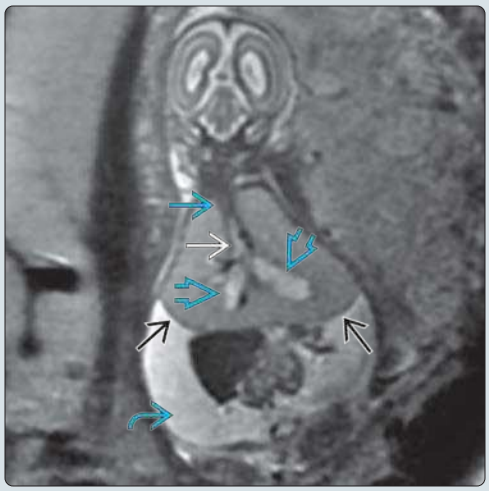
Congenital High Airway Obstruction Syndrome

KEY FACTS

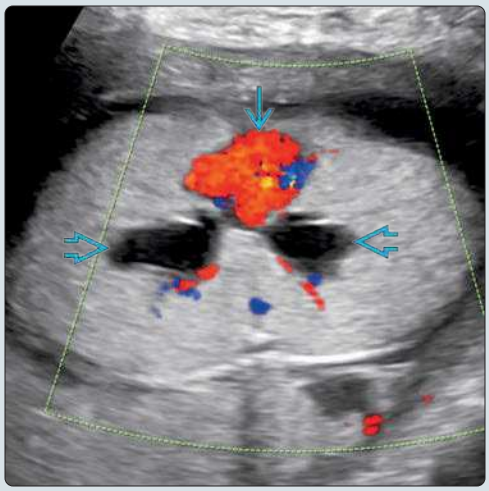
TERMINOLOGY

- Rare congenital anomaly of airway with complete intrinsic laryngeal &/or tracheal obstruction
- Results in dysfunctional & hyperexpanded lungs, everted hemidiaphragms, & cardiac/venous compression with ascites/hydrops

IMAGING

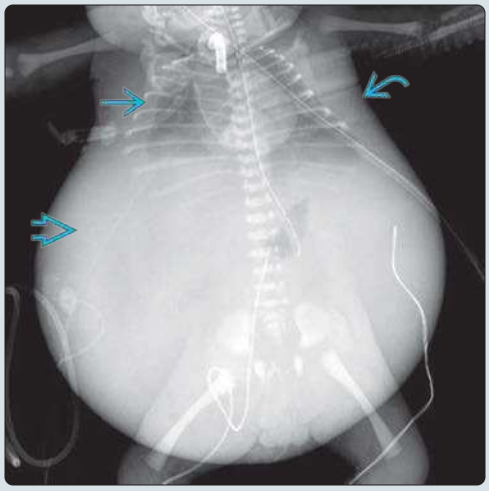


- Diffusely enlarged lungs, flattened/everted diaphragm
  - Prenatal imaging: Echogenic (US) or T2-hyperintense (MR) lungs with dilated, fluid-filled trachea inferior to obstructing lesion, ± polyhydramnios
  - Site of obstruction appears as persistent short or long segment of absent airway fluid at or below glottis
- Centralized, compressed heart
- Limited motion of abnormal diaphragm
- Abdominal distention with large volume of ascites
- Findings are lessened with stenosis, membrane perforation, or fistula (as each enables airway decompression)

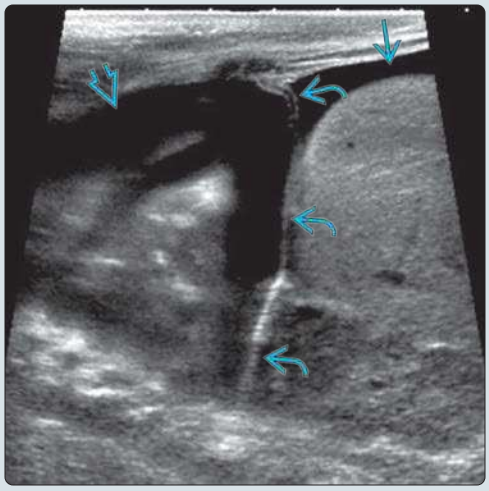


PATHOLOGY

- Most commonly due to laryngeal membrane or atresia
  - Obstruction prevents clearance of fluid from lungs
  - ↑ tracheal & lung pressures cause hyperexpansion & maldevelopment
- 50% have additional anomalies



CLINICAL ISSUES



- Presentations
  - In utero: Large, bilateral, echogenic lungs + ascites
  - At birth: Respiratory distress, aphonia, & failed intubation
    - Lethal at delivery without prenatal detection
- Ex utero intrapartum therapy (EXIT) procedure: Controlled delivery with airway secured via tracheostomy while placental circulation is maintained
  - Improves survival at delivery
  - Respiratory function remains poor
  - Survival > 1 year ~ 20% with high morbidity

(Left) *Coronal SSFSE T2 MR of a 20-weeks-gestation fetus shows the classic features of congenital high airway obstruction syndrome (CHAOS), including uniform hyperexpansion of the lungs, everted hemidiaphragms, & ascites. There is a long-segment tracheal occlusion with dilation of the lower thoracic trachea & central airways.* **(Right)** *Transverse color Doppler US of the same fetus at 20-weeks gestation shows compression of the heart by the enlarged hyperechoic lungs. Note the dilated central airways.*

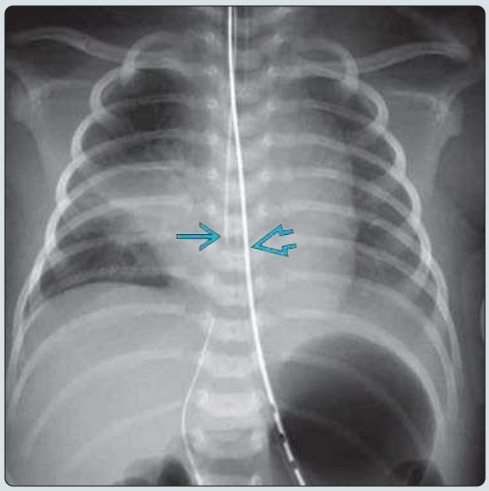
(Left) *Coronal AP radiograph of a newborn with CHAOS shows marked abdominal distention (due to ascites), a pleural effusion, & chest wall edema, consistent with hydrops. The hemidiaphragms are flattened. A tracheostomy was placed during an EXIT procedure.* **(Right)** *Right parasagittal US of the lower thorax/upper abdomen in the same patient shows an abnormal, everted, & lax diaphragm, which did not move during the exam. The pleural effusion & ascites are noted.*

KEY FACTS

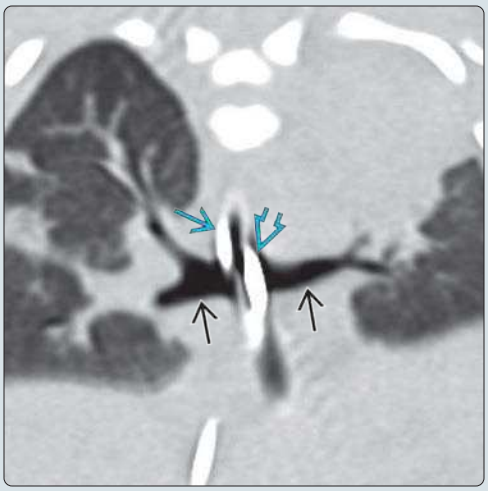
TERMINOLOGY

- Rare, highly lethal anomaly with absence of majority of trachea from subglottis to main bronchi

IMAGING

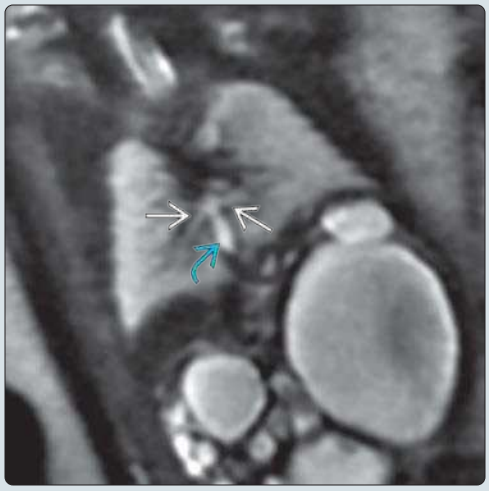


- Uncommon detection prenatally, as majority of cases have fistula from residual lower airway to intact esophagus
  - Allows decompression of otherwise obstructed lungs
  - May only demonstrate polyhydramnios in utero
    - If airway anomaly is suspected, MR is performed due to superior in utero airway evaluation vs. ultrasound
  - Minority of cases have no fistula, presenting as CHAOS
    - Lacks dilated, fluid-filled trachea of CHAOS
- Postnatally, temporary ventilation occurs via fistula
  - Low lung volumes with patchy opacities of atelectasis or aspiration
  - Low origin of horizontally oriented main bronchi
  - Endotracheal tube (ETT) lies in midline esophagus, possibly below expected location of carina
  - Nasogastric tube (NGT) may curve into main bronchi

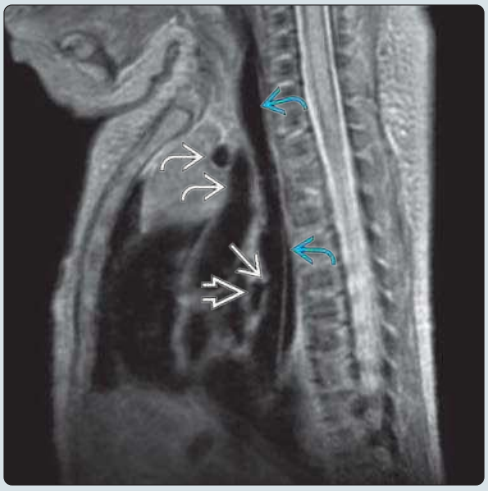


PATHOLOGY

- Classification by Floyd (most widely used): Types I-III
  - I: Absent proximal trachea; short distal trachea + TEF
  - II: Absent trachea; residual carina with main bronchi ± bronchoesophageal fistula
  - III: Absent trachea & carina; main bronchi arise from esophagus
- Associated anomalies in up to 94%



CLINICAL ISSUES



- Inability to conduct air at delivery → aphonia & insufficient ventilation; intubation is difficult
- Highly lethal due to lack of sustainable conduit for air transit from glottis to lungs
- Long-term tracheal replacement options are sparse
  - Rarely successful reconstruction with esophagus
  - Bioengineered graft material may be future therapy

(Left) *AP chest radiograph in a 34-weeks-gestation newborn with cyanosis, aphonia, & poor ventilation at delivery shows the tip of the endotracheal tube (ETT) in the thoracic midline below the expected level of the carina. The ETT follows a similar course to the nasogastric tube (NGT).* **(Right)** *Coronal CECT in the same patient shows horizontal orientation of low-lying main bronchi that connect to the esophagus. Note that both the NGT & low ETT lie in the esophagus in this patient with complete tracheal agenesis.*

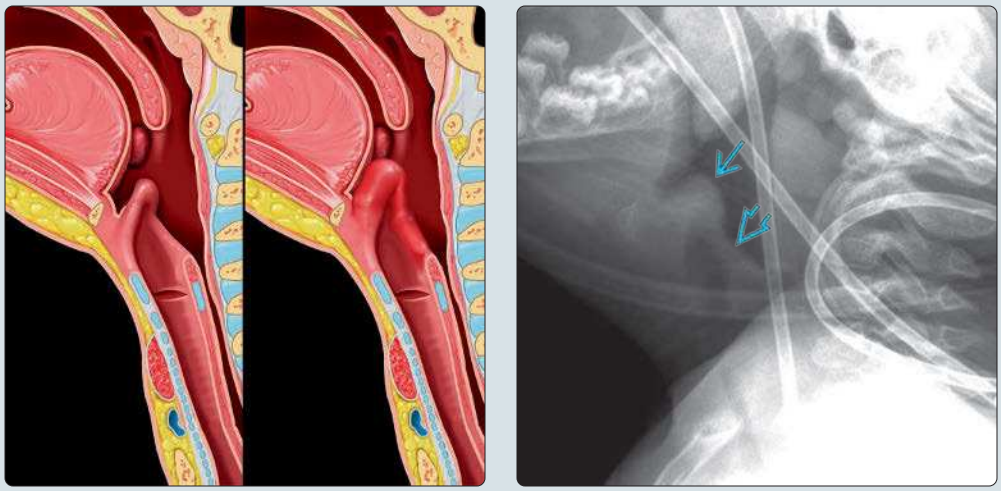
(Left) *Coronal T2 SSFSE MR in a 31-weeks-gestation fetus shows an abnormal connection of the bilateral main bronchi to the esophagus. No trachea was identified. This fetus had numerous anomalies, including radial ray, genitourinary, gastrointestinal, & cardiac.* **(Right)** *Sagittal PD MR in a 34-weeks-gestation newborn shows a fistula from the carina to the esophagus. Vessels are seen anterior to the esophagus without a discernible trachea, consistent with tracheal agenesis.*

Epiglottitis

KEY FACTS

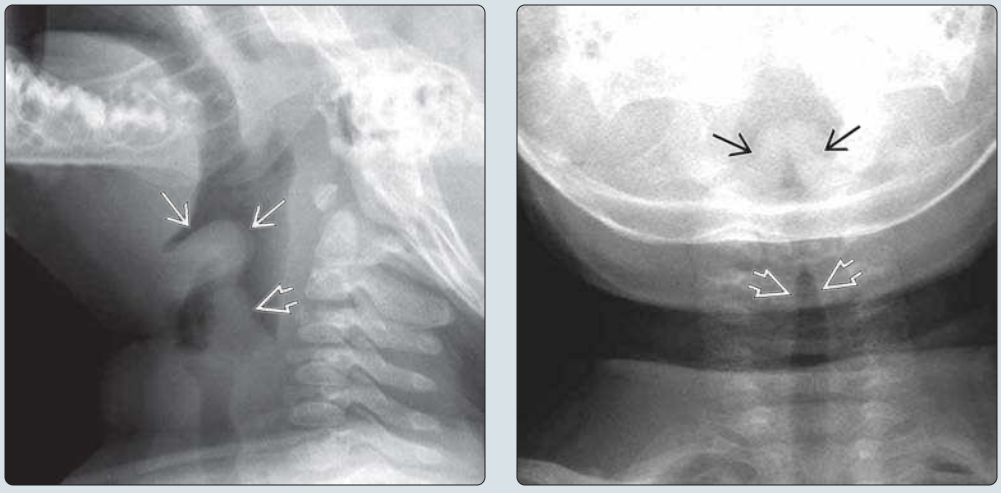
TERMINOLOGY

- Airway obstruction secondary to inflammation of epiglottis & surrounding tissues



IMAGING

- Frontal & lateral radiographs are only obtained in stable patients with questionable diagnosis
  - Child should be kept upright & comfortable
  - Patient may drool due to difficulty handling oral secretions: Should not be agitated or placed supine
- Lateral radiograph
  - Marked thickening with loss of sharp posterior margin of central epiglottis thumbprint shape/appearance
  - Thickening of aryepiglottic folds
    - Extend from epiglottis anterosuperiorly to arytenoid cartilages posteroinferiorly
    - May become thickened & convex superiorly
    - Swelling of these folds → actual airway obstruction
- Frontal radiograph
  - ± symmetric, subglottic tracheal narrowing, similar to that seen in croup
  - Swelling of epiglottis & aryepiglottic folds is often not seen on frontal view; may be visualized through foramen magnum
- CT does not play routine role in diagnosing epiglottitis



CLINICAL ISSUES

- Marked ↓ in incidence in children since vaccine for *Haemophilus influenzae* introduced
  - Mean age in children has shifted from 3.5 to 14.6 years
    - Now more common in adults than children
  - Many other infectious & noninfectious etiologies are now implicated
- Classically life-threatening if untreated; treatment includes
  - Direct laryngoscopy & bronchoscopy with intubation performed in operating room with otolaryngology present
  - Steroids & broad-spectrum IV antibiotic therapy

(Left) *Sagittal graphics show epiglottitis (right) as compared with a normal epiglottis (left). The epiglottis & aryepiglottic folds are swollen & diffusely enlarged (right).* **(Right)** *Lateral radiograph in a 13-month-old with stridor shows thickening of the epiglottis with loss of the normal sharp, central, posterior margin. There is thickening of the aryepiglottic folds as well. At scope, exudates & inflammation were visualized. Cultures grew Staphylococcus aureus.*

(Left) *Lateral radiograph in a 6-month-old shows marked thickening of the epiglottis & the aryepiglottic folds, typical of epiglottitis.* **(Right)** *AP radiograph in the same patient shows thickening of the epiglottis & aryepiglottic folds seen through the skull base/foramen magnum. There is mild subglottic narrowing, which can be seen in varying degrees with epiglottitis.*

TERMINOLOGY

Synonyms

- Supraglottitis

Definitions

- Airway obstruction secondary to inflammation of epiglottis & surrounding tissues

IMAGING

General Features

- Best diagnostic clue
  - Classic imaging appearance: Lateral radiograph shows enlargement/thickening of epiglottis & aryepiglottic folds
    - Epiglottis often appears like thumbprint (or frontal perspective of thumb with nail en face to x-ray beam)
  - Not to be confused with normal epiglottis
    - May appear similar to hitchhiker thumb (or lateral perspective of thumb with nail tangential to x-ray beam)
    - Epiglottis maintains sharp interfaces with well-defined, central posterior border; no thickening of aryepiglottic folds
- Location
  - Potentially life-threatening inflammation & swelling of epiglottis & surrounding tissues (i.e., aryepiglottic folds)
- Morphology
  - Swelling of epiglottitis → thumbprint appearance on lateral radiograph

Radiographic Findings

- Lateral radiograph
  - Marked thickening of epiglottis with loss of sharp, central posterior margin
  - Aryepiglottic folds
    - Extend from epiglottis anterosuperiorly to arytenoid cartilages posteroinferiorly
    - Normally thin & straight or concave (apex inferior), outlined by air
    - May become thickened & convex
    - Swelling of these folds causes actual airway obstruction
  - ± nonspecific "ballooning" (air distention) of hypopharynx
- Frontal radiograph
  - Only lateral radiograph is obtained if epiglottitis is highly suspected
    - Supine positioning of ill patient could lead to airway occlusion
  - ± symmetric, subglottic narrowing, similar to that seen in croup
  - Swelling of epiglottis & aryepiglottic folds may not be seen on frontal view
    - May see swollen epiglottis through skull base

Ultrasonographic Findings

- Limited studies describe findings on point-of-care-ultrasound (POCUS)
- ↑ AP dimension of epiglottis
  - Some overlap in measurement at midpoint between control & epiglottitis groups: 3.4 mm is upper limit of normal
  - No overlap in measurement at lateral margins between control (upper limit of normal is 3.2 mm) & epiglottitis groups (≥ 3.6 mm)

CT Findings

- CECT
  - CT has no role in diagnosing epiglottitis
  - If obtained (occasionally for other reasons), will show edematous, enlarged epiglottis with involvement of aryepiglottic folds
    - Epiglottis is slightly lower in attenuation when compared with other soft tissue
  - In rare cases, may see phlegmonous collection within adjacent soft tissues
  - May be helpful in evaluating for complications, such as deep neck space infection/abscess
    - Very rare in pediatric population as opposed to adult population where it can be seen in 2-29% of cases

Imaging Recommendations

- Best imaging tool
  - Due to potentially life-threatening airway emergency, unstable patients with classic clinical presentation undergo direct laryngoscopy & bronchoscopy with intubation in operating room by otolaryngology as indicated
  - Only lateral radiograph should be obtained in cases suspecting epiglottis
- Protocol advice
  - Child should be upright & comfortable
  - Patient may drool due to difficulty handling oral secretions; patient should not be agitated or placed supine
  - Patient with suspected epiglottitis should be accompanied by physician with readily available supportive equipment to secure airway if necessary
  - Obtaining lateral radiograph should never interfere with securing airway given potential for rapidly fatal outcome

DIFFERENTIAL DIAGNOSIS

Enlarged Lingual Tonsils

- Rounded &/or lobulated mass bulging from posterior tongue base, potentially filling vallecula & displacing epiglottis

Vallecular Mass

- Most commonly cyst but rarely sarcoma
- Fills vallecula, potentially displacing or effacing epiglottis depending on exact site of origin

Croup

- Most common acute airway condition of children
- Benign, self-limited condition with "barky" cough in patients usually < 3 years of age
- Symmetric subglottic tracheal narrowing (steeple sign)

Bacterial Tracheitis

- Children are typically older than those with croup

- Intraluminal filling defects (membranes), tracheal wall plaque-like irregularity, poorly defined tracheal margins, asymmetric subglottic narrowing

Retropharyngeal Abscess

- Pyogenic infection of retropharyngeal space
- Persistent thickening of retropharyngeal soft tissues despite inspiration & neck extension on lateral view
  - ± loss of normal step-off at junction of hypopharynx & esophagus

Ω Epiglottis

- Normal variant found in young infants, observed at scope (not on radiographs)
- Leads to laryngomalacia in association with short aryepiglottic folds & prolapsing arytenoids

PATHOLOGY

General Features

- Etiology
  - Most common agent remains *Haemophilus influenzae*
    - Dramatic changes in incidence, etiology, & patient demographics since *H. influenzae* (HiB) vaccine introduction
    - More cases of epiglottitis resulting from other bacterial, viral, or combined viral-bacterial infections are now seen since introduction of HiB vaccination
      - Other organisms include group A β-hemolytic *Streptococcus*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Moraxella catarrhalis*, *Pseudomonas* species, *Candida albicans*, *Pasteurella multocida*, & *Neisseria* species, COVID-19, influenza
      - Bacterial superinfections of preceding viral infections, such as herpes simplex, parainfluenzae, varicella-zoster, & EBV
  - Can also occur from noninfectious etiologies, such as allergic reaction, angioneurotic edema, mucositis, trauma, Stevens-Johnson syndrome, caustic ingestion, & vaping

Gross Pathologic & Surgical Features

- Marked inflammation & edema of epiglottis & aryepiglottic folds
- Complete airway obstruction may occur at any time

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Abrupt onset of stridor (usually inspiratory), often associated with dysphagia
- Other signs/symptoms
  - High fever, sore throat, dysphonia, "hot potato voice," hoarseness, & drooling
  - Patients have toxic appearance with fever
  - Patients are described as anxious & uncomfortable
  - ↑ respiratory distress when recumbent
  - May have characteristic "tripod position" (sitting up with neck extended & leaning forward with jaw thrust out to maximize laryngeal opening)
  - Viral prodrome & cough are more likely with croup

Demographics

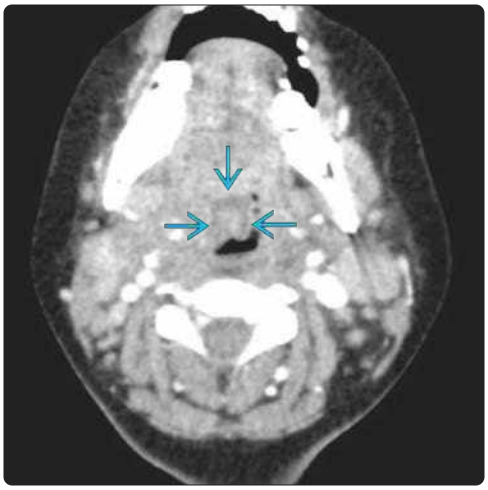
- Age
  - Marked ↓ in incidence in children since HiB vaccine introduced
    - 0.6-0.8 cases /100,000 persons immunized
    - Vaccine effectiveness 98%
  - Mean age in children has shifted from 3.5 years to 14.6 years since introduction of HiB vaccine
    - Significantly older than children with croup (mean age: 1 year)
  - Adult incidence has remained steady (although relatively uncommon) post vaccine
  - Now more common in adults than children (mean age: 40 years)

Natural History & Prognosis

- Classically: Life-threatening infectious disease often requiring emergent intubation
- Current era: May not be as clinically emergent given variety of non *Haemophilus influenzae* etiologies

Treatment

- In correct clinical setting: Emergent tracheal intubation to relieve/prevent airway obstruction & respiratory failure
  - Has evolved from tracheotomy to direct laryngoscopy & bronchoscopy with intubation performed in operating room with otolaryngology present
  - Intubation period is usually short (2-3 days)
- Steroids & broad-spectrum IV antibiotic therapy



DIAGNOSTIC CHECKLIST

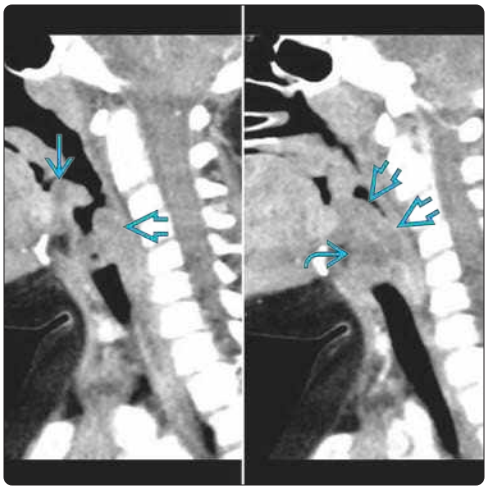


Image Interpretation Pearls

- In current era, classic radiographic appearance must be coupled with clinical presentation to determine treatment

(Left) *Axial CECT in a 9-year-old with a sore throat & fever shows a thickened, edematous epiglottis. (Right) Sagittal midline (left) & paramidline (right) CECT images in the same patient show the edematous epiglottis, aryepiglottic folds, & adjacent supraglottic tissues. Note the upward convexity of the aryepiglottic folds. No organism was able to be cultured in this infection.*

(Left) *Lateral radiograph of the airway in a 13-year-old with lymphoma shows thickening of the epiglottis & aryepiglottic folds, consistent with epiglottitis, likely due to chemotherapy-related mucositis in this case.* **(Right)** *Lateral airway radiograph in an 18-month-old with epiglottitis shows a markedly enlarged epiglottis with poorly defined margins. The right aryepiglottic fold was thickened at laryngoscopy. The patient was subsequently intubated.*

(Left) *Lateral airway radiograph shows epiglottitis as a markedly swollen & poorly defined epiglottis that has a thumbprint appearance in a patient with congenital insensitivity to pain.* **(Right)** *Gross pathology image from a deceased patient shows an inflamed & edematous epiglottis with swollen aryepiglottic folds. It is the swelling of the aryepiglottic folds that leads to airway obstruction.*

Croup

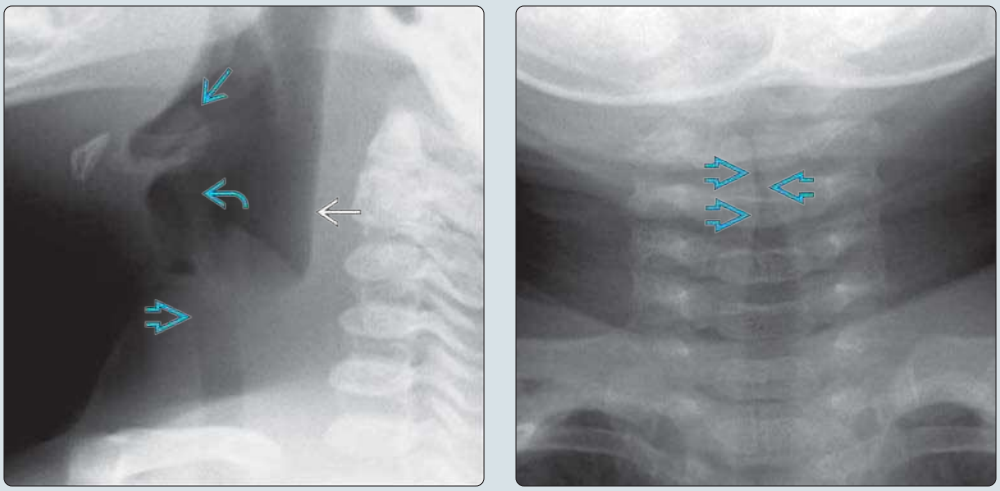
KEY FACTS

TERMINOLOGY

- Benign, self-limited viral inflammation of upper airway
- Subglottic edema results in stridor & characteristic "barky" cough

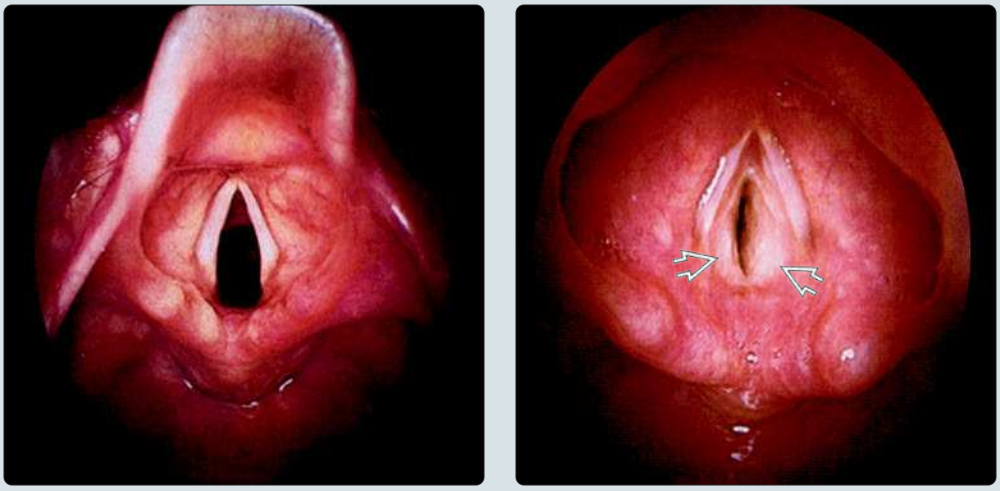
IMAGING

- Radiographs are used to exclude more serious causes of stridor (rather than diagnosing croup)
- Frontal view: Best for typical findings of croup
  - Smooth, symmetric, long-segment narrowing of subglottic airway gradually widens to normal-caliber trachea
    - Steeple or inverted V configuration
    - Loss of normal short-segment "shoulders" of subglottic trachea secondary to edema
- Lateral view: Best for excluding other diagnoses
  - Relatively mild narrowing of AP dimension
  - Haziness with loss of subglottic tracheal wall definition
  - ± hypopharyngeal overdistention



TOP DIFFERENTIAL DIAGNOSES

- Foreign body
- Vascular ring
- Bacterial tracheitis
- Infantile hemangioma
- Epiglottitis
- Angioedema
- Iatrogenic subglottic stenosis



CLINICAL ISSUES

- Acute clinical syndrome characterized by "barky" or "seal-like" ("croupy") cough, inspiratory stridor, hoarseness
  - Age range: 6 months to 3 years; uncommon > 6 years
- ± prodrome of low-grade fever, mild cough, rhinorrhea
- Majority are due to parainfluenza viruses types 1-3
- Most cases are successfully treated with glucocorticoids ± nebulized epinephrine
- Recurrent episodes or atypical age suggest alternate diagnosis

(Left) *Lateral radiograph in a 9-month-old infant with stridor shows haziness of the subglottic airway. Overdistention (ballooning) of the hypopharynx is noted. The epiglottis & aryepiglottic folds are normal.* **(Right)** *AP radiograph in the same patient shows symmetric narrowing of the subglottic trachea, typical of croup. The loss of the normal abrupt subglottic/glottic shouldering + gradual tapering of the subglottic airway lumen from inferior to superior is referred to as the steeple sign.*

(Left) *Endoscopic photograph shows a normal appearance of the subglottic airway. The subglottis is widely patent such that the mucosa is actually hidden beneath the vocal cords.* **(Right)** *Endoscopic photograph in a child with viral croup shows edematous subglottic mucosa, which is visualized through the vocal cords. There is marked narrowing of the subglottic airway lumen, predominantly in the transverse dimension.*

TERMINOLOGY

Synonyms

- Acute laryngotracheitis

Definitions

- Croup: Self-limited viral inflammation of subglottic airway
- Acute laryngotracheobronchitis: Croup + lower airway involvement
- Spasmodic croup: Recurrent episodes, typically without viral prodrome or fever
- Atypical croup: May refer to recurrent episodes, atypical patient age, prolonged/severe episodes, uncommon pathogen

IMAGING

General Features

- Best diagnostic clue
  - Symmetric, subglottic airway tapering/narrowing on frontal radiograph
  - Loss of normal subglottic "shoulders"
- Morphology
  - Normal
    - Uniform caliber of cervical & thoracic trachea from subglottis to carina
    - Normal subglottic "shoulders": Symmetric, focal, convex lateral margins at uppermost subglottic airway
      - Roughly 30-45° from horizontal

Radiographic Findings

- Radiography
  - AP/frontal view
    - Steeple or inverted V configuration of subglottic trachea
      - Smooth, symmetric narrowing of subglottic airway gradually widens to normal-caliber trachea
      - Loss of normal "shoulders" of subglottic trachea secondary to subglottic edema
      - Vertical length of narrowing is variable; ~ upper 1/3 of cervical trachea
  - Lateral view
    - Mild narrowing of subglottic trachea in AP dimension
      - Degree of narrowing is typically much less than narrowing of transverse dimension on frontal view
    - Haziness & poor definition of subglottic tracheal walls
    - ± hypopharyngeal overdistention
      - Also seen at end-inspiration in crying child
      - Hypopharynx may be collapsed with distention of lower cervical trachea on expiratory image
    - Normal epiglottis, aryepiglottic folds, retropharyngeal soft tissues; no foreign body

Imaging Recommendations

- Best imaging tool
  - Diagnosis of croup is primarily clinical
    - Radiographs are used to exclude more serious causes of stridor
      - Atypical or severe course, foreign body concern, recurrent episodes
    - Chest radiographs are sometimes obtained to exclude pneumonia
  - Frontal radiograph is most useful view to confirm croup
  - Lateral radiograph helps exclude other diagnoses
- Protocol advice
  - Ensure that neck is extended with adequate inspiration on lateral view
    - ↓ crowding of airway structures that may simulate disease in young child
  - Avoid image acquisition while child swallows

DIFFERENTIAL DIAGNOSIS

Airway Foreign Body

- Minority of foreign bodies are radiopaque
  - May appear as soft tissue density but with straight, irregular, or pointed margins
- Can lodge anywhere from nasal/oral cavities to bronchi
  - Right main bronchus is most common lower airway site
    - ± asymmetric lung aeration on chest radiographs
- Symptoms & imaging findings depend on location of object
- Esophageal foreign body may cause edema of adjacent trachea, especially if subacute/chronic or button battery ingestion

Vascular Ring

- Intrathoracic tracheal narrowing/deviation
- Double aortic arch, right aortic arch with aberrant left subclavian artery, pulmonary sling

Bacterial Tracheitis

- Typically occurs in older child, 6-10 years old
- May be toxic-appearing
- Intraluminal filling defects (pseudomembranes)
- Plaque-like irregularity &/or poor definition of tracheal walls
- Asymmetric subglottic narrowing

Infantile Hemangioma

- Younger child, often < 6 months
  - Develops in 1st few weeks of life → grows rapidly over 6-12 months → slow, spontaneous regression
- Asymmetric airway narrowing ± focal tracheal wall contour abnormality
- 50% have another visible hemangioma, most commonly of face/neck in "beard distribution"

Epiglottitis

- Typically occurs in older children
  - Historical mean age (pre-Hib vaccine) = 3 years
  - Now teenagers are more common
- Severe, life-threatening condition classically
- Marked enlargement of epiglottis & aryepiglottic folds
  - Loss of sharp posterior margin of central epiglottis on lateral view
- May cause symmetric, subglottic narrowing on frontal view

Thermal Injury

- History of smoke inhalation, burns

Angioedema

- Rapid swelling of facial soft tissues & upper airway
  - ± itching, pain, hives
- May be due to allergic reaction or hereditary angioedema

Iatrogenic Subglottic Stenosis

- History of prolonged or traumatic intubation
- Predisposes to recurrent croup-like episodes

PATHOLOGY

General Features

- Etiology
  - Typical croup is secondary to viral illness
    - Most cases: Parainfluenza viruses types 1-3
    - Less frequently: Respiratory syncytial virus, adenovirus, rhinovirus, enterovirus, influenza, herpes simplex, metapneumoviruses, measles, SARS-CoV-2; bacterial forms are uncommon (consider *Corynebacterium diphtheriae* & *Mycoplasma pneumoniae*)
  - Leads to inflammation & edema of subglottic airway
    - Redundant mucosa predisposes to edema & narrowing
      - Loose mucosal attachment of conus elasticus
    - Cricoid cartilage is complete ring with inability to expand
    - Swelling of vocal cords → hoarseness
    - Characteristic (but not specific) "barky" cough results from inflammation of larynx & trachea
    - Inspiratory stridor is due to proportionately small subglottic trachea in young children
      - Same viral infections & edema do not compromise older child or adult airway
- Associated abnormalities
  - Atypical or spasmodic croup
    - 20-64% incidence of large airway lesions: Subglottic hemangioma, stenosis, laryngeal cleft, laryngeal ulcer, tracheomalacia, laryngomalacia, papillomatosis, laryngeal web, or vocal cord paralysis
    - Additional common disorders in this group: Gastroesophageal reflux, asthma, sleep-disordered breathing, seasonal allergies, chronic cough, prematurity

Staging, Grading, & Classification

- Westley Croup Severity Score (clinical severity score)
  - Mild: Occasional "barky" cough, no stridor at rest, no or mild retractions
  - Moderate: Frequent "barky" cough, stridor at rest, mild to moderate retractions
  - Severe: Moderate criteria + marked retractions, distress, & agitation
  - Impending respiratory failure: Severe criteria + altered mental status, poor air entry, cyanosis or pallor

CLINICAL ISSUES

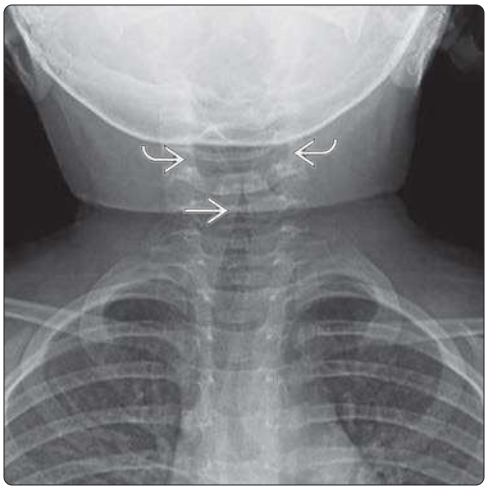
Presentation

- Most common signs/symptoms
  - Acute clinical syndrome characterized by "barky" or "seal-like" ("croupy") cough, inspiratory stridor, hoarseness, respiratory distress
- Other signs/symptoms
  - Often have prodrome of low-grade fever, mild cough, rhinorrhea
  - Typically non-toxic-appearing & able to manage secretions
  - More severe cases: Intercostal retractions, tachypnea, pallor, cyanosis, tachycardia, altered mental status
  - Symptoms worse at night or with agitation
  - May occur with other symptoms of lower respiratory tract infection (wheezing, cough, etc.)

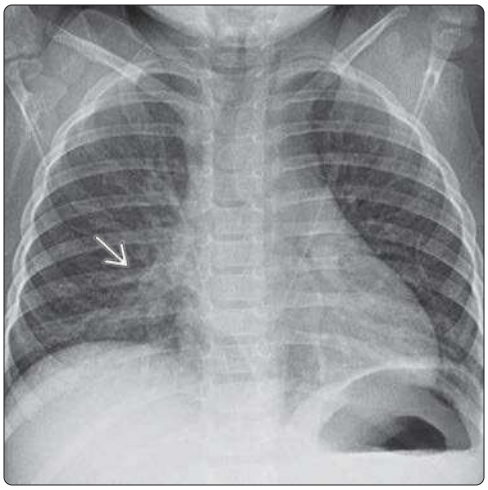
Demographics

- Age
  - Range: Most common 6 months to 3 years
    - Uncommon > 6 years
    - Mean age of atypical croup: 2.7-4.8 years
  - If > 3 years, consider other causes of acute stridor
  - If < 6 months, consider predisposing abnormality
- Epidemiology
  - Most common cause of acute upper airway obstruction in young children
    - Affects 5% of children by age 2 years
    - Affects 3% of children per year
  - Seasonal occurrence with viral disease: Most prevalent in fall-winter; historically has shown biennial peaks

Natural History & Prognosis



- Typically benign, self-limited disease
- ~ 85% are classified as mild
- 75% of mild cases resolve within 3 days
- 11% of mild & 49% of moderate cases of croup worsen
- 5% return to emergency department within 72 hours



Treatment

- Mild: Often supportive therapy at home
  - Humidified air, antipyretics if febrile, oral fluids
  - Oral glucocorticoid
- Moderate or severe
  - Oral, IV, or IM glucocorticoid + nebulized epinephrine
  - Supportive measures (antipyretics, humidified air, oxygen, oral or IV fluids)
  - Admission for inadequate response to treatment
    - Downward trend in patients requiring inpatient treatment over last several decades
    - < 5% of patients with croup require hospitalization
  - Intubation is rarely needed, should be performed by skilled provider in controlled setting
  - Death is very rare; < 1% of patients requiring intubation

(Left) *AP radiograph in a 2-year-old with stridor shows symmetric subglottic narrowing & overdistention of the hypopharynx. The trachea is otherwise normal in caliber & position.* **(Right)** *AP radiograph of the chest in the same patient shows patchy airspace opacities in the right middle lobe due to pneumonia. Chest radiographs may be obtained in children with croup if there is concern for pneumonia. Coexistent upper or lower respiratory tract infection is not uncommon.*

(Left) *Lateral radiograph in an 8-month-old infant with fever & a "barky" cough shows poor definition & haziness of the subglottic airway, a common finding in viral croup.* **(Right)** *AP radiograph in the same patient shows severe narrowing of the subglottic trachea, which gradually tapers from inferior to superior. Note the lack of a focal extrinsic mass or intrinsic filling defect.*

(Left) *AP radiograph in a 16-month-old child with stridor shows symmetric subglottic airway narrowing, typical of viral croup. No focal mass or linear/nodular filling defect is identified.* **(Right)** *AP radiograph in a normal child shows the typical normal "shoulders" of the subglottic airway, which are more focal & horizontal than the long, gradual, vertical "steepling" seen in croup.*

Bacterial Tracheitis

KEY FACTS

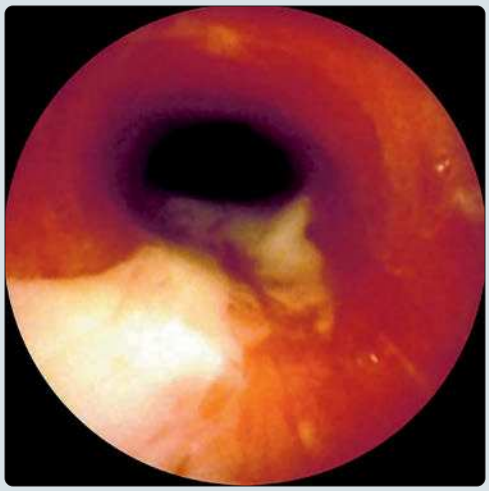
TERMINOLOGY

- Synonyms: Exudative tracheitis, membranous or pseudomembranous croup, membranous laryngotracheobronchitis
- Definition: Purulent infection of trachea
  - Results in thick, adherent exudative plaques along tracheal walls
  - Plaques can slough, leading to airway obstruction
- Controversial disease
  - While many cases with significant morbidity & mortality have been confirmed, questions remain concerning overdiagnosis/overtreatment at some centers

IMAGING

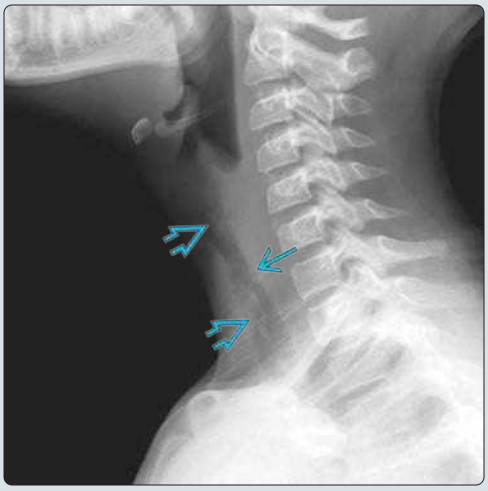
- Characteristic radiographic findings
  - Thin or thick, linear or irregular soft tissue filling defects within airway (visualized pseudomembranes)
  - Loss of smooth, well-defined, parallel tracheal walls + nodular plaque-like irregularity of walls
  - Hazy or indistinct tracheal air column
  - Symmetric or asymmetric subglottic narrowing in acutely ill child older than typically seen with viral croup

TOP DIFFERENTIAL DIAGNOSES



- Epiglottitis
- Croup
- Retropharyngeal abscess
- Upper airway obstruction by foreign body
- Intraluminal secretions

CLINICAL ISSUES



- High-grade fever, cough, severe stridor, rapid onset (2-10 hours) of respiratory distress; often after viral prodrome
  - Mild symptoms are more common in recent papers
- Peak age: 3-8 years (older than classic viral croup)
- Aggressive treatment to prevent airway obstruction, death
  - Flexible laryngoscopy → rigid bronchoscopy, removal of pseudomembranes ± intubation; IV antibiotics

(Left) *Graphic shows inflammation of the trachea with the formation of inflammatory plaques & pseudomembranes along the tracheal walls. These plaques may detach from the tracheal wall & occlude the airway.* **(Right)** *Photograph from bronchoscopic visualization of the trachea in a child with bacterial tracheitis shows multiple purulent exudative plaques along the tracheal walls.*

(Left) *Lateral airway radiograph in a child with fever & stridor shows multiple irregular, intraluminal filling defects ⇨ as well as tracheal wall irregularity ⇨ & moderate luminal narrowing, consistent with exudative tracheitis.* **(Right)** *Lateral radiograph in a 5-year-old boy with fever, throat pain, & cough shows mild, generalized tracheal narrowing with subtle lobular & linear filling defects ➡ concerning for plaques/pseudomembranes. Exudative tracheitis was confirmed at laryngoscopy.*

TERMINOLOGY

Synonyms

- Exudative tracheitis, membranous or pseudomembranous croup, membranous laryngotracheobronchitis
  - Membranous croup: Confusing term overlapping much more common benign entity of viral croup

Definitions

- Purulent infection of trachea
  - Results in thick, adherent, exudative plaques along tracheal walls with pseudomembranes extending across lumen
  - Plaques can slough & obstruct airway
- Controversial disease
  - More frequent in certain medical centers; rarely seen in other centers of similar climate
  - While many cases with significant morbidity/mortality have been confirmed, questions remain concerning overdiagnosis/overtreatment at some centers

IMAGING

General Features

- Best diagnostic clue
  - Radiography demonstrates plaque-like irregularity of tracheal walls &/or linear filling defects (pseudomembranes) within tracheal lumen
- Location
  - Purulent infection of trachea, which may extend to involve larynx & bronchi

Radiographic Findings

- Linear filling defects within subglottic airway
- Plaque-like irregularity with loss of well-defined, smooth, parallel tracheal wall contours (candle dripping sign)
  - Mucus can mimic plaques but may clear on repeat images after patient coughs
    - Coughing may be contraindicated if clinical suspicion is high (due to risk of dislodging pseudomembranes)
- Hazy, indistinct tracheal air column
- Symmetric or asymmetric subglottic narrowing in child older than typically seen with croup

CT Findings

- Not routinely used in diagnosis
- Tracheal filling defects may be detected on lung window images obtained for other clinical suspicions

MR Findings

- Not used in diagnosis

Imaging Recommendations

- Best imaging tool
  - Frontal + lateral airway radiographs

DIFFERENTIAL DIAGNOSIS

Croup

- Benign, self-limited condition classically
- Most common upper airway disease encountered in children
- Characteristic cough ("barking," "seal-like")
- Symmetric, subglottic narrowing (steepling)
- Younger age (mean: 1 year) than exudative tracheitis

Epiglottitis

- Severe, life-threatening condition
- Fever, sore throat, drooling, respiratory distress in recumbent position
- Marked enlargement of epiglottis & aryepiglottic folds
- May cause symmetric subglottic narrowing on frontal view, similar in appearance to croup (but not as isolated finding)
- Peak age has now shifted to teenage years
  - Previously 3.5 years prior to *Haemophilus influenzae* vaccine

Retropharyngeal Abscess

- True thickening of retropharyngeal soft tissues that does not change with inspiration
- CECT confirms rim-enhancing fluid collection with surrounding edema & adenopathy
- Fever, sore throat, toxic-appearing, leukocytosis
- Most often < 6 years of age

Upper Airway Foreign Body

- Rarely radiodense
- May be seen as soft tissue filling defect in oropharynx/hypopharynx
- ± recent choking episode

Intraluminal Secretions

- May cause small globular filling defect without tracheal narrowing
- May clear with coughing, though patients with suspected tracheitis should not be urged to cough (as this could theoretically dislodge plaques & obstruct airway)

PATHOLOGY

General Features

- Favored to represent bacterial superinfection following compromise of respiratory mucosa by viral illness rather than isolated primary bacterial infection
- *Staphylococcus aureus* remains most common etiology, MSSA > MRSA
  - Others: *Streptococcus* species, *H. influenzae*, *Moraxella catarrhalis*, & *Pseudomonas aeruginosa*
  - Polymicrobial infection is often present, supporting etiology of secondary infection
- Viral cultures are also frequently positive (up to 65%), which may be due to preceding illness
  - Parainfluenza, rhinovirus, & influenza A are common

Gross Pathologic & Surgical Features

- Endoscopy shows laryngeal & subglottic edema/erythema, ulcerations, copious secretions with adherent pseudomembrane formation
- Exudative plaques can slough & lead to obstruction of airway (much like historic airway obstructions with *Corynebacterium diphtheriae*)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms

- High-grade fever, cough, severe stridor (biphasic or inspiratory), voice changes, rapid onset (2-10 hours) of respiratory distress
  - Cough may be "barky," similar to viral croup
- Usually preceded by several-day history of viral upper respiratory tract infection, low-grade fever, cough

- Other signs/symptoms
  - Initial descriptions reported patients as severely toxic in appearance
  - Many patients have only mild symptoms in more recent papers
  - Affected children are typically able to handle oral secretions & tolerate supine position, unlike epiglottitis
  - Rare reports of chronic forms
- Clinical profile
  - Preexisting intubation or tracheostomy may predispose to bacterial tracheitis
    - Presentations are more indolent
      - ↑ purulent secretions requiring more frequent suctioning of airway
      - ↓ oxygen saturations
    - Most commonly develops ~ 4 days after intubation with 2-11% incidence
      - Less predictable, lower incidence with longstanding tracheostomy
    - May be precursor to pneumonia

Demographics

- Age
  - 3 months to 14 years; peak age of 3-8 years with mean age of 5 years
    - Older than patients who present with classic viral croup
- Sex
  - No predilection
- Epidemiology
  - Incidence: 4-8 per 1 million children

Natural History & Prognosis

- Systemic complications include
  - Septic shock
  - Pulmonary edema
  - Acute respiratory distress syndrome
- Mortality historically of 20-40%, now ~ 1%
  - ↓ due to more aggressive work-up & therapy, possibly earlier presentations, & changing microbes

Treatment

- If exudative tracheitis is suspected clinically/radiographically, child is usually evaluated with flexible laryngoscopy
- If tracheal pseudomembranes/plaques are confirmed with direct visualization, patient undergoes rigid bronchoscopy with stripping of pseudomembranes ± intubation
  - Multiple debridements are usually not required
  - Intubation lasts 2-7 days
    - Less frequently required in older children
      - Close monitoring is still necessary
- IV antibiotics may be transitioned to oral antibiotics once culture sensitivities return
- Failure to respond completely to racemic epinephrine & corticosteroids is typical

DIAGNOSTIC CHECKLIST

Consider

- Bacterial tracheitis may present in
  - Young child with rapid deterioration after typical viral croup manifestations
  - Older child with croup-type symptoms

Image Interpretation Pearls

- Luminal linear filling defects (pseudomembranes) + irregularity/poor definition of tracheal walls (plaques): Very suggestive of diagnosis
- Repeat radiographs after patient coughs may aid clearance of incidental adherent mucus suspected as cause of tracheal filling defects/nodularity
  - Coughing may be contraindicated if clinical suspicion is high (due to risk of dislodging pseudomembranes)

(Left) *AP airway radiograph in a 4-year-old girl with fever & rapidly progressive respiratory distress shows poor definition of the tracheal wall with adjacent luminal filling defects. Extensive pseudomembranes were found at rigid bronchoscopy.* **(Right)** *Lateral radiograph in a 9-year-old boy shows moderate to marked luminal narrowing with an associated plaque in the cervical trachea, consistent with exudative tracheitis.*

(Left) *Lateral radiograph in a 13-year-old with fever, stridor, & aphonia show multiple linear filling defects in the subglottic trachea as well as subtle wall irregularities.* **(Right)** *AP radiograph in the same patient shows the linear filling defects & wall irregularities, typical of exudative tracheitis. Bronchoscopy showed purulent secretions & crusting throughout the trachea. Multiple organisms, including MSSA & Streptococcus pneumoniae, grew from these cultures.*

(Left) *Lateral radiograph in a 12-year-old girl with fever, throat pain, & difficulty breathing shows several linear luminal filling defects along sites of wall lobularity, suspicious for pseudomembranes.* **(Right)** *Gross pathology image from a deceased patient shows exudative material along the entire subglottic trachea. Airway compromise & obstruction may result from sloughing of this exudative material.*

Retropharyngeal Space Abscess

KEY FACTS

TERMINOLOGY

- Extranodal, purulent fluid collection in retropharyngeal space (RPS)

IMAGING

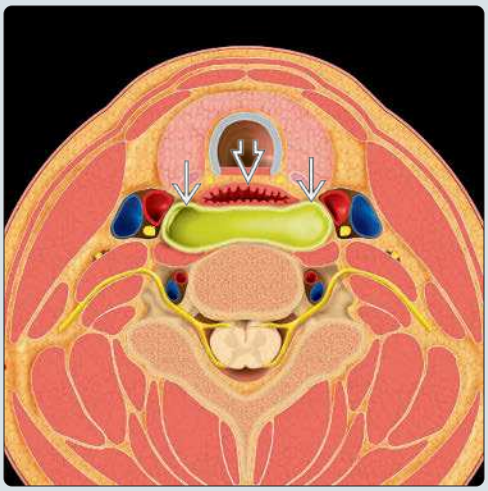
- Lateral radiograph: Wide prevertebral distance with loss of normal contours at hypopharynx-esophagus interface
- CECT is best tool for rapid characterization & evaluation of extent/complications
  - RPS is distended by defined, ovoid, rim-enhancing, low-density collection with convex anterior margin
  - Complications include airway compromise, jugular vein thrombosis/thrombophlebitis, mediastinal extension/mediastinitis, internal carotid artery (ICA) pseudoaneurysm (rare, suggests methicillin-resistant *Staphylococcus aureus*)

TOP DIFFERENTIAL DIAGNOSES

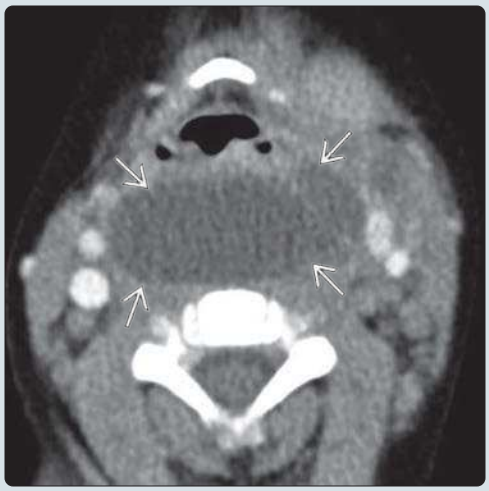
- Pseudothickening of retropharyngeal soft tissues
- Retropharyngeal space edema
- Necrotic/suppurative adenopathy in RPS
- Lymphatic malformation

PATHOLOGY

- Most common etiology: Rupture of suppurative RPS lymph node → abscess



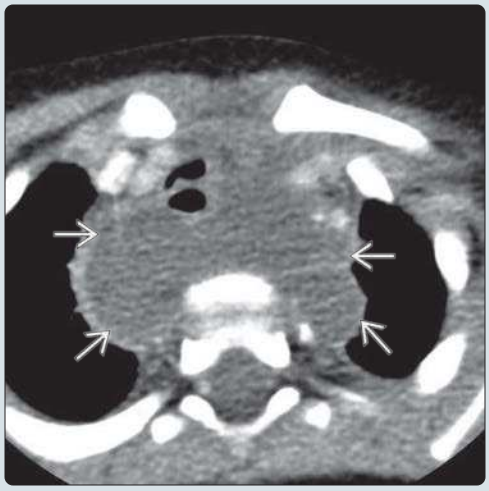
CLINICAL ISSUES



- Dysphagia, sore throat, poor oral intake, dehydration
- Toxic patient: Fever, chills, ↑ WBC & ESR
- Most < 6 years old; increasing incidence in adults

DIAGNOSTIC CHECKLIST

- Distinction from RPS edema can be difficult
  - Oval-shaped collection with convex anterior margin & rim enhancement suggests drainable abscess
    - Rim enhancement may be minimal if
      - Early in disease course
      - CECT is performed with early/arterial timing



(Left) *Axial graphic illustrates the location & typical contour of a retropharyngeal space (RPS) abscess ➡ displacing the cervical esophagus ➡ anteriorly & flattening the prevertebral muscles.* **(Right)** *Axial CECT in a 10-month-old with a 5-day history of febrile illness reveals a large, low-density, ovoid collection distending the RPS ➡ with anterior displacement of the pharynx & splaying of the carotid sheaths. There is minimal enhancement of the collection wall.*

(Left) *Sagittal reformatted CECT in the same infant reveals an abscess ➡ displacing the pharynx & esophagus anteriorly & extending inferiorly to involve the superior mediastinum ➡.* **(Right)** *Axial CECT reveals the inferior extension of this methicillin-resistant Staphylococcus aureus (MRSA) abscess to the superior mediastinum ➡. This fluid was drained through a cervical approach to the collection. There was no stridor or other sign of airway compromise in this patient despite a displaced & narrowed airway.*

TERMINOLOGY

Definitions

- Retropharyngeal space (RPS): Midline space posterior to pharyngeal mucosa & cervical esophagus from skull base to T3 vertebral level in mediastinum
- RPS abscess: Extranodal, purulent fluid collection in RPS

IMAGING

General Features

- Best diagnostic clue
  - Midline rim-enhancing RPS fluid collection with mass effect in toxic-appearing patient
- Location
  - Posterior to pharynx & anterior to prevertebral muscles
- Size
  - Variable: May extend from skull base to mediastinum
- Morphology
  - Defined collection, not just infiltrative edema
  - Axial plane: Oval shape with convex anterior margin

Radiographic Findings

- Lateral view is critical
  - Normal prevertebral soft tissue thickness
    - C2 (at hypopharynx): ≤ 7 mm at any age
    - C6 (at cervical esophagus): ≤ 14 mm if < 15 years, ≤ 22 mm in adults
  - In children: Must perform lateral radiograph during inspiration with neck extension
    - Neck flexion & expiration often cause pseudothickening of prevertebral soft tissues in young children
    - Lateral fluoroscopy can distinguish persistent true thickening vs. dynamic pseudothickening
- With RPS abscess, lateral view shows widened/thickened prevertebral soft tissues
  - Convex anterior bowing ± loss of normal step-off at interface of hypopharynx & esophagus
  - Limited utility for defining extent of collection & differentiating cellulitis/phlegmon from abscess
  - RPS gas is rare but diagnostic of abscess (if no trauma)

CT Findings

- CECT
  - RPS is markedly distended by defined fluid collection with enhancing wall
    - In early stages, enhancement may be subtle
    - Thick, enhancing wall suggests mature abscess
    - Prevertebral muscles may also appear edematous
    - Gas is rarely present
  - Assess for complications
    - Airway compromise
    - Internal jugular vein (IJV) is frequently compressed/effaced, rarely thrombosed
    - Internal carotid artery (ICA) is frequently narrowed (spasm)
      - Pseudoaneurysm is rare; suggests methicillin-resistant *Staphylococcus aureus* (MRSA)
    - Mediastinal extension

Ultrasonographic Findings

- Not able to assess full craniocaudal or deep extent of disease
- Limited by operator experience & patient tolerance
- May help evaluate jugular vein patency

Imaging Recommendations

- Best imaging tool
  - CECT
- Protocol advice
  - CT from skull base to carina
  - Contrast-loading (split) bolus &/or non-CTA technique improves soft tissue contrast resolution given rapid acquisition times of CT
    - ↑ sensitivity for collections, rim enhancement

DIFFERENTIAL DIAGNOSIS

Pseudothickening of Retropharyngeal Soft Tissues

- Common radiographic mimic of retropharyngeal pathology in infants
- Adequate extension & inspiration or fluoroscopy will confirm as transient finding

Retropharyngeal Space Edema

- Poorly defined, elongated, homogeneous fluid infiltration of prevertebral soft tissues without rim enhancement
- In axial plane: Concave anterior margin
- RPS vessels may traverse infiltrated tissues
- Drainage is not required
- Etiologies include
  - Regional inflammation
    - Pharyngitis, tonsillitis, longus colli tendinitis
  - Venous or lymphatic obstruction
    - IJV thrombosis or resection, radiation

Suppurative Adenopathy in Retropharyngeal Space

- Centrally hypodense/necrotic lymph node in lateral RPS with adjacent cellulitis
- May lead to pus formation in reactive node (suppuration): Intranodal abscess
- May progress to extranodal RPS abscess with inadequate medical therapy

Lymphatic Malformation

- Multilocular, transspatial cystic neck mass with thin, nonenhancing wall (unless infected)
- Typically involves anterior & lateral neck

PATHOLOGY

General Features

- Etiology
  - Head & neck infection (pharyngitis, tonsillitis) seeds RPS lymph node
    - Reactive node → suppurative intranodal abscess → nodal rupture → RPS abscess
    - Most common organisms: *Staphylococcus aureus*, *Haemophilus*, *Streptococcus*
  - Pharyngeal penetration by foreign body
    - Child running with object in mouth
      - Lollipop/sucker, toothbrush, stick, toy

- Ventral spread of discitis/osteomyelitis & prevertebral infection
  - Uncommon in children
  - Pyogenic or tuberculous
- Mediastinal abscess spreading cranially
  - Esophageal rupture & mediastinitis with danger space (DS) abscess

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Dysphagia, sore throat, poor oral intake, dehydration
  - Septic patient: Fever, chills, elevated WBC & ESR
- Other signs/symptoms
  - Posterior pharyngeal wall edema or bulge
  - Reactive cervical adenopathy
- Clinical profile
  - Toxic-appearing child with marked neck pain & limited movement, especially in extension
  - Uncommonly presents with airway compromise (stridor)

Demographics

- Age
  - Most often children < 6 years old
  - Increasing frequency in adult population
    - Immunocompromised states: Diabetes, HIV, alcoholism, malignancy
    - Discitis/osteomyelitis with perivertebral infection
    - Trauma with foreign body impaction
    - Following anterior cervical spine surgery
- Sex
  - M:F = 2:1
- Epidemiology
  - ↑ frequency over last decade
  - ↓ incidence of abscess when infection is detected & treated in earlier cellulitic stage

Natural History & Prognosis

- Prognosis is generally excellent with early diagnosis & aggressive management
- Complications may result from infection spread
  - Narrowing of pharyngeal lumen → airway compromise & stridor
  - Inferior spread via DS to mediastinum → mediastinitis
    - Up to 50% mortality (much less in infants)
      - ↓ mortality rate in recent years with aggressive initial & repeat surgical intervention
    - MRSA is frequent
  - Carotid space involvement
    - Jugular vein thrombosis or thrombophlebitis
    - Narrowing of ICA caliber is often found; neurological sequelae are infrequent
    - Rarely ICA pseudoaneurysm &/or rupture; described with MRSA infection
  - Perivertebral space abscess may lead to epidural abscess
  - Aspiration pneumonia
  - Grisel syndrome is rare
    - Inflammatory, nontraumatic atlantoaxial subluxation
      - Due to distention or loosening of atlantoaxial ligaments after head & neck inflammation

Treatment

- Early ENT consultation
- IV antibiotics, airway management, fluid resuscitation
- Surgical intervention (incision & drainage) for
  - Significant or complex abscess
  - Lack of improvement/worsening with IV antibiotics

DIAGNOSTIC CHECKLIST

Consider

- Lateral radiograph: Often 1st-line screening tool
- Study of choice: CECT
  - Distinguish RPS abscess from edema
  - Evaluate full craniocaudal extent
  - Evaluate for vascular/airway complications
  - Consider contrast prebolus/split bolus or venous phase imaging to maximize wall enhancement

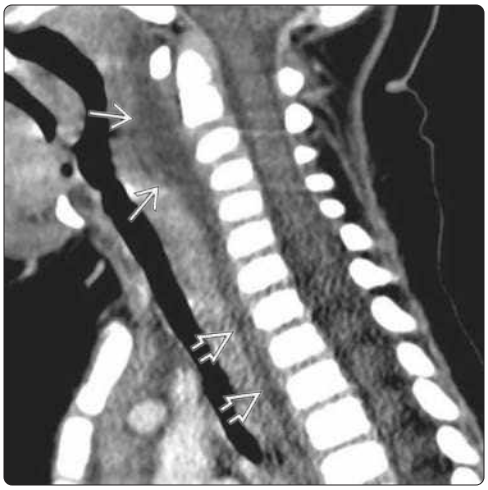


Image Interpretation Pearls

- Distinction from RPS edema can be difficult
  - Convex anterior margin or oval-shaped collection suggests abscess
  - Rim enhancement suggests abscess
    - May be minimal early in disease
    - May not be evident due to early arterial scanning
- Important to evaluate full extent of abscess & presence of complications
- ENT consultation is imperative

(Left) *Lateral radiograph in a 12-month-old boy with sepsis shows significant thickening of the prevertebral soft tissues ⇨. The normal step-off at the pharyngeal-esophageal junction has been effaced.* **(Right)** *Sagittal reformatted CECT in the same child clearly shows the cause of the prominent soft tissues to be a convex anterior RPS abscess ⇨ with extension of fluid into the posterior mediastinum ⇨. It is important to image these children from the nasopharynx to the carina, in order to evaluate the full craniocaudad extent of the collection.*

(Left) *Axial CECT in a 5-month-old boy shows an irregularly shaped RPS fluid collection ⇨ in the midline & left paramidline soft tissues, most likely an extranodal spread of a suppurative left lateral RPS lymph node. Note the bilateral nonsuppurative cervical adenopathy ⇨.* **(Right)** *Axial T1 C+ FS MR in a child allergic to iodinated contrast demonstrates a well-defined abscess ⇨ in the right lateral RPS with significant surrounding contrast enhancement & mild extension of inflammation medial to the carotid sheath vessels.*

(Left) *Lateral radiograph in a 7-month-old child with fever shows marked thickening of the prevertebral soft tissues ⇨ with ventral displacement of the pharynx & larynx. There is loss of the normal step-off at the pharyngeal-esophageal junction.* **(Right)** *Axial CECT in the same patient shows a faintly enhancing rim ⇨ at the periphery of a large RPS abscess, which displaces the hypopharynx & larynx anteriorly ⇨. The adjacent carotid sheath vessels are normal in position, enhancement, & caliber.*

Double Aortic Arch

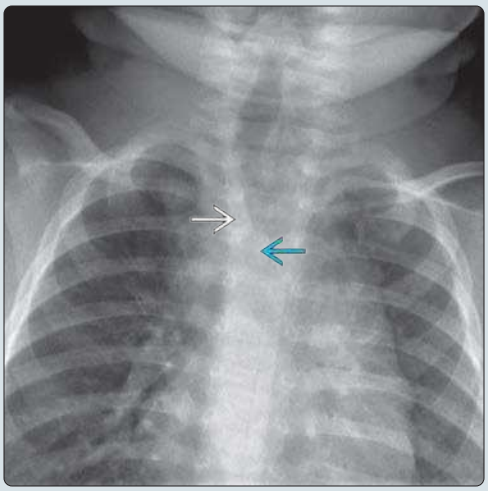
KEY FACTS

TERMINOLOGY

- Congenital aortic arch anomaly related to persistence of both left & right 4th aortic arches

IMAGING

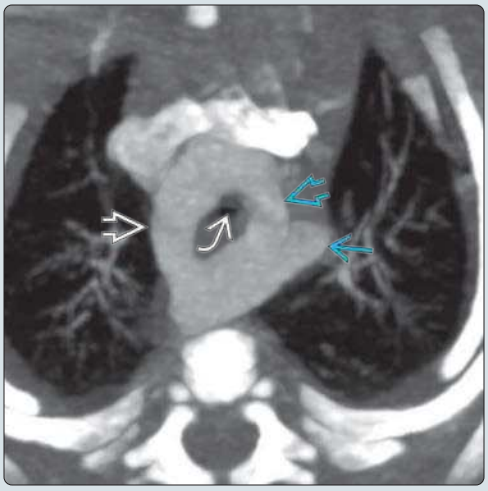
- Chest radiography is often suggestive of diagnosis
  - Bilateral tracheal indentations & midtracheal narrowing
  - Right arch indentation is commonly higher & more substantial than left ("right dominant")
- Esophagram is suggestive with characteristic bilateral & posterior indentations
- Cross-sectional imaging (CTA/MRA) for definitive diagnosis & characterization
  - Left & right arches arise from ascending aorta, encircle trachea & esophagus, & join to form descending aorta
  - Each arch gives rise to 1 ventral carotid & 1 dorsal subclavian artery (4-artery sign on axial slice)
  - Right arch is commonly larger, more superior, & more posterior extending than left (70% of cases)
    - Left descending aorta in these cases



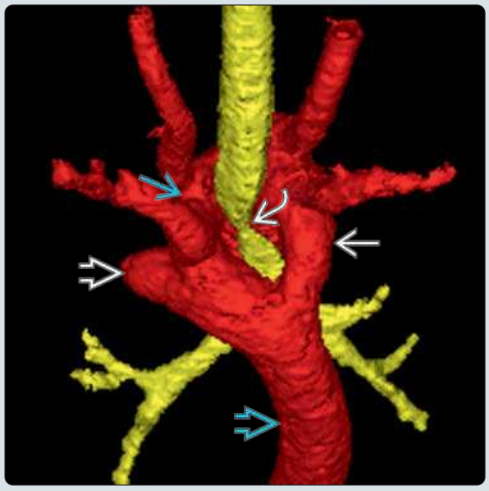
PATHOLOGY

- Typically isolated; congenital intracardiac disease in 20%
- Dominant right arch, left descending aorta: 70-75%
- Dominant left arch, right descending aorta: 15-20%
- Arches equal in size: 5-10%
- Smaller of 2 arches may be partially atretic

CLINICAL ISSUES



- Most common symptomatic vascular ring (55%)
- Often presents < 3 years of age with stridor, wheezing, & choking that worsens with feeding
- Surgery: Left (usually) thoracotomy with division of smaller arch, atretic segment, & ligamentum arteriosum with mobilization of trachea & esophagus
  - Up to 11% require 2nd operation to relieve persistent airway symptoms



(Left) *AP radiograph of a 2-month-old with biphasic stridor shows impressions on the trachea from both the right & left with the right impression ➡ being higher than the left ⇨. Radiography can be highly suggestive of a double aortic arch, though the airway morphology is often overlooked.* **(Right)** *Coronal MIP image from a chest CTA in an infant with a double aortic arch shows vascular compression of the trachea between left ⇨ & right ⇨ aortic arches. Note that the right arch is dominant, which is typical.*

(Left) *Axial CTA MIP shows right ➡ & left ⇨ aortic arches circumferentially around the compressed trachea ➡, consistent with a double aortic arch. Note the large ductal diverticulum ⇨.* **(Right)** *Posterior oblique 3D image from a chest CTA shows a double aortic arch with left ⇨ & right ➡ arches that converge to form a descending aorta ⇨. There is severe focal compression of the trachea ➡. Note the large ductal diverticulum ➡ & the symmetric branching of the great vessels.*

TERMINOLOGY

Abbreviations

- Double aortic arch (DAA)

Definitions

- Congenital aortic arch anomaly related to persistence of both left & right 4th aortic arches

IMAGING

General Features

- Best diagnostic clue
  - Radiography: Characteristic indentations of bilateral tracheal walls
  - Cross-sectional imaging: Ascending aorta splits anterior to trachea with confluence of discrete right & left arches posterior to esophagus
- Location
  - Right arch is commonly more superior & posterior than left
  - Right arch typically runs behind esophagus to join left arch to form left-sided descending aorta
- Size
  - Right arch is commonly larger than left
- Morphology
  - Part of smaller arch (usually left) may be atretic (interrupted DAA)
    - Patent portions remain connected by fibrous band, completing compressive ring around trachea & esophagus

Radiographic Findings

- Chest radiography is often suggestive of DAA
  - Symmetric mediastinal soft tissue on either side of trachea (or R > L)
    - Typically greater on left with normal left arch
  - Trachea is deviated by dominant arch or in abnormal midline position
    - Normally, trachea is slightly deviated to right by left arch
  - Bilateral tracheal indentations with midtracheal narrowing in 47%
    - Right arch indentation is commonly higher & larger than left
  - Lateral view shows generalized tracheal narrowing ± anterior indentation
  - Symmetric aeration of lungs (no unilateral air-trapping)

Fluoroscopic Findings

- Frontal view: Bilateral indentations on contrast-filled upper esophagus, often at different levels
- Lateral view: Rounded posterior indentation on esophagus; may have anterior impression as well from left mainstem bronchus

CT Findings

- CTA
  - Ascending aorta divides anteriorly into discrete right & left arches → arches encircle trachea & esophagus → arches rejoin posteriorly to form descending aorta
    - Can cause severe midtracheal compression
    - Smaller of 2 arches may be partially atretic
      - If atresia occurs between left carotid & subclavian arteries (instead of more common atresia beyond left subclavian artery), look for superior-pointing descending aortic diverticulum to confirm atresia
      - Distorted subclavian artery sign: Proximal subclavian ipsilateral to atresia shows abnormal inferior & posterior course
  - 4-artery sign: Symmetric take-off of 4 separate aortic branches on axial image at thoracic inlet
    - 2 ventral carotid & 2 dorsal subclavian arteries
      - 1 carotid & 1 subclavian arise from each arch

MR Findings

- Findings are similar to CTA
  - Lacks airway detail of CTA
- Can be depicted with variety of conventional, flow-related, & postcontrast techniques

Ultrasonographic Findings

- Prenatal diagnosis: Trident sign of 2 arches + ductus arteriosus on transverse 3-vessel trachea view

Echocardiographic Findings

- Suprasternal notch view is most helpful: 2 separate aortic arches, each giving rise to separate carotid & subclavian arteries (with no common brachiocephalic trunk)
- Does not adequately show airway & descending aorta
- Excludes intracardiac pathologies

Angiographic Findings

- Rarely required with use of cross-sectional imaging

Imaging Recommendations

- Best imaging tool
  - Radiography remains primary diagnostic test
    - Virtually all patients receive chest radiography 1st for respiratory symptoms
      - 25% can be normal in appearance
  - Esophagram rarely obviates need for cross-sectional imaging when arch anomaly is suspected clinically & radiographically
    - However, many arch anomalies are diagnosed 1st by oral contrast studies performed for feeding difficulties
  - Cross-sectional imaging (CTA or MRA) is performed to confirm diagnosis & define anatomic variations for presurgical planning
- Protocol advice
  - Multidetector CTA is faster to perform than MR
    - Generally no need for anesthesia/intubation
  - CT shows airway details somewhat better than MR
  - Multiplanar & volume-rendered images are useful for characterization & communication with referring providers
    - Particularly helpful for understanding vascular ring relationship to airway

DIFFERENTIAL DIAGNOSIS

Right Arch With Aberrant Left Subclavian Artery

- Diverticulum of Kommerell points anteriorly toward pulmonary artery

Left Pulmonary Artery Sling

- Compression on anterior aspect of esophagus & posterior aspect of trachea on lateral radiograph or esophagram
- Often associated with tracheomalacia or complete cartilaginous tracheal rings (~ 2/3 of cases)
  - Pulmonary sling is typical vascular ring associated with asymmetric aeration

Innominate Artery Compression Syndrome

- Compression on anterior aspect of trachea without esophageal compression

Nonvascular Masses

- Variety of benign & malignant solid or cystic soft tissue masses can compress & deviate trachea

PATHOLOGY

General Features

- Etiology
  - Related to embryological persistence of right & left 4th aortic arches
- Genetics
  - 22q11 deletion in ~ 25% of all arch anomalies without intracardiac disease
    - Partial arch atresia is more likely in this setting than 2 patent arches
- Associated abnormalities
  - Typically isolated lesion without associated abnormalities
    - 20% have congenital heart disease (tetralogy of Fallot, ventricular septal defect, coarctation, patent ductus arteriosus, transposition of great arteries, truncus arteriosus)
  - Underlying tracheomalacia is frequently present
- Pathophysiology
  - Variable airway & esophageal compression by vascular ring
    - Usually severe enough to present early in life
  - No hemodynamic sequelae unless associated with congenital heart disease

Gross Pathologic & Surgical Features

- True complete vascular ring with encircled trachea & esophagus
  - Dominant right arch, left descending aorta: 70-75%
  - Dominant left arch, right descending aorta: 15-20%
  - Arches equal in size: 5-10%
  - Smaller of 2 arches may be partially atretic

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 0-3 years old presenting with stridor, wheezing, & choking that worsens with feeding
  - Apnea or life-threatening respiratory arrest requiring resuscitation as initial presentation in 5-10%
- Other signs/symptoms
  - Apneic attacks, noisy breathing, "seal bark" cough
  - Feeding difficulty

Demographics

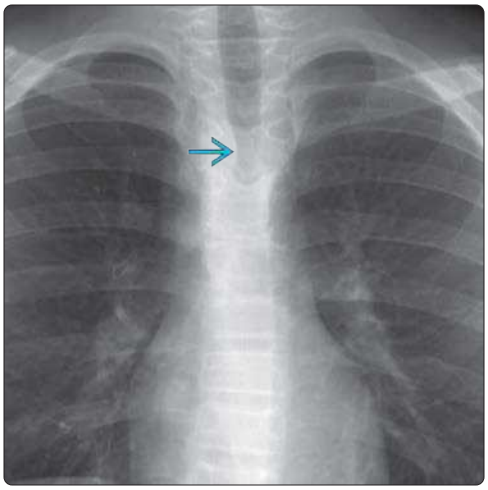
- Age
  - Typically presents with respiratory symptoms soon after birth
- Epidemiology
  - Most common symptomatic vascular ring anomaly (55%)

Treatment

- Left (usually) thoracotomy with division of smaller arch, atretic segment, & ligamentum arteriosum with mobilization of trachea & esophagus
  - Postoperative complications: Chylothorax, vocal cord paralysis, transient hypertension
  - Rare complication occurring pre- or postoperatively: Aortoesophageal fistula with severe hemorrhage
- Most common persistent symptom postoperatively: Stridor in 30%
  - Persistent airway symptoms are most commonly due to
    - Tracheal stenosis
    - Tracheobronchomalacia
    - Persistent extrinsic airway compression
      - Caused by midline/circumflex descending aorta or previously ligated arch
- Up to 11% of patients require 2nd operation to relieve airway symptoms
  - Aortopexy or other vascular suspension procedures
  - Cartilaginous tracheal ring resection followed by airway reconstruction

DIAGNOSTIC CHECKLIST

Consider



- Look for atretic segment of double arch anomaly
  - Unopacified on CTA or MRA
  - No flow void on spin-echo MR
- Smaller arch by cross-sectional imaging determines side of thoracotomy

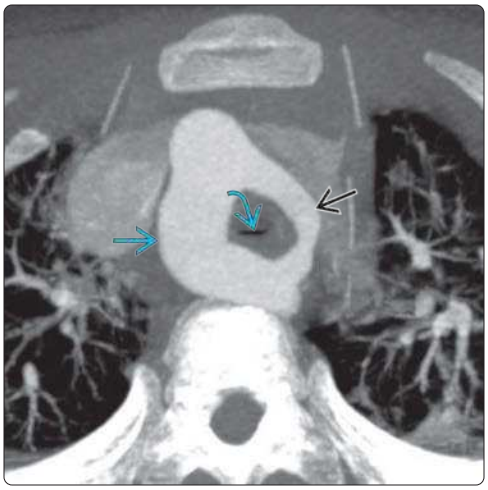


Image Interpretation Pearls

- 4-artery sign on axial CTA/MR slice at thoracic inlet

(Left) *AP radiograph of a 10-year-old with chronic stridor upon exertion shows leftward tracheal deviation. This patient had a double aortic arch with dominant right arch.* **(Right)** *Axial CTA MIP shows a double aortic arch in a 10-year-old patient with chronic stridor. Note that the right arch is larger than the left arch. Also note the tracheal compression.*

(Left) *Frontal (L) & lateral (R) views from an esophagram show vascular impressions on the right & left as well as the front & back of the esophagus in a patient with a double aortic arch.* **(Right)** *Posterior 3D image from a chest CTA shows a double aortic arch in a 10-year-old with chronic stridor. Note the dominant right arch & tracheal compression.*

(Left) *Axial CTA MIP shows a surgically confirmed interrupted double aortic arch. The right arch is dominant, while the left arch is interrupted just distal to the origin of the left subclavian artery. Note the diverticulum arising from the descending aorta.* **(Right)** *Left lateral 3D image from a chest CTA shows an interrupted double aortic arch. The left arch is interrupted between the origin of the left subclavian artery & the diverticulum arising from the descending aorta.*

Pulmonary Sling

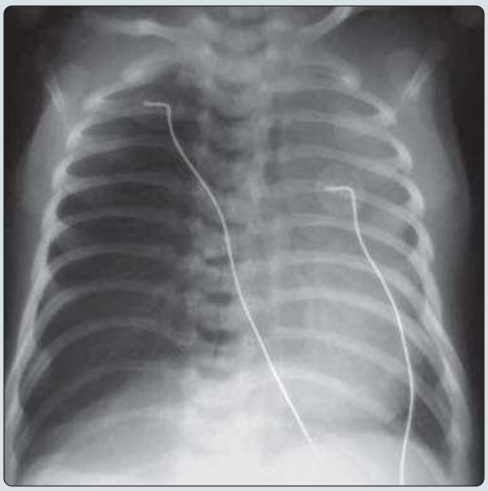
KEY FACTS

TERMINOLOGY

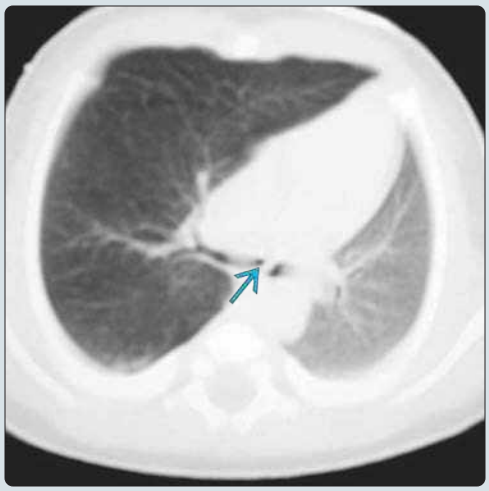
- Left pulmonary artery (LPA) originates from posterior aspect of proximal right pulmonary artery (RPA) & forms sling around right & posterior distal tracheal walls as it passes leftward between trachea & esophagus

IMAGING

- Only vascular ring to consistently course between trachea & esophagus
  - Compresses posterior trachea & anterior esophagus
  - Lateral chest radiograph: Round opacity between distal trachea & esophagus
  - Lateral esophagram: Anterior indentation on esophagus
- CT angiography is preferred over MR to confirm diagnosis & delineate anatomy prior to surgery
  - Rapid acquisition of CTA avoids intubation
  - Exquisite 3D reconstructions of airway & vessels

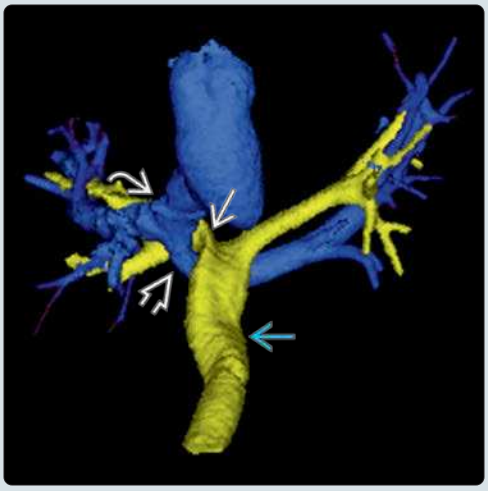


PATHOLOGY



- Type I LPA sling: Carina in normal location at T4-T5 with either normal eparterial bronchus (type IA) or tracheal bronchus to right upper lobe (type IB) → hyperinflation of right lung
- Type II LPA sling: Low carina at T6 with diffuse stenosis of intermediate left bronchus by complete cartilaginous rings at multiple levels (ring-sling complex) → bilateral or left lung hyperinflation
- Many associated airway, pulmonary, & cardiac anomalies

CLINICAL ISSUES



- Typically presents in neonatal period
  - Severe stridor, hypoxia, ventilator dependency
- Surgical repair: Division of LPA from its anomalous origin with implantation to its normal origin (main PA)
  - Tracheobronchial reconstruction is required for complete cartilaginous rings or other associated tracheobronchial malformations (types IIA & IIB)

(Left) *Frontal view of the chest shows air-trapping throughout the right lung in an infant with a known pulmonary sling that is causing asymmetric compression of the right & left mainstem bronchi. Note the leftward mediastinal shift.* **(Right)** *Axial chest CT in the same infant with a pulmonary sling shows air-trapping throughout the right lung with asymmetric compression of the right mainstem bronchus ⇨ & right-to-left mediastinal shift.*

(Left) *Superior oblique 3D volume-rendered CTA in an infant with a pulmonary sling shows the left pulmonary artery (LPA) ⇨ arising from the right pulmonary artery (RPA) ⇨ & coursing posterior to the trachea ⇨ on its way to the left lung. In this case, there was severe compression of the right mainstem ⇨ bronchus causing air-trapping.* **(Right)** *Axial MR angiogram shows the classic anatomy of a pulmonary sling with the LPA ⇨ arising from the RPA ⇨ then coursing posterior to the trachea on its way to the left lung.*

TERMINOLOGY

Abbreviations

- Pulmonary artery sling (PAS)

Synonyms

- Aberrant left pulmonary artery (LPA), LPA sling

Definitions

- LPA originates from proximal right pulmonary artery (RPA) & wraps around right & posterior walls of distal trachea (forming sling) as it passes leftward between trachea & esophagus

IMAGING

General Features

- Best diagnostic clue
  - Classic imaging appearance: Asymmetric lung inflation, narrowed distal trachea, & focal anterior impression on midesophagus
  - Only vascular ring to course between trachea & esophagus (indenting posterior tracheal & anterior esophageal margins)
- Morphology
  - Classified by associated abnormal bronchial branching patterns
    - Type I: Carina in normal location at T4-T5 with either normal eparterial bronchus (type IA) or tracheal bronchus to right upper lobe (type IB) → right lung hyperinflation
    - Type II: Low carina at T6 with diffuse stenosis of intermediate left bronchus (ILB) by complete cartilaginous rings at multiple levels (ring-sling complex) → bilateral or left lung hyperinflation
      - Type IIA: Initial bifurcation at T4 into right upper lobe bronchus & ILB, which then bifurcates at T6 into bridging right lower lobe bronchus & left main bronchus
      - Type IIB: Absent or abortive right upper lobe bronchus

Radiographic Findings

- Lateral view is most helpful
  - Round opacity between distal trachea & esophagus
  - Posterior impression on distal trachea or carina
  - Distal trachea or right main bronchus is bowed anteriorly
- Frontal view
  - Low position of left hilum
  - Leftward displacement of narrowed distal trachea

Fluoroscopic Findings

- Esophagram: Most common vascular ring to cause anterior indentation on esophagus
  - Posterior tracheal indentation at same level

CT Findings

- CTA
  - LPA arises from posterior RPA & courses to left behind distal trachea, forming sling
    - LPA passes between trachea & esophagus
  - Tracheal stenosis or compression can be severe
    - Tracheal rings result in round, small-caliber trachea on axial images
    - May also see compression of proximal bronchi, which can result in air-trapping

MR Findings

- Spin-echo T1 or black blood sequences show dark tracheal & vascular lumens
- Contrast-enhanced angiographic techniques provide 3D rendering
- Evaluation of other congenital heart abnormalities
- Functional evaluation, including QP/QS, regurgitation, & ventricular function

Echocardiographic Findings

- Absence of normal pulmonary artery bifurcation
- Anomalous origin of LPA from proximal posterior RPA
- ± other associated cardiac anomalies

Imaging Recommendations

- Best imaging tool
  - CT angiography is preferred to confirm diagnosis & delineate anatomy prior to surgery (particularly in critically ill infants with tenuous airway)
    - Rapid acquisition avoids intubation & risks of airway manipulation
    - Provides exquisite resolution & detail obtained with 3D reconstructions of airway & vessels
      - 3D reconstruction of trachea delineates length, severity, & nature of tracheal narrowing
  - Prenatal detection is becoming more common
- Protocol advice
  - Optimize intravascular contrast bolus timing
  - Paired inspiratory/expiratory or dynamic images can demonstrate contribution of tracheobronchomalacia to airway narrowing

DIFFERENTIAL DIAGNOSIS

Middle Mediastinal Mass

- Lymphadenopathy
- Bronchogenic cyst
- Esophageal duplication cyst

Primary Bronchial Malformation

- Congenital lobar overinflation
- Bronchial atresia
- Tracheobronchomalacia
- Complete cartilaginous rings

Midline Descending Aorta-Carina Compression Syndrome

- Descending aorta lies immediately anterior to spine, leading to "crowding" of mediastinum
  - Posterior compression on carina or left main bronchus
- May be isolated or associated with right lung hypoplasia, arch anomalies

Right Arch With Aberrant Left Subclavian Artery

- Rarely courses anterior to esophagus
- More superior position than LPA sling

Double Aortic Arch

- 2 aortic arches encase trachea & esophagus (but no vessel courses between them)
- Patent ductus arteriosus (PDA) may be present
- Normal course of RPA & LPA

Arterial Tortuosity Syndrome

- Tortuous pulmonary vessels may mimic pulmonary sling
- Autosomal recessive
- ± complex congenital heart disease

PATHOLOGY

General Features

- Etiology
  - Embryology
    - Agenesis or obliteration of left 6th aortic arch, which normally forms LPA
    - Arterial supply of left lung via persistent primitive artery originating from RPA
  - Pathophysiology
    - Severe stridor secondary to
      - Compression of distal trachea, carina, & main bronchi by sling, resulting in asymmetric inflation of lungs (obstructive hyperinflation > atelectasis)
      - Associated tracheobronchomalacia
      - Associated intrinsic airway narrowing (from complete cartilaginous rings)
    - Hemodynamics are determined by associated cardiac anomalies
    - Pulmonary hypertension from severe hypoxia
- Genetics
  - No specific genetic defect identified
- Associated abnormalities
  - Intrinsic tracheobronchial anomalies: Complete rings (in 2/3), tracheomalacia, branching anomalies, tracheoesophageal fistula
    - Main bronchi have abnormal horizontal course (inverted T) with abnormal branching patterns to upper & lower lobes (types IIA & IIB)
  - Other congenital lung anomalies: Right lung hypogenesis or agenesis, horseshoe lung
  - Congenital heart disease: Aortic arch anomalies, ventricular septal defect (10%), atrial septal defect (20%), PDA (25%), single ventricle, tetralogy of Fallot, partial anomalous pulmonary venous return, persistent left superior vena cava (20%)
  - Others: Imperforate anus, Hirschsprung disease, absent gallbladder, biliary atresia, Meckel diverticulum

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Severe stridor, hypoxia, ventilator dependency
- Other signs/symptoms
  - Noisy breathing, "seal bark" cough, apneic spells, recurrent pulmonary infections early in life

Demographics

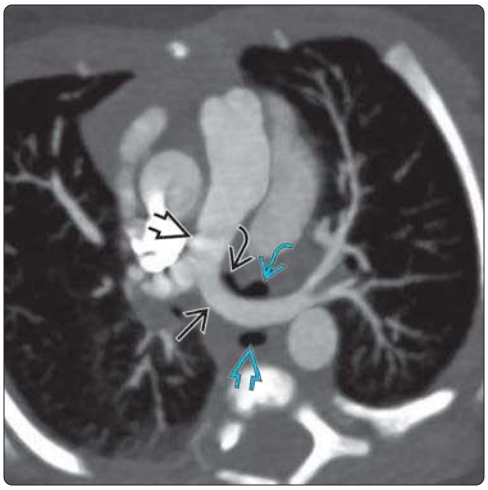
- Age
  - Typically presents in neonatal period

Natural History & Prognosis

- Type II is less favorable due to associated anomalies (60-80%)

Treatment

- Surgical division of LPA from its anomalous origin with implantation to its normal origin (main pulmonary artery)
- Tracheobronchial reconstruction if complete cartilaginous rings or other associated tracheobronchial malformations are present (types IIA & IIB)



DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Anterior indentation on esophagus = LPA sling
  - Only vascular ring consistently between trachea & esophagus; other vascular rings may rarely have this course
- Round, small-caliber distal trachea on axial images = complete cartilaginous tracheal rings

(Left) *Axial MIP CECT in an infant shows the classic pulmonary sling with the LPA ⇨ arising from the RPA ⇨ & coursing around the trachea on its way to the left lung. Note the asymmetric compression of the right mainstem bronchus ⇨ compared to the left ⇨. Also note the esophagus ⇨ posterior to the LPA.* **(Right)** *Virtual bronchoscopy CT of the tracheal bifurcation in an infant with a pulmonary sling shows asymmetric compression of the left mainstem bronchus ⇨ compared to the right ⇨.*

(Left) *Lateral image from an esophagram in a patient with a pulmonary sling shows a vascular impression of the aberrant course of the LPA on the anterior aspect of the esophagus ⇨. Note that the LPA courses between the esophagus & trachea ⇨ in this anomaly.* **(Right)** *Left posterior oblique 3D CTA of the chest in an infant with a pulmonary sling shows the LPA ➡ coursing between the esophagus (green) & the trachea (yellow). This is typical for a pulmonary sling & uncommon in other types of vascular rings.*

(Left) *Axial MIP image from a chest CTA in an infant with a pulmonary sling shows the LPA ⇨ arising from the RPA ⇨ then coursing around the trachea on its way to the left lung. Note the patent ductus arteriosus (PDA) ⇨ connecting main PA ⇨ with descending aorta ⇨.* **(Right)** *Posterior oblique 3D CTA of the chest in an infant with a pulmonary sling shows the LPA ➡ arising from the RPA ➡ & coursing around the trachea on its way to the left lung. Note the PDA (green) connecting the main PA with the descending aorta ➡.*

Innominate Artery Compression Syndrome

KEY FACTS

TERMINOLOGY

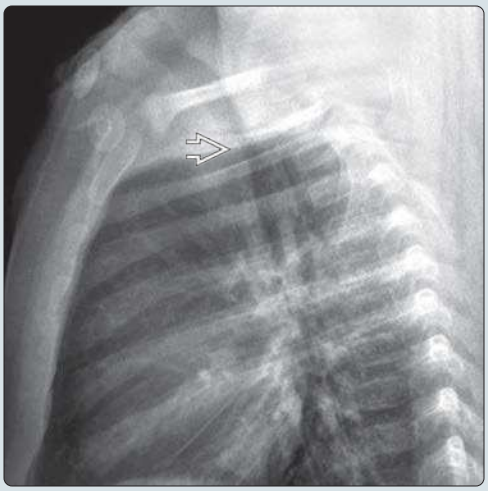
- Symptomatic tracheal compression secondary to innominate artery traversing anterior to trachea

IMAGING

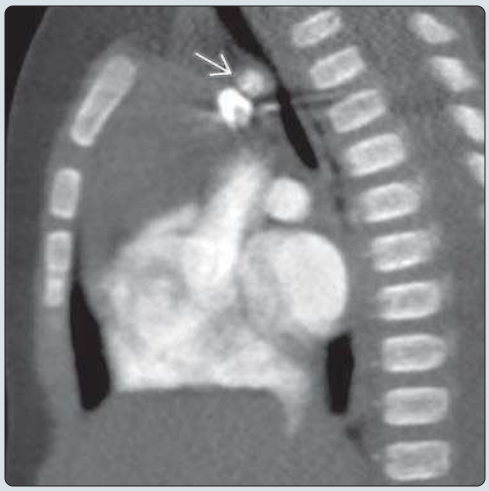
- Anterior impression on trachea from innominate artery → tracheal narrowing in AP dimension on any imaging study
  - Tracheal narrowing is confined to level at which innominate artery crosses anterior to trachea
- Detect tracheomalacia (excessive dynamic airway collapse) at level of innominate artery crossing by dynamic imaging on CT or MR
  - > 50-75% tracheal narrowing on dynamic imaging in symptomatic patient

TOP DIFFERENTIAL DIAGNOSES

- Mediastinal mass lesion causing tracheal compression
- Aberrant thyroid or ectopic thymus
- Vascular anomalies, such as vascular ring

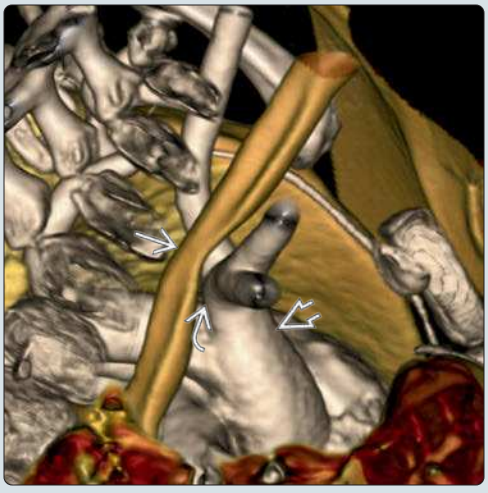


PATHOLOGY

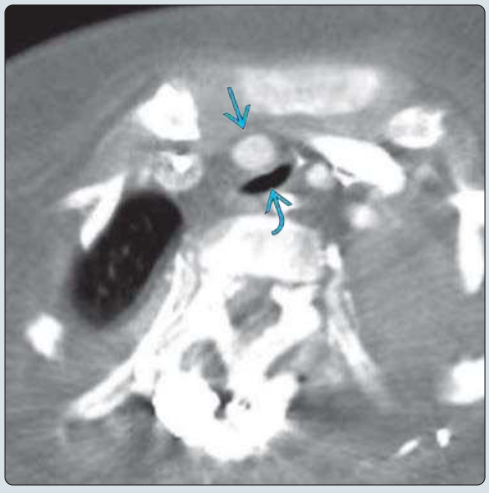


- Infantile trachea is relatively flaccid, lacking rigidity
- Normal innominate artery arises from left of trachea & courses across it anteriorly
  - Anomalous innominate artery syndrome is misnomer

CLINICAL ISSUES



- Presentations include stridor, apnea, dyspnea
  - History of recurrent bronchopulmonary infections in some patients with innominate artery compression syndrome
- Many asymptomatic children will have mild anterior compression (normal variant) on lateral radiographs & cross-sectional imaging studies
- Compression & resultant symptoms may ↓ over time as child grows



(Left) *Lateral chest radiograph shows significant narrowing of the trachea by an anterior impression just below the level of the sternal notch, compatible with innominate artery compression syndrome.* **(Right)** *Sagittal CTA in the same patient shows the relationship of the innominate artery to the trachea as it creates the anterior impression that was also seen on the lateral radiograph of the chest.*

(Left) *Right lateral view of a vessel & airway 3D CTA reconstruction in a 7-month-old child demonstrates the aortic arch with the innominate artery crossing anterior to the trachea & causing compression.* **(Right)** *Axial image from a chest CTA in an adolescent patient with stridor after spine surgery shows compression of the trachea from the innominate artery.*

TERMINOLOGY

Synonyms

- Anomalous innominate artery

Definitions

- Symptomatic tracheal compression secondary to innominate artery crossing anterior to trachea
  - Related to lack of rigidity in infantile trachea

IMAGING

General Features

- Best diagnostic clue
  - Anterior impression on trachea from innominate artery on any imaging study, typically at thoracic inlet

Radiographic Findings

- Radiography
  - On lateral radiography, anterior tracheal impression may be present with lack of air-trapping on frontal projection

CT Findings

- CECT
  - Tracheal narrowing is confined to level of innominate artery crossing
  - Can evaluate other etiologies in patients with tracheal compression on bronchoscopy
- CTA
  - 3D post processing shows relationship of vessels to trachea, along with virtual bronchoscopy views
  - Dynamic imaging can be performed to detect excessive dynamic airway narrowing (> 50-75% tracheal compression when compared to normal trachea)

MR Findings

- Tracheal narrowing as innominate artery crosses anteriorly

Other Modality Findings

- Endoscopy shows fixed, pulsatile compression on anterior aspect of trachea in most cases

Imaging Recommendations

- Best imaging tool
  - CT/MR defines degree of tracheal compression by innominate artery & excludes other causes
- Protocol advice
  - Endotracheal tube or positive pressure respiratory support can stent trachea & mask obstruction
  - CT evaluates vessels & relationships to airway; performance of dynamic imaging is plus
  - MR demonstrates anatomy on axial/sagittal imaging; dynamic airway imaging provides information on tracheomalacia

DIFFERENTIAL DIAGNOSIS

Masses Compressing Trachea

- Mediastinal bronchogenic cyst, duplication cyst, neurofibroma, lymphoma, thymic cyst, & teratoma

Normal Structures in Atypical Position

- Aberrant thyroid or ectopic thymic tissue

Vascular Abnormalities

- Right aortic arch + aberrant left subclavian artery, double aortic arch, & aneurysmal dilation of aorta or innominate artery

Lymphatic Malformation

- Mediastinal extension causing airway compression/infiltration

PATHOLOGY

General Features

- Etiology
  - Narrowing of trachea at thoracic inlet due to compression by innominate artery
    - Infantile trachea is relatively flaccid → crossing innominate artery accentuates tracheal narrowing

Gross Pathologic & Surgical Features

- Anterior wall of trachea demonstrates abnormal cartilage

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Presentations include stridor, apnea, dyspnea

Demographics

- Age
  - Young infants
- Sex
  - More common in males

Natural History & Prognosis

- Symptoms may ↓ over time as child grows

Treatment

- Most children are treated conservatively & outgrow disease
- Surgical approach is utilized in some: Aortopexy or reimplantation of innominate artery origin
  - With repeated hospitalizations due to respiratory infections
  - Symptomatic patients who fail conservative management

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Tracheal compression caused by innominate artery traversing anterior to trachea at thoracic inlet
- Typically detected on cross-sectional imaging, either incidentally or in patients with symptoms
- Associated tracheomalacia at site of crossing innominate artery can be elicited on dynamic airway imaging by CT or MR

Right Arch With Aberrant Left Subclavian Artery

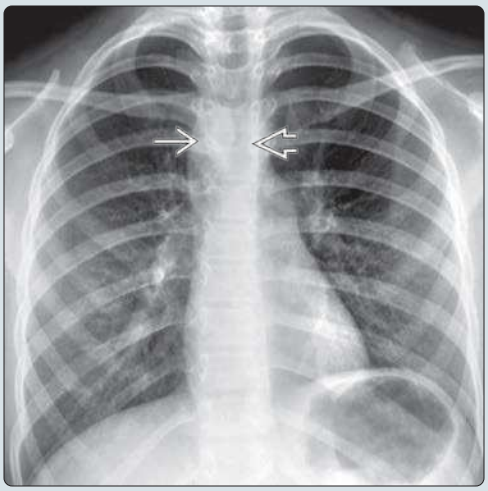
KEY FACTS

IMAGING

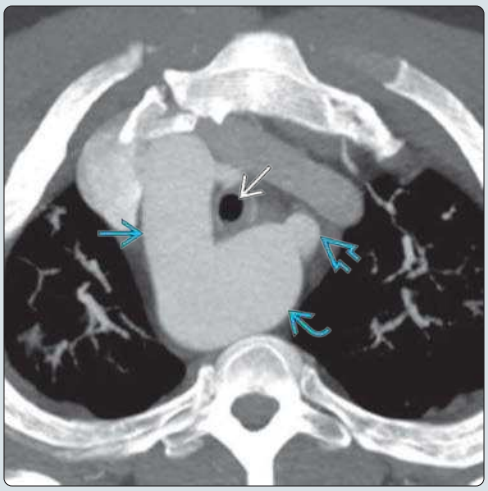
- Right-sided aortic arch (RAA) with aberrant origin of left subclavian artery (ALSCA) from Kommerell diverticulum
- Lateral radiograph: Anterior tracheal bowing due to aberrant retroesophageal vessel
- Esophagram: Posterior indentation by aberrant vessel
  - Large posterior indentation: Diverticulum of Kommerell
- CTA or MRA with 3D reconstructions is now preferred modality for diagnosis prior to surgical intervention
  - Dynamic airway imaging can evaluate tracheomalacia at level of vascular ring

PATHOLOGY

- Related to embryologic persistence of right 4th aortic arch
- Left ductus persists as ligamentum arteriosum, which completes vascular ring
- ALSCA is typically retroesophageal; rarely it may lie anterior to esophagus (15%) or anterior to trachea (5%)

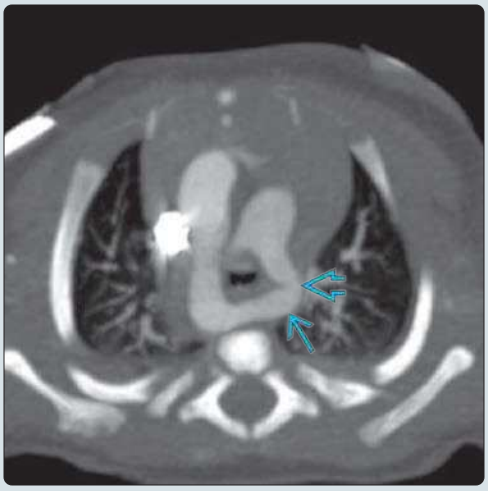


CLINICAL ISSUES

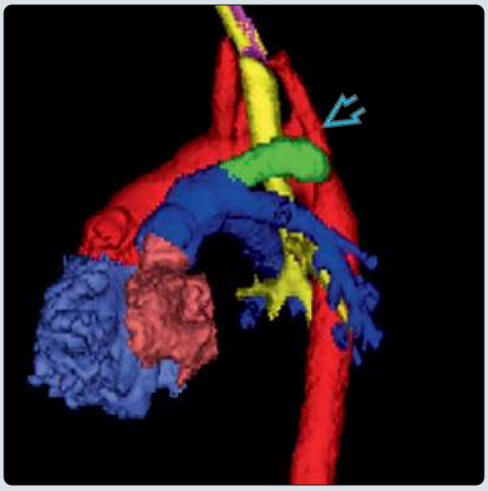


- Child presents with symptoms of stridor, apnea, cyanosis, recurrent respiratory infection, or chronic cough
  - Often referred for chest radiograph & ultimately cross-sectional imaging
- Treatment of RAA-ALSCA with constricting (symptomatic) left ligamentum arteriosum: Division of ligamentum via left thoracotomy

DIAGNOSTIC CHECKLIST



- RAA on radiograph in symptomatic child & absence of known underlying congenital heart disease (CHD) → perform further cross-sectional imaging
- RAA with airway compression & ALSCA on esophagram → perform cross-sectional imaging
- RAA, mirror image branching pattern → evaluate for underlying CHD



(Left) *PA radiograph of the chest shows a right aortic arch ➡ causing an impression on the right side of the trachea & displacing the trachea to the left ➡. This is an initial clue to diagnosing a right aortic arch with aberrant left subclavian artery (RAA-ALSCA) & is often overlooked.* **(Right)** *Axial MIP CTA in a child shows a right aortic arch ⇨ with an aberrant left subclavian artery ⇨ with mild tracheal compression ➡. Note the large diverticulum of Kommerell ⇨ that often forms at the origin of the aberrant subclavian artery.*

(Left) *Axial MIP cardiac CTA in an infant with stridor shows a right arch with an aberrant left subclavian ⇨ & patent ductus arteriosus (PDA) ⇨. This is a complete vascular ring even after the PDA closes.* **(Right)** *Lateral 3D color-coded surface-rendered CTA in an infant with stridor shows a right aortic arch (red) with an aberrant left subclavian artery ⇨ & PDA (green). Note that the trachea (yellow) is completely encased by vascular structures, consistent with a complete vascular ring.*

TERMINOLOGY

Definitions

- Aortic arch lies to right of trachea [right aortic arch (RAA)], & aberrant left subclavian artery (ALSCA) originates from proximal descending aorta to course behind esophagus

IMAGING

Radiographic Findings

- Frontal view: Round soft tissue density along right side of trachea resulting in focal right-sided indentation & leftward tracheal deviation
- Lateral view: Anterior bowing of trachea

Fluoroscopic Findings

- Esophagram
  - Frontal view: Oblique filling defect at proximal 1/3 of esophagus coursing from right inferior to left superior
  - Lateral view: Large posterior indentation of esophagus caused by diverticulum of Kommerell

CT Findings

- RAA with retroesophageal ALSCA arising from bulbous diverticulum of Kommerell from proximal descending thoracic aorta
- Mass effect & airway narrowing at level of vascular ring (caused by left-sided ligamentum arteriosum)
- Reformatted 2D planes & 3D reconstructions nicely demonstrate effect on airway

MR Findings

- Black blood, bright blood, or postcontrast MRA images show abnormal branching pattern of vessels
- Black blood images show effect on tracheobronchial tree

Echocardiographic Findings

- Defines RAA & branching pattern along with origin of ALSCA

Imaging Recommendations

- Best imaging tool
  - CTA with 3D reconstruction
    - Advantages: Fast, generally no need for sedation/anesthesia; ± dynamic airway imaging for concurrent tracheobronchomalacia
    - Disadvantages: Radiation dose, use of IV iodinated contrast, & correct timing of contrast bolus
  - MRA
    - Advantages: No radiation, multiplanar technique
    - Disadvantages: May need sedation due to long exam time; need IV gadolinium contrast

DIFFERENTIAL DIAGNOSIS

Right Aortic Arch With Mirror Image Branching

- High association with cyanotic congenital heart disease (CHD), such as tetralogy of Fallot & truncus arteriosus

Double Aortic Arch With Atretic Left Arch

- Left arch is often atretic; left ligamentum arteriosum along with dominant right arch completes vascular ring
- Inferior tenting of left common carotid artery & 4-pronged branching pattern of arches at thoracic inlet

Left Aortic Arch With Aberrant Right Subclavian Artery

- Typically isolated & incidental abnormality (without airway compression)

PATHOLOGY

General Features

- Genetics
  - Right arch is often associated with 22q11 deletion
- Embryology/anatomy
  - Related to embryologic persistence of right 4th aortic arch
  - Retroesophageal (Kommerell) diverticulum: Remnant of embryonic left 4th dorsal aortic arch; connects to left ductus ligament
  - Right ductus is obliterated & left ductus persists as ligamentum arteriosum, which completes vascular ring

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Stridor, apnea, cyanosis, recurrent respiratory infection, chronic cough, & rarely dysphagia (lusoria) due to posterior esophageal compression
  - May be incidental finding on esophagram

Demographics

- Epidemiology
  - Aberrant subclavian artery is most common congenital anomaly of aortic arch
    - RAA-ALSCA: 0.1% of asymptomatic population
    - LAA-ARSCA: 0.5% of asymptomatic population

Natural History & Prognosis

- Prognosis is generally good after division of vascular ring
- Symptoms may persist from tracheomalacia & residual stenosis after vascular ring repair

Treatment

- RAA-ALSCA with constricting (symptomatic) left ligamentum arteriosum: Division of ligamentum via left thoracotomy
  - ± aortopexy if associated with midline descending aorta

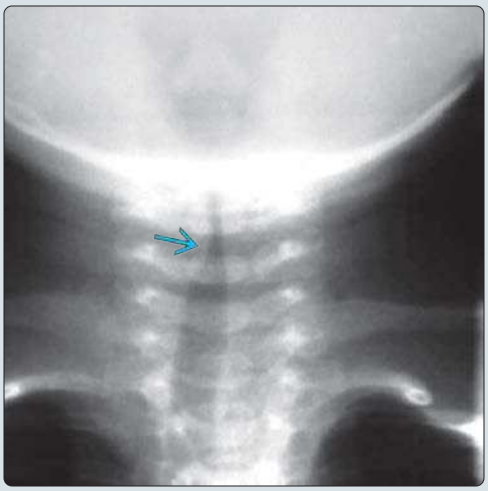
Infantile Hemangioma, Airway

KEY FACTS

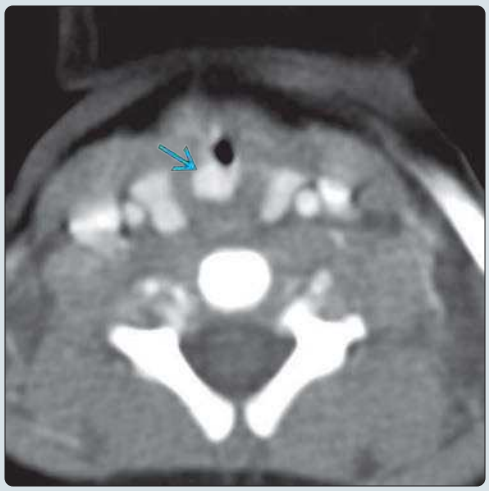
IMAGING

- Asymmetric subglottic narrowing in young child on AP radiograph
- Uniform early enhancement of submucosal mass on CT/MR
  - May be circumferential, bilateral, or unilateral; usually asymmetric
- Ultrasound with Doppler may show vascular lesion

TOP DIFFERENTIAL DIAGNOSES

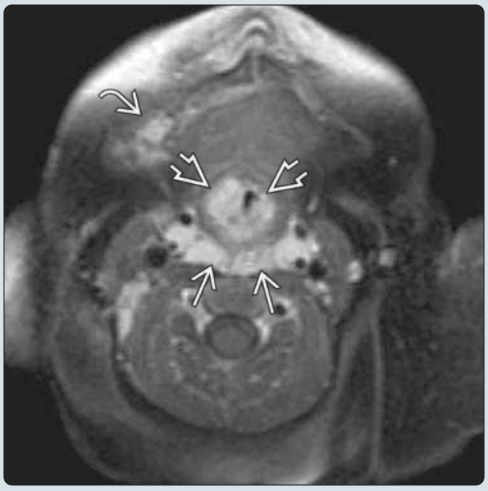


- Viral croup
- Tracheomalacia
- Airway papillomatosis
- Congenital subglottic tracheal stenosis
- Iatrogenic subglottic tracheal stenosis

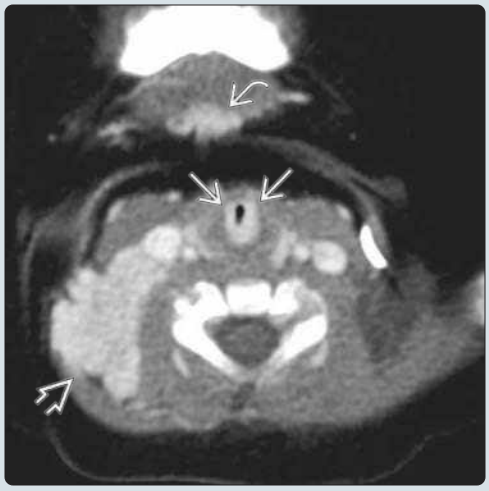


PATHOLOGY

- Benign vascular neoplasm with predictable life cycle
  - Proliferative phase with rapid growth in 1st days-weeks after birth
  - Involuting phase with slow gradual regression over months-years
- GLUT1 positive in all phases
- Consider **PHACE(S)** syndrome: **P**osterior fossa brain malformations, segmental **h**emangiomas of face, **a**rterial anomalies, **c**ardiac anomalies, **e**ye abnormalities, **s**ternal clefts or **s**upraumbilical raphe



CLINICAL ISSUES



- Inspiratory stridor in infants < 6 months
  - Majority of lesions have progressive airway obstruction during proliferative phase
- Cutaneous infantile hemangiomas in 50%
- Treatment
  - Propranolol is 1st-line therapy; also consider corticosteroids, laser therapy, surgical excision
    - Combination used in 75%

(Left) *AP radiograph shows asymmetric subglottic tracheal narrowing in a 2-week-old infant presenting with stridor. Asymmetric narrowing in this age is concerning for an infantile hemangioma (IH), as opposed to the symmetric subglottic narrowing that is typical of croup.* **(Right)** *Axial CECT in the same patient shows a well-defined, enhancing IH along the dorsolateral aspect of the subglottic airway.*

(Left) *Axial T1 C+ FS MR in a child with PHACE(S) syndrome demonstrates multiple enhancing IHs in the retropharyngeal space, surrounding the subglottic trachea, & in the right submental space.* **(Right)** *Axial CECT in an 11-week-old girl demonstrates a circumferential, well-defined subglottic IH. Note also the posterior cervical space & submental IHs, which should raise the question of PHACE(S) syndrome.*

TERMINOLOGY

Definitions

- Infantile hemangioma (IH) of subglottic airway

IMAGING

General Features

- Location
  - Classically subglottic, may be transglottic
  - Usually asymmetric or affecting only 1 side, L > R

Radiographic Findings

- Asymmetric subglottic tracheal narrowing on AP radiograph

CT Findings

- Usually solitary, homogeneously enhancing subglottic mass

MR Findings

- Intermediate T1, hyperintense T2, early homogeneous enhancement

Ultrasonographic Findings

- May show vascular subglottic mass on Doppler

Imaging Recommendations

- Best imaging tool
  - Multiplanar CECT reconstructions help define mass & tracheal compression
    - Quicker than MR & may not need sedation
  - MR is more sensitive (due to higher contrast resolution), but sedation is usually needed

DIFFERENTIAL DIAGNOSIS

Viral Croup

- Symmetric subglottic tracheal narrowing (steeple appearance on AP view)
- Most common 8 months to 3 years of age

Tracheomalacia

- Abnormal dynamic collapse of trachea

Airway Papillomatosis

- Affects entire trachea, bronchi, & lungs
- Rare in infants

Congenital Subglottic Tracheal Stenosis

- Symmetric tracheal narrowing
- Complete tracheal rings
  - Round tracheal configuration on axial images
  - ± pulmonary sling or congenital heart disease

Iatrogenic Subglottic Tracheal Stenosis

- Prior history of intubation or tracheostomy
- Secondary to scarring or granuloma formation

PATHOLOGY

General Features

- Etiology
  - Benign vascular neoplasm of proliferating endothelial cells; not vascular malformation
- Genetics
  - Majority are sporadic
- Associated abnormalities
  - **PHACE(S)** syndrome: **P**osterior fossa brain malformations, **h**emangiomas of face, **a**rterial anomalies, **c**ardiac anomalies, **e**ye abnormalities, **s**ternal clefts or **s**upraumbilical raphe
    - 7% have subglottic IHs

Staging, Grading, & Classification

- Predictable life cycle of IHs
  - Proliferative phase: ↑ size days-weeks after birth up through 9-24 months
  - Involuting phase: Gradual regression over next several years

Microscopic Features

- GLUT1 immunohistochemical marker: Positive in all phases of infantile hemangioma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Inspiratory stridor in infants < 6 months
- Other signs/symptoms
  - Cutaneous IHs in 50%
  - Hoarseness or abnormal cry

Natural History & Prognosis

- Majority of lesions have progressive airway obstruction during proliferative phase
- Symptoms resolve after involution
- Benign condition but can have fatal outcome
  - With segmental bearded distribution of cutaneous IH & PHACE(S) syndrome, may have more recalcitrant & complicated natural history
- Diagnosis is confirmed at endoscopy

Treatment

- Conservative monitoring
  - Considered in children with < 30% narrowing without respiratory or feeding difficulty
- Propranolol: 1st-line treatment in recent years
- Systemic corticosteroids
  - ± rebound growth when steroids are tapered
- Intralesional corticosteroids
- CO2 laser therapy
- Combination of therapies is used in 75%

Tracheobronchomalacia

KEY FACTS

TERMINOLOGY

- Excessive expiratory collapse of trachea &/or bronchi
  - May be purely intrinsic or in association with longstanding extrinsic compression

IMAGING

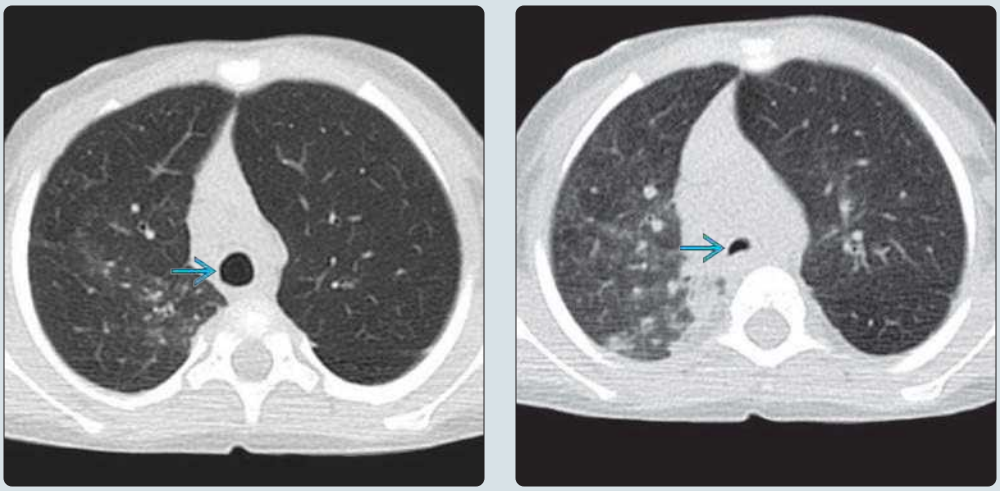
- > 50% ↓ in cross-sectional area of tracheal &/or bronchial lumen during expiration or coughing
  - Correlates well with bronchoscopy
  - Relatively underdiagnosed, as imaging is routinely performed only at end inspiration
- ↑ frequency & severity of air-trapping
- Dynamic 4D MDCT (real-time model of airway during respiration) vs. static inspiratory & expiratory CT scans
  - Multiplanar reconstructions & 3D volume rendering of airway are helpful
  - Intravenous contrast is useful to look for contributory adjacent mass or aberrant vessel
- Cine MR is also being used

TOP DIFFERENTIAL DIAGNOSES

- Difficult to control asthma
- Foreign body aspiration
- Extrinsic compression
- Complete tracheal rings

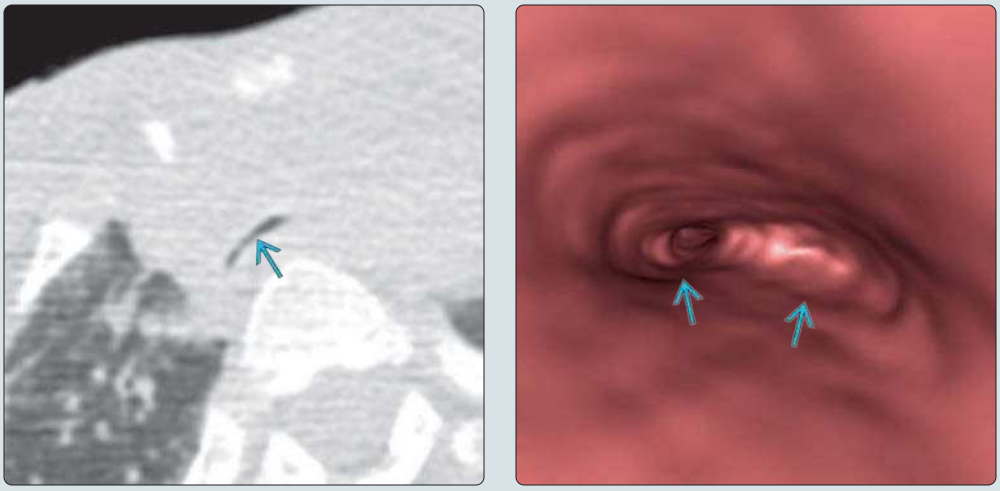
PATHOLOGY

- Primary (congenital): Impaired cartilage maturation or congenital absence of cartilage rings
- Secondary (acquired): Otherwise normal cartilage degenerates following infection, chronic inflammation, intubation, trauma, or longstanding extrinsic compression



CLINICAL ISSUES

- Presentations: Expiratory stridor, dyspnea, cough, sputum production, acute life-threatening events (ALTEs)



DIAGNOSTIC CHECKLIST

- Expiratory phase of imaging is necessary when evaluating for tracheobronchomalacia

(Left) *Inspiratory axial HRCT shows a normal, nearly rounded appearance of the trachea. The posterior aspect is often nearly flat, as it lacks supportive cartilage. The caliber of the trachea should be uniform from the glottis to the carina & relatively unchanging between inspiration & expiration.* **(Right)** *Expiratory axial HRCT in the same patient shows marked narrowing of the trachea, a substantial change from the inspiratory image that is consistent with tracheomalacia.*

(Left) *Expiratory axial HRCT shows severe tracheomalacia, nearly obliterating the lumen, with a typical horseshoe or "frowny face" appearance of the trachea in cross section.* **(Right)** *Virtual bronchoscopy 3D surface-rendered expiratory CT shows severe tracheomalacia with a typical horseshoe or "frowny face" appearance of the trachea.*

TERMINOLOGY

Synonyms

- Excessive dynamic airway collapse

Definitions

- Excessive expiratory collapse of trachea or bronchi
  - May be purely intrinsic or in association with longstanding extrinsic compression

IMAGING

General Features

- Best diagnostic clue
  - > 50% ↓ in cross-sectional area of tracheal &/or bronchial lumen during expiration or coughing
    - Correlates well with bronchoscopy, which remains gold standard for diagnosis

Radiographic Findings

- Airway radiography
  - Only 62% sensitive for tracheomalacia

CT Findings

- > 50% ↓ in cross-sectional area of tracheobronchial lumen during expiration is found to correlate well with bronchoscopy
- ↑ frequency & severity of air-trapping compared to children without tracheomalacia
- Adjacent mass or abnormal vessel (causing extrinsic compression) may contribute to collapse

MR Findings

- Cine MR: Increasingly feasible technique for assessment of tracheobronchomalacia

Imaging Recommendations

- Best imaging tool
  - CT: Dynamic airway (cine or 4D) MDCT vs. paired static inspiratory-expiratory CT
- Protocol advice
  - Intravenous contrast is helpful to define vascular anatomy as related to airway
  - Expiratory phase is necessary to evaluate dynamic large airway disease
  - Multiplanar reconstructions & 3D volume rendering are helpful

DIFFERENTIAL DIAGNOSIS

Difficult to Control Asthma

- No large airway caliber change with expiration

Foreign Body Aspiration

- Air-trapping on expiratory or ipsilateral decubitus images
- Intraluminal filling defect of airway
- ± classic history of choking episode with persistent symptoms

Extrinsic Compression

- Cystic or solid mass
- Aberrant or aneurysmal vessel, vascular ring
- Chronically dilated proximal esophageal pouch due to congenital esophageal atresia

Complete Tracheal Rings

- Completely round, small-caliber trachea
- Unchanging between inspiration & expiration
- May be associated with pulmonary sling

PATHOLOGY

General Features

- Etiology
  - Weakness of airway wall/supporting cartilage

Staging, Grading, & Classification

- Primary (congenital): Impaired cartilage maturation or congenital absence of cartilage rings
- Secondary (acquired): Otherwise normal cartilage degenerates following infection, chronic inflammation, intubation, trauma, or longstanding extrinsic compression
  - More common than primary

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Expiratory stridor, dyspnea, cough, sputum production, acute life-threatening events (ALTEs)

Demographics

- Epidemiology
  - Exact incidence is unknown
  - Found in up to 15% of infants & 30% of children < 3 years old who have undergone bronchoscopy for respiratory distress

Treatment

- Conservative therapy in mild cases; may improve with age
- Continuous positive airway pressure (CPAP) in moderate cases
  - ↓ energy expenditure for breathing by neonates
- Aortopexy
  - Most common initial operative approach
- Anterior tracheal suspension
  - Relief of airway symptoms in most severe & refractory cases
- Intraluminal tracheal stenting is rarely employed

Introduction

Chest radiography is one of the most frequently performed pediatric imaging studies. The radiographic appearance of many conditions is contingent on the age & history of the patient. Additionally, there is often overlap in the radiographic appearances of very different clinical entities. Therefore, arriving at the correct diagnosis often depends on obtaining an adequate history, reviewing prior imaging, & effectively communicating with the referring clinician(s).

Pulmonary Developmental Abnormalities

With the current use of prenatal ultrasound & MR, most developmental pulmonary abnormalities have already been imaged prior to the 1st newborn chest radiograph. This has substantially improved the perinatal care for high-risk infants, particularly given that information predicting pulmonary hypoplasia & persistent pulmonary hypertension can be extracted from these exams (which allows improved planning for the delivery suite). In such lesions, postnatal imaging may be used to confirm the diagnosis & is helpful for surgical planning, particularly given that varying degrees of spontaneous regression have been reported with some entities in late gestation. Postnatal CT for prenatally diagnosed pulmonary masses should be performed as a CT angiogram because lesions can be of mixed etiology (i.e., a hybrid lesion); it is critical for the surgeons to know the vascular supply of such lesions prior to resection.

Examples

Congenital pulmonary airway malformation (CPAM) is a multicystic pulmonary mass with variable amounts of air/fluid in the lesion after birth. The mass is often seen prenatally. Postnatal CTA is always warranted, even if the radiograph appears normal.

Bronchopulmonary sequestration (BPS) is a solid lower lobe lesion that has systemic arterial supply. It is crucial to extend the CTA through the top of the kidneys to exclude an origin of the supplying artery from the upper abdominal aorta.

Components of both CPAM & BPS are present simultaneously in hybrid lesions.

A bronchogenic cyst is a fluid-density or soft tissue-density mass in the mediastinum or medial lung. These cysts can present with respiratory distress or dysphagia.

Congenital lobar overinflation presents with a hyperlucent & hyperexpanded lobe or segment in a neonate or infant. The most frequent locations are the left upper lobe > right middle lobe > right upper lobe. Do not mistake these lesions for a pneumothorax.

Bronchial atresia presents with a characteristic-appearing round or branching hilar or pulmonary mass (finger-in-glove appearance) with a hyperinflated lung distally. These lesions may be diagnosed at any age.

Congenital diaphragmatic hernia is not a primary pulmonary developmental anomaly but may appear similar to CPAM or sequestration. Congenital diaphragmatic hernia contains variable abdominal contents (stomach, small/large bowel, liver, spleen). Use abnormal support device positions as clues to this diagnosis.

Acquired Neonatal Lung Disease

Clinical history is often key in diagnosing neonatal lung disease. For example, the diagnostic dilemma of differentiating meconium aspiration from neonatal pneumonia can be solved with a brief history or a phone call to the NICU. At the very least, the radiologist should be provided with the gestational age, as this single data point often significantly narrows the differential diagnosis.

Premature Infant

- Surfactant deficiency disease is characterized by low lung volumes & diffuse, hazy granular opacities; pleural effusions are uncommon in this setting.
- Due to low pulmonary compliance & positive-pressure ventilation, patients with surfactant deficiency disease are at risk for developing pulmonary interstitial emphysema (PIE). Characterized by bubbly or linear branching lucencies, it can be difficult to differentiate PIE from the bubbly lucencies of air bronchograms & cysts; look for linear lucencies extending to the lung periphery in PIE. Also remember that air in the interstitium prevents gas exchange, similar to a pneumothorax.
- Bronchopulmonary dysplasia (or chronic lung disease of prematurity) is characterized by hyperinflation with coarse, reticular opacities & intervening lucencies (typically with > 28 days of oxygen/ventilator support). These patients are at increased risk for pulmonary infections (e.g., RSV) in the first 2 years of life.

Term Infant

- Neonatal pneumonia classically presents as patchy, asymmetric perihilar opacities, often with pleural effusions; however, the reality is that neonatal pneumonia can mimic virtually any other neonatal lung disease. Thus, clinicians are highly conservative in treating for pneumonia until proven otherwise.
- Meconium aspiration typically shows radiating, coarse, rope-like bilateral lung opacities with hyperinflation (& sometimes small pleural effusions). These patients are at risk for pneumothorax. The clinical course is highly variable. Adequate history is key as clinicians will already know whether or not meconium was present at birth.
- Transient tachypnea of the newborn (TTN), or retained fetal lung fluid, presents with streaky perihilar or granular pulmonary opacities. Infants with TTN tend to be less seriously ill, & imaging findings resolve in 24-48 hours.
- Chylothorax should be considered in infants who present with pleural fluid, especially in the setting of a lymphatic anomaly, Turner syndrome, or Noonan syndrome.
- It must also be remembered that congenital heart disease can mimic neonatal lung disease.

Pediatric Catheters & Tubes

The most common indication for ordering a NICU chest radiograph is to evaluate the positions of various indwelling support devices (such as vascular catheters, airway tubes, & enteric tubes). Neonatologists are especially meticulous in this regard, as many of them have witnessed catastrophes or near catastrophes associated with line/tube malpositions. The ubiquitous use of lines & tubes & the low frequency of complications make it disconcertingly easy to overlook line/tube malposition. Rather than simply reporting "lines & tubes unchanged," forcing oneself to report the position of

each support device increases the likelihood of detecting malposition before a complication occurs.

Examples

The ideal position for the umbilical arterial catheter tip is between the T6 & T10 levels. The ideal position for an umbilical venous catheter (UVC) is at or just below the right atrium/inferior vena cava junction. Remember that a UVC that has not passed beyond the ductus venosus should generally not be used for a hyperosmolar infusate as it will be dispersed into the liver. (Note that the NICU will sometimes temporarily use a UVC below the liver margin for low-risk infusions.)

Esophageal intubation classically presents with hypoinflated lungs + gaseous distention of the esophagus & stomach.

ECMO may be performed with either arteriovenous or venovenous cannulae. Central great vessel catheters may rarely be used, particularly in the setting of complex heart disease.

Peripherally inserted central catheters are associated with rare but potentially catastrophic complications, particularly if left to dwell in the right atrium.

Common Pediatric Pulmonary Infections

"Rule out pneumonia" is one of the most common indications for outpatient pediatric imaging. The appearance of pediatric airway disease can be variable. The radiologist who finds that they are struggling with the diagnosis of airway disease should keep in mind that most pediatricians rely more heavily on clinical findings than on the radiologist's report to diagnose bronchiolitis or asthma. Clinicians are often more interested to know whether there are findings of bacterial pneumonia, or other explanations for the patient's symptoms.

Examples

Viral infection is shown by perihilar peribronchial opacities & hyperinflation, often with intermixed atelectasis.

Round pneumonia has a well-defined, mass-like appearance, typically occurring in patients under age 8 (due to poorly developed collateral pathways). If it is paraspinous in location, follow-up radiography is advised to ensure resolution of the pneumonia (thereby excluding paraspinal masses, such as neuroblastoma).

Management of parapneumonic effusion & empyema should be based on clinical findings, serial radiography, & ultrasound rather than CT.

Fungal pneumonia in immunocompromised patients classically presents as nodules, potentially with a halo of ground-glass opacity (that suggests hemorrhage).

Papillomatosis may present as multiple laryngeal, tracheal, &/or pulmonary nodules; the latter may cavitate.

Pediatric Mediastinal Masses

Simply differentiating a normal from abnormal mediastinum can be difficult in infants & young children. However, a few clues usually lead to confident radiographic differentiation.

Examples

The normal thymus can be large in children up to 5 years of age. Look for an undulating contour, the sail or wave sign, & overlying pulmonary vascular markings. There should be no mass effect on the trachea. Ultrasound can be useful to confirm thymic tissue if there is doubt radiographically.

Lymphoma often presents as a bulky anterior mediastinal mass without Ca^{2+}. Mass effect on the trachea & vascular structures is typical.

Mediastinal germ cell tumors present as anterior mediastinal masses, classically with fat & Ca^{2+} (teratoma).

Neuroblastoma typically presents as a posterior mediastinal mass. Look closely for Ca^{2+} as well as bony changes (with posterior rib splaying or erosion being particularly suggestive).

Noninfectious Pediatric Lung Masses

Metastases are by far the most common pulmonary malignancies in the pediatric age group. Primary pulmonary neoplasms are rare in children.

Examples

Lung metastases are most common with osteosarcoma, Ewing sarcoma, hepatoblastoma, soft tissue sarcomas, Wilms tumor, testicular tumors, & thyroid tumors.

Bronchial obstruction may be due to a foreign body, intrinsic airway mass, or extrinsic compression. Look for asymmetric inflation due to air-trapping.

Pediatric Chest Trauma

A very important element of chest radiography is to evaluate for evidence of child abuse, especially in infants & young children. The radiologist is obligated to immediately contact the referring clinician if there are any suspicious findings of nonaccidental trauma to ensure that the case is appropriately investigated & the child is appropriately protected.

Examples

Multiple rib fractures in a child < 3 years old are usually due to child abuse. While they can involve any portion of the rib, posterior rib fractures are most specific for child abuse.

Pulmonary contusion appears as a nonspecific opacity in the setting of trauma, often with a thin zone of peripheral lung sparing. The presence of an air-filled or fluid-filled cavity suggests pulmonary laceration.

Pediatric Diffuse Lung Disease

Diffuse lung disease is rare. A few etiologies have a characteristic appearance that may suggest a single diagnosis with reasonable confidence.

Examples

Neuroendocrine cell hyperplasia of infancy (NEHI) has a characteristic HRCT appearance of central & lingular + right middle lobe geographic ground-glass opacities.

Lymphangioleiomyomatosis presents in tuberous sclerosis as numerous bilateral, thin-walled cysts.

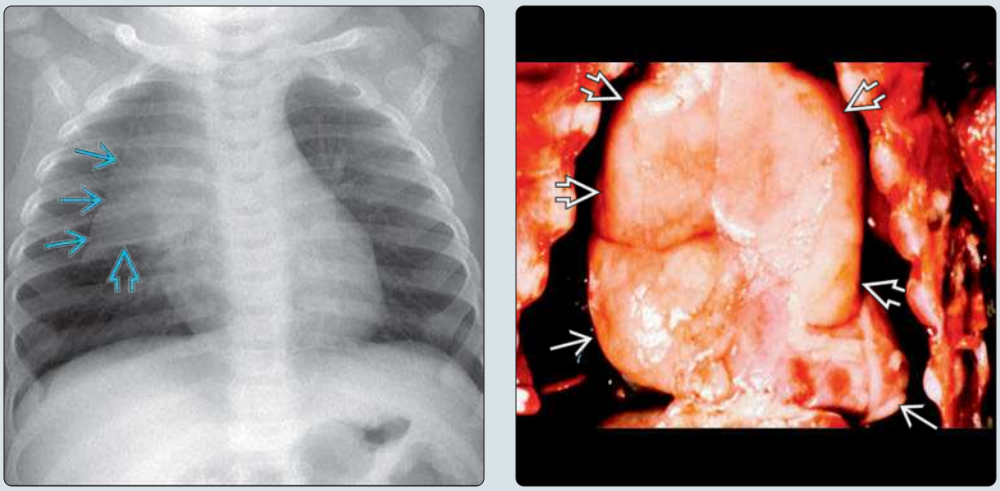
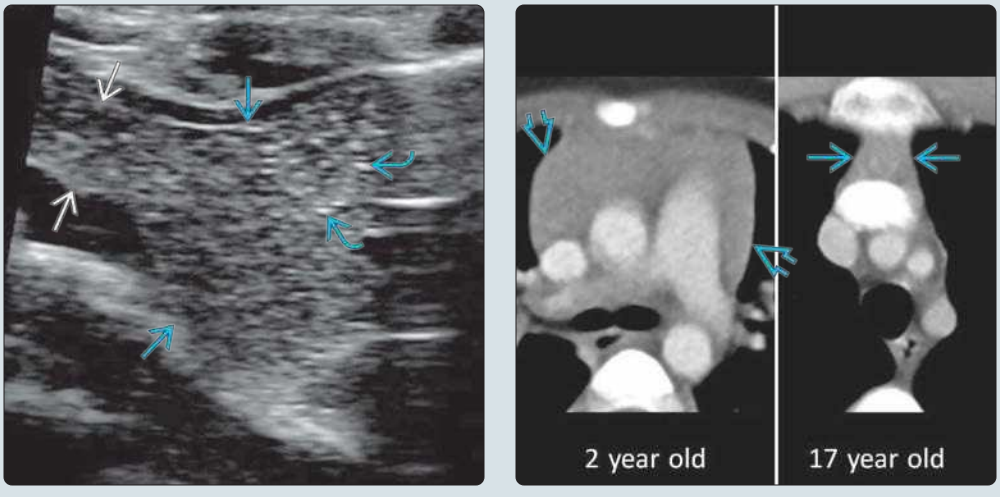
Normal Thymus

KEY FACTS



TERMINOLOGY

- Normal organ of anterior superior mediastinum involved in production of T cells
- Appears prominent in many young children



IMAGING

- Normal thymus is variable in size but ↓ with age
  - Moderate to large on chest radiograph up to 5 years of age, particularly in infancy
  - ↓ in relative size by end of 1st decade
  - No "mass" should be present in 2nd decade
- Normal thymus is variable in contour
  - Smooth curvilinear borders ± undulation with ribs
- Normal thymus is variable in shape & symmetry
  - Bilobed with convex margins in young children vs. concave margins in older children
  - Sail sign: Lateral triangular extension (R > L)
- Homogeneous consistency without Ca^{2+} or cysts
  - Slightly lucent: Vessels seen through thymus
- No mass effect on adjacent structures
- Normal variant locations: Cervical & retrocaval extensions
  - Keys to diagnosing normal variant thymic extensions
    - Continuous with & similar imaging appearance (on US, CT, or MR) to normally located thymus
      - US is best tool for confirmation in children
- Aberrant, ectopic thymic tissue may occur in inferior lateral neck or thyroid, ± thymic tissue in normal location
- Thymic rebound
  - Thymic volume can ↓ by > 40% with chemotherapy & other stresses
  - Volume rebounds to original (or larger) size upon stress cessation, potentially mimicking recurrent mass
    - Differentiation of recurrent lymphoma vs. thymic rebound aided by PET/CT or GRE & DWI MR
- Absent visualization on lateral neonatal chest radiograph occurs with ectopia, some immunodeficiencies, or prior sternotomy for congenital heart disease

(Left) *AP chest radiograph in a 6-month-old girl shows a normal prominent thymus with a triangular configuration extending into the right hemithorax (sail sign). The normal thymus is lucent & "soft" with undulations at the ribs & intercostal spaces.* **(Right)** *Gross pathology (with the anterior chest wall removed) from the autopsy of a child who died of SIDS shows a normal but prominent thymus as compared to the heart. (Courtesy J. Strife, MD.)*

(Left) *Longitudinal US from the upper midline chest in a 7-month-old boy shows a normal thymus. Punctate & linear (dot-dash pattern) echogenic foci are present throughout the hypoechoic parenchyma. There is cervical extension of the thymus in this child.* **(Right)** *Axial chest CECT images are shown in 2 boys of different ages. In the 2-year-old, the normal thymus is prominent with convex borders. In the 17-year-old, the normal thymus is small & relatively triangular in shape with concave borders.*

TERMINOLOGY

Synonyms

- Thymic sail sign

Definitions

- Normal organ of anterior superior mediastinum that appears prominent in many young children
  - Involved in production of T cells
- Thymos is Greek for "warty excrescence"

IMAGING

General Features

- Location
  - Normal location: Anterior superior mediastinum
    - Variable distribution of tissue (R vs. L)
  - Normal variant extensions of thymic tissue
    - Superior cervical extension
      - Tissue reaches superiorly in midline above thoracic inlet, anterior to airway
      - 65% of all children (> 80% ages 0-4 years)
      - Can mimic thoracic inlet or lower cervical mass
    - Retrocaval extension
      - Posterior extension of thymus between superior vena cava & great arteries
      - May displace (but not compress) adjacent structures (airway, vessels)
      - Can mimic mediastinal mass or right upper lobe collapse
    - Keys to diagnosing as normal variant thymic tissue extensions (rather than adenopathy or other mass)
      - Connects to normal thymus
      - Shows identical internal characteristics to normal thymic parenchyma by imaging (US, CT, MR)
  - Aberrant, ectopic thymic tissue rarely can be found discontinuous from (or in absence of) normal thymus
    - Aberrant cervical thymus
      - Arrest of normal embryologic descent along thymopharyngeal duct, anywhere from mandibular angle → thoracic inlet
      - Typically asymptomatic lateral cervical mass of normal thymic tissue
      - Retropharyngeal thymus may lead to airway compromise
      - Shows identical internal characteristics to normal thymic parenchyma by imaging (US, CT, MR)
    - Ectopic intrathyroidal thymic tissue
      - Prevalence is inversely associated with age
      - Typically detected incidentally on US & CT
      - Irregular hypoechoic intrathyroidal mass with punctate internal hyperechoic foci similar to normal thymus
      - With typical appearance, can be monitored with follow-up US until involution
  - Absence of normal retrosternal thymic tissue on lateral neonatal chest radiograph could suggest
    - Ectopic thymic tissue
    - DiGeorge syndrome
    - Severe combined immunodeficiency
    - Prior sternotomy for congenital heart disease
- Size
  - Variable, even among children of same age & size
    - May be large up until 5 years of age
    - ↓ in relative size by end of 1st decade
  - Thymic rebound
    - Thymic volume can ↓ by > 40% with chemotherapy or other stresses
    - Rebound of thymic volume occurs with cessation of stress, up to 50% > original size
      - Growing mediastinal mass in lymphoma patient after therapy could represent thymic rebound or recurrent lymphoma
      - Thymic rebound shows typical thymic characteristics
      - Recurrent lymphoma is typically more heterogeneous & nodular with lobulated contours
      - Overlap may necessitate additional imaging for differentiation: PET/CT or MR
- Morphology
  - Contour
    - Normal: Curvilinear smooth borders, mildly undulating with ribs
    - Abnormal: Irregular, lobulated, poorly defined
  - Shape
    - Bilobed ± triangular or quadrilateral configuration
    - Large with convex borders in young children
    - Relatively small with concave margins in older children

Radiographic Findings

- Radiography
  - Normal size is variable
    - ↓ in relative size by end of 1st decade
    - May be relatively large on chest radiograph up to 5 years of age, particularly in 1st year
    - Should not have prominent "mass" during 2nd decade
  - Normal shape is variable
    - Sail sign: Triangular extension laterally (R > L)
    - Not to be confused with spinnaker sail sign: Thymus is lifted off of heart by gas collection of pneumomediastinum
  - Homogeneous soft tissue density; no Ca^{2+}
    - Often slightly lucent relative to heart: Vessels are seen through thymus
  - Does not displace/compress airway or vessels
  - Drapes over cardiac silhouette; may make heart look prominent

Ultrasonographic Findings

- Current high-frequency transducers show predominantly hypoechoic, uniformly granular parenchyma with echogenic punctate & linear septa (dot-dash pattern)
  - Hyperechoic to costal/sternal cartilage
  - Hypoechoic to skeletal muscle

CT Findings

- Homogeneous soft tissue attenuation
  - No calcified or low-attenuation foci
  - Attenuation ↓ with age due to fatty replacement
- Smooth borders, not irregular
- Shape on axial imaging
  - Young children: Large, quadrilateral with convex borders

- Teenagers: Smaller triangle with concave borders
- Does not displace/compress airway or vessels
- Associated findings (such as pericardial or pleural effusion or pulmonary disease) favor pathology

MR Findings

- T1WI
  - Homogeneous signal intensity, typically isointense to skeletal muscle
  - Becomes brighter (due to fat) in later teen & adult years
- T1WI C+ FS
  - Homogeneously dark with little enhancement
- In- & opposed-phase T1 GRE
  - Can help differentiate thymic rebound vs. lymphoma
    - Children > 16 years of age: Thymic rebound ↓ in signal intensity on opposed-phase images due to microscopic fat in normal thymus
    - Children < 16 years: Less helpful, as thymus has less fatty replacement & may not drop signal
- T2 FS/STIR
  - Homogeneously intermediate to bright signal intensity
- DWI/ADC
  - Thymic rebound is less likely to show restricted diffusion & has higher ADC values vs. malignancies

Nuclear Medicine Findings

- FDG PET
  - Mildly FDG avid, much < tumor
  - Postchemotherapy thymic rebound shows ↑ FDG avidity, making differentiation from recurrent lymphoma more difficult
  - SUVmax < 3.4 suggests rebound while SUVmax > 4 suggests recurrent tumor

Imaging Recommendations

- If chest radiograph demonstrates unusual anterior/superior mediastinal prominence that is questionably normal for age, start with US

DIFFERENTIAL DIAGNOSIS

Lymphoma or Leukemia

- Most common pathologic anterior mediastinal mass in children; more common after infancy
- Confluent or nearly confluent nodular masses with mild heterogeneity
- Definite compression/displacement of vessels & airway
- Frequently causes pleural effusions

Germ Cell Tumor (Teratoma)

- Heterogeneous with Ca^{2+} & fat attenuation

Thymic Cyst

- Bilobed cyst coursing through thoracic inlet
- Left lateral neck is most common
- Typically lies near carotid sheath

Langerhans Cell Histiocytosis

- Systemic Langerhans cell histiocytosis (LCH) can manifest as thymic mass with Ca^{2+} or areas of low attenuation
- Associated findings: Lung, hepatic, or bone lesions

Neuroblastoma

- Posterior mediastinal mass (paraspinal)
- May splay/erode ribs, vertebral elements

Lymphatic Malformation

- Transspatial, multicystic mass involving variable portions of neck, chest wall, & mediastinum
- Numerous thin septations
- Cysts often contain fluid-fluid levels due to hemorrhage

Congenital Pulmonary Airway Malformation

- Solid-appearing (microcystic) vs. gas- & fluid-containing (macrocystic) mass
- Not midline

Foregut Duplication Cyst

- Well-circumscribed cyst of middle or posterior mediastinum or hilum

Thymoma

- Very uncommon in young children

PATHOLOGY

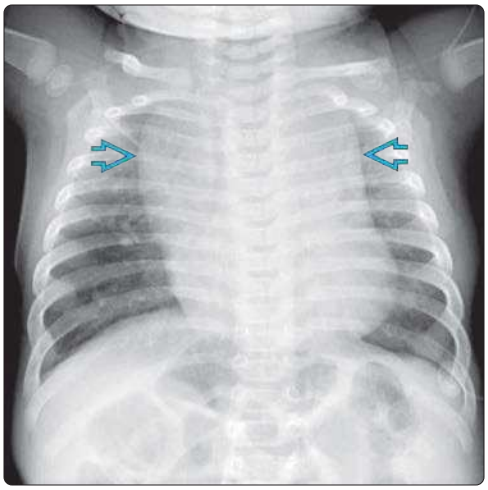
General Features

- Normal thymus is prominent relative to thoracic size in early childhood
- Thymic size is smaller relative to thorax by end of 1st decade, though largest actual size occurs in teenage years

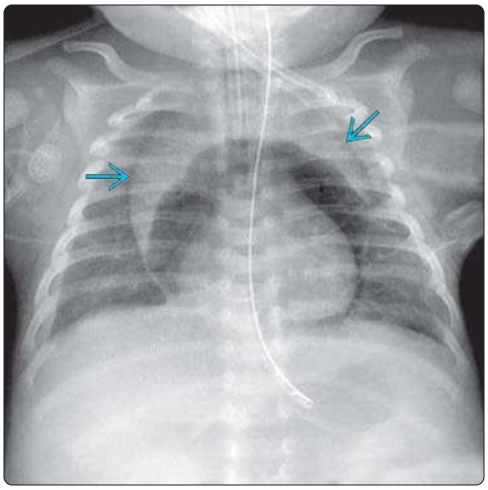
CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Prominent normal thymus: Asymptomatic
  - Ectopic retropharyngeal thymus rarely causes airway compromise



DIAGNOSTIC CHECKLIST



Consider

- US is best tool to confirm normal thymic tissue in young child with atypical size, shape, or location radiographically

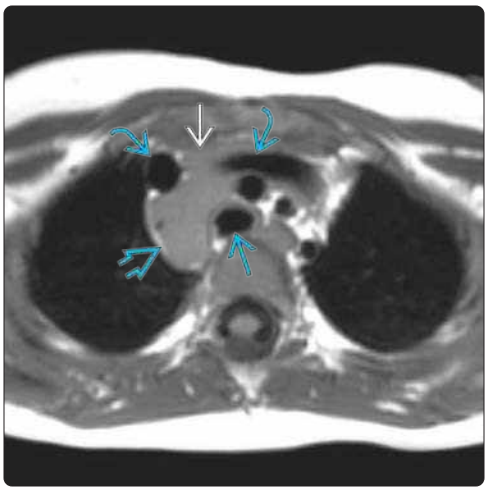
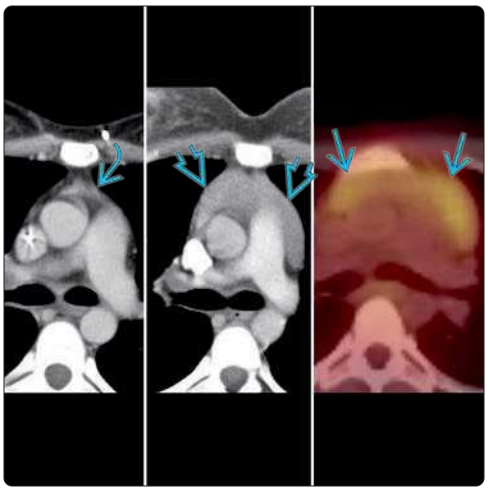
5. Costa NS et al: Superior cervical extension of the thymus: a normal finding that should not be mistaken for a mass. Radiology. 256(1):238-42, 2010





(Left) *AP radiograph in a neonate shows prominence of the superior mediastinum from L to R. This appearance of smooth convex margins is consistent with a normal thymus in a patient of this age.* **(Right)** *AP radiograph of a child in a neonatal intensive care unit shows a spinnaker sail sign, indicative of pneumomediastinum, with a lucent gas collection lifting the thymus off of the cardiac silhouette. The spinnaker sail sign should not be confused with the normal thymic sail sign.*

(Left) *Coronal STIR MR in a 4-month-old patient shows a common configuration of a normal thymus draped over the heart. The thymus is homogeneously hyperintense.* **(Right)** *Axial STIR (L) & sagittal T2 (R) MR images in a 6-year-old boy show a "mass" in the lower midline neck that could be mistaken for adenopathy on the axial image. The sagittal image shows a connection between the mass & the normal thymus that is isointense to both. This is cervical extension of the thymus.*

(Left) *Axial T1 MR shows a normal variant retrocaval thymus. Lobular soft tissue, equal in signal to the normal thymus, extends between the trachea & brachiocephalic veins.* **(Right)** *Axial CECT in a 16-year-old girl with lymphoma during chemotherapy (L) shows an atrophic thymus. After treatment completion (middle), thymic rebound hyperplasia is seen with convex smooth borders. FDG PET/CT (R) at this time shows ↑ FDG avidity with an SUVmax < 3.4, typical of rebound.*

Palpable Normal Variants of Chest Wall

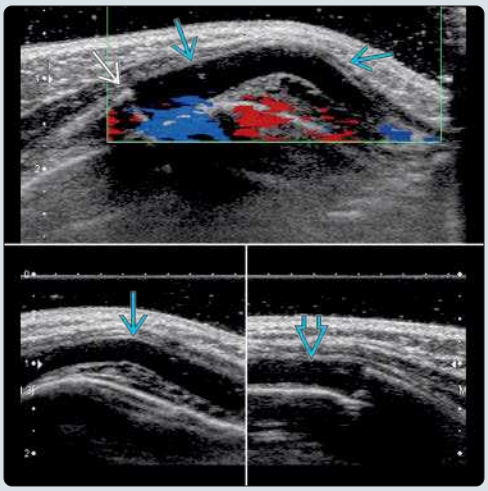
KEY FACTS

TERMINOLOGY

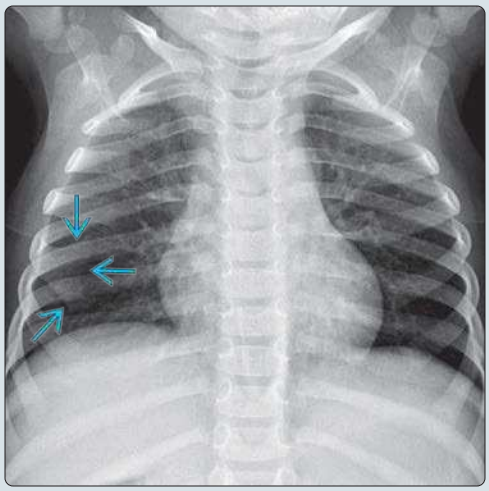
- Commonly occurring normal variations of anterior chest wall that may be mistaken for pathology
- Typically isolated variant morphologies of costal cartilages, ribs, &/or sternum
  - Prominent asymmetric convexity or thickness of costal cartilage; may be isolated or due to bifid rib
  - Tilted sternum

IMAGING

- Ultrasound is best initial study for palpable mass unless bony abnormality is primarily suspected
- Radiographs are best for initial bone evaluation
  - May show bifid rib or bony sternal anomaly
  - Purely cartilaginous variants will not be seen
  - Help exclude other significant processes
    - Bone destruction by malignancy, scoliosis

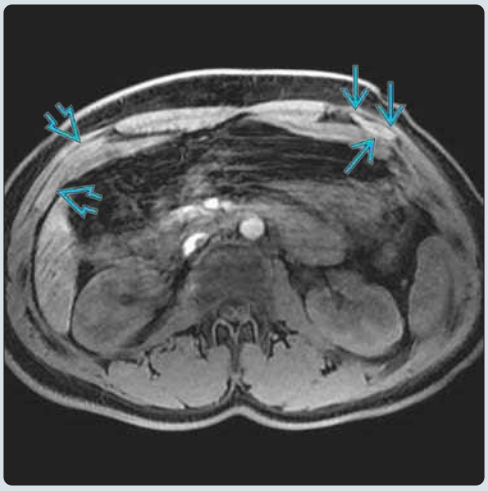


TOP DIFFERENTIAL DIAGNOSES

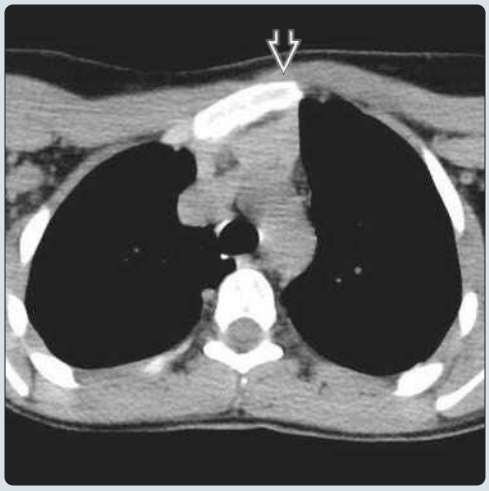


- Vascular anomaly
- Soft tissue or bone sarcoma
- Osteochondroma
- Pectus excavatum or pectus carinatum
- Scoliosis

CLINICAL ISSUES



- Asymptomatic, palpable "mass" detected by patient, parent, or clinician; usually painless
  - History often erroneously suggests finding as newly or rapidly developed
  - Recent trauma to region may bring palpable abnormality to attention
- Typically isolated finding of little consequence
  - ~ 33% of children imaged for other causes have minor variations in chest wall configuration
  - Isolated bifid rib in 0.15-3.4% of population



(Left) *Transverse color Doppler (top) & grayscale (bottom) ultrasound images of a 2-year-old with an asymptomatic, palpable abnormality of the right chest wall show an avascular, nearly anechoic, anteriorly protuberant costal cartilage that is continuous with the anterior rib. The normal comparison left side is shown at the same level.* **(Right)** *AP chest radiograph in the same 2-year-old shows a bifid configuration of the right 5th rib at this same level, a normal variant.*

(Left) *Axial 3D T1 GRE FS MR in a teenager with a left lower anterior chest wall palpable abnormality shows focal protuberance & undulation of a costal cartilage on the left, a normal variant. The normal right side is noted for comparison.* **(Right)** *Axial NECT in a patient with a palpable "mass" shows tilting of the sternum with the left margin being more anterior in location as compared to the right.*

TERMINOLOGY

Definitions

- Commonly occurring normal variations of anterior chest wall that may be mistaken for pathology
  - Usually due to variant morphologies of otherwise normal costal cartilages, ribs, &/or sternum

IMAGING

General Features

- Morphology
  - Prominent asymmetric convexity or thickness of costal cartilage; may be isolated or due to bifid osseous or cartilaginous rib
  - Tilted sternum
    - More anterior edge of sternum is palpated as hard mass on physical examination
    - Frequently associated with prominent asymmetric convexity of costal cartilage

Radiographic Findings

- May show bifid rib or bony sternal anomaly
  - Varying degrees of anterior rib broadening/bifurcation
  - Purely cartilaginous variants will not be seen
- Help exclude other significant processes
  - Bone destruction by malignancy
  - Underlying scoliosis

Ultrasonographic Findings

- Best 1st-line modality due to
  - Lack of ionizing radiation
  - Lack of need for sedation
  - Excellent superficial spatial resolution
  - Ease of comparison to normal contralateral side
- Easily demonstrates relationship of palpable abnormality to
  - Mildly lobular, mildly echogenic subcutaneous fat
  - Striated hypoechoic muscle
  - Nearly anechoic cartilage
  - Echogenic cortical bone with posterior acoustic shadowing

MR Findings

- Excellent soft tissue contrast on variety of sequences allows for characterization of palpable soft tissue or bony mass (whether normal variation or pathology)
  - Thin section axial or coronal 3D T1 FS or 3D PD ± FS may be helpful

Imaging Recommendations

- Best imaging tool
  - Ultrasound is best initial study for palpable mass unless bony abnormality is suspected
  - Radiographs are best for initial bone evaluation

DIFFERENTIAL DIAGNOSIS

Vascular Anomaly

- Slow-flow vascular malformation: Well-circumscribed or infiltrative soft tissue mass with thin septations & fluid-fluid levels
  - Venous malformation: Channels with phleboliths & gradual patchy enhancement
  - Lymphatic malformation: Cystic compartments with rim/septal enhancement only
- High-flow vascular neoplasm
  - Infantile hemangioma
    - Well-circumscribed, lobulated, high-flow mass with many low-resistance arterial waveforms (Doppler US) & early diffuse enhancement (MR)

Soft Tissue or Bone Sarcoma

- Firm, often well-circumscribed chest wall mass ± rib destruction, pleural effusion
- Variable enhancement

Osteochondroma

- May present with hard palpable mass, local symptoms of compression/irritation, or stalk fracture
- Characteristic radiographic appearance of flowing corticomedullary continuity between osteochondroma & parent bone

Pectus Excavatum or Pectus Carinatum

- Midline sternal anomalies of concavity (former) or convexity (latter)
- May be isolated or found with many syndromes
- May have associated rib protrusions & sternal tilting

Scoliosis

- Rotary component of spinal curvature leads to protrusion of anterior chest wall on side of curve concavity

Poland Syndrome

- Unilateral absence of pectoralis musculature

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic, palpable "mass" detected by patient, parent, or clinician; usually painless
  - History often erroneously suggests finding as newly or rapidly developed
    - Recent trauma to region may bring palpable abnormality to attention

Demographics

- Frequently detected in adolescence due to changing physique & heightened awareness
- ~ 33% of children imaged for other causes have minor variations in chest wall configuration
- Isolated bifid rib in 0.15-3.4% of population

Natural History & Prognosis

- Typically isolated finding of little consequence

Congenital Pulmonary Airway Malformation

KEY FACTS

TERMINOLOGY

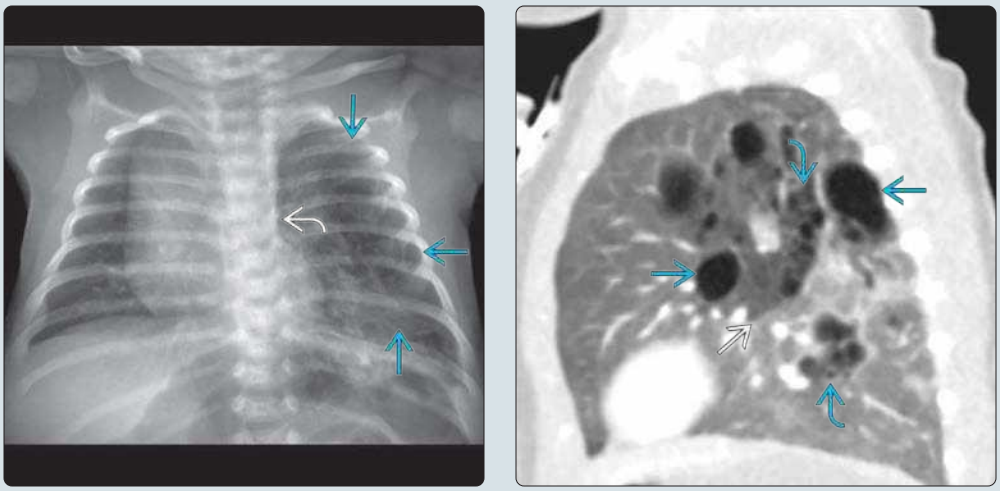
- Heterogeneous group of cystic & noncystic congenital lung lesions resulting from maldevelopment of fetal airway
- Term congenital cystic adenomatoid malformation (CCAM) is not favored because many lesions are not obviously cystic in nature & only minority have adenomatous components

IMAGING

- Presents as cystic or solid-appearing lung mass in early life
- Appearance varies by lesion type (Stocker classification)
  - Type 1: Composed of 1 or more large (3-10 cm) cysts
  - Type 2: Numerous small & medium-sized (0.5-2 cm) cysts
  - Type 3: Microcystic (1-2 mm) or solid-appearing mass
- Even with prenatal diagnosis, initial postnatal radiographs may be normal due to phenomenon of partial or complete *in utero* regression
- CT angiogram is critical for surgical planning to identify possible systemic feeding artery (pulmonary sequestration)

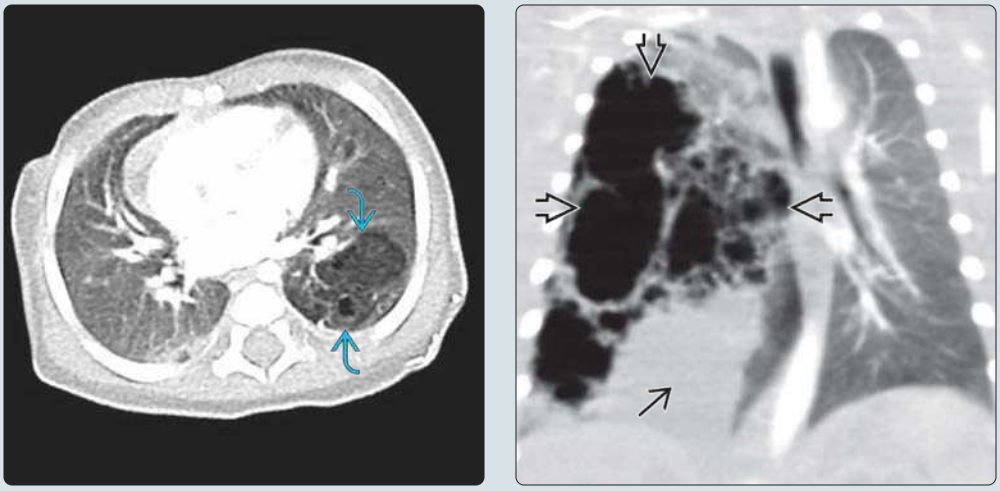
TOP DIFFERENTIAL DIAGNOSES

- Bronchopulmonary sequestration (BPS)
- Congenital diaphragmatic hernia
- Bronchogenic cyst
- Pleuropulmonary blastoma
- Congenital lobar overinflation



CLINICAL ISSUES

- ~ 25% have respiratory distress at birth
- All symptomatic congenital pulmonary airway malformations (CPAMs) are resected; asymptomatic lesions are managed expectantly or with elective resection
- Overall survival > 95%; risks include recurrent infections, underlying malignancy, future malignant degeneration



DIAGNOSTIC CHECKLIST

- Low-dose postnatal chest CTA must include celiac axis to look for extrathoracic origin of systemic arterial supply to BPS component of "hybrid lesion"

(Left) *AP radiograph in a 5-week-old with respiratory distress shows a large, multicystic lucent mass of the left lung causing mediastinal shift toward the right.* **(Right)** *Sagittal reconstruction from a CTA in the same patient reveals numerous large cysts & a few smaller cysts that blend into normal left lung. The lesion is predominantly upper lobe & has mass effect on the fissure but also extends into the lower lobe. It is unusual for CPAMs to involve > 1 lobe.*

(Left) *Axial CTA in a 4-month-old with a prenatally diagnosed CPAM shows a well-defined mass composed of numerous small- & medium-sized (0.5-2 cm) cysts. Remember that ~ 50% of patients with type 2 lesions have associated anomalies.* **(Right)** *Coronal CTA in a newborn with respiratory distress shows a large mixed cystic & solid mass. Note the numerous gas-filled cysts with a solid-appearing component in the right lower lobe. Pathologic diagnosis was a mixed type 1 & 3 CPAM.*

TERMINOLOGY

Abbreviations

- Congenital pulmonary airway malformation (CPAM)

Synonyms

- Congenital cystic adenomatoid malformation (CCAM)
  - Antiquated & unsuitable term: Lesions may be noncystic, & only type 3 lesions have adenomatoid components

Definitions

- Heterogeneous group of cystic & noncystic congenital lung lesions resulting from maldevelopment of fetal airway

IMAGING

General Features

- Best diagnostic clue
  - Cystic or solid-appearing lung lesion in fetus or newborn
    - Fluid-filled cysts at birth, gradually filling with air
- Location
  - Intrapulmonary, mostly without lobar predilection
- Size
  - Depends on type of lesion: Type 0 diffusely affects both lungs; type 3 sometimes involves entire lung; types 1, 2, & 4 usually involve just 1 lobe
- Morphology
  - Appearance varies based on histopathologic type (Stocker classification)
    - Type 0 (acinar dysplasia): Small, nonaerated lungs
    - Type 1 (large cyst type): 1 or more large (3-10 cm) cysts, ± smaller cysts that blend into normal lung
    - Type 2 (small/medium cyst type): Numerous small or medium-sized (0.5-2 cm) cysts
    - Type 3 (microcyst type): Innumerable microcysts (1-2 mm) that cause marked ↑ in size of affected lobe/lung
    - Type 4 (large peripheral cyst type): Large, thin-walled, cyst in periphery of lung, often with mass effect

Radiographic Findings

- Multicystic lung mass with variable amounts of fluid & air
- Solid radiographic appearance may be due to
  - Microcystic type 3
  - Initially fluid-filled larger cysts (types 1, 2, 4)
- Mass effect is most common with types 3 & 4
- Pneumothorax may occur, especially with type 4
- Newborn chest radiographs may be normal (despite prenatal diagnosis of lesion)
  - Complete vs. partial regression in many cases
  - Occult lesions may be found by CT

CT Findings

- CTA
  - May show partial/complete regression of prenatally detected lesion
  - Performed to determine extent of residual lesion & evaluate for systemic feeding vessel prior to surgery
    - Systemic arterial supply classically suggests component of bronchopulmonary sequestration ("hybrid lesion" with CPAM)
    - Origin of arterial supply is critical for surgical planning
      - Must cover through celiac axis to exclude extrathoracic origin of artery
  - Mass ranges from solid/microcystic to macrocystic
    - Components of each may be present
    - Cysts of variable size; contain air &/or fluid
      - Intermixed microcysts may appear as air-trapping
      - Margins with normal lung may be difficult to define
  - May cause hyperinflation or atelectasis of adjacent lung

Ultrasonographic Findings

- Typically limited to prenatal evaluation
  - Solid-appearing echogenic mass relative to normal lung
  - Discrete anechoic cysts of variable size
  - Typically stabilizes or ↓ in size > 26-weeks gestation
    - Often regresses or "resolves" by late 3rd trimester
      - False-negative rate of 40% vs. postnatal CT
  - ± pleural effusion, skin edema, other findings of hydrops
    - CPAM volume ratio (CVR) > 1.6 → 80% develop hydrops
  - Systemic arterial supply on Doppler → component of BPS ("hybrid lesion")

Imaging Recommendations

- Best imaging tool
  - Chest CT angiogram that includes celiac axis (so as to exclude diagnosis of BPS)
  - Many surgeons prefer to delay surgery until child is > 6 months of age; if possible, CT angiogram should also be delayed (so as to improve quality of imaging)

DIFFERENTIAL DIAGNOSIS

Bronchopulmonary Sequestration

- Systemic arterial supply to lesion
- Solid-appearing; only becomes air-filled after infection (as it lacks communication with airway)
- Mixed CPAM/sequestration ("hybrid") lesions are common
- Left > right lower lobes

Congenital Diaphragmatic Hernia (CDH)

- Appears radiographically as multicystic, air-containing mass
  - "Cysts" are often uniform in size & morphology
- Unexpected course or position of support devices
  - Nasogastric tube has reversed J-shaped course into left lower chest if stomach is herniated (left-sided CDH)
  - Umbilical venous catheter may be deviated toward the left if liver is herniated (left-sided CDH)
- Paucity of abdominal bowel gas (due to herniation)

Bronchogenic Cyst

- Round mass lesion; typically mediastinal or perihilar location
- Fluid-attenuation mass may become air-filled if infected

Pleuropulmonary Blastoma (PPB)

- Rare in newborns, but vast majority present before age 6
- Type 1 PPB is indistinguishable from types 1 & 4 CPAM
  - Large cyst, solid soft tissue component, multilobar or bilateral involvement, lack of 2nd trimester prenatal detection, & *DICER1* mutation ↑ likelihood of PPB

Cavitary Necrosis/Abscess Complicating Pneumonia

- Older children; typically not neonates
- Typically ill with respiratory distress, fever, cough

- Thick-walled cavitary necrosis surrounded by consolidated lung
- Temporal factors favoring cavitary necrosis: Prior normal chest radiograph, progression of findings during illness, resolution after illness

Congenital Lobar Overinflation

- Progressive lobar overdistention of lung segment or lobe
- Preserved pulmonary markings without discrete cyst walls
- Strong upper & middle lobe predilection

PATHOLOGY

General Features

- Etiology
  - Congenital lung mass of various cell origins
  - Lesion development is poorly understood; related to varying degrees & levels of early airway obstruction
- Associated abnormalities
  - Type 2 lesions are associated with other congenital anomalies (50%)

Staging, Grading, & Classification

- Stocker classification is based on size of cysts & lesion's histologic resemblance to developing bronchial tree & lung
  - Type 0 (1-2%): Diffuse acinar dysplasia/dysgenesis; diffuse & bilateral → unresectable & fatal
  - Type 1 (60-65%): Large cyst type; usually presents in newborns, may be found incidentally in older children; almost always resectable
  - Type 2 (10-15%): Small & medium cyst type; presents in 1st year; outcome is often poor due to other anomalies
  - Type 3 (5-10%): Microcystic/solid type; fetal or newborn presentation, often with polyhydramnios or hydrops
  - Type 4 (10-15%): Peripheral cyst type; present in newborn period or early childhood with respiratory distress, infection, or pneumothorax from rupture

Microscopic Features

- Type 0: Contains bronchial-like structures lined with ciliated pseudostratified epithelium & goblet cells; may contain bronchiolar cartilage & muscle
- Type 1: Lined by ciliated columnar epithelium; may contain mucus-producing cells, muscle, & cartilage
- Type 2: Lined with respiratory epithelium with smooth muscle in wall; absent mucin-producing cells & cartilage
- Type 3: Adenomatoid appearance with randomly scattered, bronchiolar/alveolar, duct-like structures
- Type 4: Lined with alveolar epithelial cells &/or low columnar epithelium (hamartomatous malformation of distal acinus)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Prenatal diagnosis ± symptoms at birth
  - Respiratory distress in newborn (~ 25%)
    - Depends on size of lesion, mediastinal shift, hydrops
  - Recurrent lung infections in older child

Demographics

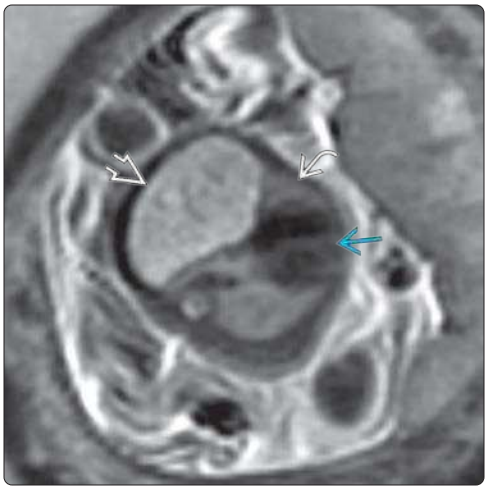
- Age
  - Most commonly detected prenatally or during infancy
  - Can present at any age
- Epidemiology
  - Incidence: 1 per 15,000-25,000 live births

Natural History & Prognosis

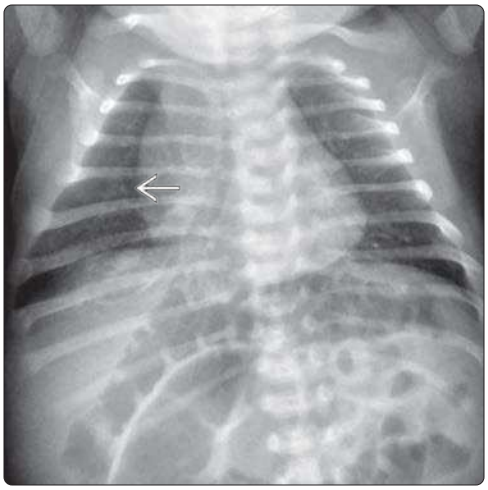
- Overall survival > 95%
- ~ 13% require neonatal respiratory support
- Prenatally detected CPAM may grow until 26-weeks gestation followed by varying degrees of regression
  - ~ 20% become sonographically undetectable in 3rd trimester but with false-negative rate of 40%
  - 10% (typically microcystic with low initial CVR) show complete regression by postnatal CT &/or pathology
- Type 2 lesions are associated with other congenital anomalies (especially esophageal atresia & TE fistula, renal dysgenesis/agenesis, cardiovascular anomalies, intestinal atresias, & sirenomelia)
- Risks of unresected CPAM
  - Recurrent infections
  - Small risk that lesion actually represents PPB
  - Future malignant degeneration
    - Bronchioloalveolar carcinoma, rhabdomyosarcoma

Treatment

- Prenatally detected lesions are followed with ultrasound/MR
  - Smaller lesions without hydrops: Close follow-up ± corticosteroids
  - Larger lesions at risk for/with hydrops: Corticosteroids, consider fetal interventions
    - Aspiration/shunting of dominant cyst
    - Resection of lesion
- Symptomatic CPAM after delivery → surgical resection
- Asymptomatic CPAM management is controversial
  - Most advocate elective resection due to risks of infection & malignancy
  - Fewer complications if surgery is performed prior to development of symptoms
    - ~ 2/3 of expectantly managed patients ultimately become symptomatic



DIAGNOSTIC CHECKLIST



Consider

- Most true multicystic pulmonary masses containing air in neonatal period represent CPAM

(Left) *Axial T2 SSFSE MR in a 23-weeks-gestation fetus shows a large, homogeneously hyperintense lesion occupying the majority of the right hemithorax & compressing the residual normal right lung. The heart is displaced into the left chest.* **(Right)** *Newborn AP chest radiograph in the same patient shows interval regression of the lesion with only mild architectural distortion identified in the right lung. The heart now has a normal position.*

(Left) *Coronal CTA in the same patient shows a residual, predominately hyperlucent right lung lesion consisting of cysts of variable size. The lesion splays normal pulmonary vessels. A mixed type 1 & type 2 CPAM was confirmed upon resection.* **(Right)** *Coronal CTA in a neonate shows a hyperlucent right lower lobe CPAM. There is a single large macrocyst laterally in the lesion. Other smaller cysts are intermixed with microcysts &/or air-trapping.*

(Left) *AP chest radiograph in a 3-week-old boy shows a large dense mass of the left lung causing left to right mediastinal shift.* **(Right)** *Follow-up AP chest radiograph in the same infant 6 weeks later shows that the large left lower lobe lesion has become aerated, typical of a CPAM. The mediastinal shift has slightly ↓ in severity.*

Bronchopulmonary Sequestration

KEY FACTS

TERMINOLOGY

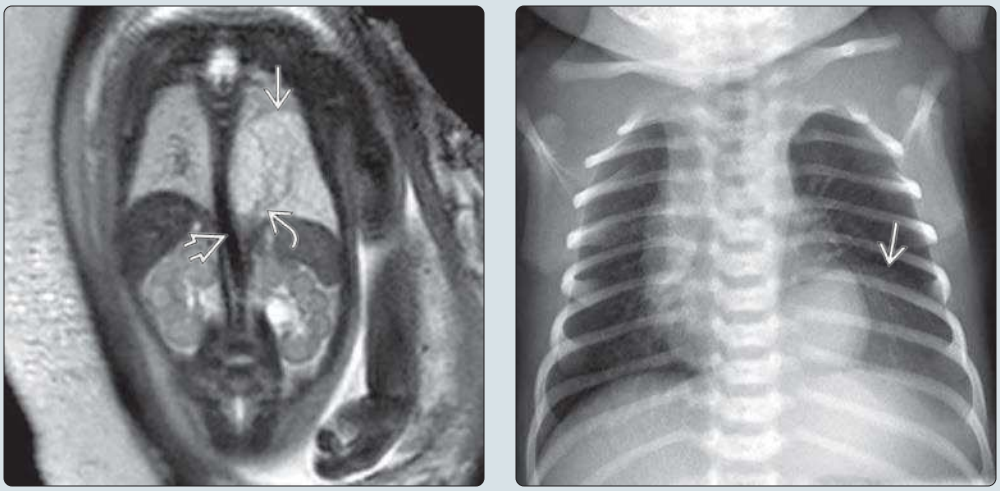
- Congenital focus of abnormal lung that does not connect to bronchial tree or pulmonary arteries
- Divided into intralobar (75%) & extralobar (25%) types
  - Intralobar shares pleural investment with normal lung & usually has pulmonary venous drainage
  - Extralobar has separate pleural investment from lung & usually has systemic venous drainage

IMAGING

- Lower lobe (L > R) opacity persisting over time
  - Mass may occur in mediastinum or in/below diaphragm
- Systemic arterial supply is characteristic; identification is critical for diagnosis & surgical planning
  - Postnatal CTA (vs. MR) is recommended for all congenital lung lesions (even with 3rd-trimester regression)
  - Arterial supply may be subdiaphragmatic in origin even if BPS is supradiaphragmatic
    - Chest CTA must cover through celiac axis
- Often occurs as "hybrid lesion" with congenital pulmonary airway malformation (CPAM)

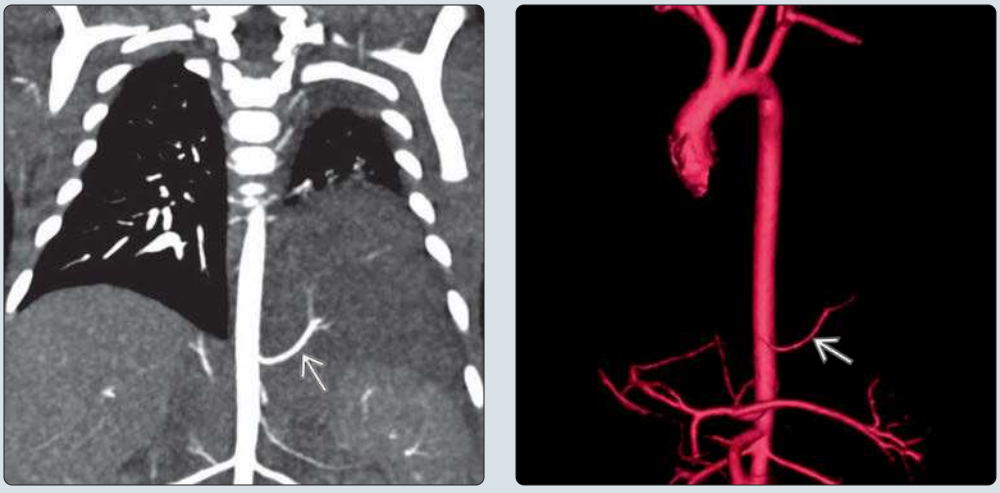
TOP DIFFERENTIAL DIAGNOSES

- Depends on location & imaging features
  - Chronic lung opacity
  - Anomalous systemic blood flow to lung
  - Focal chest mass
  - Solid suprarenal mass



CLINICAL ISSUES

- Intralobar typically presents as isolated anomaly in older children/adults with recurrent pneumonia
- Extralobar is typically detected in prenatal/neonatal period, often with additional congenital anomalies
- Symptomatic is BPS resected; management of asymptomatic lesions is controversial



DIAGNOSTIC CHECKLIST

- Consider BPS with recurrent lower lobe pneumonia

(Left) *Coronal T2 SSFSE MR of a 31-weeks-gestation fetus shows a large, homogeneously hyperintense left lower lobe mass ➡ displacing the left upper lobe & aorta ➡. Flow voids ➡ are seen extending into the mass from the aorta.* **(Right)** *AP radiograph in the same patient 5 days after birth shows mild ↓ size of the left lower lobe mass ➡.*

(Left) *Coronal CT angiogram in the same patient 11 days later shows an arterial feeding vessel ➡ extending into the solid mass from the upper abdominal aorta, confirming systemic arterial supply in a bronchopulmonary sequestration (BPS). Upon resection, the mass contained components of both BPS & CPAM, consistent with "hybrid lesion."* **(Right)** *3D coronal oblique reconstruction from the same CT angiogram in the same patient shows the feeding vessel ➡ relationship to other upper abdominal arterial origins.*

TERMINOLOGY

Definitions

- Bronchopulmonary sequestration (BPS): Dysplastic nonfunctional lung tissue with no connection to bronchi or pulmonary arteries
- Intralobar (75%) vs. extralobar (25%) types
  - Intralobar sequestration (ILS) typically has pulmonary venous drainage without separate pleural investment
  - Extralobar sequestration (ELS) typically has systemic venous drainage with separate pleural investment

IMAGING

General Features

- Best diagnostic clue
  - Lower lobe opacity that persists over time
  - Systemic arterial supply to lesion
- Location
  - 98% in lower lobes (L > R)
  - Up to 15% of ELS occurs below diaphragm
  - Rarely in diaphragm, mediastinum, neck
- Feeding artery usually arises from descending aorta
- ± elements of other congenital lung lesions, especially congenital pulmonary airway malformation (CPAM)
  - 17-42% of congenital lung lesions are "hybrid" or "complex"
- May be difficult to differentiate ILS vs. ELS by imaging
  - May not affect surgical management

Radiographic Findings

- Radiography
  - Persistent lower lobe opacity over time
  - May contain gas from infection, bronchial fistula (in ILS), collateral flow, or CPAM components ("hybrid lesion")
  - ELS may present as subdiaphragmatic mass displacing adjacent interfaces, such as paraspinal stripes

Ultrasonographic Findings

- Postnatal ultrasound
  - Abnormal lung may provide acoustic window
  - Doppler ultrasound may demonstrate feeding vessel
- Prenatal ultrasound
  - Homogeneous echogenic lung mass ± cystic components in hybrid lesions
  - May see systemic feeding artery with Doppler

CT Findings

- CTA
  - Recommended for all congenital lung lesions to evaluate systemic vascular supply prior to surgery
    - Descending thoracic aorta is most common source of feeding vessel
    - Other sources: Abdominal aorta; celiac, splenic, intercostal, subclavian, coronary arteries
      - Rarely aberrant pulmonary artery
    - Arterial supply may be subdiaphragmatic in origin even if sequestration is supradiaphragmatic
    - Feeding artery diameter may help predict need for resection
    - 3D reconstruction is helpful for surgical planning
  - Discrete solid mass ± cysts vs. opacification of lower lobe parenchyma
  - ± peripheral/perilesional foci of low attenuation
  - ± gas in lesion with infection, fistula, collateral alveolar communication, or hybrid lesion with CPAM
  - ELS may torse, thrombose, or hemorrhage, making diagnosis more difficult

MR Findings

- Fetal MR is often used for prenatal lung lesion assessment
- Increasing reports of postnatal utilization of MR
- Most frequently: Homogeneous, T2-hyperintense, solid-appearing mass; ± cystic components in hybrid lesions
- Feeding artery is visualized as flow void on SE/FSE sequences; may be bright GRE sequences

Imaging Recommendations

- Best imaging tool
  - Prenatal imaging
    - Ultrasound is excellent 1st-line study for detection/characterization; may not need fetal MR
  - Postnatal imaging
    - When BPS is suspected prenatally, obtain postnatal CTA for feeding vessel detection prior to surgery
- Protocol advice
  - Extend chest CTA through celiac axis to detect subdiaphragmatic arterial supply

DIFFERENTIAL DIAGNOSIS

Chronic Lung Opacity

- Chronic or recurrent pneumonia
  - Typically no systemic arterial supply
- Chronic bronchial obstruction
  - Aspirated foreign body
  - Endobronchial lesion (e.g., carcinoid)

Anomalous Systemic Blood Flow to Lung

- Hypogenetic lung syndrome (scimitar)
  - Hypoplasia of right lung & pulmonary artery
  - Partial anomalous pulmonary venous return
  - Systemic arterial supply of right lung base ± BPS
- Chronic inflammation with hypertrophied bronchial arteries
  - Cystic fibrosis, chronic pneumonia
- Pulmonary artery atresia
  - Multiple aortopulmonary collateral arteries (MAPCAs)
- Bronchial atresia may have systemic supply
  - Overlaps with ILS
- Isolated aberrant artery without lung abnormality

Focal Chest Mass

- CPAM
  - Often has cystic components filling with air postnatally
  - No systemic arterial supply unless hybrid lesion
  - May be seen in middle, upper lobes
- Bronchogenic cyst
  - Mediastinal or central pulmonary location
  - Well-defined cyst without feeding artery
  - May compress bronchus leading to overinflation lesion (mimicking BPS prenatally)
- Round pneumonia
  - Most common round lung opacity in young children

  - Usually < 8 years of age
  - Should resolve/improve with antibiotics
- Pleuropulmonary blastoma (rare)
  - Type I is indistinguishable from benign lung cysts
  - Large thoracic soft tissue mass (types II & III)
- Neuroblastoma
  - Ovoid paraspinal mass displacing paraspinal stripe(s)
  - ± rib splaying, erosion
- Lymphatic malformation
  - Multicystic mass crossing multiple soft tissue planes
  - Often involves upper mediastinum, neck, chest wall

Solid Suprarenal Mass

- Adrenal hemorrhage
  - No central vascularity
  - Often diagnosed later in gestation than BPS
  - ↓ or resolves over time
- Neuroblastoma
  - Often calcifies & engulfs normal vessels

PATHOLOGY

General Features

- Abnormal dysplastic lung tissue lacking normal/functional tracheobronchial connection
- Development is likely related to caudal accessory lung bud with abnormal vascular supply from foregut
- Underlying airway obstruction likely contributes to maldevelopment
  - Foci of bronchial atresia are found in most congenital lung lesions including BPS (ELS > ILS)
- Aberrant feeding artery in all cases
  - Usually systemic (5% from pulmonary artery)
  - Single supplying artery in 80%; 2 or more in 20%
  - May not be visualized by imaging
- ELS
  - Always congenital
  - Often associated with other anomalies (65%)
    - Congenital diaphragmatic hernia, cardiac abnormalities, pulmonary hypoplasia, foregut duplication cysts, separate congenital lung lesions
  - Most common hybrid lesion: ELS + type II CPAM
  - Separate pleural investment; usually has systemic venous drainage
- ILS
  - Not all lesions are congenital; some may develop from chronic postnatal inflammation
  - Infection may lead to bronchial fistula
  - Not associated with other anomalies
  - Shares pleural investment with normal lung; usually drains into pulmonary venous system

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - ELS: Often asymptomatic postnatally
    - May cause neonatal respiratory distress from mass effect or adjacent pulmonary hypoplasia
    - Infection is much less common than ILS
  - ILS: Recurrent pneumonia symptoms in older child/adult
- Other signs/symptoms
  - ELS: May torse, infarct
    - Prenatally can develop hydrothorax, hydrops
    - Postnatally may cause chest/abdominal pain
  - ILS: Chest pain, hemoptysis; incidental in 15%

Demographics

- Age
  - ELS: Usually detected in prenatal/neonatal period
  - ILS: Classically, late childhood/early adulthood presentation; 50% > 20 years old

Natural History & Prognosis

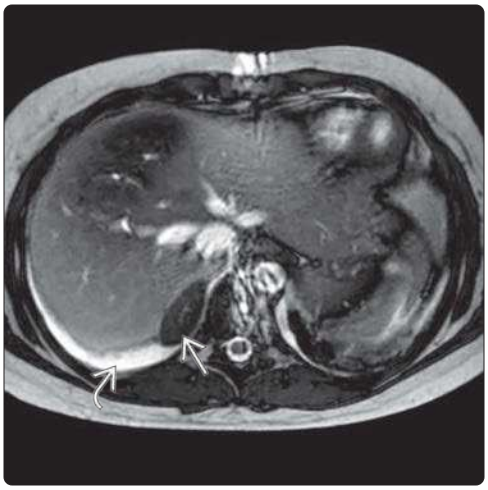
- High rate (up to 67%) of spontaneous in utero regression (partial or complete) of prenatal echogenic lung lesions
  - ~ 50% of prenatally detected BPS lesions

Treatment

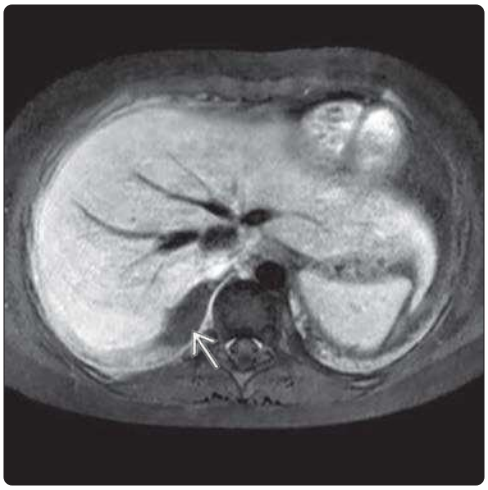
- Surgical resection in symptomatic cases
  - Reports of preoperative vs. isolated embolization of feeding artery (with variable success as primary therapy)
- Management of asymptomatic cases is controversial
  - Elective surgical resection vs. monitoring
    - Easier surgery prior to infection
  - If no feeding artery is seen on imaging, may be excised for concern of other lesions
- High mortality if ELS leads to hydrops in utero (possibly due to torsion of lesion on vascular pedicle)
  - High success rates of minimally invasive in utero laser ablation of feeding vessel → ↓ size of mass & effusion with resolution of hydrops → up to 100% survival

DIAGNOSTIC CHECKLIST

Consider



- Raise BPS possibility with recurrent lower lobe pneumonia &/or paraspinal mass
- Postnatal CTA (or possibly MR) should be performed for prenatally detected lung lesions (even with 3rd-trimester regression)



Reporting Tips

- Imaging differentiation of ELS vs. ILS may not be possible
- Describe size, location, vascular supply/drainage, aeration, involvement of adjacent structures, associated anomalies
  - Critical to define feeding vessel origin prior to surgery

(Left) *Axial SSFP MR in a 10-year-old patient with right abdominal pain & fever shows an ovoid, hypointense mass ➡ medially in the right lower hemithorax with an adjacent pleural effusion ➡.* **(Right)** *Axial T1 C+ FS MR in the same patient shows no enhancement of the mass ➡.*

(Left) *Thoracoscopy of the right hemithorax in the same patient shows a small, hemorrhagic mass ➡ in the pleural space. Histology revealed a torsed & infarcted extralobar BPS.* **(Right)** *Coronal T2 SSFSE MR in a 27-weeks-gestation fetus shows a large, uniformly hyperintense, solid left lower lobe lesion ➡ with a large, trifurcating feeding vessel ➡ arising from the thoracic aorta, consistent with BPS.*

(Left) *Right upper quadrant color Doppler ultrasound in a newborn with a prenatally diagnosed suprarenal vs. hepatic mass shows an ovoid, mixed solid & cystic lesion ➡ with no significant internal vascularity or feeding vessel.* **(Right)** *Coronal T2 MR SSFSE in the same patient shows a heterogeneously hyperintense, lobular mass ➡ along the posterior liver. Upon resection, a retroperitoneal extralobar BPS was confirmed with CPAM components ("hybrid lesion"). No feeding vessel was ever seen on imaging or surgical exploration.*

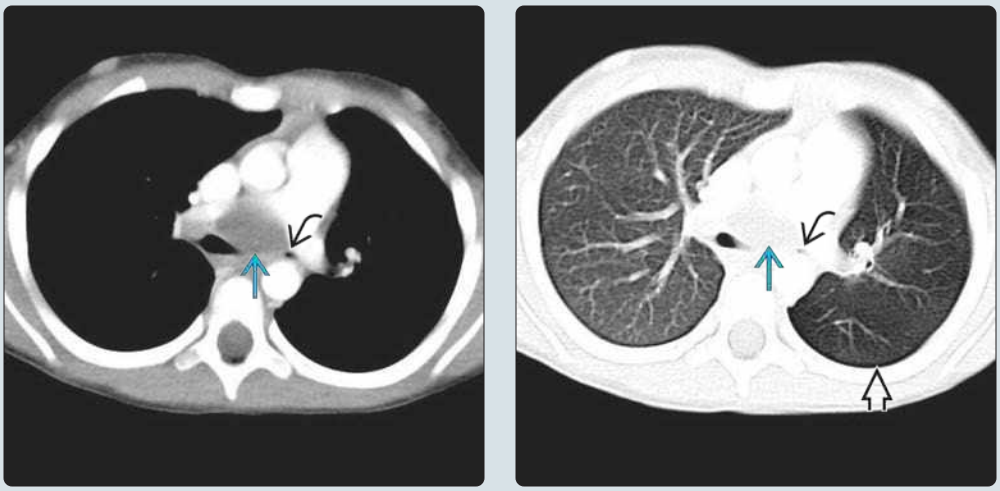
Bronchogenic Cyst

KEY FACTS

TERMINOLOGY

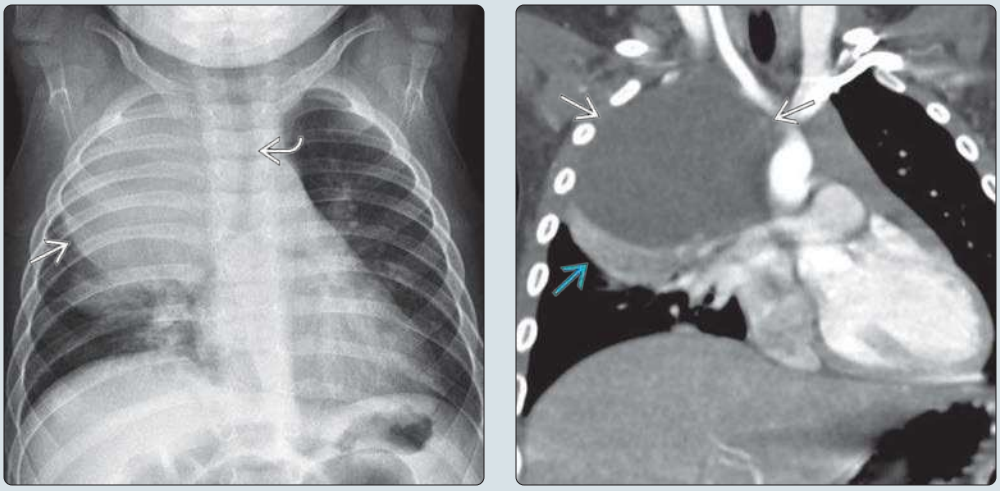
- Congenital mass in family of foregut duplication cysts: Bronchogenic cysts, enteric cysts, neurenteric cysts
- Results from abnormal ventral budding of tracheobronchial tree between 26th & 40th days of gestation

IMAGING



- Well-defined, round to ovoid, unilocular, thin-walled cyst
- Mediastinal location >> lung (medial 1/3 of lower lobes) > extrathoracic
  - Typically subcarinal, paratracheal, or hilar
- May compress airway → adjacent atelectasis or air-trapping
- Fluid filled; gas in cyst is uncommon unless active or prior infection
- CECT: Variable attenuation of cyst contents due to protein, hemorrhage, or (rarely) calcium; minimal enhancement of thin wall
- MR: Variable T1 signal; T2 FS or STIR imaging maximizes conspicuity of high fluid signal in cyst

TOP DIFFERENTIAL DIAGNOSES



- Esophageal duplication cyst
- Neurenteric cyst
- Round pneumonia
- Neuroblastoma
- Lymphadenopathy
- Lymphatic malformation
- Congenital pulmonary airway malformation
- Bronchopulmonary sequestration

CLINICAL ISSUES

- Common presentations
  - Respiratory distress, recurrent pneumonia, chest pain, dysphagia
    - Infants are more likely to be symptomatic
  - Infection is more common in pulmonary lesions
  - Often asymptomatic in older children & adults
- Definitive treatment: Surgical resection

(Left) *Axial CECT of a 5-year-old girl with recurrent left lower lobe pneumonia shows a 2-cm, well-circumscribed, fluid-attenuation mass in a subcarinal location. There is marked narrowing of the adjacent left main bronchus. (Right) Axial lung window in the same CECT in the same patient shows diffuse hyperlucency of the left lung, indicating postobstructive air-trapping due to extrinsic compression of the left main bronchus by the bronchogenic cyst (with the cyst being poorly visualized on this setting).*

(Left) *AP chest radiograph in a 9-month-old with respiratory distress & wheezing shows a large, rounded density in the right upper hemithorax with mass effect on the airway. There is patchy airspace opacity in the right lung base.* **(Right)** *Coronal CECT in the same patient shows a large, well-defined, fluid-attenuation mass arising from the right paratracheal region. The adjacent right upper lobe atelectasis is a result of mass effect on the right upper lobe airways & parenchyma. A bronchogenic cyst was confirmed at resection.*

TERMINOLOGY

Definitions

- Congenital mass in family of foregut duplication cysts: Bronchogenic cysts, enteric cysts, neurenteric cysts

IMAGING

General Features

- Best diagnostic clue
  - Well-circumscribed, round, middle mediastinal mass of soft tissue or water density
- Location
  - Mediastinal: 75-85%
    - 79% middle, 17% posterior, 3% anterior
    - Typically subcarinal, paratracheal, or hilar
  - Pulmonary: 15-25%
    - Majority in medial 1/3 of lower lobes
  - Rarely extrathoracic; can occur anywhere along foregut
    - Diaphragm, retroperitoneum, base of tongue, suprasternal or presternal soft tissues, pericardium or myocardium, subcutaneous tissues
- Size
  - 1-11 cm; average: 4.8 cm
- Morphology
  - Well-defined ovoid or round mass with smooth or slightly lobulated borders
  - Almost always unilocular
  - No communication with airway unless prior infection

Radiographic Findings

- Radiography
  - Well-defined spherical mass with smooth borders
  - Soft tissue/fluid density
  - Typically in mediastinum or central lung
  - Compression of adjacent bronchus may lead to hyperinflation or atelectasis

Fluoroscopic Findings

- Extrinsic mass effect on esophagus on esophagram or upper GI series

CT Findings

- CECT
  - Sharply marginated mass with smooth borders
  - Cyst contents are variable: Water or proteinaceous fluid, air
    - Mediastinal: 50% water attenuation, 50% soft tissue attenuation
    - May contain air if current or prior infection
  - Ca^{2+} is uncommon; may occur in wall or as layering calcium oxalate in cyst contents
  - Typically shows non- or minimally enhancing thin wall
    - Thicker enhancing wall implies infection
    - Solid nodular components favor neoplasm
  - No central enhancement
  - May see lucency in adjacent lung in pulmonary lesions indicating air-trapping

MR Findings

- T1WI
  - Well-circumscribed, thin-walled cystic mass
    - Variable internal signal, often hyperintense due to proteinaceous or hemorrhagic fluid
- T2WI FS
  - Central contents have fluid signal hyperintensity
    - Intermediate or dark T2 signal intensity could be due to hemorrhage or (rarely) Ca^{2+}
- DWI
  - Uncomplicated cyst should not restrict diffusion
- T1WI C+ FS
  - No central enhancement
  - Thin wall may mildly enhance
  - Thicker enhancing wall implies infection

Ultrasonographic Findings

- Grayscale ultrasound
  - Well-circumscribed, round mass with posterior acoustic enhancement
  - Thin wall with variable echogenicity of internal contents
- Color Doppler
  - No internal vascularity
  - With inflammation, thickened cyst wall & surrounding tissues may be hyperemic

Imaging Recommendations

- Best imaging tool
  - MR or CT is usually best for diagnosis
    - MR provides more comprehensive evaluation of lesion to exclude other diagnoses & determine full extent (particularly if paraspinal)
    - Lung parenchyma & small airways are better visualized on CT
    - May be occult or subtle on radiography
  - If mass location allows adequate acoustic window, ultrasound may demonstrate cystic nature of lesion without radiation or sedation
- Protocol advice
  - T2 FS or STIR MR to maximize contrast of cyst fluid against surrounding tissues
  - Consider additional MR sequences
    - Flow-sensitive sequence to exclude aneurysm/varix & show exact relationship to mediastinal/hilar vessels
    - Precontrast T1 FS in single plane for subtraction from postcontrast sequence (to confirm absence of true enhancement)

DIFFERENTIAL DIAGNOSIS

Esophageal Duplication Cyst

- Often has identical imaging appearance
- Duplication cyst may have thicker wall (as smooth muscle is always present)

Neurenteric Cyst

- Cyst communicates with spinal canal
- Commonly has associated vertebral anomaly

Round Pneumonia

- Well-circumscribed lung opacity in child < 8 years of age
- Air bronchograms confirm airspace disease
- No mass effect on adjacent structures
- Follow-up radiographs will show resolution after antibiotics

Neuroblastoma

- Moderately enhancing, solid paraspinal mass
- Intermediate T2 MR signal intensity; frequently calcified
- Typically restricts diffusion on MR
- ± adjacent rib & vertebral changes, intraspinal extension

Lymphadenopathy

- Generally multifocal, ovoid, solid-appearing
- Necrotic lymph nodes
  - Usually have associated pulmonary findings of infection (e.g., histoplasmosis or tuberculosis)
  - Thick, irregular rim of enhancement
  - Other nearby nodes are usually enlarged

Lymphatic Malformation

- Multilobulated, multiseptated cystic mass
- Infiltrates across multiple soft tissue compartments
  - Neck, chest wall, upper extremity
- Surrounds & displaces adjacent structures, typically without significant venous compression
- Macrocysts may contain fluid-fluid levels from hemorrhage

Congenital Pulmonary Airway Malformation

- Heterogeneous, multicystic lesion with architectural distortion of lung parenchyma
- Individual cysts in lesion vary widely in size
- Initially fluid-filled at birth with subsequent aeration

Bronchopulmonary Sequestration

- Heterogeneous cystic &/or solid mass, typically in lung bases
- Borders tend to be less well defined
- Systemic feeding vessel from aorta is pathognomonic

PATHOLOGY

General Features

- Etiology
  - Congenital lesions that develop from abnormal budding of ventral foregut between 26th & 40th days of gestation
    - Early budding results in mediastinal/tracheobronchial cysts
    - Later budding results in lung parenchymal cysts
    - Can occur anywhere along foregut (but rarely extrathoracic)
- Associated abnormalities
  - Occasional association with other congenital cardiopulmonary malformations
    - BPS, lobar overinflation, diaphragmatic hernia
    - Pericardial defect, congenital heart disease

Gross Pathologic & Surgical Features

- Well-circumscribed, unilocular cystic lesion
- Almost 50% have stalk connecting lesion to trachea/carina, pleura, or esophagus
- No communication with airway unless prior infection
- Contents usually thick or gelatinous fluid

Microscopic Features

- Lined by ciliated respiratory epithelium
- May contain bronchial glands, smooth muscle, bronchial cartilage, or (rarely) gastric mucosa

CLINICAL ISSUES

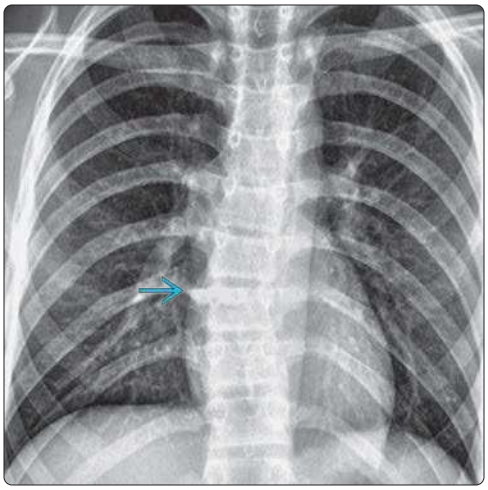
Presentation

- Most common signs/symptoms
  - Infants are more likely to be symptomatic
  - Mass effect
    - Airway: Respiratory distress, stridor, wheezing, recurrent pneumonia
    - Esophagus: Dysphagia
  - Infection is more common in pulmonary lesions
  - Often asymptomatic, incidentally discovered in older children & adults
- Other signs/symptoms
  - May be detected in utero ± mass effect
    - Can compromise airway, lead to overinflation of adjacent lung
  - Cervical & subcutaneous lesions frequently present as palpable masses

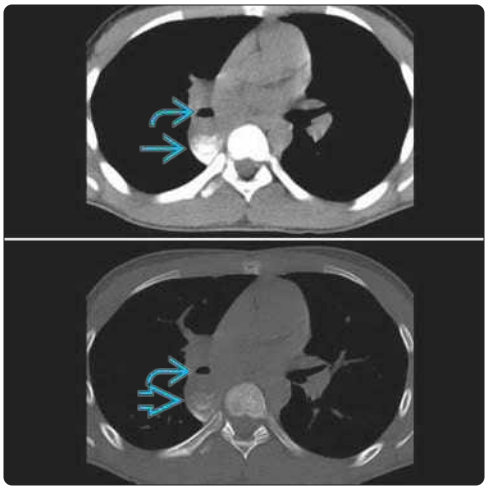
Demographics

- Age
  - May present at any age but usually in childhood
- Epidemiology
  - Frequency unknown due to asymptomatic population

Natural History & Prognosis



- Propensity for infection
- Rare case reports of malignancy arising in lesions



Treatment

- Typically surgical resection
  - Earlier resection is favored to avoid morbidity of resection after infection occurs
  - Potential for malignancy arising in lesion
- Conservative treatment may be considered in patients of high surgical risk

(Left) *Upright frontal radiograph in a 14-year-old boy with suspected scoliosis shows Ca^{2+} layering dependently in an otherwise occult lesion. (Right) Axial NECT images in the same patient show dependent positioning of the calcium within the otherwise fluid-attenuating mass (seen here in both soft tissue & bone windows). The mass is intimately related to the bronchus intermedius.*

(Left) *Axial T2 MR in the same patient shows dependently layering low signal intensity material (corresponding to the known Ca^{2+}) within the rounded mass.* **(Right)** *Axial T1 FS MR images in the same patient before (top) & after (bottom) contrast administration show no significant change in the mass. Note the intrinsically bright material within the mass, likely due to complex proteinaceous fluid. Small foci of the lesion extend posterior to the pulmonary artery. A bronchogenic cyst was confirmed upon resection.*

(Left) *Frontal esophagram image from a 3-year-old patient with choking episodes shows a round, relatively lucent mass extrinsically compressing the contrast-filled midesophagus from the right. The lesion was occult radiographically.* **(Right)** *Coronal CECT in the same patient shows the round mass to be of fluid attenuation with minimal rim enhancement. This bronchogenic cyst was directly apposed to the bronchus intermedius.*

Congenital Lobar Overinflation

KEY FACTS

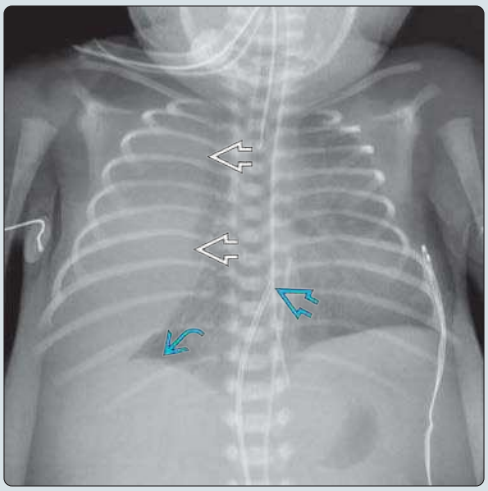
TERMINOLOGY

- Congenital lobar overinflation (CLO): Malformation of lower airways that results in overexpansion of pulmonary segment or lobe
- CLO is preferred term (vs. lobar emphysema), as microscopic analysis shows airspace overinflation, not alveolar destruction
- Considered final common pathway in various disruptions of bronchopulmonary development

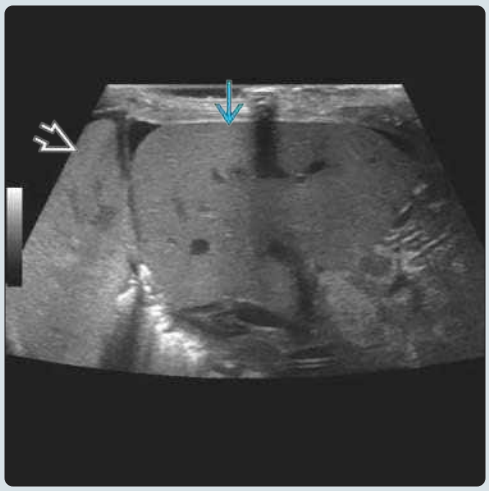
IMAGING

- Progressively hyperlucent & hyperexpanded lobe in neonate → mass effect on adjacent lung, mediastinal shift
  - Lobar predilection: LUL > RML > RUL > > lower lobes
- Typically diagnosed by serial chest radiographs
- CTA is performed to confirm diagnosis, elucidate potential cause, & exclude other lung malformations (especially pulmonary sequestration)
  - No discrete cyst or feeding vessel

TOP DIFFERENTIAL DIAGNOSES

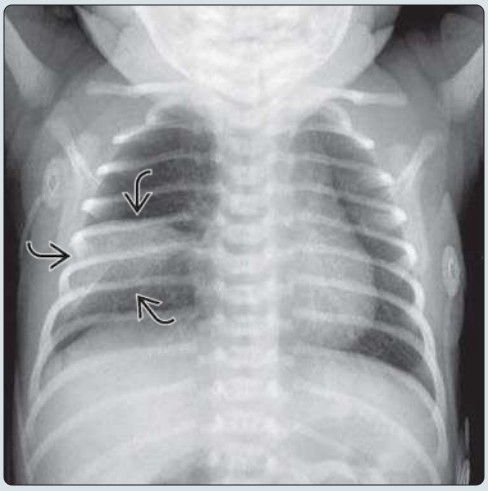


- Pneumothorax
- Bronchial atresia
- Congenital pulmonary airway malformation
- Aspirated foreign body
- Persistent pulmonary interstitial emphysema
- Swyer-James syndrome

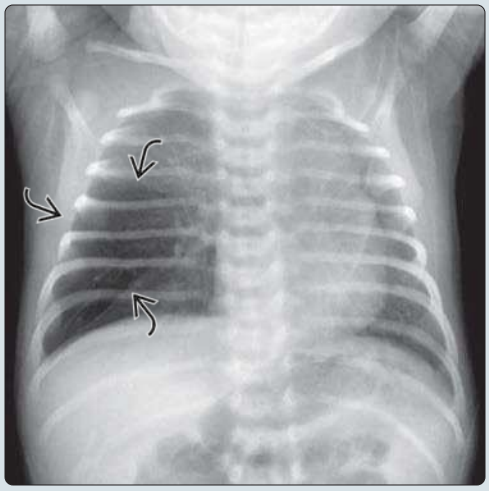


PATHOLOGY

- Partial bronchial obstruction due to wall abnormality, luminal obstruction, or extrinsic compression leads to check-valve mechanism
- Air enters involved region but has difficulty leaving → progressive hyperinflation → mass effect



CLINICAL ISSUES



- Usually presents as neonatal respiratory distress resulting from progressive hyperexpansion & mass effect
- Treated by thoracoscopic lobectomy

(Left) *Newborn radiograph shows a large, expansile, lentiform opacity peripherally. This example of CLO appears uniformly dense because it still contains retained fetal fluid. Note the malpositioned umbilical venous catheter in the right atrium & the depressed right hemidiaphragm, both of which are displaced by the mass.* **(Right)** *Longitudinal US in the same patient shows that the fluid-filled CLO is hyperechoic but otherwise has normal lung architecture, giving it an appearance similar to the liver on this image.*

(Left) *AP radiograph obtained in the 1st few hours of life demonstrates segmental airspace opacification of the right middle lobe. The opacity reflects retained fetal fluid-filling alveoli in the affected segment.* **(Right)** *Follow-up AP radiograph in the same patient the next day shows that the same segment is now gas filled, quite lucent, & hyperexpanded. The retained fetal fluid has been resorbed, & the findings now reflect localized air-trapping, consistent with CLO.*

TERMINOLOGY

Abbreviations

- Congenital lobar overinflation (CLO)

Synonyms

- Congenital lobar hyperinflation
- Congenital lobar emphysema is no longer used, as microscopic analysis shows airspace overinflation, not alveolar destruction

Definitions

- Congenital lung malformation consisting of overdistended pulmonary segment or lobe; caused by partial bronchial obstruction acting as 1-way valve → air-trapping
- Considered final, common pathway of various disruptions of bronchopulmonary development
  - 50% are idiopathic
  - 25% are due to intrinsic cartilaginous abnormality
  - 25% are due to extrinsic compression

IMAGING

General Features

- Best diagnostic clue
  - Neonate with hyperexpanded lucent pulmonary lobe
    - Especially left upper lobe
    - May be fluid-filled in 1st few hours after birth
- Location
  - Lobar predilection
    - Left upper lobe: 40%
    - Right middle lobe: 35%
    - Right upper lobe: 20%
    - Lower lobes: 5%
  - May involve ≥ 1 lobe or only segment

Radiographic Findings

- Classic newborn appearance: Fluid-filled, radiopaque pulmonary segment or lobe becomes progressively hyperlucent & hyperexpanded
  - May have reticular pattern as fluid clears via distended lymphatics
- Classic appearance is uncommon
  - Usually detected as gas-filled hyperexpanded lobe beyond immediate newborn period
- Pulmonary vessels may appear attenuated & evenly splayed
- Mass effect
  - Compression of ipsilateral lung
  - Mediastinal shift with possible tracheal deviation & compression of contralateral lung
  - Deviation of anterior junction line
  - Occasional rib separation & hemidiaphragm depression
  - Persistent hyperinflation of lobe/segment despite ipsilateral decubitus positioning

CT Findings

- NECT
  - Hyperinflation with uniform hyperlucency of affected lung parenchyma (reflecting distended alveoli)
  - No discrete cysts
- CTA
  - IV contrast is used to evaluate vascular structures & aid in detecting other abnormalities (e.g., sequestration, congenital pulmonary airway malformation, bronchogenic cyst)
  - Attenuated vessels: Smaller & more widely spaced than those in adjacent lung
    - Vessels are not focally splayed (as seen with cystic mass)

Ultrasonographic Findings

- Grayscale ultrasound
  - Prenatal: Uniformly hyperechoic lung mass without macrocysts or systemic arterial supply
    - Some show hypervascularity
  - Postnatal: Useful if affected lung is still fluid-filled → homogeneous & similar to liver

MR Findings

- Fetal MR
  - Homogeneous, T2-bright pulmonary mass without architectural distortion or discrete cyst
  - Pulmonary vessels in involved segment may appear elongated
  - May see adjacent T2-bright tubular/branching structure (due to dilated, fluid-filled bronchus)
  - Mass effect with compression of ipsilateral remaining lung & mediastinal deviation
  - Location of lesion is helpful, but mass effect can make localizing lesion difficult
  - Hydrops is less common compared to CPAM
- Postnatal MR
  - Gaining interest, particularly with ultrashort TE sequences for lung parenchyma

Imaging Recommendations

- Best imaging tool
  - Diagnosis is typically made by serial chest radiographs
  - CTA is performed to
    - Confirm diagnosis
    - Exclude other neonatal hyperlucent lung lesions
    - Evaluate for causal obstructing mass
    - Define extent of disease

DIFFERENTIAL DIAGNOSIS

Pneumothorax

- Pleural line + characteristic location &/or shape confirm abnormal gas collection of pleural space
  - Look for nondependent gas collection that varies by patient position
  - No lung markings beyond pleural line
  - Lung is collapsed, not hyperexpanded

Bronchial Atresia

- Central tubular, rounded, or branching fluid- or mucus-filled mass representing atretic bronchus
- Air accumulates via collateral ventilation rather than check-valve mechanism
  - No significant mass effect from progressive hyperexpansion

Congenital Pulmonary Airway Malformation

- Composed of variable-sized, gas-filled cysts

Bronchopulmonary Sequestration

- Nonfunctioning lung tissue separated from tracheobronchial tree
- Differentiated from other lung lesions by its systemic arterial blood supply
- Unless fistulized (usually by infection), remains fluid-filled (& thus radiopaque) postnatally

Aspirated Foreign Body

- Typically older infants or toddlers with acute-onset breathing difficulties after choking/coughing episode

Persistent Pulmonary Interstitial Emphysema

- In rare cases, persistent pulmonary interstitial emphysema can present as expanding hyperlucent mass
- Pulmonary vessels & bronchi are surrounded by air as gas dissects into pulmonary interstitium

Swyer-James Syndrome

- Presents later in childhood after viral infection
- Often affects > 1 lobe

PATHOLOGY

General Features

- Etiology
  - Most likely related to bronchial obstruction with check-valve phenomenon
    - Air enters involved region but has difficulty leaving → progressive hyperinflation
  - Specific cause is found in ~ 50% of cases
    - Wall abnormality
      - Deficient, immature, or dysplastic bronchial cartilage
      - Redundant bronchial mucosal folds
      - Stenotic or kinked bronchus
    - Lumen obstruction
      - Inspissated mucus plug
      - Mucosal web or fold
    - Extrinsic compression
      - Foregut duplication cyst
      - Vascular anomaly
- Associated abnormalities
  - 15-20% have cardiac anomalies
  - May also have renal, GI, & MSK abnormalities

Staging, Grading, & Classification

- 2 forms
  - Hypoalveolar: Normal or fewer alveoli than expected
  - Polyalveolar: More alveoli than expected

Gross Pathologic & Surgical Features

- Hyperexpanded lobe is rounded
- Sponge-like appearance
- Resected lobe does not deflate
  - Compressed ipsilateral lobe will reinflate & eventually compensatorily hyperinflate

Microscopic Features

- Dilated alveoli
- Alveolar walls are thinned but intact
  - Not true emphysema (hence effort to abandon congenital lobar emphysema nomenclature)
- Defective cartilage in bronchial walls is seen in < 50%

CLINICAL ISSUES

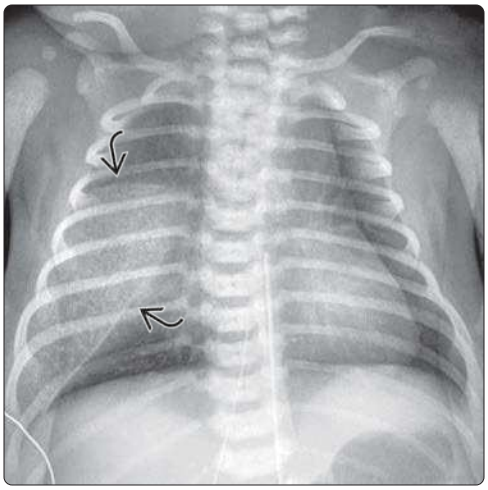
Presentation

- Most common signs/symptoms
  - Respiratory distress in neonatal period
  - May be progressive
- Other signs/symptoms
  - Asymmetry of movement of chest with respiration
  - Use of accessory muscles of respiration
  - ↓ breath sounds on affected side
  - Hyperresonant hemithorax

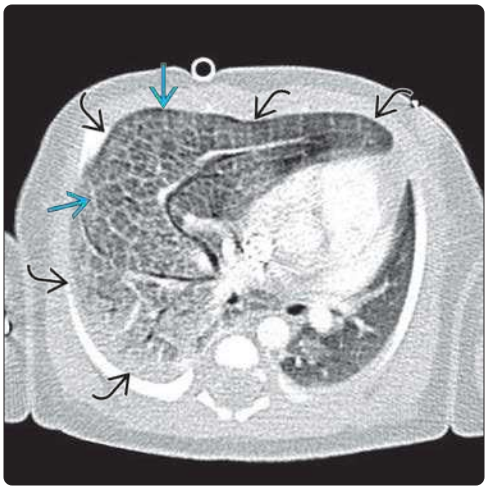
Demographics

- Age
  - May be diagnosed in utero
    - Many of these are asymptomatic after birth
  - Of those developing symptoms, majority occur as neonates or infants
    - 50% present in 1st 4 weeks; 75% in 1st 6 months
  - May present with symptoms later in childhood or may be incidental finding

Natural History & Prognosis



- Fluid seen in neonatal period is removed by lymphatics & capillary reabsorption
- Lobe is subsequently filled with air by collateral air drift
- May cause progressive respiratory distress as lobe continues to expand & cause lung compression; can be fatal if not resected
- Some patients have minor symptoms & can be observed
- Over time, involved lobe becomes small with diminished markings
- No ↑ risk of malignancy or infection



Treatment

- Consider bronchoscopy to exclude endobronchial lesion, especially if presenting beyond newborn period
- Mitigate respiratory distress caused by mass effect
  - Elective intubation of opposite lung
  - Place patient in ipsilateral decubitus position
- Thoracoscopic lobectomy
  - May be needed emergently if progressive hyperinflation occurs; can be life threatening
  - Most common complications: Air leak & need to convert to open approach
- Conservative treatment has been advocated for patients with minimal symptoms

(Left) *Chest radiograph of CLO during the period when fetal fluid has not fully been resorbed, but air-trapping has already begun, shows a picture of lobar hyperexpansion with distinct reticular interstitial markings ⇨. (Right) Axial CECT in the same patient shows how the right middle lobe is hyperexpanded & herniates across the midline ⇨. The radiographic reticular pattern resulted from fluid engorgement of lymphatics causing interlobular septal thickening ⇨.*

(Left) *AP radiograph of an infant with chronic wheezing shows an abnormally lucent left upper lobe ⇨ that is so hyperexpanded that it herniates across the midline ⇨. Note the mass effect causing mediastinal shift ⇨ & lower lobe atelectasis ⇨.* **(Right)** *Axial NECT from the same patient reveals smaller vessels in the affected hyperexpanded & hyperlucent left upper lobe ⇨ with compressive atelectasis in the right lung ⇨. There are no gas-filled cysts as would be seen in congenital pulmonary airway malformation (CPAM).*

(Left) *AP radiograph shows subtle asymmetric lucency & hyperexpansion of the left upper lobe ⇨ that went unnoticed on initial imaging. Note the malpositioned umbilical venous catheter in the right atrium ⇨. (Right) AP radiograph in the same patient 9 months later, when he presented with worsening respiratory distress, shows progressive hyperexpansion & lucency in the LUL ⇨. The resulting mass effect causes shift of the heart toward the right ⇨ with compressive atelectasis in the LLL ⇨.*

Bronchial Atresia

KEY FACTS

TERMINOLOGY

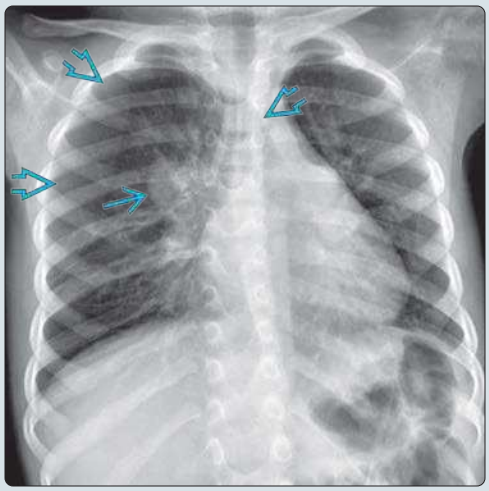
- Focal interruption of bronchus → distal mucoid impaction (bronchocele/mucocele) & hyperinflation of distal lung
  - ± hyperplasia of distal lung

IMAGING

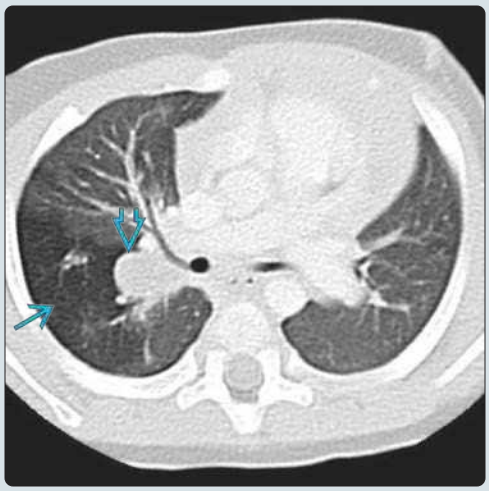
- Classic appearance: Ovoid/round or tubular branching mass (finger-in-glove sign) with hyperinflated lung distally
  - May occur in any lobe/segment/subsegment
- Neonates & infants may present with atelectatic, fluid-filled segment that gradually fills with air
- Protocol: CTA with multiplanar reconstructions
  - Fluid-attenuation round or tubular branching mass
  - Hyperinflated distal lung + ↓ vascularity
    - Expiratory images are helpful to confirm air-trapping
  - No systemic feeding artery

TOP DIFFERENTIAL DIAGNOSES

- Congenital lobar overinflation (CLO)
- Congenital pulmonary airway malformation (CPAM)
- Bronchogenic cyst
- Bronchopulmonary sequestration (BPS)
- Allergic bronchopulmonary aspergillosis
- Scimitar syndrome (hypogenetic lung syndrome)

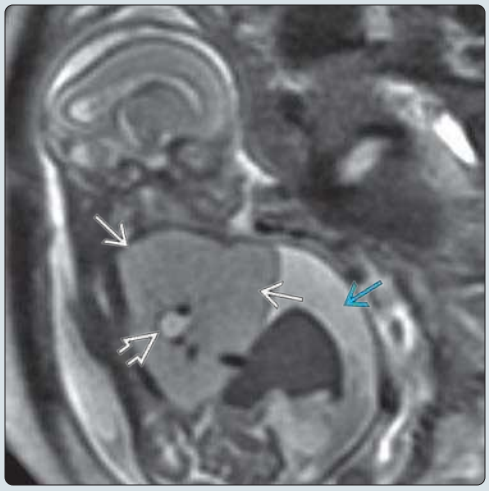


PATHOLOGY

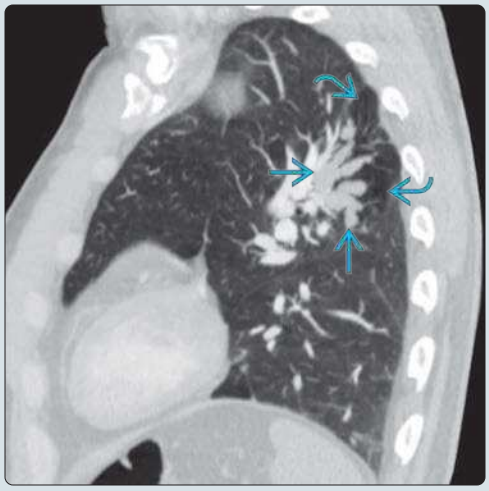


- Within spectrum of other congenital lung lesions (CLO, CPAM, BPS, bronchogenic cyst)
  - Components of atretic bronchi are frequently found pathologically in other congenital lung lesions
- Aeration of distal lung occurs through collateral air drift

CLINICAL ISSUES



- Older children/adults (majority of cases) are often asymptomatic
- May present with recurrent respiratory tract infections, chronic cough, dyspnea, &/or wheezing in early childhood
- Resection is usually reserved for recurrent infections



(Left) *AP radiograph in a 3-year-old with a cough & diminished breath sounds shows a round, perihilar, mass-like opacity due to a dilated, atretic right upper lobe (RUL) segmental bronchus. Note the relatively lucent & hyperexpanded RUL.* **(Right)** *Axial CECT (in lung windows) in the same patient confirms the findings of segmental RUL bronchial atresia. Note the RUL hyperinflation due to collateral air drift beyond the obstructed & dilated RUL bronchus (bronchocele).*

(Left) *Sagittal SSFSE T2 fetal MR shows a distended hyperintense right lung. The round, fluid-signal focus in the hilum accompanying the arterial flow void represents the fluid-filled atretic right main bronchus. Note the hydropic change, including ascites.* **(Right)** *Sagittal MIP CTA shows branching mucous-plugged bronchi in the posteroapical segment of the left upper lobe with distal air-trapping, typical of bronchial atresia.*

TERMINOLOGY

Definitions

- Focal interruption of main, lobar, segmental, or subsegmental bronchus with associated mucoid impaction (bronchocele/mucocele) & hyperinflation of distal lung
  - ± hyperplasia of distal lung depending on level of bronchial obstruction

IMAGING

General Features

- Best diagnostic clue
  - Round or tubular branching mass (finger-in-glove sign) + hyperinflated distal lung

Radiographic Findings

- Neonates & infants
  - Presentation is more variable than in children or adults
  - Lobe or segment may be atelectatic or fluid-filled initially → gradually fills with air
  - Hyperinflation is less frequent than in children & adults
- Children & adults
  - Radiating, branching, tubular opacity (mucoid impaction of dilated airway) distal to atretic bronchus
  - More central perihilar round or ovoid mass (bronchocele)
  - Distal lung is hyperinflated with ↓ vascularity

CT Findings

- CTA
  - Fluid-attenuation round or tubular branching mass
  - Hyperinflated distal lung + ↓ vascularity
    - Expiratory images confirm air-trapping

MR Findings

- Fetal MR
  - Discrete & uniformly T2-hyperintense "solid" lung mass with varying degrees of mass effect
    - No visible cysts
  - Dilated, fluid-filled bronchus in medial/central aspect of lesion helps differentiate from other lesions

Ultrasonographic Findings

- Obstetric ultrasound
  - Homogeneously hyperechoic segment or lobe
  - May see dilated, fluid-filled bronchi

Imaging Recommendations

- Best imaging tool
  - CTA confirms that tubular opacity represents impacted atretic bronchus & not vessel
    - Expiratory images can confirm air-trapping

DIFFERENTIAL DIAGNOSIS

Congenital Lobar Overinflation

- Overlapping appearance; no mass/bronchocele
- Usually involves entire lobe with progressive hyperinflation

Congenital Pulmonary Airway Malformation

- Often heterogeneous due to macroscopic cysts with distortion/splaying of residual lung
- No associated bronchial dilation/impaction

Bronchogenic Cyst

- Discrete, round (nonbranching), fluid-filled cyst in central lung or mediastinum

Bronchopulmonary Sequestration

- Systemic arterial supply, usually from aorta
- Usually in left lower lobe
- May present beyond infancy with recurrent infections

Allergic Bronchopulmonary Aspergillosis

- FInger-in-glove sign is often present
- Frequently bilateral with widespread bronchiectasis

Scimitar Syndrome (Hypogenetic Lung Syndrome)

- Hypoplastic lung with partial anomalous pulmonary venous drainage
  - Typically right lower lobe with curvilinear opacity (vein) directed toward medial right hemidiaphragm

Slow-Growing Endobronchial Tumor

- Mass is usually smaller than mucoid impaction
- Distal lung is usually atelectatic, not hyperinflated

PATHOLOGY

General Features

- Etiology
  - Occurs between 5th-15th weeks of gestation, though exact mechanism unclear
    - Intrauterine interruption of arterial supply to bronchus → scarring of primitive bronchus
    - Disconnection of primitive bronchial cells at tip of bronchial bud with continued normal growth distally
  - Aeration of distal lung through collateral air drift
- Associated abnormalities
  - Components of atretic bronchi are frequently found pathologically in other congenital lung lesions

CLINICAL ISSUES

Presentation

- Congenital lesion but may be diagnosed at any age
  - Older children/adults (majority of diagnoses): Often asymptomatic
  - Infancy, early childhood (< 3 years): Recurrent respiratory tract infections, chronic cough, dyspnea, wheezing
  - Uncommon main bronchus atresia can be lethal in utero

Treatment

- Surgical resection is typically reserved for patients with repeated infections

Esophageal Atresia and Tracheoesophageal Fistula

KEY FACTS

TERMINOLOGY

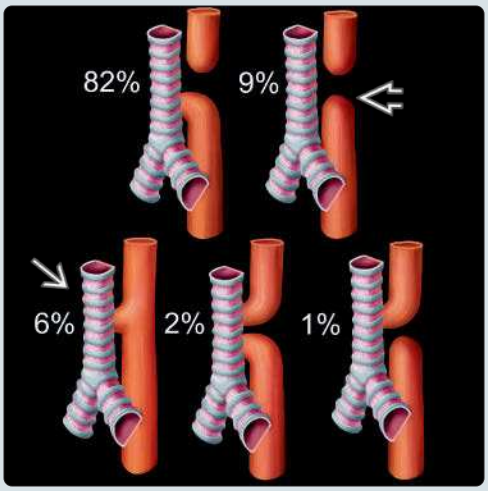
- Atresia: Congenital occlusion of upper esophagus
- Fistula: Anomalous congenital connection(s) from esophagus to trachea

IMAGING

- 5 major anatomic variations of esophageal atresia (EA)-tracheoesophageal fistula (EA-TEF)
- Fistula level is variable depending on type of EA-TEF
  - Most commonly above/near carina
- Atretic segments are variable in length
  - Gap is often long in EA without TEF
- Radiographs
  - Air-distended upper esophageal pouch
  - Enteric tube tip near thoracic inlet in pouch, often coiled
  - EA with TEF: Gas in stomach & bowel
  - EA without TEF: Gasless stomach & bowel
- Limited indications for preoperative esophagram (except isolated TEF)
- Postoperative esophagram
  - Esophageal anastomotic leak, anastomotic stricture, recurrent/additional TEF, esophageal dysmotility, gastroesophageal reflux

TOP DIFFERENTIAL DIAGNOSES

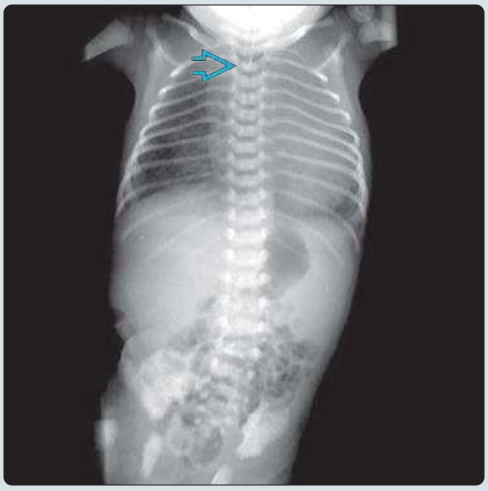
- Tube malposition
- Laryngotracheal cleft
- Chronic respiratory issues (mimicking H-type TEF)
- Esophageal strictures of various etiologies
- Extrinsic esophageal compression



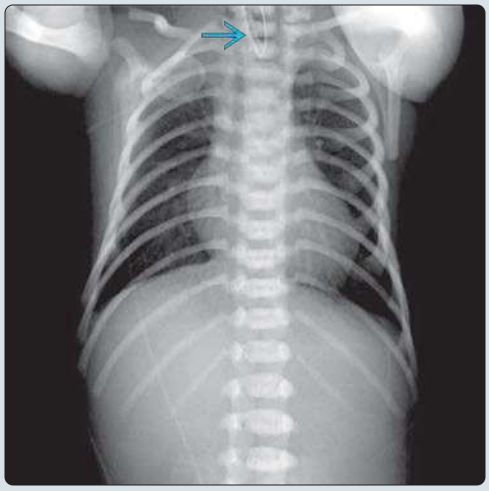
PATHOLOGY

- 47-75% have associated anomalies

CLINICAL ISSUES



- Presentation: Excessive oral secretions, cyanosis, choking, coughing during feeding
- Postsurgical survival: 75-95% (depends on associated cardiac anomalies, birth weight)



(Left) *Graphic shows the 5 main types of esophageal atresia with tracheoesophageal fistula (EA-TEF), including the isolated TEF without EA (H-type fistula) ⇨ & the isolated EA without TEF ⇨.* **(Right)** *Sagittal T2 SSFSE MR of a 26-weeks-gestation fetus imaged for polyhydramnios shows a collection of fluid in the region of the upper esophagus ⇨ that is suggestive of an atretic esophageal pouch, which was confirmed during surgery in the newborn period.*

(Left) *AP radiograph of a premature newborn boy with a history of not handling secretions shows a nasogastric tube (NGT) tip ⇨ overlying the thoracic inlet due to EA. The bowel gas confirms the presence of a distal TEF. Cardiomegaly suggests congenital heart disease.* **(Right)** *AP chest radiograph in a newborn shows an NGT coiled at the thoracic inlet ⇨, suggesting EA. Note the lack of gas in the upper abdomen, which is typical of EA without a distal TEF.*

TERMINOLOGY

Definitions

- Esophageal atresia (EA): Congenital occlusion of upper esophagus
- Tracheoesophageal fistula (TEF): Single (less commonly multiple), anomalous, congenital connection(s) from esophagus to trachea

IMAGING

General Features

- Best diagnostic clue
  - Enteric tube tip in gas-distended proximal esophageal pouch on newborn chest radiograph
- Location
  - Fistula level is variable depending on type of EA-TEF
    - Most commonly above/near carina
    - Higher levels with multiple fistulas
    - Rarely esophagobronchial fistula
  - Atresia is usually above junction of superior & middle 1/3 of esophagus
- Size
  - TEF is usually small
  - Atretic segments of esophagus are variable in length
    - Gap is often long in EA without TEF
- Morphology
  - 5 major anatomic variations of EA-TEF

Radiographic Findings

- Radiography
  - Intermittently air-distended, dilated upper esophageal pouch
  - Enteric tube tip near thoracic inlet in pouch
  - Gas in stomach & bowel: EA with TEF
  - Gasless stomach & bowel: EA without TEF
  - Displaced, bowed, narrowed trachea due to dilated esophageal pouch & associated tracheomalacia
  - Signs of other congenital anomalies
    - Cardiomegaly, abnormal pulmonary vascularity, vertebral anomalies, dilated bowel
  - Side of aortic arch is important for surgical repair (thoracotomy performed opposite side of arch)

Fluoroscopic Findings

- Rarely needed for diagnosis of EA (clinical + radiographic diagnosis)
  - Confirm blind-ending pouch: Inject air into nasogastric tube (NGT)
- Contrast esophagram is useful preoperatively for
  - H-type TEF without EA (clinical; radiographic diagnosis is less clear in this type)
    - Oblique fistula from esophagus craniad to trachea (looks like "N")
  - EA without TEF (often long gap)
    - Often 2-stage repair if long gap
    - Preoperative measurement of gap
      - Surgical bougie into upper pouch ± contrast
      - Surgical bougie into lower pouch ± contrast via gastrostomy
      - Measure gap prior to 2nd surgery
- Esophagram/upper GI after EA-TEF repair (using iso-osmolar water-soluble contrast)
  - Esophageal anastomotic leak (early)
  - Recurrent or additional TEF
  - Esophageal dysmotility in nearly 100%
  - Gastroesophageal reflux (GER)
  - Malrotation
  - Esophageal anastomotic stricture (early or delayed)

MR Findings

- Fetal: Fluid signal in intermittently distended esophageal pouch ± decompressed stomach, associated anomalies, polyhydramnios
- Neonatal: Ultrashort echo time (UTE) sequence may allow visualization of fistula & esophageal gap length

CT Findings

- Improves surgical planning in up to 40%
  - Visualization of fistula & esophageal gap length

Imaging Recommendations

- Best imaging tool
  - Radiographs ± air injection of NGT for EA
  - Esophagram for suspected isolated TEF or postoperative complication
- Protocol advice
  - Esophagram/upper GI for isolated (H-type) TEF
    - Lateral position for H type
    - Barium by mouth in most cases (tube rarely needed)
    - If contrast injected, 5- or 8-French feeding tube sideports at mid- to distal trachea
    - Pulsed fluoroscopy in lateral position coned from pharynx to below carina
    - No exposures until convinced: Normal vs. fistula
      - ± exposures in multiple positions
    - Do not mistake aspiration for missed fistula
    - Image stomach to duodenojejunal junction to exclude malrotation, if patient stable
  - Postoperative esophagram: Evaluate for leak or other complication
    - At least 1 scout image (± other positioning)
    - By mouth vs. tube injection of iso-osmolar, nonionic, water-soluble contrast in orthogonal views
      - If by tube, position new tube just above anastomosis or retract NGT to anastomosis
      - Careful distention of esophagus to detect leak
    - If no leak with water-soluble contrast, consider using barium to ↑ detection of subtle leaks
    - Re-review images at workstation after study
      - May miss subtle leak on real-time imaging

DIFFERENTIAL DIAGNOSIS

Tube Malposition

- Traumatic pharyngeal perforation with NGT into mediastinum
  - Inject air or iso-osmolar, water-soluble contrast via NGT to differentiate air-filled pharyngeal pouch vs. pneumomediastinum

Laryngotracheal Cleft

- High fistulous connection, variable length

Chronic Respiratory Issue

- GER with aspiration
- Bronchial foreign body
- Cystic fibrosis
- Infected congenital lung lesion

Esophageal Strictures

- Caustic injury, eosinophilic esophagitis, prior foreign body, epidermolysis bullosa, mediastinal radiation

Extrinsic Esophageal Compression

- Vascular rings
- Mediastinal masses

PATHOLOGY

General Features

- Etiology
  - Likely faulty division of foregut into trachea & esophagus in 1st month of gestation
- Genetics
  - Chromosomal anomalies in 2-10%
    - Trisomy 18 & trisomy 21 are most common
- Associated abnormalities
  - 47-75% have associated anomalies
    - Musculoskeletal: 14-24%
    - Cardiovascular: 11-55%
    - GI: 8-27%
    - Genitourinary: 8-21%
    - Craniofacial: 10%
    - Neurologic: 3-15%
    - Pulmonary: 2-6%
    - VACTERL (vertebral, anal, cardiac, tracheoesophageal, renal, limb anomalies): 10-20%

Staging, Grading, & Classification

- Most widely cited surgical classification (Gross)
  - Type A: EA with no TEF (7-9%)
  - Type B: EA with proximal TEF (1%)
  - Type C: EA with distal TEF (82-86%)
  - Type D: EA with proximal & distal TEF (2%)
  - Type E: Isolated (H-type) TEF (no EA) (4-6%)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Excessive oral secretions, cyanosis, choking, coughing during 1st attempts at feeding
- Other signs/symptoms
  - Enteric tube fails to reach stomach
  - Recurrent pneumonia, dysphagia (H-type TEF)

Demographics

- Age
  - Newborn or early child (isolated H type)
  - 20-35% are premature
- Epidemiology
  - 1:3,000 live births

Natural History & Prognosis

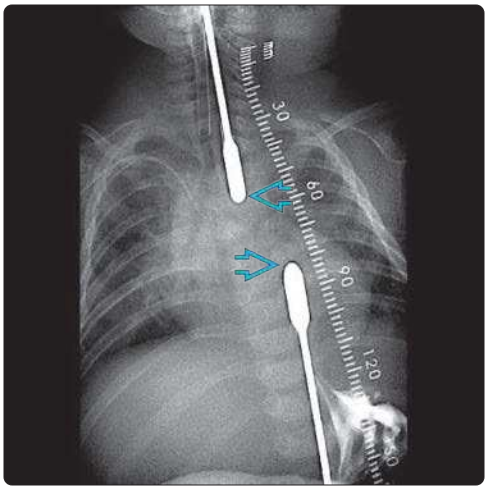
- Postoperative survival: 75-95% (depends on associated cardiac anomalies, birth weight)

Treatment

- Surgical
  - Bronchoscopy, esophagoscopy to visualize fistula(s) + extrapleural ligation of fistula + anastomosis of esophageal segments
  - If EA without TEF, proximal & distal esophagus are often widely spaced
    - 1st surgery: Place gastrostomy tube
    - 2nd surgery months later: Connect lengthened esophageal ends
    - Ultralong gap requires conduit
      - Colonic interposition vs. gastric pull-up/tube
    - Foker procedure: Actively stretches esophagus over time → primary anastomosis
    - Magnetic compression for strictures or primary repair
- Early postsurgical complications
  - Anastomotic leak (up to 15%; most small leaks resolve spontaneously)
  - Additional TEF not seen initially
- Longer term postsurgical issues
  - Anastomotic stricture (18-50%)
    - ↑ with ↑ EA gap length, anastomotic tension, GER
    - Treated with repeated balloon or bougie dilations
  - Recurrent TEF (up to 10% of cases)
  - Esophageal dysmotility (nearly 100%)
  - GER; esophagitis (51%), Barrett esophagus (6%)
    - Surgical treatment (Nissen) if medical therapy fails
  - Respiratory infections
  - Tracheomalacia (10-20%)

DIAGNOSTIC CHECKLIST

Consider



- Is there distal bowel gas?
- Are there associated anomalies?

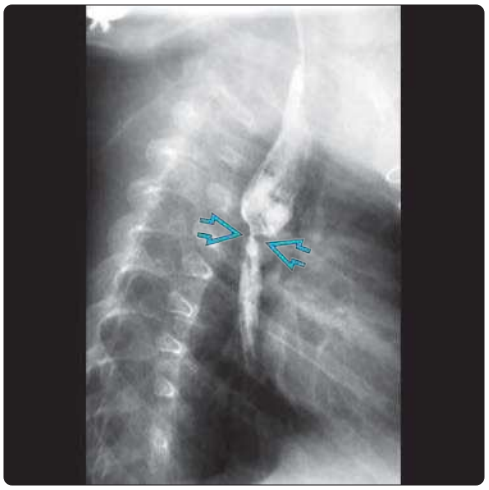


Image Interpretation Pearls

- Always rereview postoperative fluoroscopic studies at workstation for subtle leak or fistula not seen in real time

(Left) *Esophagram in an EA patient without TEF shows a long gap atresia, as measured by placing surgical bougies orally (into the upper pouch) & through the gastrostomy (into the distal atretic segment). A Foker procedure was then performed over several weeks to stretch the esophagus.* **(Right)** *Lateral esophagram in the same patient (who underwent a primary anastomosis of the esophagus in the interval) shows an anastomotic narrowing after repair. No contrast leak was seen.*

(Left) *Frontal esophagram with balloon dilation was performed on the same patient to relieve the anastomotic stricture.* **(Right)** *Lateral esophagram performed in a neonate status post EA-TEF repair shows prompt flow through the anastomosis without a leak. There is tracheomalacia in the vicinity of the atresia, a common finding in patients with EA. Note that the study was performed via an additional 5 French feeding tube above the anastomosis (instead of retracting the NGT to near the surgical site).*

(Left) *Postoperative frontal esophagram in a neonate status post EA-TEF repair shows an extrapleural leak from a small tract next to the anastomosis. The upper esophageal dilation is likely related to residual in utero dilation rather than a postoperative obstruction.* **(Right)** *Lateral postoperative esophagram in a neonate after EA-TEF repair shows no leak; however, an additional, unsuspected proximal TEF was detected ~ 10 mm above the anastomotic site (the rare Gross type D, occurring in only 2% of all EA).*

Congenital Diaphragmatic Hernia

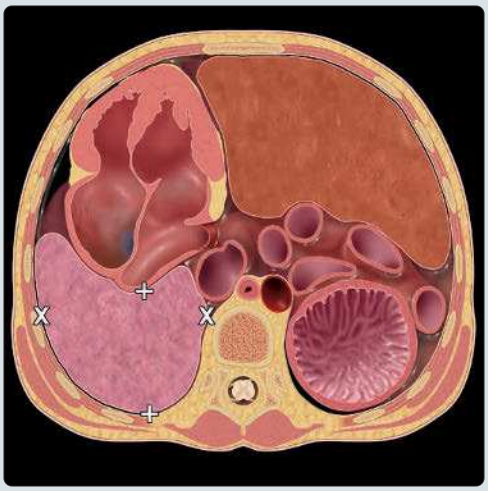
KEY FACTS

TERMINOLOGY

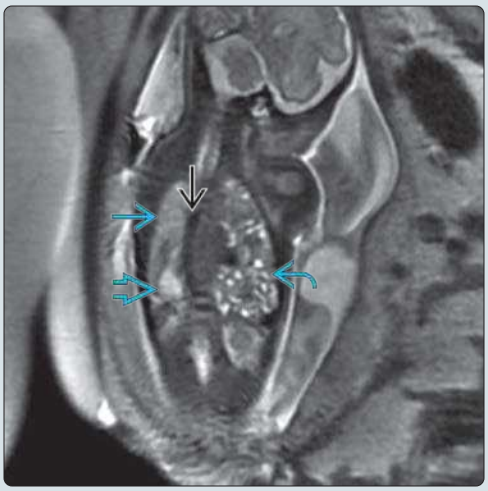
- Herniation (intrapleural in 80%, mediastinal in 20%) of abdominal contents into chest via congenital defect in diaphragm, most commonly posterior (Bochdalek type of intrapleural hernia)

IMAGING

- Best clue: Bubbly, round, or tubular, relatively uniform, air-filled lucencies in chest displacing mediastinum
- Intrathoracic herniated contents may include stomach, small & large bowel, liver, gallbladder, spleen
  - Results in paucity of bowel gas in abdomen
- Support devices are distorted in specific ways
  - Nasogastric tube due to stomach herniation
  - Umbilical venous catheter due to liver herniation
- Location of congenital diaphragmatic hernia (CDH)
  - Intrapleural: Left 85%, right 13%, bilateral 2%
  - Mediastinal: Anterior or posterior



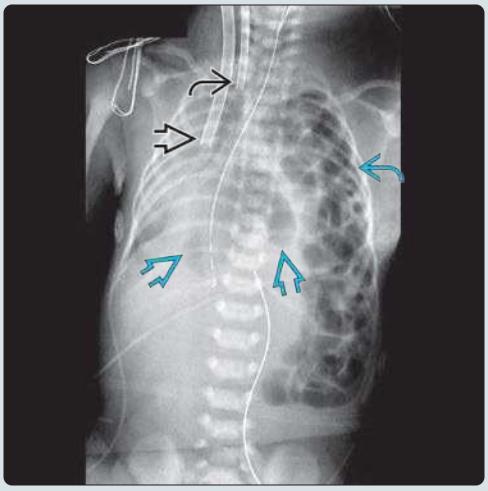
TOP DIFFERENTIAL DIAGNOSES



- Congenital pulmonary airway malformation
- Diaphragmatic eventration
- Congenital lobar overinflation
- Bronchopulmonary sequestration

CLINICAL ISSUES

- Most are detected prenatally; respiratory distress at birth occurs in majority; delayed presentation is uncommon
- Immediate initiation of supportive postnatal care until patient can tolerate surgical repair (primary vs. patch)
- Prognosis is most related to severity of pulmonary hypoplasia, pulmonary arterial hypertension, congenital heart disease, & other anomalies
  - Various fetal ultrasound & MR parameters are used to guide prognosis & postnatal management
- Survival ↑ if diagnosis is known prenatally & patient delivers at high-volume center
- ↑ awareness of long-term morbidity in survivors



(Left) *Axial graphic shows a large left congenital diaphragmatic hernia (CDH) with portions of the liver, bowel, & stomach residing in the left hemithorax. The right lung is denoted by calipers as being measured for the prenatal LHR value that predicts lung hypoplasia.* **(Right)** *Coronal SSFSE T2 MR of a 32-weeks-gestation fetus shows herniated bowel loops filling the left hemithorax. The hypoplastic right lung overlies the aorta & herniated stomach, which are shifted into the right hemithorax.*

(Left) *Sagittal T1 MR in the same fetus shows a herniated left hepatic lobe separated from the remaining intraabdominal right hepatic lobe by residual anterior diaphragm. Note the herniated stomach & meconium-containing bowel.* **(Right)** *AP radiograph in the same patient after delivery shows gas-distended bowel filling the left hemithorax. The herniated stomach has an organoaxial rotation & overlies the herniated left hepatic lobe. Note the arterial & venous ECMO cannulae.*

TERMINOLOGY

Definitions

- Congenital diaphragmatic hernia (CDH): Herniation of abdominal contents into chest via developmental defect in diaphragm
  - Intrapleural hernia (80%): Worse prognosis
    - Bochdalek (posterolateral) is most common subtype
  - Mediastinal hernia (20%)
    - Anteriorly involves central tendon of diaphragm
      - Morgagni hernia: Smaller paramedian subtype
    - Posteriorly may involve hiatus of esophagus or IVC

IMAGING

General Features

- Best diagnostic clue
  - Bubbly, round, & tubular lucencies in neonatal hemithorax with contralateral mediastinal shift
- Location
  - Left 85%, right 13%, bilateral 2%
- Size
  - Degrees of diaphragmatic deficiency & herniated contents are variable
    - May contain stomach, small & large bowel, liver, gallbladder, spleen

Radiographic Findings

- Depend on hernia contents & presence vs. absence of air in herniated bowel
  - Uniform soft tissue density of herniated solid organs
  - Herniated bowel may appear solid prior to progression of swallowed air
    - Upon air entering bowel, loops appear relatively uniform in size with round & tubular morphologies
      - Degree of gaseous distention changes day to day
    - Herniated, gas-filled stomach is larger than bowel & often abnormally rotated
- Mediastinal shift away from hernia
- Low lung volumes from hypoplasia
  - Ipsilateral lung is more severe than contralateral
- Abnormal positions of support devices
  - Esophageal portion of nasogastric tube (NGT): Contralateral shift & convexity
    - NGT often descends into upper abdomen then back into left hemithorax ("reverse J")
    - NGT tip may lodge at gastroesophageal junction
  - Umbilical venous catheter (UVC) is shifted toward side of hernia (if "liver up"); may not advance to right atrium
    - If UVC extends to right atrium, catheter is typically convex toward hernia
- ↓ intraabdominal bowel gas
- Postoperative appearance
  - Resolution of herniated contents
  - Pleural fluid in 28% (typically chylothorax), eventually resolves
  - Ex vacuo negative-pressure pneumothorax: Hypoplastic lung does not fill space initially
  - Gradual expansion & growth of hypoplastic lungs
  - Repaired hemidiaphragm is often angular or laterally sloped

Ultrasonographic Findings

- Prenatal ultrasound
  - Absent crescentic hypoechoic hemidiaphragm
  - Mixed echogenicity mass in lower hemithorax with mediastinal shift into contralateral hemithorax
    - Bowel & liver are difficult to differentiate from lung lesion: Look for displacement of gallbladder & hepatic vessels
    - Herniated fluid-filled stomach helps confirm CDH
  - Lung:head ratio (LHR): Critical prognostic parameter in left CDH
    - Predictor of pulmonary hypoplasia based on residual, contralateral lung
    - LHR = Area of right lung at level of heart 4-chamber view is divided by head circumference
      - LHR < 1: Poor prognosis
- Postnatal ultrasound
  - Visualization of diaphragmatic defect size may aid in surgical planning

MR Findings

- Fetal MR
  - T2 SSFSE
    - Serpentine, fluid-filled structures (small bowel loops) fill most of hemithorax
    - Stomach is usually herniated with abnormal rotation
    - Partial herniation of low signal intensity colon
    - ± herniation of low signal intensity liver, spleen
    - Contralateral mediastinal shift
    - ↓ total, observed/expected, & predicted lung volumes
      - Lungs of lower signal intensity than normal
      - Residual ipsilateral lung is much smaller than contralateral & typically displaced superomedially
    - Sac-type hernia has better prognosis
      - Cap of lung is evenly distributed over hernia apex
    - Paucity of normal bowel in abdomen
  - T1 GRE
    - Helps localize intermediate signal intensity liver & high signal intensity meconium of small & large bowel against low signal intensity lungs
- Postnatal MR
  - Vascular density ipsilateral to CDH as assessed by time-of-flight imaging correlates with pulmonary hypertension (HTN) markers
  - Accelerated growth of hypoplastic ipsilateral lung parenchyma after repair

CT Findings

- CECT
  - Not typically used for diagnosis of CDH; may be obtained if other cystic chest mass is suspected
  - Follow-up lung CT in survivors shows variable degrees of abnormalities: Low-attenuation foci, subpleural opacities, & atelectasis
    - Severity correlates with respiratory & feeding issues

DIFFERENTIAL DIAGNOSIS

Congenital Pulmonary Airway Malformation

- Macrocystic type appears as multicystic, air-containing mass
  - Cysts are typically not uniform in size

- After gas replaces fluid in cysts (in 1st few days after birth), congenital pulmonary airway malformation (CPAM) appearance is typically static
  - CPAM is more likely to have air-fluid levels than CDH
- Support device positions are less altered by CPAM vs. CDH

Diaphragmatic Eventration

- Focal muscle aplasia of diaphragm without free protrusion of bowel into thorax
  - Abdominal contents are contained by sac of peritoneum, diaphragm tendon, & parietal pleura

Congenital Lobar Overinflation

- Progressive overdistention of single lobe
- Rarely involves lower lobes

Bronchopulmonary Sequestration

- Solid mass near diaphragm with systemic arterial supply

PATHOLOGY

General Features

- Etiology
  - Normal diaphragm development (4th-12th weeks of gestation)
    - Lateral pleuroperitoneal folds fuse with septum transversum
    - Migrating myogenic precursors reach primitive diaphragm & proliferate
    - Error in any portion of process may lead to CDH
  - Underlying cause of defective development is unknown in ~ 70-80%
    - Various chromosomal anomalies (2-35%)
      - Trisomy 18 is most common (2-5%); Down syndrome (trisomy 21) is most likely to have Morgagni type
    - Known specific genetic mutations (< 10%)
- Associated abnormalities
  - Isolated in ~ 50%
  - Cardiac malformations in 20-40%
  - Variety of other systemic anomalies described

CLINICAL ISSUES

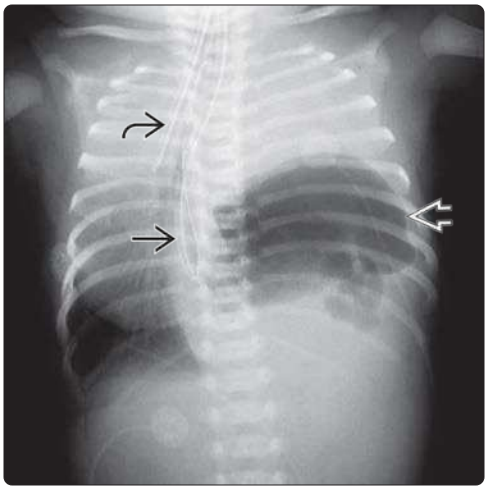
Presentation

- Most common signs/symptoms
  - Diagnosis is known prenatally in 60-80%
  - Respiratory distress at birth
- Other signs/symptoms
  - Presence of intrathoracic bowel sounds
  - Absence of ipsilateral breath sounds
  - Scaphoid abdomen
  - < 3% present after 30 days (100% survival)
    - Gastrointestinal symptoms are more likely

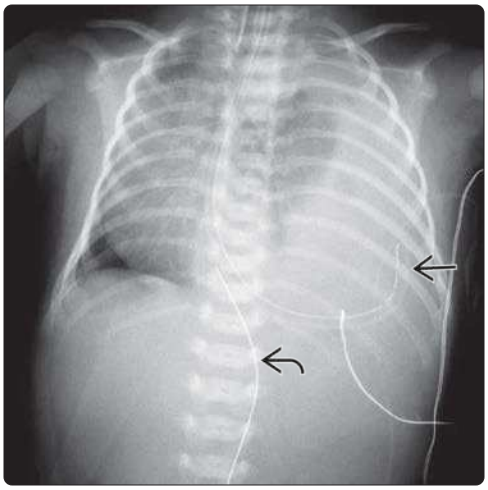
Demographics

- Epidemiology
  - 1 in 2,000-4,000 live births

Natural History & Prognosis



- Prognosis is related to severity of pulmonary hypoplasia, pulmonary HTN, & other anomalies (especially heart disease)
  - Most common fetal calculations used for prognosis
    - Lung volumes: Total, observed/expected, & percent predicted by MR; LHR by ultrasound
    - Volume of thorax occupied by herniated liver by MR
  - Utility of these measurements are established for left CDH; do not clearly correlate for right CDH
- Mortality rates are variable: 10-68%
  - ↑ survival reported at single high-volume centers
  - Worse with specific syndromes, cardiac anomalies, esophageal atresia, bilateral hernias, large defects/hemidiaphragm agenesis, extracorporeal membrane oxygenation (ECMO) requirement, higher pulmonary support requirement at 30 days of life
- Long-term morbidity: Impaired lung function + recurrent respiratory infections, neurocognitive & language delays, gastroesophageal reflux disease, gastroparesis, failure to thrive, chest wall deformities, scoliosis



Treatment

- Varying degrees of supportive care are required until definitive surgery can be tolerated
  - Ventilation/oxygenation
    - Immediate intubation with gentle ventilation
    - ± ECMO
  - Pulmonary HTN: Inhaled nitric oxide or IV sildenafil
- Surgery: Primary closure of small defects vs. patch repair for larger; timing is debated
  - Complications include chylothorax, abdominal compartment syndrome, recurrent hernia; malrotation of midgut is expected but does not carry typical risk of volvulus
- Fetal tracheal occlusion (FETO) therapy: Temporary balloon occlusion of trachea in utero (to stimulate lung growth)
  - Beneficial in left CDH with severe pulmonary hypoplasia, not moderate

(Left) *AP radiograph shows a newborn with a left CDH. The nasogastric tube (NGT) ⇨ is coiled in the distal esophagus. The heart & endotracheal tube ⇨ are shifted to the right. The stomach ⇨ lies in the left lower chest.* **(Right)** *Subsequent AP radiograph of the same patient shows the NGT tip ⇨ decompressing the herniated stomach in the left lower chest. An umbilical venous catheter (UVC) shows convexity toward the left ⇨ due to partial liver herniation. Decompressed bowel also fills the left chest.*

(Left) *AP radiograph shows herniated bowel ⇨ filling the right hemithorax. The heart & support devices are shifted to the left. The UVC ⇨ is malpositioned in the herniated right hepatic lobe.* **(Right)** *Coronal SSFSE T2 MR in a 29-weeks-gestation fetus shows bilateral diaphragmatic hernias with liver filling the right hemithorax ⇨ & stomach/bowel filling the left hemithorax ⇨. There is polyhydramnios + an incompletely visualized horseshoe kidney ⇨ in this fetus with Cornelia de Lange syndrome.*

(Left) *AP radiograph in a patient after repair of a left-sided CDH shows a large ex vacuo left pneumothorax. The heart, peripherally inserted central catheter (PICC), & NGT are still shifted to the right. However, a chest tube is not required as this is a postsurgical, negative-pressure pneumothorax.* **(Right)** *AP radiograph of the same patient 8 months later shows resolution of the pneumothorax & mediastinal shift. The hypoplastic left lung is now mildly hyperexpanded & hyperlucent.*

Surfactant Deficiency Disease

KEY FACTS

TERMINOLOGY

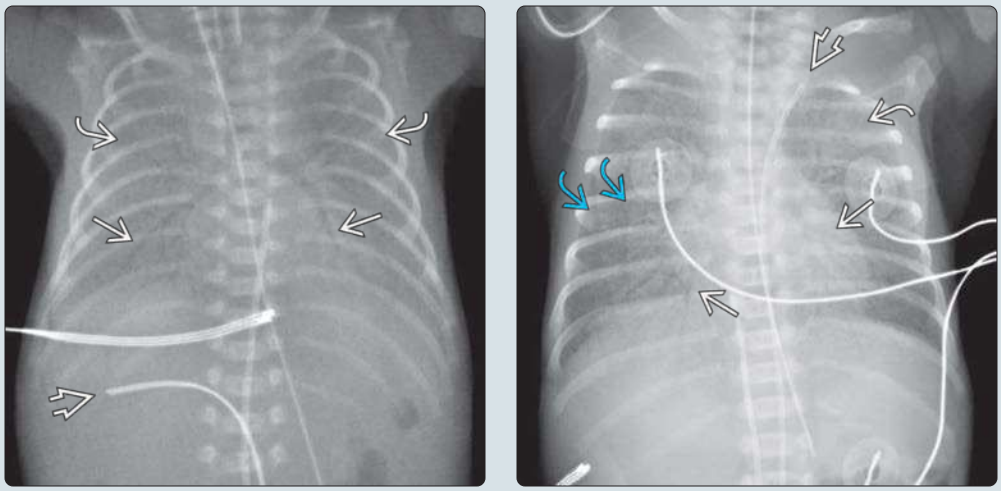
- Surfactant deficiency disease (SDD) is favored term
- Common lung disease occurring in premature infants due to lack of surfactant
- Microatelectasis & abnormal pulmonary compliance are hallmarks of disease

IMAGING

- Premature infants < 32-weeks gestation are at risk
- Initial findings are low lung volumes & diffuse hazy/granular opacities
- High incidence of patent ductus arteriosus, which causes pulmonary edema ("whiteout" of lungs with cardiomegaly)
- Bronchopulmonary dysplasia eventually occurs in 17-55% of premature infants
- Lung ultrasound is increasingly used for diagnosis
  - Normal ultrasound findings include A & Z lines
  - SDD causes B lines (vertical lines extending from pleura); scattered in mild SDD, more confluent in severe disease

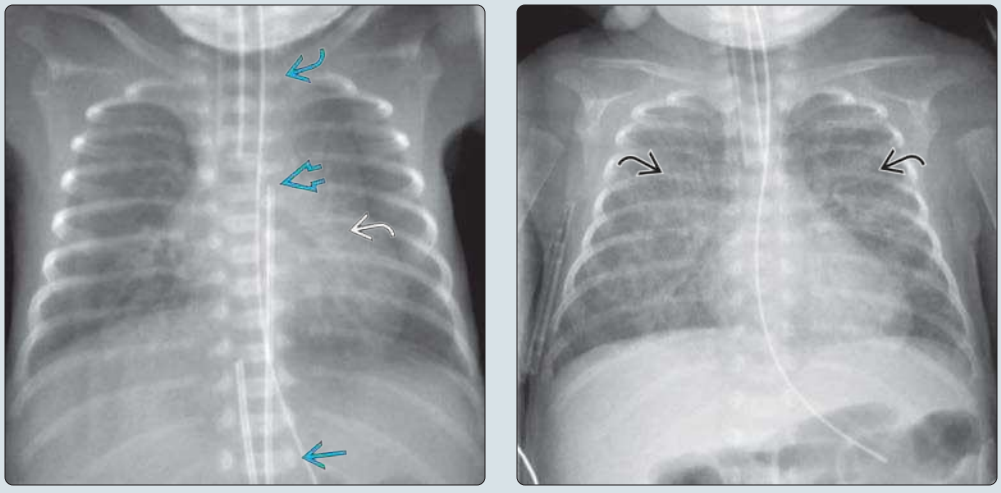
TOP DIFFERENTIAL DIAGNOSES

- Congenital heart disease: Echocardiography is gold standard for diagnosis
- Group B streptococcal pneumonia: Similar low long volumes; more common to have pleural effusions (67%)
- Meconium aspiration syndrome: Term infants with rope-like densities radiating from hila & high lung volumes
- Transient tachypnea of newborn: Findings similar to pulmonary edema but resolve by 24-48 hours of life



PATHOLOGY

- Surfactant normally coats alveoli & ↓ surface tension, allowing alveoli to stay open
- In prematurity, immature type II pneumocytes cannot produce sufficient surfactant



CLINICAL ISSUES

- Most common cause of death in live newborn infants

(Left) *Frontal radiograph in a 23-weeks-gestation triplet shows low lung volumes with severe, diffuse granular opacities of both lungs & central air-bronchograms. Note the malpositioned UVC in the right portal vein.* **(Right)** *Frontal radiograph in a premature newborn shows less severe granular opacities with central air-bronchograms. Skin folds mimic a right pneumothorax. Note the malpositioned UAC, terminating in the left subclavian artery.*

(Left) *Frontal radiograph in a premature newborn shows a more hazy pattern of SDD with patchy opacities in the central lungs. The UAC is too high, at T4. As the 1st ribs in newborns commonly align with C7, malpositioned lines can be better recognized by counting from the lowest thoracic level (T12).* **(Right)** *Frontal radiograph in the same infant 4 weeks later shows evolving findings of chronic premature lung disease with diffuse, bilateral, heterogeneous, granular opacities & architectural distortion.*

TERMINOLOGY

Abbreviations

- Surfactant deficiency disease (SDD)

Synonyms

- Lung disease of prematurity
- Respiratory distress syndrome
- Hyaline membrane disease (archaic)

Definitions

- Prematurity-related SDD (most common usage)
  - Surfactant deficiency in premature newborns
  - Lungs begin producing surfactant at ~ 24-weeks gestational age (GA); adequate amounts are usually present by 36-weeks GA
  - Lack of sufficient surfactant causes diffuse microatelectasis & abnormal pulmonary compliance
- Secondary SDD (less common usage)
  - Meconium aspiration or pneumonia can cause surfactant deactivation
  - Results are similar to those seen in prematurity, but usually heterogeneous & superimposed on other findings
- Primary SDD (least common usage)
  - Abnormal gene products adversely affect composition &/or function of surfactant
  - Often termed surfactant dysfunction disorders
  - Most well-known causes: Surfactant protein-B, surfactant protein-C, ABCA3, & TTF-1 deficiencies
  - Synergistically ↓ outcome with prematurity & 1° SDD

IMAGING

General Features

- Best diagnostic clue
  - Initial findings are low lung volumes & diffuse granular opacities
    - Air bronchograms & poor lung expansion
    - Cardiac size is normal
  - Subsequent imaging shows significant bilateral lung disease
    - Localized areas of atelectasis
    - Barotrauma leads to pneumothorax, pneumomediastinum, pulmonary interstitial emphysema (PIE)
    - Complications of patent ductus arteriosus (PDA)
    - Bronchopulmonary dysplasia (BPD) or chronic lung disease of premature infant
- Age
  - Premature infants < 32-weeks GA (or sometimes in term infants)

Radiographic Findings

- Radiography
  - Initial features
    - Low lung volumes secondary to microcollapse of innumerable alveoli
    - Diffuse granular opacities represent collapsed alveoli interspersed with open alveoli (microatelectasis)
    - Air bronchograms demonstrate patent bronchi in abnormal lung
    - Pleural effusions are very uncommon
    - Potential acute complications include PIE, pneumomediastinum, pneumothorax, superimposed pneumonia, pulmonary hemorrhage
  - Features after surfactant administration
    - Clearing of granular opacities + ↑ lung volumes
    - May have asymmetric or partial response
  - Findings after several days
    - Intubation & ventilatory support change imaging appearance
    - High incidence of PDA, which may cause pulmonary edema ("whiteout" of lungs with cardiomegaly)
  - BPD develops in 17-55% of premature infants
    - Chronic lung disease characterized by coarse interstitial opacities with focal areas of atelectasis & hyperinflation vs. diffuse hyperinflation

Ultrasonographic Findings

- Grayscale ultrasound
  - Range from scattered to completely confluent B lines
  - Severe SDD results in diffusely hyperechoic lung due to confluent B lines, a.k.a. "white lung"
  - Less severe findings include: (1) Predominance of nonconfluent B lines, or (2) mostly A lines & Z lines with scattered B lines
    - A lines: Series of horizontal lines caused by pleural reverb artifact in normally aerated lung
    - B lines: Comet-tail artifact extending from points on pleural surface into deep field, which is sign of subpleural interstitial edema &/or microatelectasis
    - Z lines: Broad-based, ill-defined, short vertical lines that do not erase A lines
  - Ultrasound is prone to missing pneumothorax, pneumomediastinum, interstitial emphysema

CT Findings

- HRCT
  - Not typically used to make diagnosis of SDD
  - Used to follow chronic lung disease

Other Modality Findings

- Premature infants have many associated diseases
  - Ultrasound: Used to detect intracranial hemorrhage
  - Abdominal radiographs/ultrasound: Used to detect necrotizing enterocolitis

DIFFERENTIAL DIAGNOSIS

Congenital Heart Disease

- Echocardiography is gold standard for diagnosis
- PDA is common in infants > 1,000 g
  - Usually closed with prostaglandin inhibitor
  - Transcatheter occlusion vs. surgery if contraindication is present

Group B Streptococcal Pneumonia

- Very common in neonates, especially premature infants
- Acquired during birth (25% of women are colonized)
- Bilateral granular opacities & low lung volumes
- Pleural effusion is common (67%): Only imaging finding that helps differentiate from SDD

Meconium Aspiration Syndrome

- Term infants
- Rope-like densities radiating from hila
- Usually have high lung volumes
- High incidence of barotrauma

Transient Tachypnea of Newborn

- Findings are similar to pulmonary edema but resolve by 24-48 hours
- Prominent interstitial markings with normal heart size
- Pleural effusions may be present

PATHOLOGY

General Features

- Etiology
  - Immature type II pneumocytes cannot produce surfactant
  - Surfactant normally coats alveoli & ↓ surface tension, allowing alveoli to stay open & improving lung compliance
  - Deficiency of surfactant results in alveolar atelectasis
  - ↓ lung compliance is associated with interstitial edema
  - Secondary surfactant insufficiency occurs due to
    - Meconium aspiration pneumonia
    - Pulmonary infections
    - Intrapartum asphyxia
- Genetics
  - Prematurity-related SDD
    - Mothers who deliver premature infants are more likely to have subsequent premature infants
    - Premature infants have many associated abnormalities
  - Uncommon primary (genetic) SDD
    - Several genetic mutations are associated with dysfunction of key surfactant components/regulators
      - Surfactant protein-B, surfactant protein-C, ABCA3, & TTF-1 deficiencies

CLINICAL ISSUES

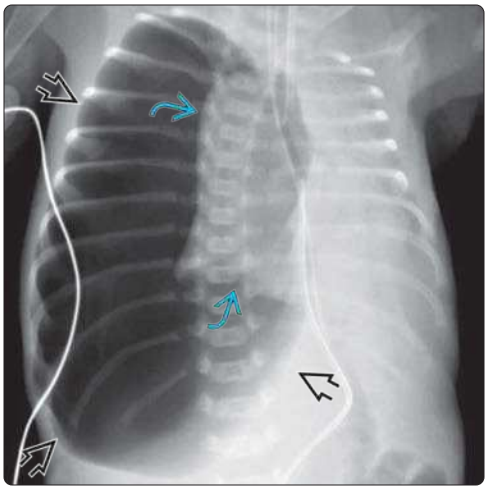
Presentation

- Most common signs/symptoms
  - History of prematurity
  - Respiratory distress

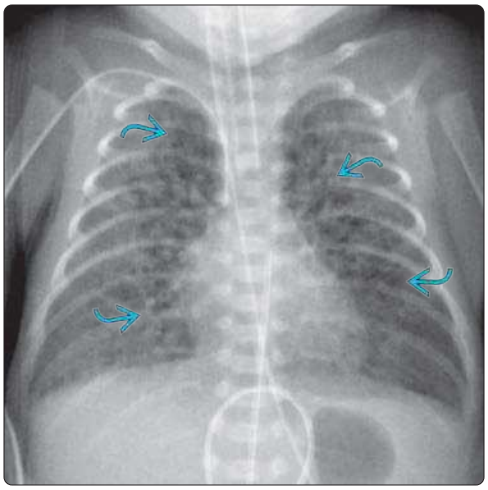
Demographics

- Age
  - Disease of premature infants (< 36-weeks GA, < 2.5 kg)
    - 50% of premature infants will have SDD
  - Infants < 27-weeks GA have higher incidence of sequelae
- Ethnicity
  - All races are affected worldwide
- Epidemiology
  - Sex: M > F
  - Most common cause of death in live newborn infants
  - Occurs in 40,000 infants each year in USA
  - Common in all causes of premature labor & delivery
  - More common in infants of diabetic mothers

Natural History & Prognosis



- Acute complications & associations
  - Alveolar rupture with pneumothorax, pneumomediastinum, PIE
  - Sepsis & pulmonary infections
  - PDA with shunting & wide pulse pressure
  - Pulmonary hemorrhage
  - Apnea
  - Necrotizing enterocolitis ± perforation
  - Intracranial hemorrhage, periventricular leukomalacia
- Chronic complications
  - BPD is defined as ≥ 28-days oxygen (O_2) dependence in premature infant
    - Assessed by O_2 challenge at 36-weeks postmenstrual age
  - Retinopathy of prematurity
  - ↑ incidence of sudden death
  - Gastroesophageal reflux
  - Neurologic impairment in 10-70% (depending on GA)
  - Family psychodynamic complications
    - 2-year risk of parental divorce/separation is 2x higher compared to parents of term newborns
    - Maternal depression/anxiety rates are 5x higher than in mothers of term newborns



Treatment

- Prenatal prevention by treatment of mother
  - Efforts to delay delivery, allowing fetus to mature
  - Maternal steroid administration: Steroids will cross placenta & ↑ surfactant
- Surfactant administration
  - Can be given in nebulized or aerosol forms
  - Injected into trachea via endotracheal tube or via catheter inserted into trachea
  - May be given prophylactically or after symptoms develop
  - Improves oxygenation & ventilator setting requirements; ↓ rates of barotrauma, intracranial hemorrhage, BPD, & death
  - ↑ risk of PDA & pulmonary hemorrhage
- Mechanical ventilation with positive end-expiratory pressure
- High-frequency oscillatory ventilation
- Meet special needs of premature patient
  - Respiratory support
  - Monitor temperature, prevent hypothermia
  - Treat metabolic acidosis
  - IV access with fluid & caloric needs

(Left) *Frontal radiograph in a 22-weeks-gestation newborn shows a massive right tension pneumothorax. Note that despite the enormous degree of tension, the lung is not collapsed; this is due to its lack of compliance from absent surfactant.* **(Right)** *Frontal radiograph in 23-weeks-gestation triplet shows irregular, branching lucencies in the central lungs from pulmonary interstitial emphysema. The lack of surfactant makes premature newborns' lungs quite noncompliant & therefore more prone to barotrauma.*

(Left) *Lung US in a near-term newborn show normal A lines, horizontal reflections from the pleural surface that extend across aerated lung. The short, broad-based comet-tail artifacts are Z lines & are also normal; note how they do not cross the A lines.* **(Right)** *Lung US in another premature infant, this one with mild SDD, shows scattered B lines extending from the pleural surface into the far field. Note how closely the A line follows the same contour as the pleura. Unlike Z lines, B lines cross A lines.*

(Left) *Lung US in another premature newborn, this one with moderate SDD, shows more numerous B lines that have become almost completely confluent. Sharp, hypoechoic shadows are caused from the child's ribs,* **(Right)** *Longitudinal US of the lower chest in a premature newborn with severe SDD shows the appearance of lungs when B lines become completely confluent: "Total whiteout" of the lungs. Compare the markedly echogenic lungs with the relatively hypoechoic liver.*

Neonatal Pneumonia

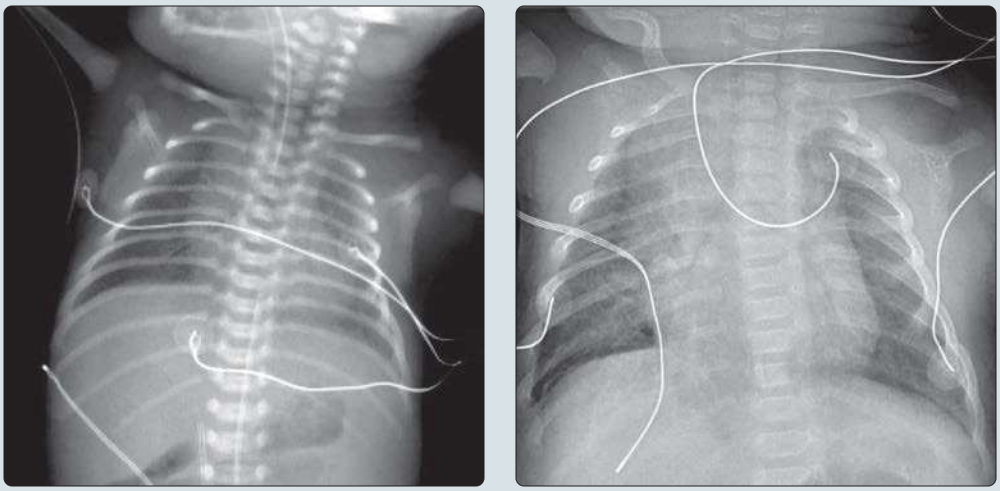
KEY FACTS

TERMINOLOGY

- Pneumonia in first 28 days of life
- Congenital: Infection established during fetal life
- Early onset: First 7 days of life, typically within 48 hours
- Late onset: Presents in 2nd-4th weeks of life

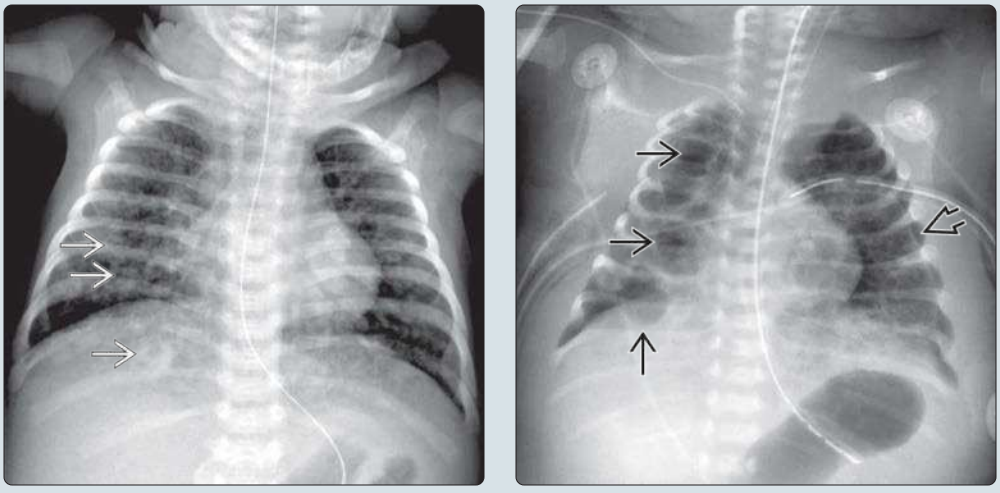
IMAGING

- Radiographs
  - Low lung volumes & granular opacities similar to surfactant deficiency (but pleural effusion in up to 67%)
  - Confluent, patchy, reticular, &/or perihilar opacities
  - Complications: Pneumothorax, pneumomediastinum, pulmonary interstitial emphysema
- Ultrasound
  - Pleural line abnormality
  - Hepatization of parenchyma with air bronchograms
  - > 3 B lines (areas of white lung)
  - Disappearance of lung sliding
  - Pulsation of lung synchronized with heart



PATHOLOGY

- Bacterial pathogens are most common in early & late onset
- Group B *Streptococcus* (developed countries) & *Escherichia coli* (developing countries) are most common in early onset
- Transmission
  - Congenital: Ascending infection across chorioamniotic membrane or hematogenous transplacental route
  - Early onset: Perinatal exposure (intrauterine or during birth canal passage)
  - Late onset: Contaminated/colonized equipment or individuals



CLINICAL ISSUES

- Typical presentations: Respiratory distress, sepsis
- Prevention: Universal screening at 35- to 37-weeks gestation for maternal group B streptococcal (GBS) colonization
  - Intrapartum antibiotic prophylaxis with penicillin
- Treatment: Empiric antibiotics, antivirals, &/or antiparasitics

(Left) *AP radiograph of the chest in a neonate with group B streptococcal (GBS) pneumonia shows diffuse, bilateral, hazy opacities with low lung volumes. This appearance is very similar to patients with surfactant deficiency disease.* **(Right)** *AP view of the chest in a term neonate with pneumonia & a birth history of prolonged rupture of membranes, chorioamnionitis, & maternal GBS colonization shows diffuse hazy & reticular opacities bilaterally.*

(Left) *AP radiograph in a neonate with tuberculosis shows multiple cavitating nodules in the right lung* ➔ *with generalized peribronchial thickening otherwise.* **(Right)** *AP radiograph in a patient with neonatal pneumonia shows a left pneumothorax* ➔ *& multiple bilateral pneumatoceles* ➔*, complications that can be seen with neonatal pneumonia. Scattered hazy & coarse opacities are otherwise seen throughout.*

TERMINOLOGY

Definitions

- Pneumonia in first 28 days of life
- Congenital: Infection established during fetal life
- Early onset: First 48 hours of life; some define as < 7 days
- Late onset: 2nd-4th weeks of life

IMAGING

Radiographic Findings

- Group B *Streptococcus* (GBS)
  - Low lung volumes + granular opacities similar to surfactant deficiency
  - Pleural effusion in up to 67%
- Other appearances
  - Confluent/patchy alveolar or reticular opacities
  - Regions of hyperinflation
- Complications: Pneumothorax, pneumomediastinum, pulmonary interstitial emphysema

Ultrasonographic Findings

- Absent, irregular, disrupted, or coarse pleural line
- Parenchymal hepatization & air bronchograms (punctiform or linear hyperechogenicities)
- > 3 B lines or areas of white lung
- Disappearance of lung sliding
- Pulsation of lung synchronized with heart rate

Imaging Recommendations

- Best imaging tool
  - Chest radiography
  - ↑ use of ultrasound but role is still debated
    - Metaanalysis shows sensitivity of 96% & specificity of 93% for pneumonia in children of all ages
      - Similar findings are also seen in surfactant deficiency

DIFFERENTIAL DIAGNOSIS

Surfactant Deficiency Disease

- Premature infants < 32-weeks gestation
- Mimics GBS infection but no effusion

Congenital Pulmonary Airway Malformation

- Mixed cystic &/or solid mass

Meconium Aspiration Syndrome

- History of meconium staining with respiratory distress

Transient Tachypnea of Newborn

- Occurs in term infants delivered by C-section
- Interstitial pattern with effusions
- Resolves within 48 hours

Congenital Heart Disease

- Abnormal cardiac silhouette & vascularity ± edema
- Echocardiography for diagnosis

PATHOLOGY

General Features

- Etiology
  - GBS is most common cause of early-onset neonatal pneumonia/sepsis in developed countries
    - β-hemolysin (pore-forming cytolysin) → ↑ epithelial cell permeability → alveolar edema & hemorrhage
    - β-hemolysin is inactivated by surfactant → premature infants at ↑ risk
  - *Escherichia coli* is most common cause of early-onset neonatal pneumonia in developing countries
  - Numerous other bacterial, viral, & fungal etiologies

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Respiratory distress: Rapid/noisy/difficult breathing, respiratory rate > 60, chest retractions, cough, grunting
  - Sepsis: Lethargy, poor feeding, poor reflexes, temperature instability, abdominal distention
  - Abnormal WBC with > 20% bands, ↑ CRP, ↑ ESR
  - Positive cultures

Demographics

- Epidemiology
  - Congenital-onset transmission: Ascending infection across chorioamniotic membranes or hematogenous transplacental route
  - Early-onset transmission: Perinatal exposure (intrauterine or during birth canal passage)
  - Late-onset transmission: Contaminated/colonized equipment or individuals
  - GBS is leading infectious cause of infant morbidity & mortality in USA (0.34-0.37 cases/1,000 live births)

Natural History & Prognosis

- Found in up to 38% of deaths occurring in first 48 hours
- GBS case fatality rate is up to 30% if ≤ 33-weeks gestation, 2-3% if full term
- Can be associated with intraventricular hemorrhage, neurological damage, & developmental delay

Treatment

- GBS screening at 35- to 37-weeks gestation; intrapartum antibiotic prophylaxis with penicillin if positive
- Neonatal antibiotic regimen otherwise depends on pathogen, early vs. late onset, antimicrobial susceptibility

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Consider if effusion accompanies radiographic findings otherwise suggestive of surfactant deficiency

Meconium Aspiration Syndrome

KEY FACTS

TERMINOLOGY

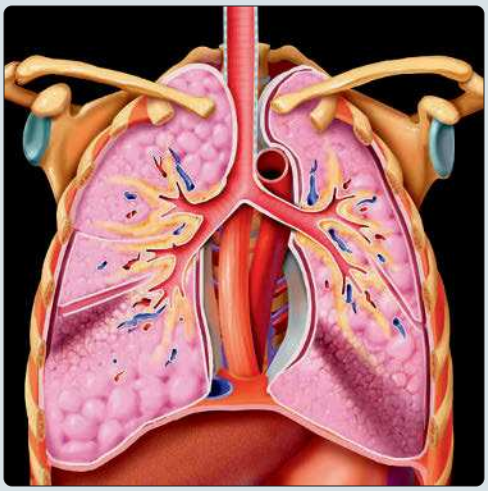
- Meconium aspiration syndrome (MAS): Respiratory distress after aspiration of meconium-stained amniotic fluid (MSAF)
  - Causes ↓ lung compliance & hypoxia ± pulmonary hypertension (HTN) & air leak syndrome

IMAGING

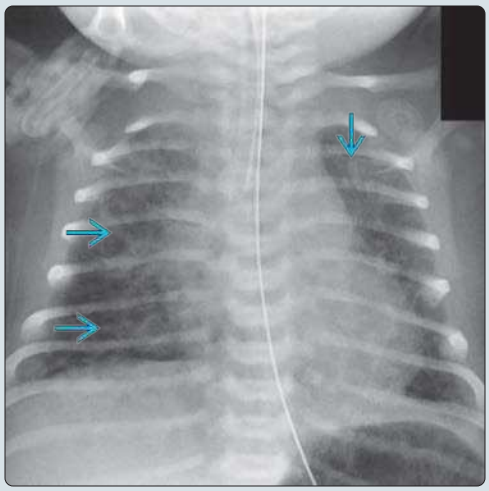
- Coarse, rope-like, linear perihilar opacities
- Asymmetric hyperinflation
- Patchy, hazy opacities of atelectasis & pneumonitis
- ± pleural effusion
- ± air leak: Pneumomediastinum, pneumothorax, pulmonary interstitial emphysema

TOP DIFFERENTIAL DIAGNOSES

- Congenital heart disease, neonatal pneumonia, transient tachypnea of newborn, surfactant deficiency disease, pulmonary hypoplasia

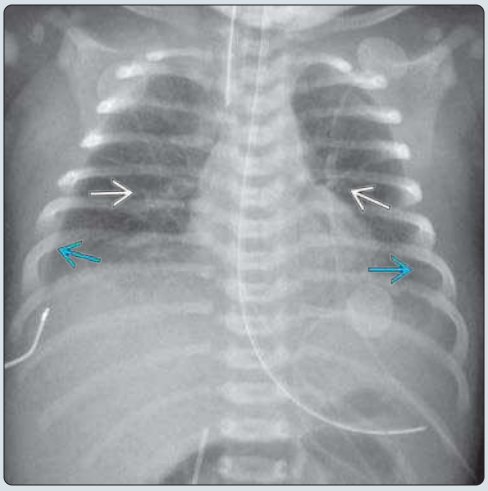


PATHOLOGY

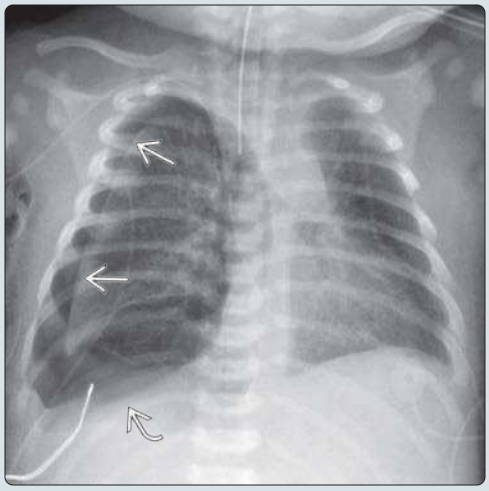


- Aspirated meconium causes injury by several mechanisms
  - Mechanical obstruction of small airways → air-trapping, air leak complications
  - Chemical pneumonitis of airways & parenchyma
  - Surfactant inactivation & ↓ production
  - Pulmonary vasoconstriction → persistent pulmonary HTN

CLINICAL ISSUES



- Disease of term & postterm neonates
- Meconium staining of amniotic fluid occurs in infants with in utero or intrapartum hypoxia or stress
  - 2-10% of patients with MSAF develop MAS
- ECMO for severe pulmonary HTN
- Mortality is up to 4%; chronic lung disease in 2.5%



(Left) *Graphic demonstrates asymmetric areas of hyperinflation & atelectasis as well as rope-like perihilar densities of aspirated meconium & inflamed airways.* **(Right)** *AP chest radiograph in a 41-weeks-gestation newborn with meconium staining of amniotic fluid & respiratory distress shows coarse, reticular, rope-like perihilar opacities, typical of meconium aspiration. There are also patchy, asymmetric regions of ↑ hazy lung opacity bilaterally.*

(Left) *AP chest radiograph in a term newborn with meconium aspiration shows linear perihilar opacities. Small pleural effusions are present.* **(Right)** *AP chest radiograph obtained 8 hours later in the same patient shows a new right pneumothorax. Depression of the hemidiaphragm & leftward mediastinal shift indicate a tension pneumothorax. Pneumothorax is seen as a complication in 10-40% of patients with meconium aspiration syndrome.*

TERMINOLOGY

Definitions

- Meconium aspiration syndrome (MAS): Respiratory distress due to aspiration of meconium-stained amniotic fluid (MSAF)

IMAGING

General Features

- Best diagnostic clue
  - Coarse, rope-like perihilar opacities bilaterally + hyperinflation in term infant
  - Usually with history of MSAF

Radiographic Findings

- Linear, nodular, rope-like opacities radiating from hila
- Hyperinflated lungs, often asymmetric
- Patchy, asymmetric opacities of atelectasis & pneumonitis
- ± air leak: Pneumothorax, pneumomediastinum, pulmonary interstitial emphysema (PIE)
- ± pleural effusion

Ultrasonographic Findings

- Lung ultrasound is increasingly used at bedside of ill children: Point of care ultrasound (POCUS)
  - Findings relate to artifacts from interaction of sound with air & interstitial fluid
  - Can help predict need for mechanical ventilation
- MAS findings include: Sonographic B lines (interstitium), consolidation, bronchograms, abnormal pleural line, loss of sonographic A lines, atelectasis, airway inflammation, pleural effusion
  - Uneven & changing distribution over clinical course

DIFFERENTIAL DIAGNOSIS

Congenital Heart Disease

- Clues to underlying congenital heart disease include
  - Abnormal cardiac &/or mediastinal silhouette
  - ↑ or ↓ pulmonary vascular flow

Neonatal Pneumonia

- Patchy, asymmetric perihilar densities & hyperinflation
- Common to see pleural effusion
- Usually no history of meconium aspiration

Transient Tachypnea of Newborn

- Delayed clearance of fetal pulmonary fluid (often in cesarean section)
- ± pleural effusion or fissural thickening
- Benign, self-limited course over 24-72 hours

Surfactant Deficiency Disease

- Diffuse granular pulmonary opacities in premature infant with low lung volumes
- Pleural effusions are uncommon

Pulmonary Hypoplasia

- Pneumothoraces are common
- Bell-shaped thorax in severe cases

PATHOLOGY

General Features

- Etiology
  - Fetal distress near or beyond term → passage of meconium into amniotic fluid, which may enter lungs
- Aspirated meconium causes injury by several mechanisms
  - Mechanical obstruction of small airways → air-trapping, air leak complications
  - Chemical pneumonitis of airways & parenchyma
  - Surfactant inactivation & ↓ production
  - Pulmonary vasoconstriction leading to pulmonary hypertension (HTN)
    - Cause of pulmonary HTN is multifactorial
    - Leading cause of death in MAS

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Meconium staining of amniotic fluid at birth
  - Respiratory distress

Demographics

- Epidemiology
  - 0.1-1.8% of live births in resource-rich countries
  - Term or postterm infants with in utero or intrapartum hypoxia or stress
    - MSAF in up to 38% at 41 weeks; rare in preterm
  - 2-10% with MSAF develop MAS

Natural History & Prognosis

- Complications
  - Meconium injury & hypoxia
    - Respiratory support with supplemental oxygen ± mechanical ventilation, surfactant administration
  - Air leak complications in 10-40%
  - Severe pulmonary HTN in 10%
    - May be treated with inhaled nitrous oxide &/or ECMO
  - Anoxic brain injury, may be multifactorial with perinatal stress
- Outcomes have greatly improved in recent decades
  - Most recover within 72-96 hours
  - Mortality up to 4%, recently reported at 1.2%

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Relevant history is essential for accurate interpretation of all neonatal chest disease, particularly MAS
  - Term or postterm infant
  - MSAF at delivery

Transient Tachypnea of Newborn

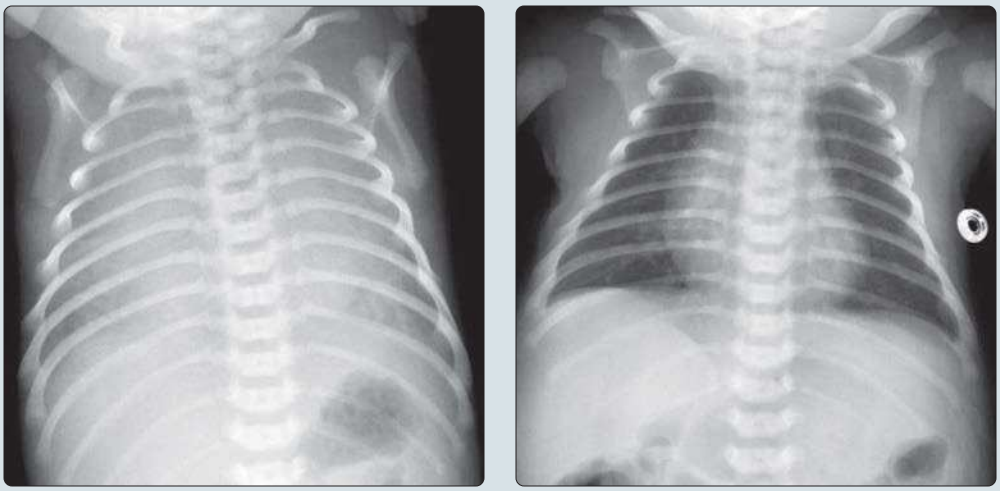
KEY FACTS

TERMINOLOGY

- Transient tachypnea of newborn (TTN), a.k.a. wet lung disease, retained fetal fluid
- Caused by delayed evacuation of fetal lung fluid that creates engorgement of pulmonary lymphatics & capillaries
- Classically seen after cesarean section due to lack of normal thoracic compression during vaginal delivery

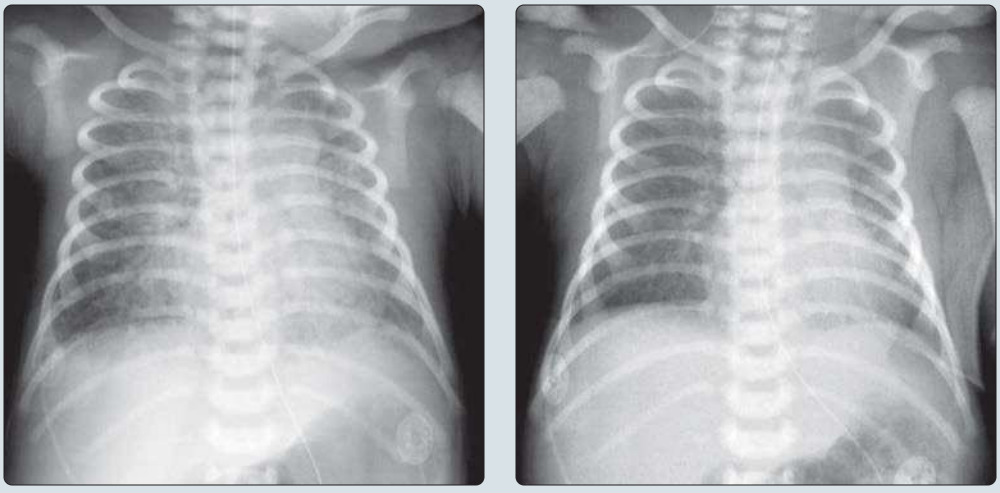
IMAGING

- Patients are usually not intubated
- Radiograph is historically considered gold standard
  - Findings similar to pulmonary edema
  - Diffuse, bilateral, & often symmetric ↑ lung markings ± pleural effusion
- US is becoming more widely used
  - Scattered B lines separated by A lines
  - Double lung point sign
- Lungs become normal within 24-48 hours
- Diagnosis of exclusion



TOP DIFFERENTIAL DIAGNOSES

- Surfactant deficiency
  - Usually occurs in premature newborns
  - Radiograph: Low lung volumes with diffuse, hazy, or granular opacity throughout both lungs
  - US: Lungs are diffusely echogenic (confluent B lines), no preserved normal areas (lacks A lines)
- Congenital heart disease
  - Pulmonary edema from obstructed total anomalous pulmonary venous return or left-sided obstruction
  - Echocardiogram is gold standard for making diagnosis
- Meconium aspiration syndrome
  - Occurs in term infants (like TTN)
  - Rope-like perihilar markings, barotrauma



CLINICAL ISSUES

- Presents shortly after birth: Tachypnea, grunting, nasal flaring, retractions, occasional cyanosis
- Infants usually improve rapidly & are normal on follow-up

(Left) *AP radiograph of the chest in a full-term infant with tachypnea demonstrates diffuse, bilateral, hazy opacities. The findings & symptoms resolved over the 1st few days of life, & the diagnosis of transient tachypnea of the newborn (TTN) was made.* **(Right)** *Follow-up AP radiograph of the chest shows interval clearing of the previously seen diffuse opacification of the lungs. TTN is a diagnosis of exclusion & cannot be confidently diagnosed radiographically unless the findings resolve.*

(Left) *AP radiograph of the chest in a full-term infant with tachypnea shows diffuse nodular opacities throughout the lungs. No pneumothorax or pleural effusion is seen.* **(Right)** *AP radiograph of the chest in the same patient the following day shows partial clearance of the previously seen diffuse nodular opacities, consistent with TTN.*

TERMINOLOGY

Abbreviations

- Transient tachypnea of newborn (TTN)

Definitions

- TTN occurs when evacuation of fetal lung fluid is delayed, causing engorgement of pulmonary lymphatics & capillaries
  - Usually occurs in term infants
  - More common (3x) in those born by cesarean section
    - Normal thoracic compression that occurs during vaginal delivery is bypassed by cesarean section

IMAGING

General Features

- Best diagnostic clue
  - Interstitial edema on chest radiographs
  - History of cesarean section or maternal asthma
  - No signs of infection

Radiographic Findings

- Chest radiographs in first 24-48 hours of life
  - Patients are usually not intubated
  - No/minimal cardiomegaly
  - Normal to ↑ lung volumes
  - Findings are similar to pulmonary edema
    - Prominent interstitial markings
    - ± pleural effusion
      - Fluid in fissures
  - Lungs become normal within 24-48 hours
  - No consolidation or other focal lung lesion

Ultrasonographic Findings

- Scattered B lines separated by A lines
  - A lines: Series of lines horizontal to pleura, caused by reverberation artifact in normally aerated lung
  - B lines: Comet-tail artifact extending from points on pleural surface (sign of subpleural interstitial edema)
- Double point lung sign
  - In TTN, upper lungs are often normal while lower lungs reveal numerous compact or confluent B lines
  - On lung US, point where these findings are juxtaposed is termed "double lung point"
  - High sensitivity & specificity but controversial

DIFFERENTIAL DIAGNOSIS

Surfactant Deficiency

- Usually occurs in premature newborns
- Low lung volumes with diffuse, hazy, or granular opacity throughout both lungs
- US: Lungs are diffusely echogenic (confluent B lines), no preserved normal areas (lacks A lines)

Congenital Heart Disease

- Pulmonary edema from obstructed total anomalous pulmonary venous return or left-sided obstructive lesions can mimic TTN
- Echocardiogram is gold standard for making diagnosis

Meconium Aspiration Syndrome

- Occurs in term infants (similar to TTN)
- Rope-like perihilar markings
- Pneumothorax & pneumomediastinum are common

Congenital Lymphangiectasia

- Very rare, presents with persistent tachypnea
- Persistent interstitial pattern ± pleural effusions

Intrathoracic Causes of Tachypnea

- Neonatal pneumonia
- Neonatal chest masses

PATHOLOGY

General Features

- Etiology
  - During fetal life, lungs are expanded with ultrafiltrate of fetal fluid
  - During & after birth, lung fluid is replaced with air
    - Chest is normally compressed & fluid expelled during vaginal delivery: Thoracic squeeze
    - Pulmonary capillaries & lymphatics remove remaining fluid
  - Most infants with TTN are healthy & normal within 48 hours
- Associated abnormalities
  - Usually healthy infants with no other anomalies

Gross Pathologic & Surgical Features

- Not associated with any mortality or morbidity

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Mild to moderate respiratory distress
  - Frequent history of cesarean section delivery
  - Typically do not require intubation

Demographics

- Epidemiology
  - More common in cesarean section infants
  - High association with maternal asthma

Natural History & Prognosis

- Mild/moderate respiratory distress within 6 hours of birth
- Relatively benign clinical course
- Radiographic resolution usually by 24-48 hours

Treatment

- Exclude other causes of tachypnea in term newborn
- Normal support of infant

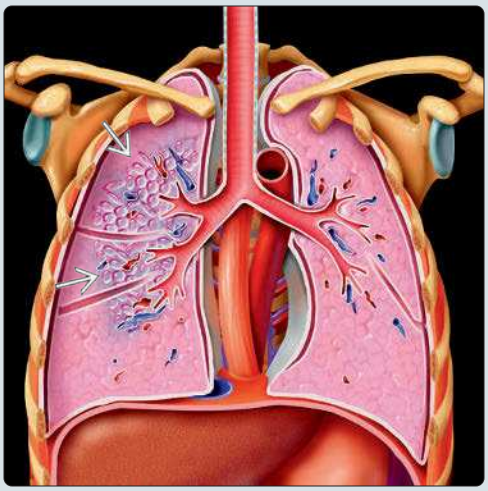
Pulmonary Interstitial Emphysema

KEY FACTS

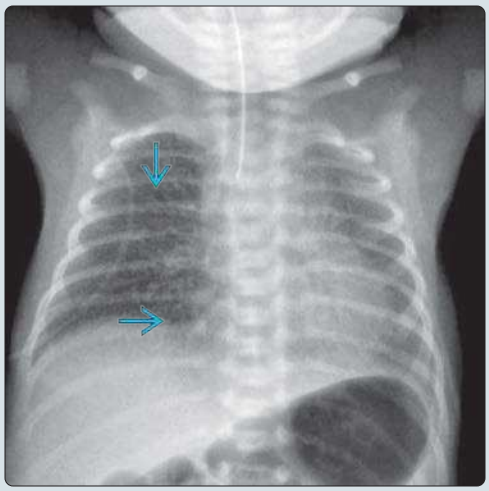
TERMINOLOGY

- Pulmonary interstitial emphysema (PIE): Air within pulmonary interstitium & lymphatics
- Neonatal air leak syndrome: Air escapes tracheobronchial tree to spaces where it is not normally found
- Persistent PIE: Development of persistent, mass-like interstitial cysts

IMAGING

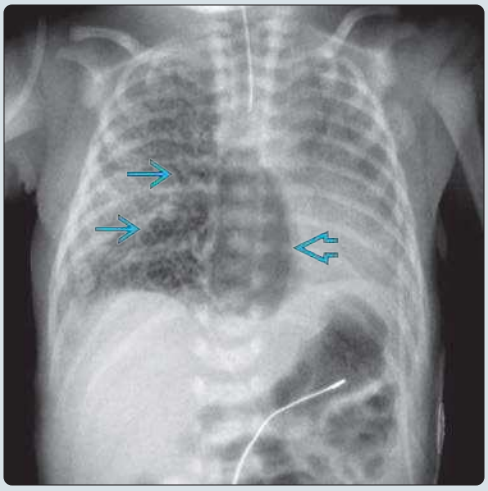


- Best clue: New small, "bubbly," cystic or linear lucencies within lung of intubated premature infant
- Ranges from single lobe to widespread involvement
- Precursor to pneumothorax or pneumomediastinum
- Persistent PIE may have mass-like cystic/multicystic lesion
  - CT shows pulmonary vessels as linear (dash) or round (dot) densities within gas collections

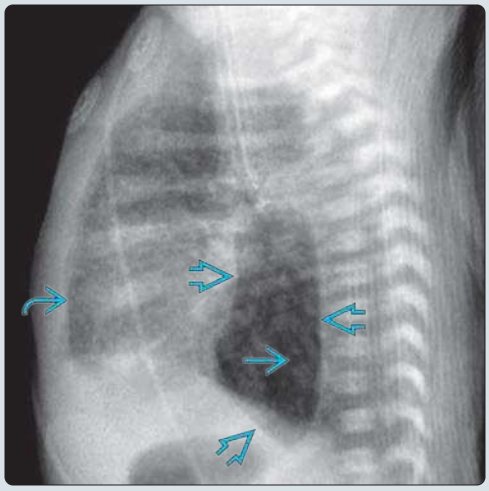


TOP DIFFERENTIAL DIAGNOSES

- Surfactant deficiency disease
- Air bronchograms in diffuse lung disease
- Chronic lung disease of prematurity
- Lucent or cystic congenital lung lesions
- Pleuropulmonary blastoma



CLINICAL ISSUES



- Usually secondary to barotrauma & volutrauma of positive-pressure mechanical ventilation in setting of prematurity & surfactant deficiency disease (SDD)
  - Not always on mechanical ventilation
  - May rarely be seen in older patients with underlying lung disease or after Valsalva
- Often asymptomatic, detected on NICU radiographs
- Usually occurs during first 10 days of life
- Usually transient with supportive therapy & ventilatory adjustments
  - ↓ mean airway pressure, use high-frequency ventilation

(Left) *Coronal graphic depicts round & linear foci of gas in the right lung parenchyma secondary to air escaping into the pulmonary interstitium.* **(Right)** *AP chest radiograph in an intubated 2-day-old, former 31-weeks-premature infant with surfactant deficiency disease (SDD) shows typical diffuse granular pulmonary opacities. There are mild, scattered, linear & "bubbly" lucencies of pulmonary interstitial emphysema (PIE) in the right lung.*

(Left) *AP chest radiograph 24 hours later in the same patient shows more extensive "bubbly" & linear lucencies throughout the right lung, typical of PIE. A large, inferomedial gas collection has also developed, shifting the heart leftward.* **(Right)** *Cross-table lateral radiograph in the same patient shows localized infraazygous posterior pneumomediastinum. Lucencies from the right lung PIE are superimposed on the collection. Note that there is no free gas in the nondependent chest to suggest a pneumothorax.*

TERMINOLOGY

Abbreviations

- Pulmonary interstitial emphysema (PIE)

Definitions

- PIE: Air within pulmonary interstitium & lymphatics
- Persistent PIE: Development of persistent, mass-like interstitial cysts
- Neonatal air leak syndrome: Air escapes from tracheobronchial tree into spaces where it is not normally found
  - PIE, pneumothorax, pneumomediastinum, pneumopericardium, subcutaneous emphysema; rarely pneumoperitoneum

IMAGING

General Features

- Best diagnostic clue
  - New, "bubbly," cystic or linear lucencies within lung of intubated premature infant
- Location
  - Extent of involvement may range from single lobe to widespread bilateral PIE
- Size
  - Ranges from small interstitial lucencies to large focal/multifocal cysts

Radiographic Findings

- Radiography
  - "Bubbly," cystic or linear lucencies in lung parenchyma
    - Lucencies are typically uniform in size
    - Often radiate from hilum
  - Usually occurs on background of noncompliant lung parenchyma
    - Most commonly surfactant deficiency disease (SDD) in preterm newborn
  - Typically transient: May last days to weeks
    - Precursor to other complications: Pneumothorax, pneumomediastinum
  - Persistent PIE
    - Variable involvement from single lobe to bilateral multilobar
      - Most commonly affects left upper lobe
    - May develop mass-like cystic/multicystic lesions
      - May compress other thoracic structures to cause worsening respiratory distress

CT Findings

- Not routinely obtained to evaluate PIE
- May be utilized to evaluate persistent PIE & differentiate it from other lucent neonatal lung masses
  - Round or linear lucencies in lung interstitium
  - Lucencies do not follow normal bronchial anatomy & may widen peripherally (unlike air bronchograms)
  - With persistent PIE, pulmonary vascular branches are seen as linear (dash) or round (dot) soft tissue densities within prominent gas collections
    - Characteristic dot-dash pattern in 82% of patients with persistent PIE
    - Not seen in congenital cystic lung lesions

Ultrasonographic Findings

- ↑ use of beside ultrasound in neonatal lung disease; may detect foci of PIE

Imaging Recommendations

- Best imaging tool
  - Frontal radiograph of chest

DIFFERENTIAL DIAGNOSIS

Surfactant Deficiency Disease

- Often underlies PIE
- Uneven distribution of administered exogenous surfactant may result in heterogeneous aeration amidst granular & hazy opacities
  - Pattern of alternating distended & collapsed acini may mimic PIE

Air Bronchograms in Diffuse Lung Disease

- May be seen with pulmonary edema, hemorrhage, neonatal infections, surfactant dysfunction/deficiency, other diseases
- Follow normal bronchial course

Chronic Lung Disease of Prematurity

- "Bubbly" lucencies of developing bronchopulmonary dysplasia (BPD) can appear similar to PIE
  - On CT, vessels are not engulfed by interstitial air (unlike PIE)
- BPD is seen at > 1 month of age
- Timing of onset: PIE is abrupt, BPD is gradual

Congenital Lobar Overinflation

- Found in perinatal period; often worsens after birth
- Typically first seen as lucent neonatal lung lesion
  - May present initially as perinatal lobar opacity with gradual clearing & ↑ lobar expansion
  - Lobar architecture is preserved but uniformly splayed without discrete cysts

Congenital Pulmonary Airway Malformation

- Lung mass of cystic lucencies of varying size
- Transition from fluid-filled to air-filled mass after birth

Pleuropulmonary Blastoma

- Rare tumor of young children (but uncommon in perinatal period)
- Typically cystic in neonatal period

Meconium Aspiration

- Linear, nodular, rope-like opacities radiating from hila
- Heterogeneous lucencies related to air-trapping
- May develop air-leak complications, including PIE

PATHOLOGY

General Features

- ↑ alveolar pressure & overdistention (barotrauma + volutrauma) → disruption of alveolar basement membrane → air enters pulmonary interstitium
- Preterm infants have more abundant interstitial perivascular connective tissue, which limits further dissection relative to older infants & children

- Trapping within this space gives characteristic linear & "bubbly" lucencies of PIE
- Compresses airways & alveoli, impairing gas exchange, compliance, & possibly blood flow
- Air may further dissect, leading to pneumothorax or pneumomediastinum
- Cysts may enlarge due to ball-valve mechanism

Microscopic Features

- Air-distended lymphatics & air along vascular sheaths
  - Seen along bronchovascular bundles as well as interlobular septa & visceral pleura
- Persistent PIE
  - Fibrotic cyst walls lined by multinucleated giant cells in reaction to prolonged air trapping

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Often asymptomatic & detected incidentally on routine NICU radiographs
- Other signs/symptoms
  - Difficulty with ventilation secondary to pneumothorax
  - Impaired gas exchange

Demographics

- Age
  - Premature infants, most commonly occurring in first 10 days of life
  - Rarely occurs in
    - Neonates with other lung diseases (pulmonary hypoplasia, meconium aspiration, sepsis)
    - Older children due to
      - Underlying lung disease
      - Valsalva with alveolar rupture
- Sex
  - No significant sex difference
- Ethnicity
  - No significant race predilection
- Epidemiology
  - 2-3% of NICU patients
  - 20-30% of premature neonates with SDD
    - Incidence ↓ with use of surfactant in appropriate population
  - Patients on positive-pressure mechanical ventilation are most at risk
    - Rarely develops in patients not on ventilator

Natural History & Prognosis

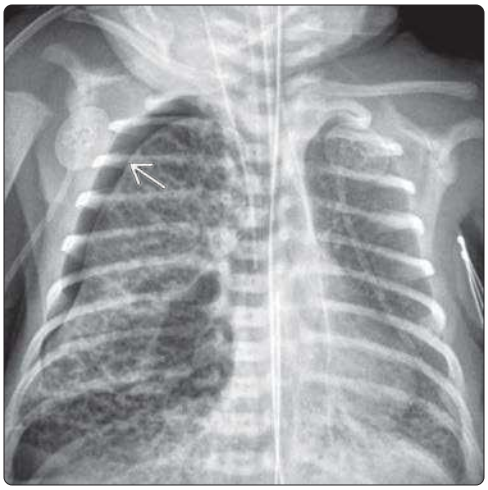
- Usually transient with supportive therapy & careful management of ventilatory support
- Rarely develops into persistent PIE
- Complications: Pneumothorax, pneumomediastinum, pneumopericardium, ↓ pulmonary compliance, air embolus
- ↑ rates of intraventricular hemorrhage

Treatment

- Adjustments in mechanical ventilation
  - Lower mean airway pressures
  - ↑ FiO_2 to allow for dec ↓ airway pressures
  - Switch from conventional to high-frequency ventilation
- ↑ frequency of clinical & radiographic monitoring for complications, such as pneumothorax
- Heliox & steroids may be useful, evidence lacking
- Additional management options
  - Selective intubation of uninvolved lung
  - Temporary balloon blockage of main bronchus of affected side
  - Decubitus positioning with affected side down
  - Surgical resection of large cystic foci is reserved for unmanageable respiratory distress
    - ~ 53% of patients with persistent PIE in one series

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls



- Age of patient & rapidity of development help differentiate PIE from BPD

Reporting Tips

- Early detection & ventilatory adjustments may help avoid complications

(Left) *AP chest radiograph in a 6-day-old, 27-weeks-gestation infant shows "bubbly" & linear lucencies of diffuse PIE, greater on the right. A right pneumothorax is also seen.* **(Right)** *Axial CECT in the same patient at 26 days of age shows development of persistent PIE with aggregate mass-like cysts. Note the "dots" of pulmonary vascular branches surrounded by the interstitial cysts. There is leftward mediastinal shift indicating mass effect, commonly seen in this entity.*

(Left) *AP chest radiograph in an intubated 4-day-old, 23-weeks-gestation premature infant shows diffuse bilateral "bubbly" lucencies of PIE intermixed with hazy opacities of surfactant deficiency.* **(Right)** *AP chest radiograph in a 4-day-old, 27-weeks-gestation infant shows linear lucencies, greatest in the left upper lobe. Involvement in PIE may be asymmetric. A chest tube has been placed for a right pneumothorax.*

(Left) *Coronal CECT of the chest demonstrates linear lucencies in the interstitium of the left upper lobe (superimposed on a background of SDD). The lucencies in PIE do not follow the anatomy of a bronchus & may get wider near the periphery of the lung, helping to differentiate PIE from air bronchograms.* **(Right)** *Microscopic H&E slide shows PIE as gas collections in the pulmonary interstitium/lymphatics. The foci of gas abut & surround the bronchial arteries.*

Neonatal Pneumothorax

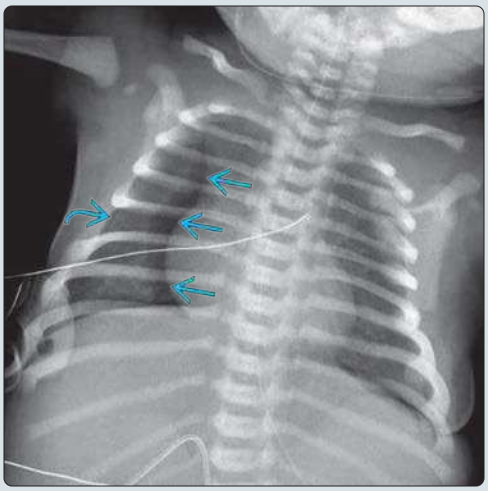
KEY FACTS

IMAGING

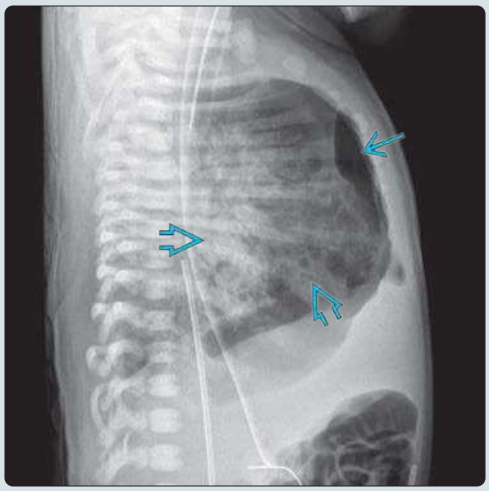
- Neonatal chest radiographs are typically obtained supine
  - Clues to pneumothorax diagnosis on supine study
    - Large, hyperlucent hemithorax
    - Lucency "cloaking" diaphragm, mediastinum, &/or lung
    - Medial stripe sign: Lucency along mediastinum
    - Deep sulcus sign: Well-defined costophrenic sulcus
    - Gas-filled pleural sac herniated across midline
    - Visualization of anterior junction line if bilateral
  - Cross-table lateral view shows air anterior to lung
  - Edge enhancement on PACS may improve visibility
- Ultrasound: Absence of lung sliding & comet-tail artifact

TOP DIFFERENTIAL DIAGNOSES

- Pneumomediastinum
- Air-filled mass
- Artifact
- Recent surgical evacuation of hemithorax

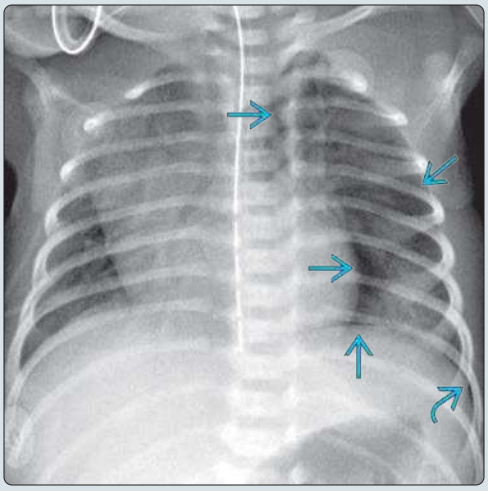


PATHOLOGY

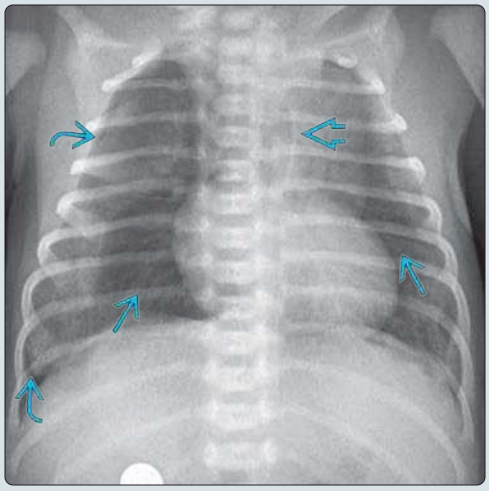


- Overdistention & rupture of alveoli
  - Directly into pleural cavity → pneumothorax
  - Into lung interstitium first → interstitial emphysema
- Risk factors: Low birth weight, premature or postmature gestation, male sex, surfactant deficiency disease, meconium aspiration, pulmonary hypoplasia, resuscitation at birth, mechanical ventilation, macrosomia

CLINICAL ISSUES



- Common signs/symptoms: Ipsilateral ↓ breath sounds, respiratory distress, cyanosis, retractions, grunting, nasal flaring, chest asymmetry (↑ on affected side), hypercapnia, hypoxemia; tension pneumothorax → hypotension, shock
- Treatment
  - Expectant/supportive management in asymptomatic patients or those with mild disease
  - Needle aspiration or chest tube drainage if symptomatic



(Left) *Supine chest radiograph in a neonate demonstrates a pneumothorax with lucency "cloaking" the right heart boarder. A pleural line is seen laterally in this case, though sharp pleural lines are often not visible on supine views.* **(Right)** *Cross-table lateral view of the chest in a 1-day-old shows a circumscribed lucency anteriorly deep to the chest wall, compatible with a pneumothorax. Patchy & coarse pulmonary opacities are secondary to meconium aspiration.*

(Left) *Supine chest radiograph in a 2-day-old neonate born at 34-weeks gestation shows lucency "cloaking" the left hemithorax with a well-defined, left costophrenic angle as compared to the right. This appearance was due to a moderate left pneumothorax.* **(Right)** *Supine chest radiograph in a newborn demonstrates relative lucencies over the lungs bilaterally, a pleural line on the right, & the anterior junction line, compatible with bilateral pneumothoraces.*

TERMINOLOGY

Definitions

- Air in pleural space between visceral & parietal pleura

IMAGING

Radiographic Findings

- Neonatal chest radiograph is typically obtained with patient in supine position
- Air collects anterior & medial → pleural line is often not seen
- Clues to pneumothorax in supine position
  - Large, hyperlucent hemithorax
  - Lucency "cloaking" diaphragm, mediastinum, &/or lung
    - Thymus may be compressed → "pseudomass"
  - Medial stripe sign: Lucency along mediastinal edge
  - Deep sulcus sign: Well-defined costophrenic sulcus
  - Gas-filled pleural sac herniates across midline
    - Appearance is similar to pneumomediastinum
  - Bilateral anterior pneumothoraces displace thymus & allow visualization of anterior junction line
    - Anterior junction line is usually not seen in neonates
    - Uneven tension → support devices are displaced away from side of greater tension
- Cross-table lateral view
  - Intrapleural lucency anterior to lung & mediastinum
  - Minimizes neonate manipulation vs. decubitus view
- Tension pneumothorax
  - Large pneumothorax with lung collapse
    - Diseased "stiff" lungs may not collapse despite tension
  - Flattened or everted hemidiaphragm
  - Bulging intercostal spaces
  - Mediastinal shift toward/into contralateral hemithorax

Ultrasonographic Findings

- Absence of lung sliding & comet-tail artifact

Imaging Recommendations

- Best imaging tool
  - Bedside ultrasound can enable more rapid diagnosis than radiograph
  - Edge enhancement on PACS may improve radiographic visibility

DIFFERENTIAL DIAGNOSIS

Pneumomediastinum

- Air confined to upper retrosternal space
- Mediastinal shift is unlikely
- Lifting of thymus: Spinnaker sail sign

Artifact

- Skin fold
- Materials external to patient
- Mach effect

Air-Filled Mass

- Congenital pulmonary airway malformation (CPAM)
- Congenital lobar emphysema
- Congenital diaphragmatic hernia (CDH)

Recent Surgical Evacuation of Hemithorax

- Early radiographs after CDH repair or large CPAM resection demonstrate negative pressure ex vacuo pneumothorax
- Fills with fluid; ultimately ↓ in size due to lung growth

PATHOLOGY

General Features

- Uneven alveolar ventilation, air-trapping, ↑ transpulmonary pressure → alveolar overdistension → rupture into pleural cavity → pneumothorax
  - Rupture may first occur into interstitium (pulmonary interstitial emphysema) with ultimate dissection to mediastinum or pleural cavity
- Risk factors: Low birth weight, premature or postmature gestation, male sex, surfactant deficiency disease, meconium aspiration, pulmonary hypoplasia, resuscitation at birth, mechanical ventilation, macrosomia

CLINICAL ISSUES

Presentation

- Timing of pneumothorax presentation
  - Infants > 2,500 g: Median of 5.5 hours after birth
  - Infants < 2,500 g: Median of 2nd day of life
- Most common signs/symptoms: Ipsilateral ↓ breath sounds, respiratory distress, cyanosis, retractions, grunting, nasal flaring, chest asymmetry (larger on affected side), hypercapnia, hypoxemia
- Asymptomatic pneumothoraces are more common in nonlow birth weight neonates
- Tension pneumothorax may result in hypotension, shock

Natural History & Prognosis

- Incidence: 1% of term births, 6-7% of preterm births
  - ↑ morbidity & mortality in preterm infants
- High-frequency positive pressure ventilation may ↓ incidence compared to conventional mechanical ventilation

Treatment

- Expectant/supportive management in asymptomatic patients & those with mild disease
- Needle aspiration or chest tube drainage if symptomatic

DIAGNOSTIC CHECKLIST

Reporting Tips

- Unexpected or tension pneumothoraces should be communicated to clinical team immediately

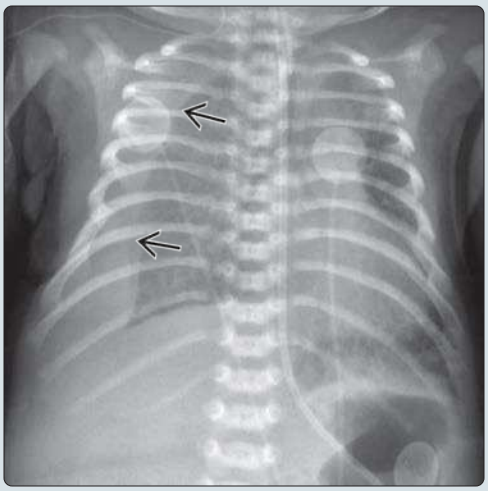
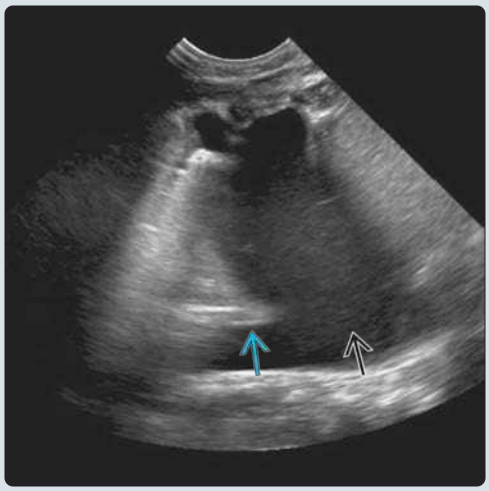
KEY FACTS

TERMINOLOGY

- Lymphatic fluid in pleural space secondary to congenital or acquired conditions, including congenital lymphatic conducting channel anomaly, ↑ pressure, impaired drainage/obstruction, or trauma to thoracic duct

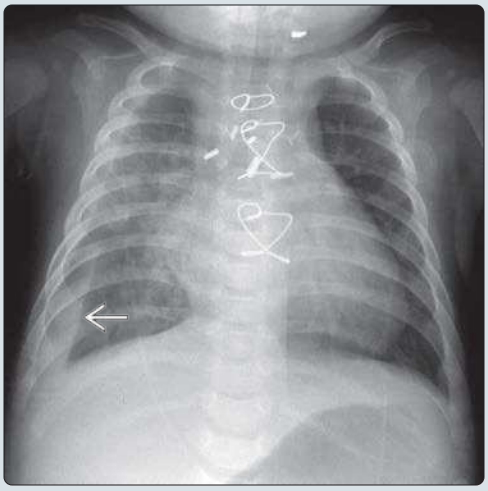


IMAGING

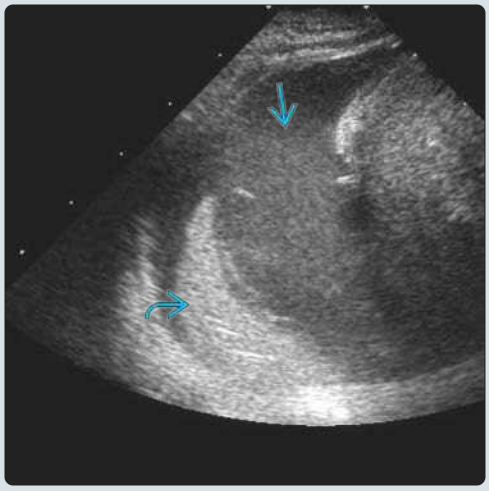


- US, CT, MR may be done to discover underlying cause of chylothorax & evaluate treatment options
  - Persistent pleural effusion following cardiac surgery
  - Congenital chylothorax from Turner or Noonan syndrome
  - Various associated lymphatic disorders, including conducting channel anomalies, generalized lymphatic anomaly, Gorham-Stout disease, & discrete cystic lymphatic malformations
- Lymphangiogram (conventional, nuclear, or MR): Used to investigate suspected central conducting channel anomalies
  - Disorders (including atresia/absence, obstruction, disruption, or dysmotility) may show abrupt halt to visualization of normal lymphatic pathways, reflux into tissues, collaterals, delayed transit, &/or abnormal accumulations

CLINICAL ISSUES



- Symptoms may include tachypnea & dyspnea, generalized edema, chylous ascites, immunosuppression, protein-losing enteropathy (if gut involved)
- Treatment options include: Fat-restricted diet, rapamycin/sirolimus, thoracentesis or draining procedure, thoracic duct ligation or embolization, microsurgical thoracic duct repair, pleurodesis
  - Isolated neonatal chylothorax may be cured by ethiodized oil lymphangiography
- Thoracic duct injury may resolve spontaneously in 50%
- Poorer prognosis with syndromes, multiple sites of chylous fluid accumulations, prematurity



(Left) *AP radiograph shows a large pleural effusion in a neonate. Laboratory evaluation showed a chylous effusion, consistent with congenital chylothorax.* **(Right)** *Longitudinal ultrasound of the right chest in the same patient shows a right pleural effusion in a patient with known congenital chylothorax. Note the inferior aspect of the right lower lobe.*

(Left) *AP radiograph in a 4-month-old infant status post surgery for congenital heart disease shows a moderate right chylothorax from a thoracic duct injury.* **(Right)** *Transverse ultrasound of the right chest in the same 4-month-old patient status post heart surgery & thoracic duct injury shows a large, mildly echogenic pleural effusion. Note the compressed echogenic right lung surrounded by the effusion.*

TERMINOLOGY

Definitions

- Chylothorax: Lymphatic fluid in pleural space secondary to congenital or acquired conditions, including congenital anomaly, ↑ pressure, impaired drainage/obstruction, or trauma to thoracic duct
- Lymphangiectasia: Abnormal dilation of lymphatics
  - 1°: Abnormal development of lymphatics in isolation or with genetic anomaly
  - 2°: Related to congenital heart disease (CHD) or repair
- Neonatal/congenital lymphatic flow disorders (central lymphatic conducting channel anomaly)
  - Pulmonary lymphatic perfusion syndrome: Abnormal lymphatic flow in lungs & pleura → chylothorax
  - Central lymphatic flow disorder: Abnormal flow into additional tissues/cavities → body wall, peritoneum, etc.
  - Congenital chylous ascites

IMAGING

General Features

- Best diagnostic clue
  - Isolated unilateral pleural effusion in newborn
  - Newborn with obstructive CHD or lymphatic disorders
    - ± Turner syndrome, Noonan syndrome
    - Lymphangiectasia with bilateral interstitial thickening, anasarca, protein-losing enteropathy, & chylous accumulations in body cavities
  - Persistent pleural effusion following CHD repair
  - Macroscopic lymphatic malformation of neck & chest
  - Bone disease with chylothorax: Gorham-Stout disease ("vanishing bone disease"), generalized lymphatic anomaly (GLA)

Radiographic Findings

- Persistent, nonspecific pleural effusion
  - Associated disorders dictate other findings
- ± interstitial thickening, body wall edema

Ultrasonographic Findings

- Anechoic or mildly hypoechoic fluid without septations
- Lung sonography of lymphangiectasia in setting of CHD: Surface irregularity; subpleural, cystic-appearing foci

CT Findings

- CECT
  - Lymphangiectasia with diffuse pulmonary interstitial thickening
  - ± poorly defined paraspinal soft tissue infiltration from abnormal lymphatics
  - Macro- &/or microcystic lymphatic malformation may infiltrate mediastinum & pleura
    - ± bone lesions
  - ± solid mediastinal mass obstructing vessels

MR Findings

- Fetal MR may show "nutmeg lung" (due to abnormal pulmonary lymphatics) + effusion

Lymphangiogram

- Can be performed with nuclear medicine, MR, or conventional fluoroscopy
- Depending on specific question & modality being employed, specific agent is injected into dermal or nodal lymphatics of proximal or distal lower extremity
- Extremity & body are subsequently imaged over 10-60 minutes while agent travels proximally through central lymphatic system to cisterna chyli & thoracic duct, ultimately emptying into left subclavian vein
  - MR: Gadolinium-based contrast is injected into lymph nodes, typically at groin
    - Multiple repeats of rapid T1 FS GRE
    - May also use preinjection heavily T2W 3D sequence
- Disorders (including atresia, absence, disruption, dysmotility) may show abrupt halt to visualization of normal channels
  - ± reflux of contrast into adjacent tissues, visualization of adjacent collaterals, leak into adjacent cavity, or localized extraluminal accumulation
    - Isolated abnormal flow into lungs in neonate → pulmonary lymphatic disorder, often with chylothorax

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Tachypnea & dyspnea
  - Classic symptoms of pleural effusion
    - ↓ breath sounds, usually with cough
- Other signs/symptoms
  - Generalized edema, chylous ascites, immunosuppression, protein-losing enteropathy (if gut is involved)

Natural History & Prognosis

- Thoracic duct injury may resolve spontaneously in 50%
- Poorer prognosis with syndromes, multiple sites of chylous fluid accumulations, prematurity

Treatment

- Conservative or medical treatment
  - ↓ chyle production
    - Fat-restricted oral diet
    - TPN
  - Rapamycin/sirolimus is of benefit with some lymphatic disorders, not clearly shown in conducting channel anomalies
  - Octreotide
- Interventions may be indicated with chyle leak > 1 L/day for 5 days or persistent leak for > 2 weeks
  - Thoracentesis or draining procedure of pleural space
  - Thoracic duct repair, lymphovenous anastomosis, ligation, or embolization
    - Ethiodized oil embolization is particularly effective in isolated neonatal chylothorax
  - Pleurodesis

Bronchopulmonary Dysplasia

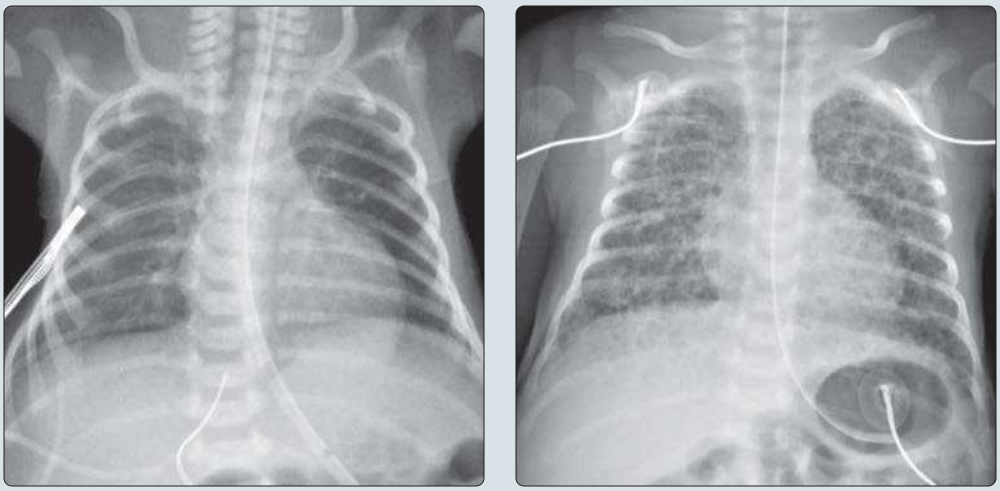
KEY FACTS

TERMINOLOGY

- Bronchopulmonary dysplasia (BPD), chronic lung disease of prematurity
- Old BPD: Occurred in larger, later preterm infants with prolonged mechanical ventilation & O_2 therapy
- New BPD: Occurs in earlier, smaller preterm infants with overall milder disease
  - Alveolar simplification & dysmorphic vasculature; more uniform parenchymal inflation, less fibrosis

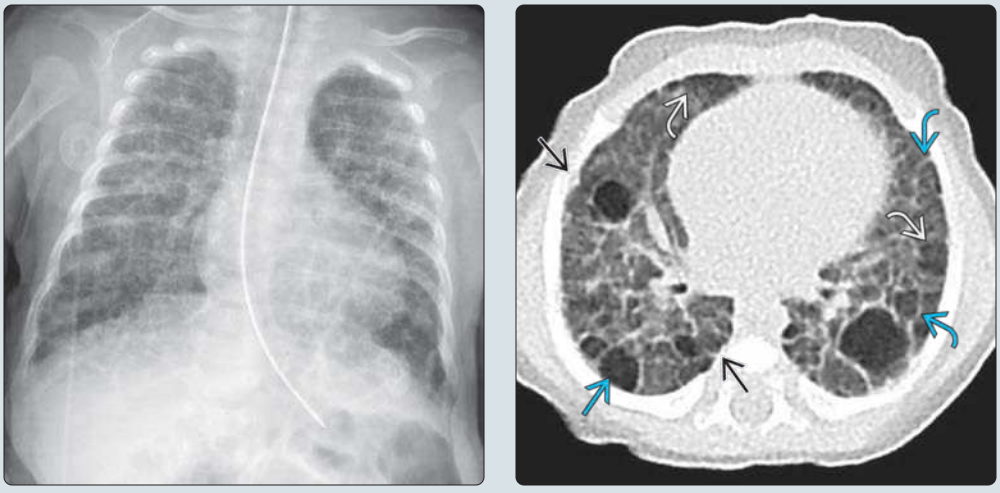
IMAGING

- Old BPD: Heterogeneous, hyperinflated lungs with patchy, focal lucencies + coarse, reticular, & band-like opacities
- New BPD: Diffuse, hazy opacification &/or cystic lucencies
  - Severe surfactant deficiency disease (SDD) patients may follow old imaging patterns
- Overlapping chest CT findings in old & new BPD
  - Subpleural opacities, septal thickening, air-trapping, emphysema, bronchiectasis, atelectasis, consolidation
- MR is emerging as useful modality
  - Gradient-echo & ultrashort echo time (UTE) sequences
  - Higher density lung tissues (fibrosis/inflammation) have higher signal intensity
- US may help predict progression to BPD in SDD



PATHOLOGY

- Antenatal & postnatal insults to immature lungs → impaired vascular & alveolar development
- Strongest predictors: Gestational age < 28 weeks, low birth weight, intrauterine growth restriction



CLINICAL ISSUES

- Affects 40% ≤ 28-weeks gestation, 68% of 22-26 weeks
- Most new BPD has mild/no initial respiratory disease → deterioration → slow improvement
- 16-25% develop pulmonary hypertension associated with up to 48% 2-year mortality
- Prevention: Antenatal steroids, exogenous surfactant, gentler ventilatory strategies, less aggressive oxygenation

(Left) *AP radiograph in a 1-day-old, 28-weeks-gestation infant shows hypoinflation with mild, hazy opacities, greater in the right lung than left.* **(Right)** *AP radiograph in the same infant at 3 weeks of age demonstrates hyperinflation with developing cystic & bubbly lucencies throughout the lungs. The patient was able to be managed with noninvasive positive pressure ventilation & did not require intubation.*

(Left) *AP radiograph in the same infant at 2 months of age demonstrates enlarging cystic spaces among coarsened, reticular opacities. The lungs demonstrate progressive hyperinflation.* **(Right)** *Axial CT of the chest in the same infant at 2 months of age shows characteristic findings of BPD, including subpleural opacities, cysts, air-trapping, & septal thickening. Due to difficulty in weaning respiratory support, CT was obtained for a more detailed characterization of the parenchymal abnormalities.*

TERMINOLOGY

Abbreviations

- Bronchopulmonary dysplasia (BPD)

Synonyms

- Chronic lung disease (CLD) of prematurity

Definitions

- Definition has continually evolved over last several decades
- Initial definition (1979): 28 days oxygen (O_2) requirement + characteristic radiographic changes
- Most recent definition (2018): Born at < 32-weeks gestational age (GA) + persistent parenchymal lung disease with radiographic confirmation + requires ≥ 3 consecutive days of defined respiratory support to maintain arterial O_2 saturation 90-95% at 36-weeks postmenstrual age (PMA)
  - Grades I-III based on degree of respiratory support required
  - Grade IIIA: Early death due to persistent parenchymal lung disease (between 14 days of age & 36-weeks PMA)
- Old BPD: Larger, later preterm infants with prolonged mechanical ventilation & O_2 therapy
  - Developed severe chronic respiratory failure with heterogeneous hyperinflation & fibrosis
- New BPD: Earlier, smaller preterm infants with overall milder disease in setting of antenatal steroids, postnatal surfactant administration, & gentler methods of ventilation/O_2 support
  - More uniform parenchymal inflation, less fibrosis, characterized by alveolar simplification & dysmorphic vasculature

IMAGING

General Features

- Best diagnostic clue
  - Varying degrees of hazy opacities, cysts, hyperinflation, & coarse linear opacities diffusely in premature infant

Radiographic Findings

- Old BPD
  - Heterogeneous lung parenchyma with patchy, focal lucencies separated by coarse, reticular, & band-like opacities of fibrosis, atelectasis
- New BPD
  - Diffuse, hazy opacification &/or bubbly, cystic lucencies

CT Findings

- Overlapping chest CT findings between old & new BPD
  - Linear or triangular subpleural opacities
  - Thickening of interlobular septa
  - Air-trapping, mosaic attenuation, emphysema, bullae
    - Minimum intensity projection (MinIP) images highlight mosaic attenuation
  - Bronchiectasis, peribronchial thickening
  - Atelectasis or consolidation; architectural distortion
- Abnormalities are present on > 80% of adolescent & adult studies of former preterm infants with BPD
  - Subpleural opacities, air-trapping, bullae, & emphysema are most common
- Studies have shown CT correlation with disease severity, need for supplementary O_2 at discharge

MR Findings

- Current MR techniques can show hyperexpansion, mosaic lung attenuation, emphysema, cysts, subpleural opacities, & architectural distortion
  - Benefit of parenchymal detail without ionizing radiation
  - Sequences (GRE, UTE) can allow for nonsedated, quiet-breathing scans
- Gradient-echo (GRE) sequences depict areas of high tissue density (fibrosis, inflammation)
  - High tissue density = higher intensity
  - High contrast between high density fibrosis & remaining lung
  - Not able to differentiate hypodense lung tissue (alveolar simplification, emphysema, cysts) vs. normal lung
- Ultrashort echo time (UTE) radial/spiral acquisition sequences depict broader spectrum of tissue density
  - Higher density tissue = higher intensity; produces density-like intensity spectrum with resemblance to CT images
  - Allows differentiation of normal vs. hypodense lung tissue in addition to higher density abnormalities
- Cardiac MR may be of utility in patients with concern for pulmonary vascular disease (PVD) & pulmonary hypertension (HTN)
  - Echocardiogram can be challenging due to poor sonographic windows, hyperinflation; MR may be noninvasive alternative to gold standard cardiac catheterization
- Potential for future functional imaging utilizing hyperpolarized gas MR methods

Ultrasonographic Findings

- Investigation into lung ultrasound for diagnosis/prediction of BPD is ongoing but not yet practical vs. radiography
  - Homogenous hyperechogenicity (echogenicity = diaphragm) of lung bases is described with surfactant deficiency disease (SDD)
  - Subsequent development of streaky, irregular areas of lower echogenicity between days 9-18 may predict progression to BPD

Nuclear Medicine Findings

- V/Q scan: Ventilation/perfusion mismatch

Imaging Recommendations

- Best imaging tool
  - Chest radiography for early monitoring; CT for more detailed assessment of structural changes

DIFFERENTIAL DIAGNOSIS

Pulmonary Interstitial Emphysema

- Air in interstitium of premature neonate, usually on positive pressure ventilation
- Cystic & linear lucencies, often in background of SDD
  - May create unique dot-dash appearance of interstitial air collections surrounding pulmonary vessels
- Usually rapid onset in first 10 days of life
- Typically transient with switch to high-frequency ventilation

Meconium Aspiration

- Aspiration of meconium-stained amniotic fluid → toxic pneumonitis

- Usually in postmature infants ± distress in utero
- Rapid onset of radiographic changes
- Coarse perihilar opacities with hyperinflation ± pneumothorax, pneumomediastinum

Neonatal Pneumonia

- Often bilateral & diffuse but may be unilateral
- Pleural effusion is common, unlike BPD

Congenital Pulmonary Airway Malformation

- Often fluid-filled, multicystic mass at birth with progressive aeration due to airway communication
- Typically involves 1 lobe
- Smaller lesions may present later in life

Congenital Lobar Overinflation

- Opacified lobe with progressive aeration & expansion
- Asymptomatic until significant compression of adjacent lung &/or mediastinum occurs

PATHOLOGY

General Features

- Etiology
  - Disease of preterm low birth weight infants with (still emerging) multifactorial etiology
    - Likely result of antenatal & postnatal insults to immature/developing lungs
      - Maternal, (epi)genetic, infectious/inflammatory, & microbiome/dysbiosis factors are possible contributors
      - Mechanical ventilation & oxygen exposure
      - Disordered repair mechanisms in response to postnatal insults may play role
    - Greatest risk factors: GA < 28 weeks, lower birth weight, intrauterine growth restriction
      - 24- to 28-weeks gestation: Time of transition from canalicular through saccular stage of pulmonary development
  - Old BPD resulting from volutrauma & O_2 toxicity is less common now
    - Due to antenatal steroids, early surfactant administration, gentler ventilation, & oxygenation

Microscopic Features

- Old BPD
  - Airway injury, inflammation, & metaplasia
  - Smooth muscle hypertrophy of airways & vessels
  - Patchy atelectasis, emphysema, & septal fibrosis
- New BPD
  - Uniform inflation, less heterogeneity, less interstitial fibrosis
  - Impaired vascular & alveolar growth
    - Alveolar simplification
    - Dysmorphic vessels, abnormal capillary distribution

CLINICAL ISSUES

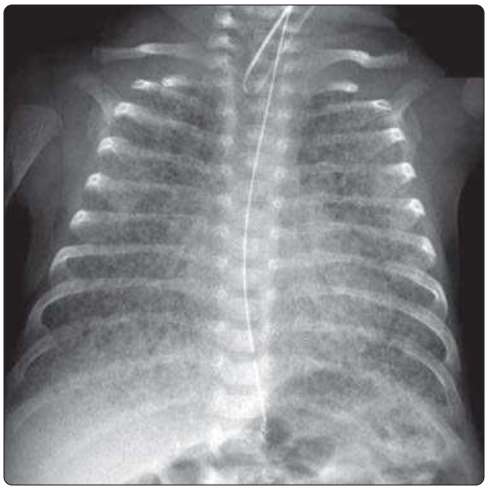
Presentation

- Most common signs/symptoms
  - New BPD is often mild or no respiratory disease initially followed by progressive deterioration
    - Most have subsequent slow improvement & wean respiratory support
    - Some worsen, ± development of pulmonary HTN
  - Patients with severe SDD may progress like old BPD

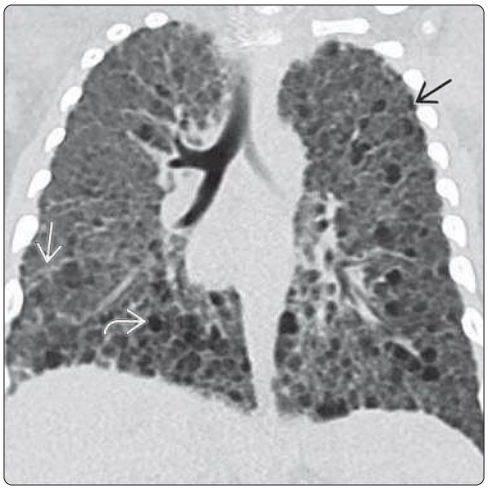
Demographics

- Age
  - Premature infants < 32-weeks gestation at birth
- Sex
  - M:F = 2-5:1
- Epidemiology
  - Most common chronic pulmonary disease of infancy
    - 40% of ≤ 28-weeks-gestation infants; 68% of 22- to 26-weeks gestation
    - 25% of infants weighing < 1,500 g at birth; 40% of those weighing < 1,000 g
  - Unchanged incidence of BPD since initial description
    - Due to ↑ survival of very premature infants

Natural History & Prognosis



- ↑ risk of pulmonary infections in first 2 years of life with ↑ morbidity & mortality, especially with RSV
  - Slowly improving pulmonary function with fewer respiratory infections later in childhood
  - > 50% hospital readmission rate during infancy
- Pulmonary HTN in 16-25% of BPD patients
  - Up to 48% 2-year mortality in this group
- Abnormal pulmonary function with ↑ airway hyperreactivity & obstruction may persist into adulthood



Treatment

- Many conflicting results in BPD prevention/therapy trials
- For prevention (strongest evidence)
  - Antenatal steroids
  - Exogenous surfactant
  - Gentle ventilation (noninvasive delivery, pressure limited, volume targeted)
  - Lower inspired oxygen concentrations, lower oxygenation targets
  - Vitamin A
- Less conclusive evidence: Caffeine, early PDA closure, inhaled nitric oxide, postnatal steroids (inhaled vs. systemic), sildenafil, Clara cell 10 protein

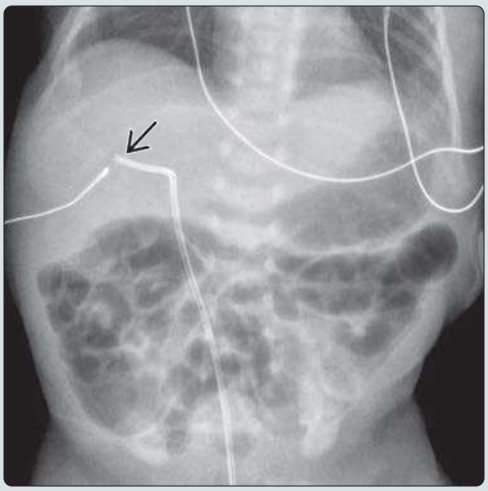
Umbilical Catheter Positions and Complications

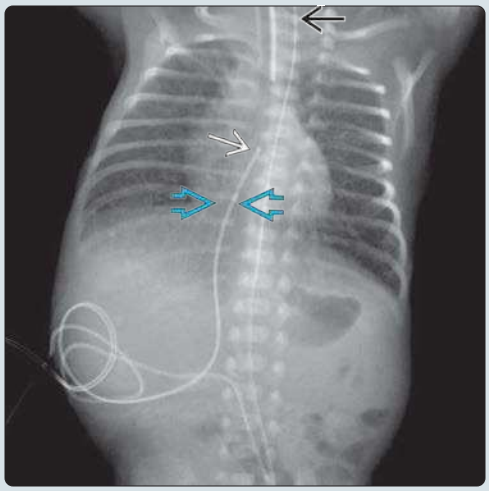
KEY FACTS

TERMINOLOGY

- Umbilical venous catheter (UVC)
  - Normal course: Umbilical vein → umbilical recess → crosses left portal vein → ductus venosus → middle or left hepatic vein → inferior vena cava (IVC) → right atrium (RA)
  - Indications: Central venous access in ill/premature neonate for fluids/medications, TPN, exchange transfusion, venous pressure monitoring
- Umbilical arterial catheter (UAC)
  - Normal course: Umbilical artery → internal iliac artery → common iliac artery → aorta
  - Indications: Frequent blood sampling, monitoring of arterial pressures, angiography, exchange transfusion

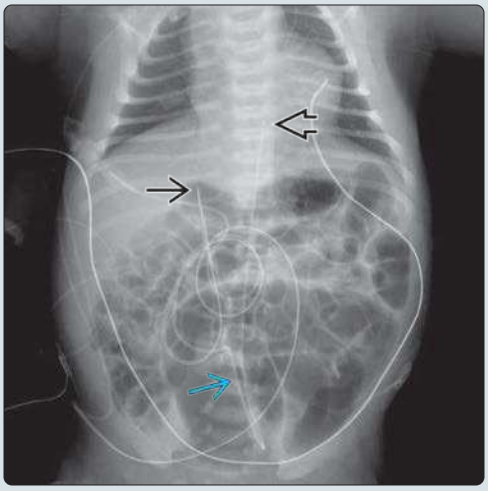


IMAGING

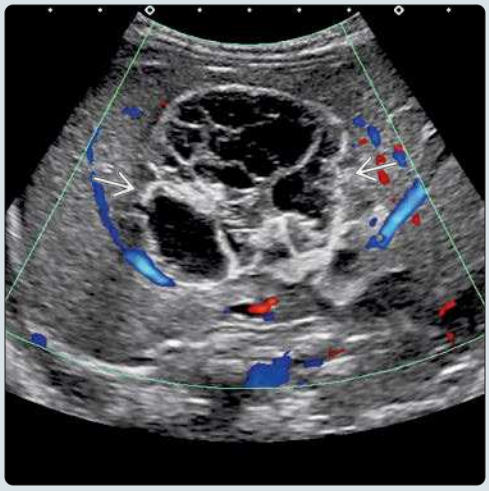


- UVC tip optimal location: IVC-RA junction
  - At/just above diaphragm, usually T8-T9
- UAC tip optimal location
  - Ideal high line: Descending thoracic aorta (T6-T10)
  - Acceptable low line: Distal abdominal aorta (L3-L4)
- Complications include
  - UVC or UAC: Malposition, thrombosis, infection
  - UVC: Hepatic laceration, hematoma, TPN extravasation (intrahepatic or intraperitoneal), arrhythmia, atrial perforation, pericardial effusion
    - Hepatic extravasation may mimic mass
  - UAC: Aneurysm/pseudoaneurysm

DIAGNOSTIC CHECKLIST



- Correct position must be confirmed prior to use
- Umbilical catheter position is most quickly assessed by AP chest/abdomen radiograph
  - Cross-table lateral view can provide additional detail
- Ultrasound is most reliable way to confirm appropriate UVC position initially or with abnormal anatomy
- Ultrasound is best modality to assess complications



(Left) *AP radiograph shows malposition of a umbilical venous catheter (UVC) ⇨, which courses laterally over the liver shadow. This catheter tip is likely within the right portal vein.* **(Right)** *AP radiograph shows malposition of a umbilical arterial catheter (UAC) ⇨ into the left common carotid artery, though the tip is not included on this image. A malpositioned UVC tip ➡ courses toward the left atrium across a patent foramen ovale (PFO). Ideal radiographic position ⇨ of the UVC tip would be at or just above the diaphragm.*

(Left) *AP radiograph of the chest & abdomen in a newborn shows a low position of the UVC ⇨, which may be in the umbilical vein or recess. There is a satisfactory UAC position ⇨. Note the initial caudal course of the UAC ⇨, which can be useful in differentiating umbilical catheters.* **(Right)** *Transverse Doppler ultrasound of the liver in the same patient at 26 days old shows a heterogeneous, septated, avascular lesion ➡. The appearance & subsequent evolution were consistent with a hematoma complicating a malpositioned UVC.*

TERMINOLOGY

Definitions

- Umbilical venous catheter (UVC)
  - Normal course: Umbilical vein → umbilical recess → crosses left portal vein → ductus venosus → central portion of middle or left hepatic vein → inferior vena cava (IVC) → right atrium (RA)
  - Indications: Fluids/medications, TPN, exchange transfusion, venous pressure monitoring
- Umbilical arterial catheter (UAC)
  - Normal course: Umbilical artery → internal iliac artery → common iliac artery → aorta
  - Indications: Frequent blood sampling, monitoring of arterial pressures, angiography, exchange transfusion

IMAGING

Radiographic Findings

- UVC tip optimal location: IVC-RA junction
  - Best radiographic correlate is controversial
    - At/just above diaphragm; vertebral level is variable, most recommend T8-T9
  - Portal venous gas may be normal transient finding after placement
- UAC tip optimal location
  - Ideal high line: Descending thoracic aorta, T6-T10
  - Acceptable low line: Distal abdominal aorta, L3-L4
- Incorrect position in > 50% of 1st attempts
  - Common UVC malposition
    - Low: Umbilical vein or recess
    - High: RA, superior vena cava (SVC); right ventricle (via tricuspid valve); left atrium (via foramen ovale), pulmonary vein
    - Wrong vessel: Branch or main portal, splenic, or superior mesenteric vein
  - Common UAC malposition
    - Low: Internal iliac artery or branches (e.g., superior gluteal, inferior gluteal, pudendal)
    - High: Aortic arch or branch artery; pulmonary artery (via ductus arteriosus)
    - Wrong vessel: Celiac, superior mesenteric artery (SMA), renal arteries, lower extremity
- Correctly positioned catheter may be shifted or distorted with diaphragmatic hernia, large thoracic/abdominal mass, congenital heart disease, or heterotaxy

Ultrasonographic Findings

- Can be used to confirm catheter position during routine placement or if vascular anatomy is distorted/abnormal
- Normal catheter: Parallel echogenic lines surrounded by anechoic flowing blood in vessel lumen
  - Portal venous gas: Mobile echogenic foci in portal veins
- Thrombus: Lobular echogenic material surrounding catheter, often at tip
- Hepatic extravasation/hematoma/abscess (from UVC): May mimic mass
  - Multilobulated/multiseptated collection of variable echogenicity & heterogeneity
    - TPN collection/abscess may contain fat → hyperechoic rim on US, fat density on CT
  - Regresses after UVC removal, may calcify
- TPN ascites (UVC): Hypoechoic peritoneal fluid ± debris
- Aneurysm/pseudoaneurysm (UAC): Dilation or irregular outpouching of artery with turbulent flow on Doppler

PATHOLOGY

General Features

- UVC complications
  - Thrombosis: 13-30% of UVCs
    - Portal & hepatic veins are at highest risk
  - Hepatic complications: Tip proximal to ductus venosus or in portal vein
    - Vascular perforation, hepatic laceration → hematoma, extravasation of infusion
    - Infusion of hypertonic solution (often TPN) directed into portal venous rather than systemic circulation
      - Chemical irritation → parenchymal necrosis, abscess
    - May develop TPN ascites
  - Cardiac complications: Tip beyond IVC-RA junction
    - Arrhythmia, thrombotic endocarditis, atrial wall perforation with pericardial effusion ± tamponade, hemothorax
  - Up to 30% of UVCs fail prior to completion of UVC-dependent therapy
- UAC complications
  - Thrombosis, arterial aneurysm/pseudoaneurysm
    - Risk to aortic arch branches if tip above T5
    - Risk to abdominal aortic branches if tip at T12-L1
      - SMA: Gut ischemia, necrotizing enterocolitis
      - Renal arteries: Hypertension, kidney injury
    - Aortic thrombosis is more likely with low line
- Infection (UVC or UAC)
  - UVC placement is highest risk factor for neonatal sepsis

CLINICAL ISSUES

Treatment

- In general, reposition or remove malpositioned catheter
- Hepatic collections may require drainage
- Infection necessitates antibiotic therapy
- Incidental UVC or UAC thrombus may be observed (frequent spontaneous resolution)
- Symptomatic or propagating UVC or UAC thrombus: Heparinization ± thrombolytics

Esophageal Intubation

KEY FACTS

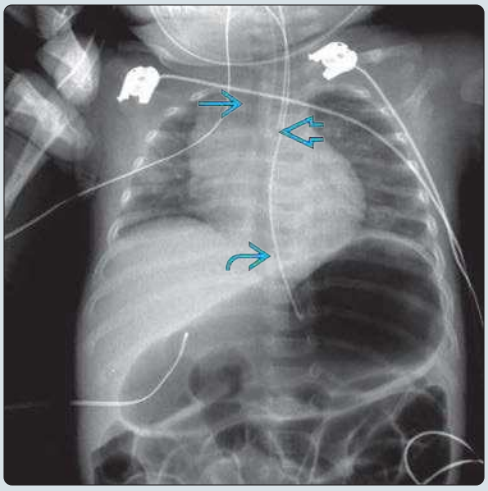
TERMINOLOGY

- Inadvertent placement of endotracheal tube (ETT) in esophagus

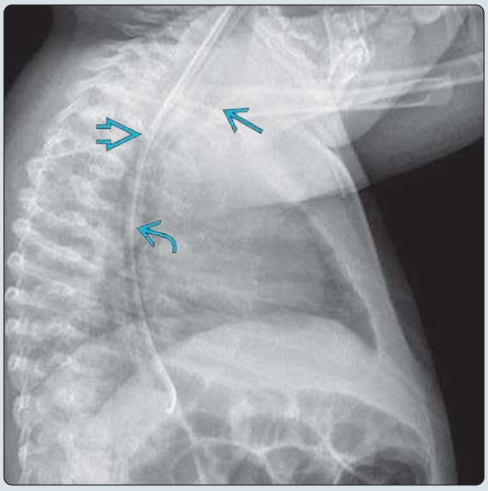
IMAGING

- Radiography
  - Esophagus normally lies posterior & left of trachea
  - Frontal view
    - Malpositioned ETT overlies esophageal air column, typically left of trachea
      - May directly overlie enteric tube
      - ± deviation of trachea to right
    - Malpositioned ETT may extend caudal to carina
    - Gaseous distention of stomach &/or esophagus
  - Lateral view
    - ETT overlies esophageal air column posterior to trachea
  - 25° right posterior oblique view with head turned right
    - Presents esophagus & trachea relationship en face
    - Facilitates visualization of esophagus to left of trachea
- Ultrasound
  - Point of care confirmation of ETT placement
  - Advantages: No radiation exposure, rapid detection of position in real-time at bedside, less handling of patient, potential for early surfactant delivery
  - Disadvantages: User dependent, lack of widespread availability
  - Technique & findings
    - High-frequency linear transducer is placed transversely on anterior neck just above suprasternal notch
    - Distortion of glottis & trachea is not observed with esophageal intubation
    - Lateral & posteriorly positioned esophagus is stented open by tube with hyperechoic curvilinear anterior wall & posterior acoustic shadowing
  - Ultrasound for esophageal intubation: Sensitivity 93%, specificity 97% in recent metaanalysis

TOP DIFFERENTIAL DIAGNOSES



- Tracheal intubation
  - ETT projects over tracheal air column
  - No significant esophageal distention
- Hypopharyngeal intubation
  - Ineffective ventilation
  - Gastric & esophageal distention
- Right main bronchus intubation
  - Left lung atelectasis
  - Right upper lobe atelectasis if ETT tip is distal to right upper lobe bronchus
- Tracheal perforation
  - Pneumomediastinum or pneumothorax
  - Aberrant lateral deviation of tube
- Tracheal intubation of tracheoesophageal fistula
  - Tip should be positioned distal to fistula
  - Tip may enter fistula, cause esophageal distention



CLINICAL ISSUES

- American College of Emergency Physicians policy for verification of endotracheal intubation
  - Confirm placement with: Direct visualization of tube passing through vocal cords, auscultation of chest & epigastrium, bilateral symmetric chest rise, fogging of ETT with respiration, pulse oximetry, chest radiography, capnography (most accurate)
- Complications of esophageal intubation
  - Hypoxemia, regurgitation, aspiration, cardiac dysrhythmia, death
- Esophageal intubation frequency in pediatrics
  - 28% of all intubation adverse events
  - Immediately recognized in 4.1% of intubations
  - Delayed recognition in 0.19% of intubations
    - Radiology may be 1st to recognize malposition

DIAGNOSTIC CHECKLIST

- Esophageal intubation is emergent finding, potentially fatal
- Immediate communication to clinical team is required

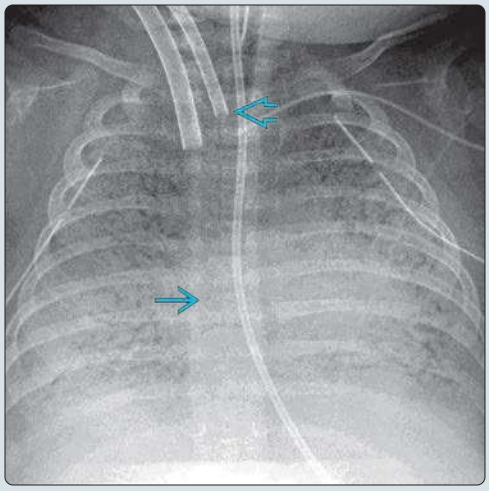
(Left) *AP radiograph in a septic 3-month-old shows the endotracheal tube to the left of the air-filled trachea, compatible with esophageal intubation. There is associated gaseous distention of the stomach & upper abdominal bowel loops. An enteric tube is also present.* **(Right)** *Lateral radiograph in a 3-month-old who required intubation for a sedated MR demonstrates the endotracheal tube projecting over the esophagus, posterior to the tracheal air column. An enteric tube is also present.*

KEY FACTS

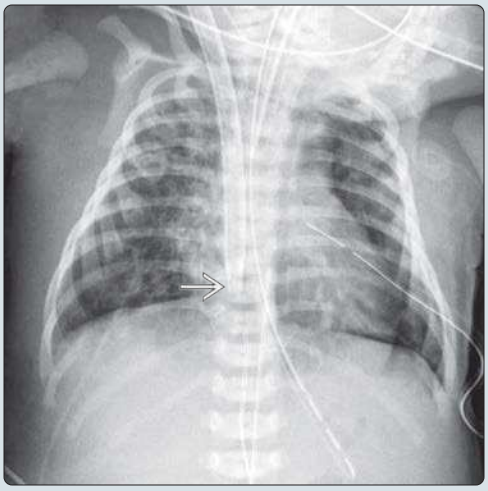
TERMINOLOGY

- Extracorporeal membrane oxygenation (ECMO): Modified pulmonary or cardiopulmonary bypass circuit
- Deoxygenated blood removed from venous system → oxygenated → returned to circulation via venous [venovenous ECMO (VV-ECMO)] or arterial system [venoarterial ECMO (VA-ECMO)]

IMAGING



- Radiographs to monitor catheter positions, complications
  - Most common VV-ECMO circuit
    - Internal jugular vein (dual- or triple-lumen catheter)
    - 1 or 2 lumina for venous extraction
    - 1 lumen for venous return of oxygenated blood
    - Tip in right atrium (RA) at posterior 8th or 9th rib
  - Most common VA-ECMO circuit
    - Internal jugular vein-common carotid artery (CCA)
      - Venous tip in RA at posterior 8th or 9th rib
      - Arterial tip in CCA origin at 2nd or 3rd posterior rib
  - Other circuits include
    - Femoro-femoral: VA-ECMO or VV-ECMO
    - RA-aorta/pulmonary artery: VA-ECMO
  - Right-sided vessels are favored for cannulation due to more direct central route; requires ligation of vessels
  - Expected radiographic findings
    - Generalized dense pulmonary opacification
      - Does not correlate with severity of lung disease
      - Related to low "rest" ventilator settings & systemic inflammatory response syndrome from bypass
- US to evaluate for intracranial hemorrhage or ischemia, thoracic & abdominal fluid collections
  - Benign enlargement of subarachnoid CSF spaces is common; may resolve after ECMO
- CT for suspicion of ECMO complication, underlying thoracic disease, delay in clinical improvement, &/or to identify & further characterize intracranial lesions beyond head US
- Imaging protocols vary by institution
  - Typically include head US & chest radiographs before & after ECMO is initiated & at specified intervals



PATHOLOGY

- Mechanical complications
  - General: Thrombus in circuit
    - Prevention requires adequate anticoagulation
  - Venous cannula too distal: Peripheral venous return obstruction, blocked sideholes ↓ venous extraction
  - Venous cannula too proximal: Sideholes outside lumen or dislodged → ↑ risk air of emboli, hemorrhage
  - Arterial cannula too distal: Aortic flow obstruction, ↑ left ventricle afterload
  - Arterial cannula too proximal: Inadvertent dislodgement → ↑ risk of hemorrhage
- Clinical complications
  - Intracranial hemorrhage & ischemia are most common
    - 85% of hemorrhages occur in first 72 hours
      - Common locations: Intraparenchymal (64%), posterior fossa (27%)
    - Risk of ischemia ↑ with duration of ECMO
  - Other complications: Lung consolidation, infarction, necrosis ± cavitation, barotrauma, hemothorax, pulmonary emboli; intra-/retroperitoneal hemorrhage, adrenal hemorrhage, solid organ infarct

CLINICAL ISSUES

- Indications: Severe reversible cardiac &/or respiratory failure: Meconium aspiration, congenital diaphragmatic hernia, pulmonary hypertension, sepsis, cardiomyopathy, preoperative stabilization of congenital heart disease
  - Respiratory failure + normal cardiac function → VV-ECMO
  - Cardiac or cardiopulmonary failure → VA-ECMO
- Contraindications: < 34-weeks gestation, birth weight < 2 kg, mechanical ventilation > 10-14 days, significant coagulopathy, uncorrectable congenital heart defects, lethal anomalies, major intracranial hemorrhage, irreversible brain damage

(Left) *AP chest radiograph in a 4-month-old with sepsis shows a venous ECMO cannula radiopaque marker projecting over the right atrium at T8. The arterial catheter projects over the common carotid artery origin at T2-T3. The pulmonary opacities & interstitial emphysema relate to underlying pulmonary disease.* **(Right)** *AP chest radiograph of a 5-day-old term infant with meconium aspiration shows the venovenous ECMO cannula tip in the right atrium at the T9 level.*

PICCs

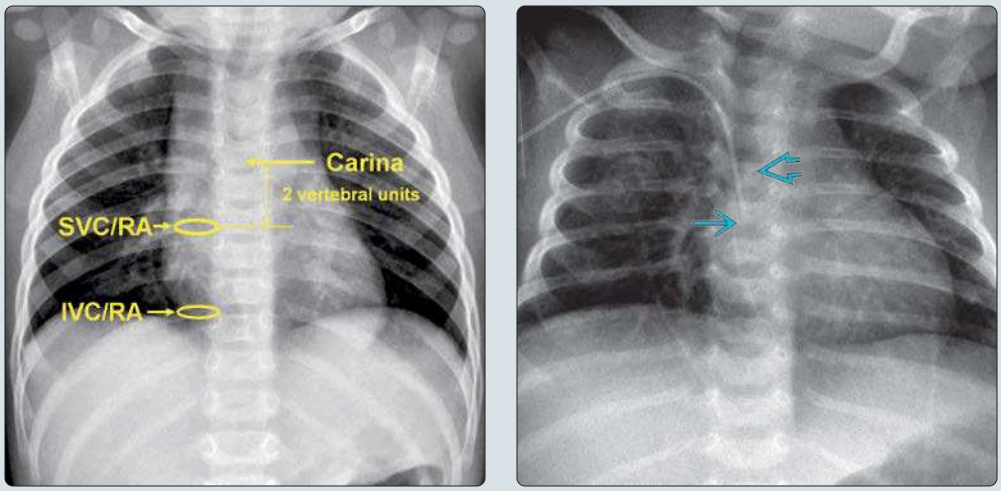
KEY FACTS

TERMINOLOGY

- Vascular line inserted percutaneously into peripheral vein with tip residing in central vein

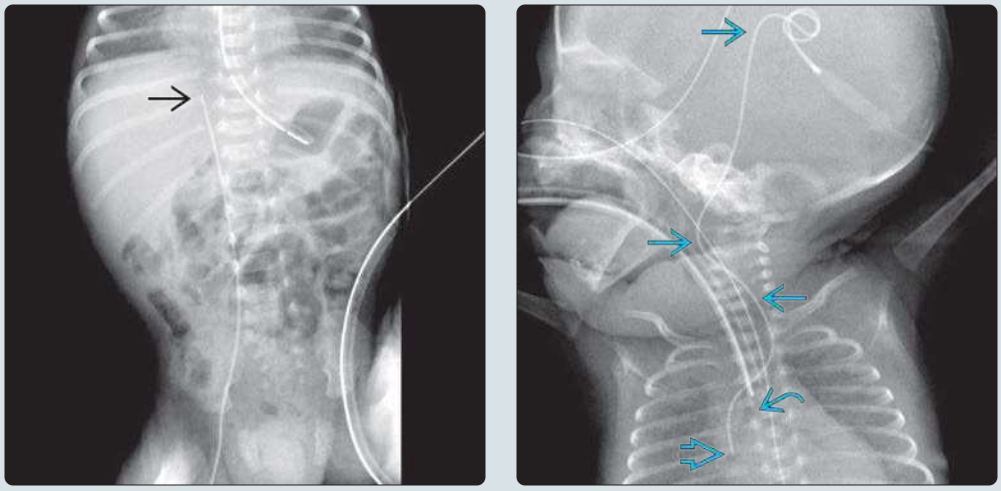
IMAGING

- Optimal upper extremity tip position: Lower 1/3 of superior vena cava (SVC), near SVC-right atrial (RA) junction
  - SVC-RA junction: ~ 2 vertebral bodies + disc spaces ("vertebral units") below carina
  - Approximate SVC boundaries: Superior at right tracheobronchial angle, inferior just below right superior cardiac border
  - SVC is always to right of trachea
    - Descent left of trachea suggests venous or arterial malposition (or possibly left-sided SVC)
      - Must confirm presence of left SVC with cross-sectional imaging prior to PICC use
  - Tip is most cranial when arm is at straight 90° abduction
  - Tip appears caudal with supine position & poor inspiration
- Optimal lower extremity PICC position: IVC-RA junction
  - IVC-RA junction: ~ T8 or T9, close to level of diaphragm
  - Consider ascending lumber or inferior epigastric vein malposition with kink or bend, zigzag paraspinal course, or failure of left approach PICC to cross midline at L5



PATHOLOGY

- Risk of complications is 8x greater if tip is noncentral
- Complications include: Thrombosis, thrombophlebitis, infection, sepsis, pulmonary embolus, mechanical malfunction, extravasation, arrhythmia, myocardial perforation, arterial placement with distal tissue necrosis



CLINICAL ISSUES

- Indicated for long-term central venous access (1-8 weeks): Antibiotics, TPN, repeated transfusions, short course of chemotherapy, frequent venous sampling, central venous pressure measurements, tenuous venous access

(Left) *AP chest radiograph depicts commonly used radiographic definitions of the superior vena cava (SVC)-right atrium (RA) & inferior vena cava (IVC)-RA junctions.* **(Right)** *Supine chest radiograph in a 3-month-old with meningitis shows a right upper extremity peripherally inserted central catheter (PICC) tip ⇨ projecting ~ 2 vertebral bodies below the carina ⇨ in the region of the SVC-RA junction.*

(Left) *AP abdominal radiograph shows a right lower extremity PICC tip ⇨ in an appropriate position in the IVC above the level of the renal veins & below the right atrium.* **(Right)** *Supine chest radiograph in a premature infant demonstrates a scalp PICC ⇨ with its tip ⇨ projecting ~ 2 vertebral units below the carina ⇨ in the expected region of the SVC-RA junction.*

TERMINOLOGY

Definitions

- Peripherally inserted central catheter (PICC): Vascular line inserted percutaneously into peripheral vein with tip residing in central vein

IMAGING

General Features

- Location
  - Most common insertion sites
    - Upper extremity veins: Basilic, cephalic, brachial
    - Lower extremity veins: Saphenous; occasionally deep veins used, especially in newborns
    - Scalp veins are used if extremity access is difficult
  - Tip considered central if in
    - Right atrium (RA): Not recommended due to risks of perforation & arrhythmia (specific to PICCs)
    - Superior vena cava (SVC), inferior vena cava (IVC) above renal veins
    - Brachiocephalic veins (controversial)
  - Central tip position allows for effective infusion with appropriate hemodilution given greater blood flow

Radiographic Findings

- Optimal upper extremity PICC position: Lower 1/3 of SVC, near SVC-RA junction
  - Definition of SVC on AP chest radiograph is controversial as use of landmarks varies
    - Best estimation of SVC-RA junction: 2 vertebral units (bodies + disc spaces) below level of carina
    - Superior SVC boundary: Right tracheobronchial angle
    - Inferior SVC boundary: Below right superior cardiac border
  - SVC remains right of trachea, even on rotated image
- Optimal lower extremity PICC position: IVC close to IVC-RA junction, above renal veins
  - Landmarks on supine radiograph
    - IVC-RA junction: ~ T8 or T9, close to diaphragm
    - Renal vein entrance to IVC: ~ L1
    - Common iliac vein confluence at IVC: ~ L5
- Malposition examples
  - Arterial: PICC descends left of trachea/midline (upper approach) or ascends left of midline (lower approach)
  - Internal jugular vein: Tip directed cephalad into neck
  - Left SVC: PICC descends left of trachea, typically from left upper extremity approach
    - Must be confirmed with prior or subsequent cross-sectional imaging (including echocardiography) before use
    - Acceptable except in rare circumstances of left SVC draining into left atrium
  - Ascending lumbar veins
    - Arise from common iliac veins at L5-S1
    - Left approach PICC fails to cross midline at L5
    - Bend or kink at L4-L5 with paraspinal zigzag course
    - Marked posterior deviation at L4-S1 on lateral view
  - Inferior epigastric veins
    - Arise from external iliac veins
    - Anterior course on lateral view

Imaging Recommendations

- Protocol advice
  - If position is unclear, inject contrast during fluoroscopy
    - If arterial position is being questioned, retract tip to lateral subclavian prior to injection (to avoid neck arteries)

PATHOLOGY

General Features

- Complications: 1-19 per 1,000 catheter days
  - Infection, sepsis (↑ with PICC duration)
  - Arterial placement can lead to distal tissue necrosis
  - Pulmonary embolus (air, thrombus, catheter fragment)
  - Mechanical malfunction (catheter damage, extravasation or leakage, unplanned catheter removal)
  - Thrombosis & thrombophlebitis
  - Arrhythmia or myocardial perforation if tip is in RA
  - Spinal cord injury if tip is in lumbar vein
- Risk of complications is 8x greater if tip noncentral
  - ↓ vein diameter → ↓ blood flow/hemodilution → ↑ turbulence + prolonged intimal contact of infusates → ↑ risk of endothelial injury

CLINICAL ISSUES

Indications

- Need for intermediate or long-term central venous access (1-8 weeks): Antibiotics, TPN, repeated transfusions, short course of chemotherapy, frequent venous sampling, central venous pressure measurement
- Tenuous venous access otherwise

DIAGNOSTIC CHECKLIST

Consider

- Each institution should develop standard PICC placement/verification protocols, nomenclature, & communication criteria
- PICC position varies with respiratory motion & arm position

Reporting Tips

- Avoid phrase "cavoatrial junction" as this could represent either SVC-RA or IVC-RA junction

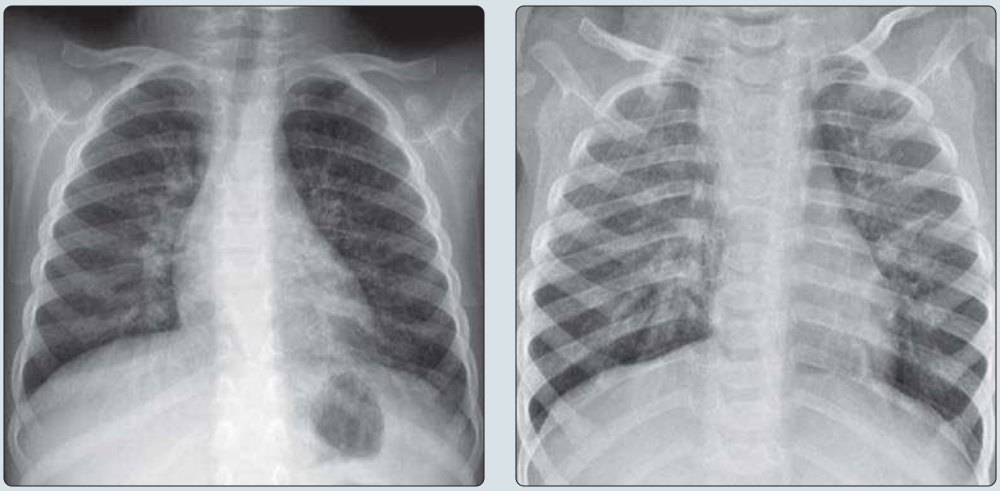
Viral Chest Infection

KEY FACTS

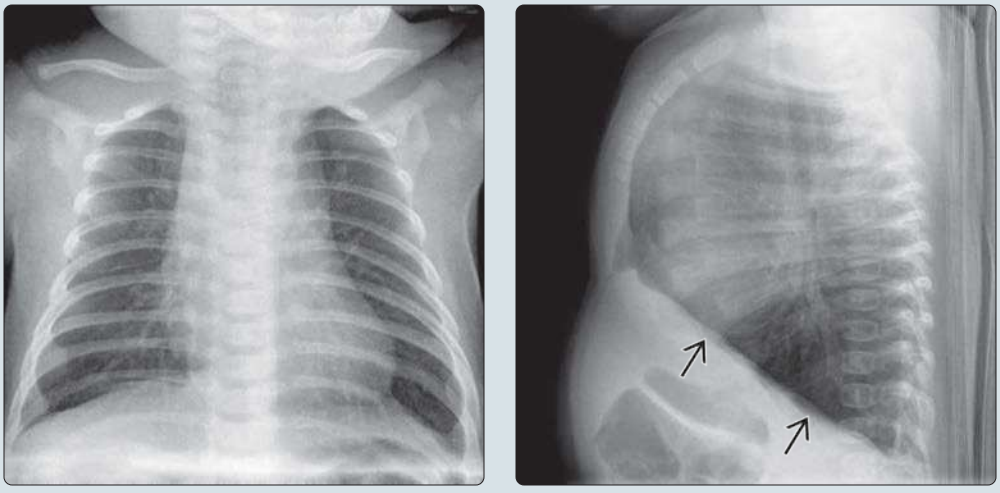
TERMINOLOGY

- Viral infection may involve airways &/or lung parenchyma (alveoli, interstitium)
- Bronchiolitis: Acute inflammation & necrosis of epithelial cells lining small airways with ↑ mucus production
  - Classically < 2 years of age
- Other terms: Viral pneumonia, lower respiratory tract infection, peribronchial pneumonia



IMAGING

- Primary goal of chest radiography: Differentiate viral airway infection from bacterial pneumonia (which requires antibiotics)
  - 92% negative predictive value for bacterial pneumonia
- Best imaging clues for viral airway infection
  - ↑ peribronchial markings
    - Radiating coarse linear or "dirty" perihilar opacities
    - "Doughnuts" of circumferentially thickened bronchial walls (viewed in cross section)
  - Hyperinflation: Depression of hemidiaphragms with downward sloping on lateral view; ↑ AP chest diameter on lateral view; ± convex bulging of lungs between ribs
  - Subsegmental atelectasis, possibly multifocal
  - Lack of focal/lobar consolidation or pleural effusion
- Best imaging clues for viral parenchymal involvement
  - Interstitial, nodular, or patchy ground-glass opacities



CLINICAL ISSUES

- Pathogens detected in hospitalized pediatric pneumonia patients: Viral 73%, bacterial 15%
- Most common viral etiologies differ by age
  - RSV < 2 years, rhinovirus > 2 years
- Treatment
  - Antibiotics for concomitant bacterial infection
  - Nebulized hypertonic saline in hospitalized infants may shorten length of stay
  - Antiviral therapy where indicated

(Left) *Frontal chest radiograph in a 2-year-old with viral bronchiolitis shows symmetric, mild hyperinflation with ↑ perihilar peribronchial markings, as is commonly seen with small airways infection.* **(Right)** *PA view of the chest in an 11-month-old shows mildly hyperinflated lungs with ↑ perihilar peribronchial opacities, consistent with bronchiolitis secondary to known human metapneumovirus infection.*

(Left) *AP radiograph in a wheezing infant shows hyperinflated lungs with ↑ rope-like perihilar markings, consistent with viral airways disease. There is no focal lung consolidation.* **(Right)** *Lateral radiograph in the same infant shows marked hyperinflation with flattening of the hemidiaphragms ⇨ (much more evident than on the corresponding frontal view) & widening of the AP diameter of the chest. Also note the ↑ markings radiating from the hila.*

TERMINOLOGY

Definitions

- Terminology varies, can be confusing
- Bronchiolitis (per American Academy of Pediatrics): Viral lower respiratory tract infection in infants affecting small airways with inflammation, edema, & epithelial necrosis
- Lower respiratory tract infection may describe findings identical to bronchiolitis in patients ≥ 2 years old but may also refer to any infection of lower airways & parenchyma
- Viral pneumonia may refer to viral infection of lung parenchyma ± airways
- Peribronchial pneumonia is sometimes used to differentiate airways infection from parenchymal involvement
- Lower airways disease includes viral airways infection as well as asthma

IMAGING

General Features

- Best diagnostic clue
  - ↑ peribronchial markings, hyperinflation, interlobular septal thickening, & ground-glass densities
    - Dominant feature & distribution varies with pathogen
  - Lymphadenopathy, effusion, & pneumothorax are atypical

Radiographic Findings

- Primary goal: Differentiate viral airways infection from bacterial pneumonia
- Small airways viral infection
  - Lack of focal dense geographic, round, or "fluffy" lung consolidation (hallmark of bacterial infection)
  - ↑ peribronchial markings/↑ number of visible bronchi
    - Symmetric, coarse linear markings radiating from hila
    - ↑ thickness of bronchial walls appearing as "doughnuts" in cross section
    - Central lungs may appear "dirty" or "busy"
    - Hila may appear prominent on lateral view
    - Somewhat subjective finding
  - Hyperinflation
    - Hyperlucency
    - Depression of diaphragm > 10 posterior ribs or > 6 anterior ribs
    - Flattening/downward sloping hemidiaphragms
    - ↑ AP chest diameter (in infants, chest wider than tall on lateral view)
    - ± convex bulging of lungs between ribs
    - Less common > 2 years old (as bronchi are larger & less prone to narrowing or obstruction by inflammation)
  - Subsegmental atelectasis
    - Wedge-shaped or triangular opacities, often narrow
    - Commonly misinterpreted as bacterial pneumonia
- Parenchymal involvement
  - Interstitial nodular or patchy/hazy opacities
  - Lobar consolidation rarely occurs
  - Associated findings of airways infection

CT Findings

- Not used primarily to make diagnosis of viral disease but may be obtained in patient with unclear clinical/imaging presentation or concerns for complications
- Small airways viral infection
  - Prominent, ill-defined hila & peribronchial markings radiating into lung
  - Bronchial & bronchiolar wall thickening
  - Mosaic attenuation: Patchy heterogeneity of attenuation due to hypoventilation & air-trapping
- Parenchymal involvement
  - Interlobular septal thickening
  - Patchy, ill-defined consolidation
  - Ground-glass opacities (GGO)
  - Nodules, micronodules
  - ± findings of small airways infection

General Features of Epidemic & Pandemic Pathogens

- SARS-CoV-2 (COVID-19)
  - Bilateral peripheral/subpleural GGO ± consolidation with lower lung zone predominance
  - Reverse halo sign: Consolidation with rim of GGO
  - Associated with multisystem inflammatory syndrome
- SARS-CoV
  - Uni-or multifocal, peripheral or peripheral & central GGO ± consolidation with mid & lower lower lung zone predominance
- MERS
  - Bilateral peripheral GGO ± consolidation with lower lung zone predominance
  - Interstitial reticular opacities
  - Pleural effusion & pneumothorax are more common in fatal cases
- H1N1
  - Bilateral bronchovascular thickening, multifocal central GGO ± consolidation with lower lung zone predominance
  - Peribronchial thickening & peribronchovascular nodular densities
  - Pneumomediastinum is seen with some cases

Imaging Recommendations

- Best imaging tool
  - Chest radiographs (frontal & lateral)
    - Goal: Antibiotic therapy for all children with bacterial pneumonia while minimizing unnecessary antibiotic administration (for isolated viral infection)
      - Positive predictive value (PPV) for identifying bacterial pneumonia 30%
      - Negative predictive value (NPV) for excluding bacterial pneumonia 92%
    - Difficult to differentiate viral from bacterial pneumonia (i.e., lung parenchymal infection) on imaging
      - One study showed lobar infiltrate in 15% of exclusively viral pneumonia & exclusively interstitial infiltrate in 28% with bacterial pneumonia

DIFFERENTIAL DIAGNOSIS

Bacterial Pneumonia

- Focal/lobar lung consolidation > interstitial infiltrate

- Confluent geographic, round, or fluffy opacities
- Pleural effusions (more common than viral)
- Lack of ↑ peribronchial markings or hyperinflation

Asthma

- Small airways inflammation with ↑ peribronchial markings & hyperinflation (common to asthma & viral infection)
- Primary asthma diagnosis is difficult to establish in young children

Bronchial Foreign Body

- May present with wheezing very similar to viral disease
- Asymmetric hyperinflation is characteristic
  - Affected lung volume is static throughout respiratory cycle
- Foreign body is often radiographically occult

Left-to-Right Cardiovascular Shunts

- In infants, left-to-right shunts with ↑ pulmonary arterial flow may mimic ↑ peribronchial markings
- Shunts have associated cardiomegaly (& may cause air-trapping)

Miliary Tuberculosis

- Diffuse, small nodules; thickened, interlobular septa
- Lymphadenopathy (may be low in attenuation)
- History of sick contact with TB
- Very uncommon in young children

PATHOLOGY

General Features

- Etiology
  - Acute inflammation & necrosis of epithelial cells lining small airways with ↑ mucus production
  - ↓ caliber of small, relatively compliant airway lumina significantly ↑ resistance to airflow in infants
  - Occlusion of airways results in hyperinflation & foci of subsegmental atelectasis
  - Parenchymal findings vary: Interstitial pneumonitis with lymphocytic infiltration, infection of alveolar epithelium, diffuse alveolar damage, desquamation of pneumocytes, hyaline-membrane formation, alveolar hemorrhage
  - Typical pathogens
    - Bronchiolitis: RSV > rhinovirus, adenovirus, influenza > coronavirus, human metapneumovirus (hMPV), parainfluenza
      - Multiple viruses in up to 25%
    - Hospitalization-inducing, community-acquired pneumonia: RSV, rhinovirus > hMPV, adenovirus, *Mycoplasma pneumoniae*, parainfluenza, influenza, coronavirus, *Streptococcus pneumoniae*, *Staphylococcus aureus*, *S. pyogenes*

CLINICAL ISSUES

Presentation

- Signs & symptoms
  - Bronchiolitis: Rhinorrhea, cough, tachypnea, wheezing, rales, ↑ respiratory effort (grunting, nasal flaring, intercostal/subcostal retractions)
  - Community-acquired pneumonia: Cough, fever, anorexia, dyspnea, wheezing (up to 62%)
    - Difficult to differentiate bacterial from viral parenchymal infection based on physical exam or laboratory tests

Demographics

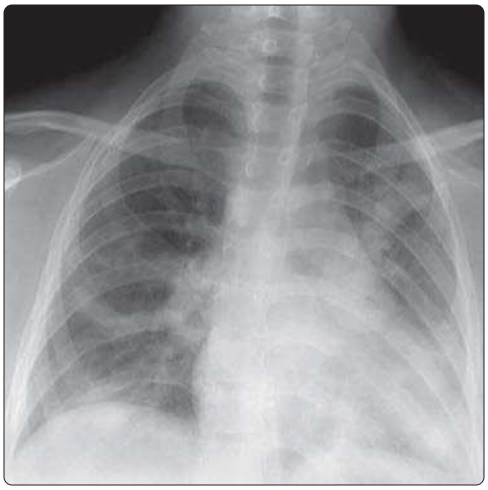
- Age
  - Typical striking radiographic findings of viral disease are more common in young children (< 5 years of age)
- Epidemiology
  - Bronchiolitis: Most common cause of hospitalization in 1st year of life
  - Viruses cause majority of chest infections in preschool children (4 months-5 years of age)
    - < 2 years old: RSV is most common
    - > 2 years old: Rhinovirus is most common
  - Pneumonia-related hospitalization from multicenter prospective study
    - Greatest in children < 5 years old
    - Viral in 73%, bacterial in 15%
  - Predisposing conditions for severe viral chest infections: Age < 6 months, prematurity, congenital heart disease, immunosuppression/immunodeficiency, asthma

Natural History & Prognosis

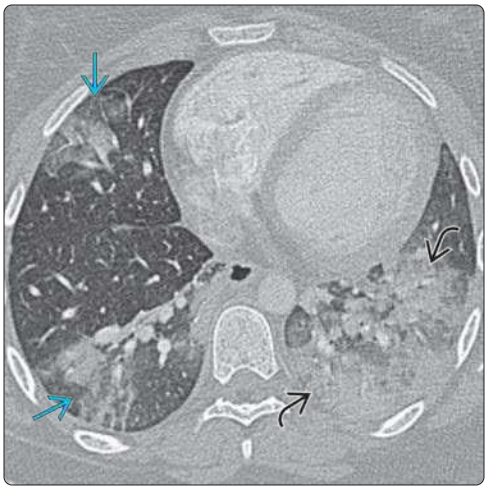
- Resolution of symptoms over time, typically days to weeks

Treatment

- Antibiotics only for concomitant bacterial infection
- Bronchiolitis
  - Nebulized hypertonic saline in infants may shorten hospitalization by increasing mucociliary clearance
  - Oxygen supplementation if saturations < 90%
  - Palivizumab (RSV prophylaxis, not vaccine): Given in 1st year of life to infants born before 29-weeks gestation or infants with hemodynamically significant heart disease or chronic lung disease of prematurity
  - Routine use of albuterol & nebulized epinephrine are not recommended
  - Corticosteroid use is not supported
- Clinical pneumonia with viral pathogen
  - Hospitalization for hypoxemia or respiratory distress
  - Antiviral therapy where indicated



DIAGNOSTIC CHECKLIST



Consider

- Consider aspirated foreign body if lung volumes are asymmetric

(Left) *Frontal radiograph in a 14-year-old with shortness of breath demonstrates patchy peripheral & basilar opacities.* **(Right)** *Axial CECT in the same patient depicts lower lung zone predominant peripheral patchy ground-glass densities mixed with consolidation as well as more confluent left lower lobe consolidation. The patient tested positive for COVID-19.*

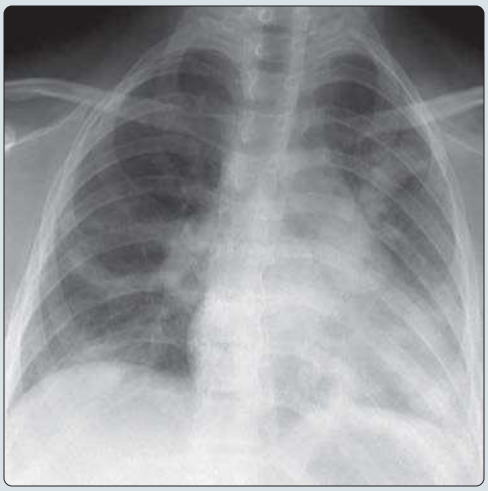
(Left) *Frontal chest radiograph in a 5-month-old patient with cough & difficulty breathing shows bilateral "dirty" perihilar peribronchial opacities & lung hyperinflation with diaphragm depression, consistent with bronchiolitis.* **(Right)** *Lateral radiograph in the same patient shows linear opacities extending from the hila, thickened bronchial walls, & downward sloping of the flattened hemidiaphragms. Note the widened AP dimension of the chest.*

(Left) *Frontal view of the chest in a 6-year-old with known influenza infection demonstrates bilateral ↑ perihilar peribronchial & reticulonodular opacities.* **(Right)** *Axial CECT in a 7-year-old patient with influenza A shows bilateral, patchy, consolidative & ground-glass opacities.*

KEY FACTS

TERMINOLOGY

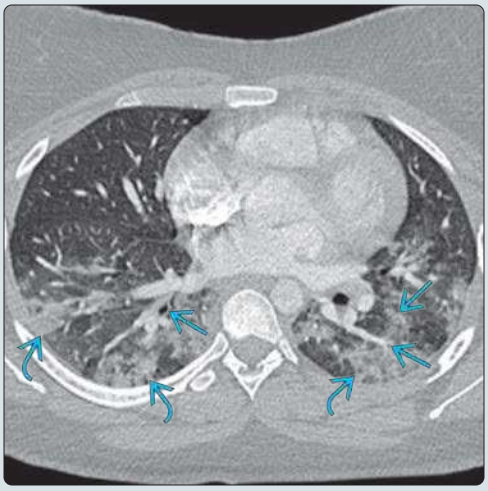
- COVID-19: Acute infection with SARS-CoV2
- MIS-C: Condition characterized by fever, inflammation, & multiorgan dysfunction that has temporal association with SARS-CoV-2 infection



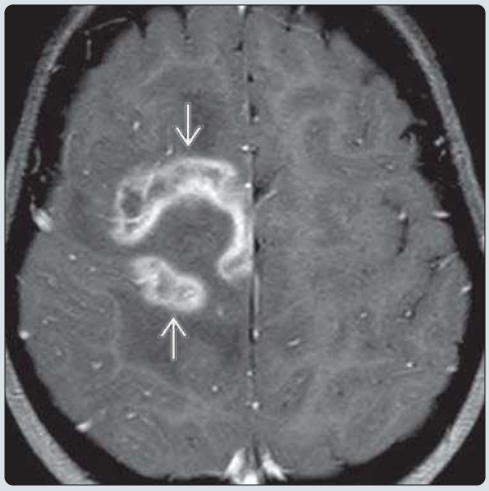
IMAGING

- COVID-19
  - Chest: Bilateral or unilateral peripheral subpleural &/or peribronchial lower lobe-predominant ground-glass opacities (GGO) ± consolidation, bronchial wall thickening, halo sign
    - Uncommon features: Nodules, cavitation, pleural effusions
  - Neuro: ADEM-like imaging pattern, myelitis, neuritis, cerebrovascular complications
- MIS-C
  - Cardiac in 86.5%: Left ventricular (LV) dysfunction, shock, myocarditis, coronary artery dilatation/aneurysm
  - GI: Ascites, RLQ inflammation, bowel wall thickening, pancreatitis, hepatomegaly, splenomegaly, gallbladder sludge, pericholecystic fluid, lymphadenopathy
  - Chest: Pulmonary edema, pleural effusions, GGO related to ARDS, pulmonary embolism
  - Neuro: ↑ T2 signal lesions + restricted diffusion in corpus callosum, restricted diffusion in thalami, focal cerebral arteriopathy, ADEM-like findings, myelitis, neuritis, cerebrovascular complications, myositis of face & neck

CLINICAL ISSUES



- COVID-19
  - Initial data showed less severe disease in children overall, though rates of infection & severity of disease have been affected by newer variants & vaccination rates/eligibility
- MIS-C
  - > 60% require ICU & vasopressors, mortality 1.8%
  - LV ejection fraction normalizes in most 1-2 weeks after presentation



(Left) *Frontal radiograph in a 14-year-old patient with shortness of breath & fever demonstrates hazy & patchy bilateral pulmonary opacities.* **(Right)** *Axial CECT in the same patient shows bilateral lower lung zone-predominant ground-glass & consolidative densities. The patient tested positive for COVID-19 on nasopharyngeal RT-PCR. Other features seen in pediatric cases of COVID-19 include bronchial wall thickening & the halo sign (not shown).*

(Left) *Axial CECT in a 17-year-old demonstrates bilateral symmetric lower lung zone-predominant ground-glass & patchy densities. Bronchial wall thickening is also noted.* **(Right)** *Axial T1 C+ FS MR in 9-year-old with left-sided weakness shows a right cerebral lesion with cortical enhancement & hemorrhagic necrosis (confirmed on T2 & SWI with minimal precontrast T1 shortening) due to COVID-19-associated vasculitis & infarction.*

TERMINOLOGY

Definitions

- COVID-19: Severe acute respiratory syndrome caused by SARS-CoV-2 virus
- Multisystem inflammatory syndrome in children (MIS-C): Condition characterized by fever, inflammation, & multiorgan dysfunction that has temporal association with SARS-CoV-2 infection

IMAGING

Radiographic Findings

- COVID-19
  - Bilateral or unilateral peripheral lower lobe-predominant patchy consolidation & ground-glass opacities (GGO)
- MIS-C
  - Cardiomegaly, pulmonary edema, pleural effusions, acute respiratory distress syndrome (ARDS)

CT Findings

- COVID-19
  - Bilateral or unilateral peripheral subpleural &/or peribronchial lower lobe-predominant GGO ± consolidation
  - Bronchial wall thickening (more common in children compared to adults)
  - Halo sign: Round consolidative opacity with rim of GGO
  - Uncommon: Pulmonary nodules, pleural effusions, cavitation, lymphadenopathy
- MIS-C
  - Chest: Pulmonary edema, pleural effusions, GGO related to ARDS, pulmonary embolism, lower lobe opacities
  - Cardiac: Cardiomegaly, coronary artery ectasia/aneurysm, pericardial effusion
  - GI: Ascites, right lower quadrant (RLQ) inflammation, bowel wall thickening, pancreatitis, hepatomegaly, splenomegaly, gallbladder sludge &/or wall thickening, pericholecystic fluid, lymphadenopathy

MR Findings

- COVID-19
  - Neurologic
    - Acute disseminated encephalomyelitis (ADEM)-like imaging pattern: Patchy ↑ T2 involving gray & white matter ± enhancement or diffusion restriction
    - Myelitis: Long-segment central cord ↑ T2
      - Rarely can rapidly progress to acute necrotizing myelitis with cord edema, enhancement, diffusion restriction, & hemorrhage
    - Neuritis: Enhancement of cranial/spinal nerves
- MIS-C
  - Cardiac
    - ↓ left ventricle ejection fraction (LVEF)
    - Valvular dysfunction
    - Myocarditis: Myocardial edema with ↑ T2 signal globally or at basal septal segments
  - Neurologic
    - Encephalopathy: ↑ T2 ± restricted diffusion in corpus callosum (splenium + genu), restricted diffusion in bilateral lateral thalamic nuclei
    - Focal cerebral arteriopathy: Cerebral artery stenosis, wall thickening, & concentric contrast enhancement
    - Susceptibility-induced signal drop-out due to parenchymal microthrombi
    - Myositis of neck & face musculature
    - ADEM-like imaging pattern, myelitis, neuritis

Ultrasonographic Findings

- COVID-19
  - Lung findings: Pleural irregularity, vertical artifact, confluent B lines, subpleural consolidation
- MIS-C
  - Echocardiography: Coronary artery ectasia/aneurysm, ↓ LVEF, LV diastolic dysfunction, ↑ echogenicity of interventricular septum & pericardium, valve dysfunction
  - GI: Ascites, RLQ inflammation, bowel wall thickening, pancreatitis, hepatomegaly, splenomegaly, gallbladder sludge, pericholecystic fluid, lymphadenopathy
  - Genitourinary: Echogenic kidneys

Imaging Recommendations

- COVID-19
  - Imaging is not indicated for screening or for known or suspected COVID-19 with mild disease without risk factors for progression
  - Chest radiograph is appropriate for initial imaging for pediatric patients with moderate-to-severe known/suspected COVID-19
  - Chest radiograph & CT can be considered for pediatric patients with known/suspected COVID-19 & worsening disease or lack of response to therapy
- American College of Rheumatology Clinical Guidance for Pediatric Patients with MIS-C
  - Imaging of chest, abdomen, &/or CNS as needed
  - Echocardiogram at diagnosis & during clinical follow-up & repeated at minimum of 7-14 days & 4-6 weeks after presentation; LV dysfunction & coronary artery aneurysm will require more frequent follow-up
  - Cardiac MR may be indicated 2-6 months after MIS-C diagnosis with significant transient LV dysfunction
  - Cardiac CT if suspicion of distal coronary artery aneurysm not well seen on echocardiogram

DIFFERENTIAL DIAGNOSIS

COVID-19 DDx

- **Other infectious pneumonias**
  - Bacterial: Typically focal, single segment or lobe
  - Fungal: Nodules, cavitation, air crescent sign
  - Viral (influenza): Centrilobular nodules
- **E-cigarette vaping-associated lung injury (EVALI)**
  - Subpleural sparing
  - Centrilobular nodules & GGO
  - Atoll sign
- **ADEM**
  - Similar imaging but may not meet clinical definition

Multisystem Inflammatory Syndrome in Children DDx

- **Kawasaki disease (KD)**
  - More common ≤ 5 years old
  - LV dysfunction & shock are less common in KD (~ 10%)

- Neurologic & GI findings are less common in KD
- KD is more common in patients of Asian descent, whereas MIS-C is more common in patients of African & Hispanic descent

- **Toxic shock syndrome**
  - Toxin-mediated systemic disease with shock & multiorgan failure caused by *Staphylococcus aureus* & *Streptococcus pyogenes*
- **Hemophagocytic lymphohistiocytosis (HLH)**
  - Gene-mediated or infection-/malignancy-triggered systemic hyperinflammation
  - Hemophagocytosis in liver, marrow, spleen, lymph nodes
- **Severe COVID-19 with hyperinflammation**
  - Respiratory symptoms are more prominent
  - MIS-C typically occurs 3-6 weeks after SARS-CoV2 exposure
- **Myocarditis of other etiologies**
  - Lack multisystem findings of MIS-C & temporal association with COVID-19
- **Infectious/inflammatory enterocolitis & appendicitis**
  - Lack multisystem findings of MIS-C & temporal association with COVID-19
- **ADEM**
  - Similar imaging but may not meet clinical definition
  - No temporal association with COVID-19
- **Postviral autoimmune encephalitis of other etiologies**
  - Similar encephalitis is also seen with herpes & West Nile virus infections
- **Other pediatric arteriopathies with acute stroke**
  - Moyamoya disease, arterial dissection, vasculitis

PATHOLOGY

General Features

- Single-stranded RNA virus
- Respiratory droplet transmission
- SARS-CoV2 binds ACE2 receptor & transmembrane serine protease 2 (TMPRSS2) & ↑ expression of proinflammatory cytokine IL-6, IL-8, & TNF-α
- ACE2 receptors are also found in heart, intestinal smooth muscle, liver, kidneys, neurons, & immune cells

CLINICAL ISSUES

Presentation

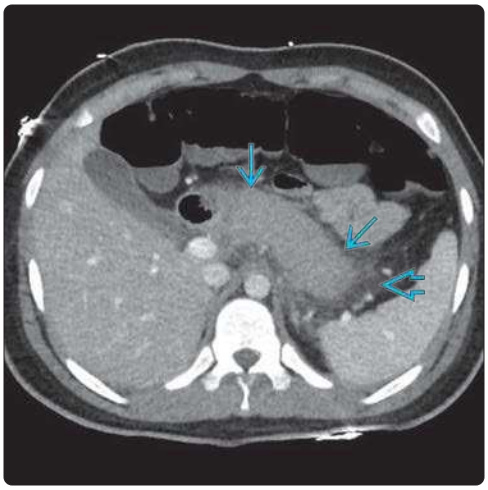
- Most common signs/symptoms
  - COVID-19
    - Fever, cough, sore throat, rhinorrhea, congestion, diarrhea, fatigue, dyspnea, rash, conjunctivitis
    - GI in > 50%: Diarrhea, abdominal pain, vomiting
    - ↑ CRP, ESR, LDH, D-dimer
    - Neutropenia, lymphopenia, thrombocytopenia
  - MIS-C CDC case definition
    - < 21 years old, fever, laboratory evidence of inflammation (↑ CRP, ESR, fibrinogen, procalcitonin, D-dimer, ferritin, LDH, IL-6, or neutrophils, &/or ↓ lymphocytes or albumin), & evidence of clinically severe illness requiring hospitalization with multisystem (> 2) organ involvement (cardiac, renal, respiratory, hematologic, GI, dermatologic or neurological), +
    - No alternative plausible diagnoses, +
    - (+) for current or recent SARS-CoV-2 infection by RT-PCR, serology, or antigen test; or COVID-19 exposure within 4 weeks prior to onset of symptoms
      - In largest study, 25.8% with (+) PCR test for SARS-CoV2 & 46.1% with (+) serology test for SARS-CoV2
- Other signs/symptoms
  - MIS-C
    - Neurologic in 31-47%: Headache, altered mental status, encephalopathy, seizure, coma, encephalitis, demyelinating disorder, aseptic meningitis
    - GI in 90.9%: Abdominal pain 61.9%, vomiting 61.8%, diarrhea 53.2%
    - Cardiovascular in 86.5%: Dysfunction 40.6%, shock 35.4%, myocarditis 22.8%, coronary artery aneurysm 18.6%
    - Dermatologic/mucocutaneous in 70.9%

Demographics

- Children initially accounted for ~ 6.5% of COVID-19 cases in USA
- More transmissible B.1.617.2 (Delta) variant & varying vaccination rates/eligibility may have shifted demographics
- COVID-19 & MIS-C have been more common & severe in patients of African & Hispanic descent
- Mean age of MIS-C patients: 8 years old

Natural History & Prognosis

- Children generally have milder disease with COVID-19
  - Initially accounted for ~ 1.5% of hospitalizations & 0.3% of deaths related to COVID-19 in USA
    - After vaccine development, age-matched unvaccinated populations have had greater rates of infection & severity of illness
  - Up to 1/4 of hospitalized children need ICU
- In largest study of MIS-C patients describing 570 patients
  - 63.9% required ICU care, 62% required vasopressor support, 1.8% died



Treatment

- COVID-19
  - Remdesivir is available through Emergency Use Authorization or compassionate use in pediatric patients
  - Dexamethasone may benefit patients with respiratory disease who are on mechanical ventilation
- MIS-C
  - Immunomodulatory therapy: IVIG &/or glucocorticoids, anakinra (recombinant human IL-1 receptor antagonist) for refractory disease
  - Antiplatelet/anticoagulation therapy: Low-dose aspirin until normalization of platelet count & normal coronary arteries at ≥ 4 weeks after diagnosis; enoxaparin or warfarin if coronary artery z-score > 10.0; also consider anticoagulation if moderate-severe LV dysfunction

(Left) *Short-axis T2 STIR cardiac MR in a 16-year-old with 10 days of fever & abdominal pain shows high signal intensity of the left ventricular (LV) myocardium ⇨ vs. skeletal muscle ⇨ (ratio of 2.5, with > 1.9 being abnormal), consistent with edema. COVID-19 IgG was positive, consistent with MIS-C.* **(Right)** *Axial CECT in the same patient shows diffuse pancreatic thickening & homogeneous enhancement ⇨ with surrounding edema ⇨, consistent with acute interstitial edematous pancreatitis in MIS-C.*

(Left) *Axial CECT of a 15-year-old with pain demonstrates inflammatory stranding at the right lower quadrant ➡ & multiple prominent lymph nodes ⇨, some with low density ⇨. The appendix was normal (not shown).* **(Right)** *Frontal radiograph in the same patient shows diffuse interstitial opacities compatible with pulmonary edema. Echocardiography showed LV dysfunction & ↓ LVEF. Inflammatory markers were elevated, & COVID-19 RT-PCR test was positive. The patient was diagnosed with MIS-C.*

(Left) *Coronal CECT in a 10-year-old with right lower quadrant pain, fever, rash, & conjunctivitis shows multiple enlarged lymph nodes ⇨ & fluid-filled bowel ➡.* **(Right)** *Transverse US in the same patient shows distal ileal wall thickening & hyperechogenicity ⇨ with adjacent fat induration ⇨. Serology was positive for COVID-19 exposure. Decreased systolic LV function & coronary artery ectasia were seen on echocardiography. The patient met the criteria for MIS-C & also had elevated inflammatory markers.*

Round Pneumonia

KEY FACTS

TERMINOLOGY

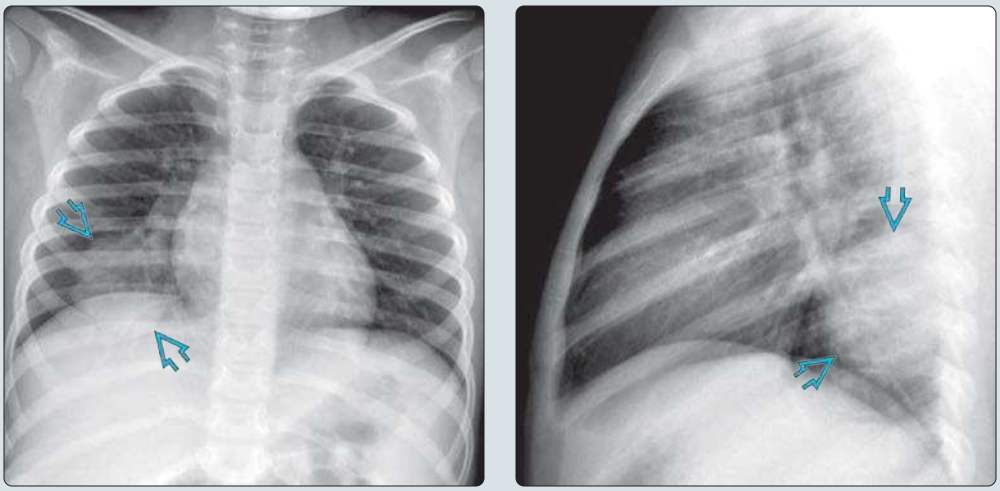
- Bacterial lung infection with very round, well-defined appearance on chest radiography; simulates mass lesion
- Majority seen in patients < 8 years of age

IMAGING

- Well-circumscribed, round opacity ± air bronchograms
- Most common posteriorly in lower lobe superior segments
- No mass effect on or invasion of adjacent tissues
  - No mediastinal or vascular distortion
  - No splaying or erosion of ribs
- Margins of round lung "mass" classically create acute angles with mediastinum or chest wall but can be obtuse

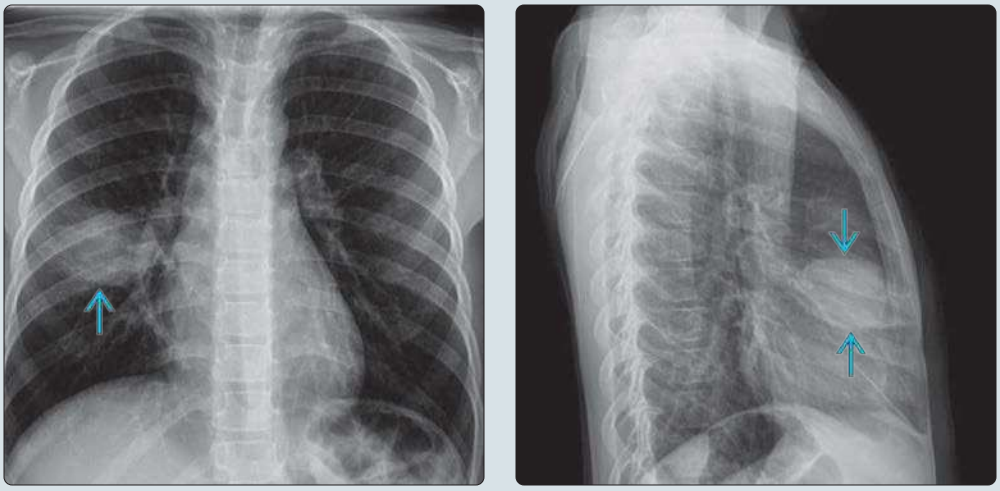
TOP DIFFERENTIAL DIAGNOSES

- Bronchogenic cyst
- Neuroblastoma
- Congenital pulmonary airway malformation
- Bronchopulmonary sequestration



PATHOLOGY

- Collateral pathways of air circulation in lung are not well developed until ~ 8 years of age
  - Channels of Lambert, pores of Kohn
- Spread of bacterial infection through lung is therefore hindered in young children, predisposing to round appearance
- Typically occurs with *Streptococcus pneumoniae* infection



DIAGNOSTIC CHECKLIST

- Round lung opacity in child < 8 years of age → strongly consider round pneumonia
- With classic symptoms of pneumonia (cough, fever) in this age range, other masses do not need to be excluded
- If any doubt of diagnosis, consider
  - Targeted US or CT through lesion
  - Follow-up radiograph after completion of antibiotic course
    - Resolution of "mass" excludes other etiologies

(Left) *Frontal radiograph in a young child with cough & fever shows a round, mildly lobulated, well-circumscribed density in the medial aspect of the right lower lobe.* **(Right)** *Lateral radiograph in the same patient confirms that the round "mass" is located posteriorly in the right lower lobe. Note that the lesion makes acute angles with the posterior chest wall, consistent with a pulmonary origin. These findings are typical of a round pneumonia.*

(Left) *Frontal radiograph in a 7-year-old with respiratory symptoms shows a fairly well-circumscribed, round to ovoid right middle lobe opacity.* **(Right)** *Lateral view of the chest in the same patient again shows the circumscribed round to ovoid opacity at the right middle lobe. The radiographic findings & patient's clinical course were compatible with round pneumonia.*

TERMINOLOGY

Definitions

- Bacterial lung infection with very round, well-defined appearance on chest radiography; simulates mass lesion
- Majority seen in patients < 8 years of age
- Typically occurs with *Streptococcus pneumoniae* infection

IMAGING

General Features

- Best diagnostic clue
  - Round lung opacity with well-defined borders in febrile child < 8 years of age
- Location
  - Most common posteriorly in superior segments of lower lobes
  - No peripheral or central predisposition
  - Single focus is most common (98%)
    - Multiple (2 or 3) foci can rarely occur
- Size
  - Ranges from 1-7 cm
  - Varies in size depending on timing of imaging relative to pneumonia development
  - With adequate treatment, usually resolves/clears (rather than progressing to lobar consolidation)
    - Resolution on follow-up imaging in 95%
- Morphology
  - Well-defined borders in 70%

Radiographic Findings

- Radiography
  - Round lung opacity typically marginated by clear lung
    - Paraspinal pneumonia may have acute or obtuse angle borders with posterior mediastinum/spine
  - Respects lobar anatomy without crossing fissures
  - Does not exert mass effect or invade adjacent tissues
    - No osseous changes (such as splaying or erosion) in adjacent ribs or spine
  - Air bronchograms help confirm airspace disease
  - Pleural effusion is uncommon
  - Rarely progresses to lobar pneumonia

CT Findings

- NECT
  - Not advocated for cases of suspected round pneumonia
    - May be obtained if mass lesion is primary concern
    - Abdominal CT may show round pneumonia in lower lobe as cause of abdominal pain
  - Homogeneous, round opacity ± air bronchograms
  - Respects lobar anatomy, does not cross fissures
  - No changes in adjacent bones
- CECT
  - Normal pulmonary vessels course through consolidated lung without mass effect
  - No enhancing rim or wall
  - No systemic arterial supply from descending aorta (as seen with bronchopulmonary sequestration)
  - Central cavity or fluid level favors alternative diagnosis

MR Findings

- Not utilized for primary suspicion of round pneumonia
- May be encountered if MR is performed to further work-up round paraspinal mass suspected to be neuroblastoma
- Round pneumonia appears as moderately high (but not fluid bright) T2 signal intensity lesion within pulmonary parenchyma ± air bronchograms
- With contrast, enhancing nondisplaced vessels course through mildly enhancing, otherwise homogeneous "mass"

Ultrasonographic Findings

- Increasingly used for diagnosis of childhood pneumonia
  - Sensitivity 96%, specificity 93% overall
    - May be lower if round pneumonia is completely surrounded by aerated lung
- Abnormality of normally echogenic pleural line: Irregular, coarse, interrupted, or absent
- "Hepatization" of subpleural parenchyma with branching mobile hyperechogenicities (air bronchograms)
- Interstitial involvement: > 3 B lines (type of comet-tail artifact in which vertical echogenic line extends from pleural surface to inferior edge of field of view)

Imaging Recommendations

- Pediatric Clinical Practice Guidelines for chest radiography in pneumonia
  - Not necessary to confirm suspected community-acquired pneumonia (CAP) in patients well enough to be treated as outpatients; exceptions include
    - Hypoxemia
    - Respiratory distress
    - Failed antibiotic therapy
  - Chest radiographs (frontal & lateral) should be obtained in all patients hospitalized for management of CAP
- If child < 8 years old has symptoms of pneumonia + round opacity on chest radiograph, additional imaging (such as CT) is not necessary
  - Look carefully at adjacent bones
- Follow-up radiograph after antibiotic therapy may be helpful to document resolution of round opacity
  - Particularly helpful for paraspinal round pneumonia that may mimic neuroblastoma
- > 8 years old: Consider evaluation for other pathologies with CECT or MR

DIFFERENTIAL DIAGNOSIS

Bronchogenic Cyst

- Round, well-defined soft tissue mass
- Most common in perihilar regions
- ± mass effect on adjacent structures
  - Airway compression may cause air-trapping/atelectasis
- Only contains air or air-fluid levels if infected
- CECT: Water-attenuation mass without air bronchograms; ± rim enhancement if infected

Neuroblastoma

- Round or elongated posterior mediastinal/paraspinal mass
- Obtuse angle borders with mediastinum
  - May only widen paraspinal stripe without focal bulge
- Rib erosion or splaying is common
- Ca^{2+} in majority by CT

Congenital Pulmonary Airway Malformation

- Round/lobulated parenchymal mass distorting adjacent lung & vessels
- Most commonly presents in utero or during newborn period
- Macrocystic type may temporarily appear solid after birth due to retained fluid
  - Quickly fills with air due to communication with airway

Bronchopulmonary Sequestration

- Lobulated or triangular parenchymal mass
- Most common in lower lobes
- Typically congenital, presenting in perinatal period; may present as recurrent pneumonia (always in same location) later in life
  - Round pneumonia almost never recurs in same location
- Characteristic systemic feeding artery arises from descending thoracic or abdominal aorta
  - May be seen prenatally or on postnatal CTA

Lung Abscess

- Round cavity containing air-fluid level
- Surrounded by irregular or poorly defined consolidation

Metastatic Disease

- Small, multifocal nodules are typical
- Rarely found incidentally in children

Pleural Pseudocyst

- Partially circumscribed, focal fluid collection within fissure
- Very uncommon as isolated finding in children without preceding history of thoracic pathology

Chest Wall Ewing Sarcoma

- Partially circumscribed, round mass with definite bony destruction (lysis, permeation)
- Associated pleural effusion is frequent
- More common in children > 8 years of age

PATHOLOGY

General Features

- Etiology
  - Collateral pathways of air circulation are not well developed until ~ 8 years of age
    - Channels of Lambert & pores of Kohn
  - Lack of well-developed collateral circulation is thought to hinder spread of bacterial infection, predisposing to round appearance on radiography

Gross Pathologic & Surgical Features

- Exudative opacification of pulmonary airspaces related to bacterial infection
  - *S. pneumoniae* is most common pathogen

CLINICAL ISSUES

Presentation

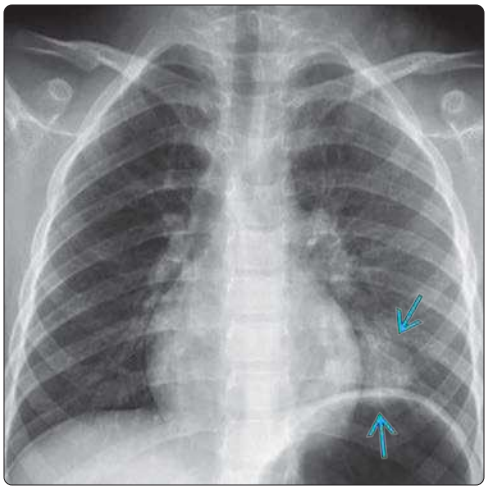
- Most common signs/symptoms
  - Cough & fever
- Other signs/symptoms
  - Abdominal pain, malaise, anorexia

Demographics

- Age
  - 75% < 8 years old; 90% < 12 years old; mean age: 5 years
  - Cases rarely reported in older children & adults
    - Sometimes leads to biopsy
    - Antibiotics & short-term follow-up may be considered if round pneumonia diagnosis is not clear

Natural History & Prognosis

- With appropriate antibiotic therapy, symptoms & opacity should resolve over days-weeks
  - Resolution of "mass" on follow-up radiograph after completion of antibiotic course confidently excludes other etiologies
- With antibiotic resistance, may progress to lobar pneumonia ± complications



DIAGNOSTIC CHECKLIST

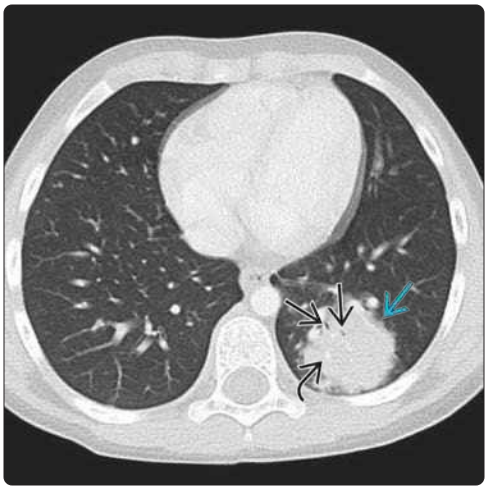


Image Interpretation Pearls

- Round lung opacity in child < 8 years of age → strongly consider round pneumonia
  - With classic symptoms of pneumonia at presentation, other causes of radiographic mass do not need to be excluded with imaging
- > 8 years old, consider other pathologies & further work-up

(Left) *PA view of the chest from a 7-year-old with a clinically suspected respiratory infection demonstrates a circumscribed left lower lobe density.* **(Right)** *Axial CECT in the same patient shows a round left lower lobe air space opacity. Air bronchograms & pulmonary vessels are seen coursing through the density. No mass effect is demonstrated. The findings are consistent with round pneumonia.*

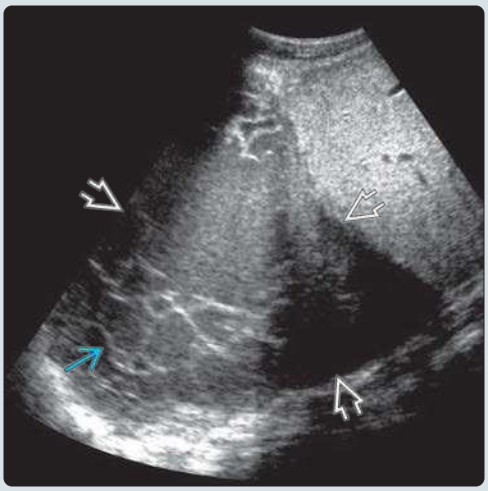
(Left) *PA chest radiograph of a 6-year-old girl with a cough demonstrates a round opacity projecting over the left hilum, suggesting a round pneumonia.* **(Right)** *Lateral chest radiograph in the same patient localizes the round opacity to the superior segment of the left lower lobe. The acute (rather than obtuse) angles at the interface of the opacity with the posterior chest wall are suggestive of its origin within the lung parenchyma.*

(Left) *Frontal chest radiograph from a 4-year-old with cough, fever, & chest pain shows a large, round right lower lobe opacity. Follow-up after 2 weeks of antibiotic therapy was normal. The findings & clinical course are consistent with a round pneumonia.* **(Right)** *Frontal radiograph in a 2 year-old with fever, shortness of breath, & cough demonstrates a round opacity at the left upper lung. Note the absence of mass effect or bone changes. The findings are compatible with round pneumonia & resolved at follow-up.*

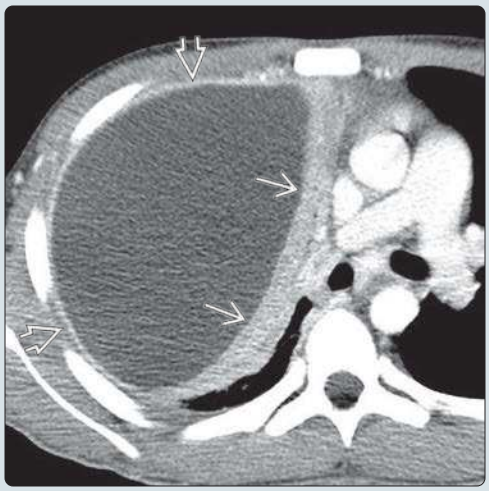
Parapneumonic Effusion and Empyema

KEY FACTS

TERMINOLOGY

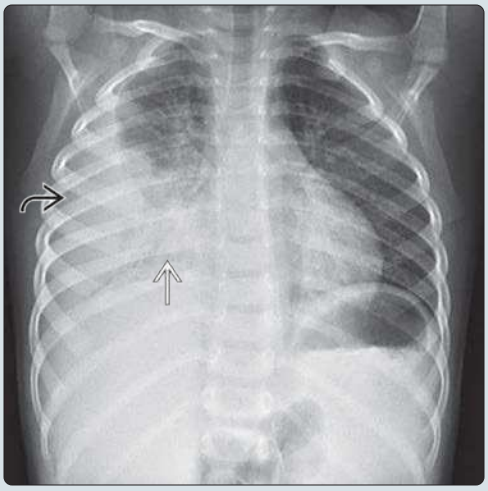


- Pleural effusions are classified as transudative or exudative
- Parapneumonic effusions are exudative secondary to adjacent lung infection & ↑ capillary permeability

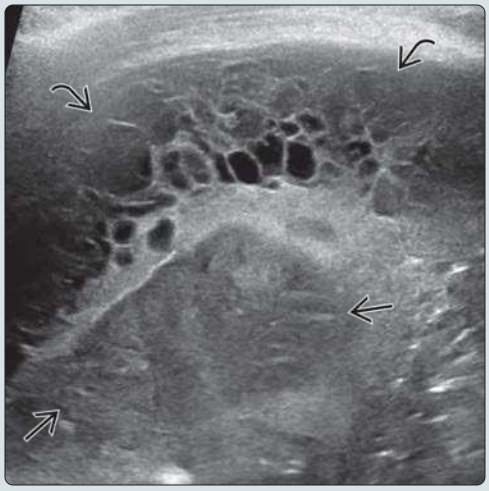


IMAGING

- Upright chest radiograph
  - Flattened & elevated hemidiaphragm, lateral shift of diaphragm apex, gastric bubble > 1.5 cm from diaphragm secondary to subpulmonic fluid
  - Blunted posterior costophrenic angle (~ 50 mL)
  - Blunted lateral costophrenic angle (~ 200 mL)
  - Hemidiaphragm inversion (> 2,000 mL)
- Supine chest radiograph may require up to 500 mL
  - Homogeneous vs. gradation of hazy/dense opacification of hemithorax ± pleural cap, mass effect
- US: Effusion appears anechoic, echoic, or mixed with floating/swirling/undulating echoes
  - Floating fibrin strands attached to pleural surface, septations, &/or pleural rind/thickening; immobile lung suggests entrapment by pleural rind
  - Loculation: Nonshifting fluid with position change
- CECT: Parietal pleural enhancement & thickening, thickening of extrapleural space, & chest wall edema are seen with transudative & exudative effusions in children
- Imaging recommendations
  - US if pleural disease is suspected on chest radiograph
  - CECT for persistent/progressive illness on treatment



CLINICAL ISSUES



- American Pediatric Surgical Association recommendations
  - Antibiotics
  - Chest tube drainage if effusion is of large volume, loculated, or for worsening/persistent symptoms
  - For empyema: Chest tube + tissue plasminogen activator
    - Video-assisted thoracoscopic surgery (VATS) if no improvement

(Left) *Sagittal US in a patient with near-complete opacification of the right hemithorax on chest radiograph (not shown) shows a large pleural effusion with debris & echogenic septa, consistent with a fibrinopurulent parapneumonic effusion.* **(Right)** *Axial CECT in the same patient shows the pleural effusion compressing the right lung. The septations seen on the US are not visible on CT. Pleural enhancement is depicted but can be seen with transudative or exudative effusions.*

(Left) *Frontal view of the chest in a 19-month-old with pneumonia shows a large pleural effusion with basilar consolidation.* **(Right)** *Transverse US in the same patient demonstrates a complex, multiloculated pleural collection. A focal area of underlying lung parenchyma is heterogeneous & hypoechoic, concerning for associated necrosis. An absence of flow was seen on Doppler interrogation (not shown).*

TERMINOLOGY

Definitions

- Pleural effusions are classified as transudative or exudative
  - Transudative: Due to hydrostatic & oncotic imbalances
  - Exudative: Due to ↑ capillary permeability
- Parapneumonic effusions are exudative
- Empyema is fibrinopurulent parapneumonic effusion

IMAGING

Radiographic Findings

- Pneumonia + adjacent pleural effusion
- Sequence of accumulation on upright view
  - Flattened & elevated hemidiaphragm, lateral shift of diaphragm apex, gastric bubble > 1.5 cm from diaphragm secondary to subpulmonic fluid
  - Blunted posterior costophrenic angle (~ 50 mL)
  - Blunted lateral costophrenic angle (~ 200 mL)
  - Hemidiaphragm inversion (> 2,000 mL)
- Supine images: Homogeneous vs. gradation of hazy/dense opacification of hemithorax ± pleural cap, mass effect (may require up to ~ 500 mL)
- Loculation is suggested by lenticular shape or nonshifting fluid on decubitus views but better characterized on US
- Fissural thickening or pseudotumor in minor fissure

Ultrasonographic Findings

- Effusion: Anechoic, echoic, or mixed with debris
- Fibrin deposition: Floating/flapping strands attached to pleural surface, septations, pleural rind/thickening; lack of lung mobility suggests pleural rind entrapping lung
- Loculation: Nonshifting fluid with position change

CT Findings

- Parietal pleural thickening & enhancement, thickened extrapleural space, & chest wall edema are seen with both transudative & exudative effusions in children
- Inferior to US at demonstrating fibrin strands or septations
- Loculation is inferred if air in collection separates into bubbles rather than single air-fluid level

MR Findings

- Empyema: Pleural thickening & enhancement, pleural fluid with heterogeneous signal, septation, & restricted diffusion

Imaging Recommendations

- US if pleural space disease is suspected on chest radiograph
  - Must scan dependent & nondependent pleural cavity
- CECT if persistent/progressive illness despite treatment (to evaluate for malpositioned chest tube, necrosis, abscess, purulent pericarditis)

DIFFERENTIAL DIAGNOSIS

Chylothorax

- Birth trauma, lymphangiectasia, lymphatic malformation

Lung Abscess

- Walled-off collection with pneumonia & progressive illness

Malignant Pleural Effusion

- Lymphoma, Ewing sarcoma, pleuropulmonary blastoma
- Look for nodularity/mass &/or rib destruction

PATHOLOGY

General Features

- Transudate vs. exudate classification is based on fluid analysis
- Light's criteria for exudate (≥ 1 required): Pleural fluid to serum protein ratio > 0.5 or LDH ratio > 0.6; pleural fluid LDH > 2/3 upper limit of normal serum level
- If exudative, then empyema is suggested by: pH < 7.2, lactate dehydrogenase (LDH) > 1,000 U, glucose < 40 mg/dL or < 25% blood glucose, positive Gram stain or positive culture, > 10,000 WBC/μL, loculations on imaging
- Common causes include *Streptococcus pneumoniae* & methicillin-resistant *Staphylococcus aureus*
  - Test for tuberculosis with lymphocytic exudate
- Stages of parapneumonic effusion progression
  - Precollection: Pleuritis, inflammation
  - Exudative (simple): Free fluid with low white cell count
  - Fibrinopurulent (complicated): Deposition of fibrin & purulent material
  - Organized: Thick pleural peel, which may entrap lung

CLINICAL ISSUES

Presentation

- Fever, cough, chest pain, dyspnea, tachypnea, splinting to affected side, respiratory distress if large in volume

Demographics

- Complicates 28-53% of pediatric pneumonias

Natural History & Prognosis

- Pediatric mortality < 3% in 1 study (up to 20% in adults)

Treatment

- American Pediatric Surgical Association recommendations
  - Antibiotics
  - Evacuation with chest tube for large volume &/or loculated effusion or with worsening/persistent symptoms
  - For empyema: Chest tube + intrapleural tissue plasminogen activator
    - Video-assisted thoracoscopic surgery (VATS) is required if no clinical improvement & pleural disease persists on imaging

Pneumonia With Cavitary Necrosis

KEY FACTS

TERMINOLOGY

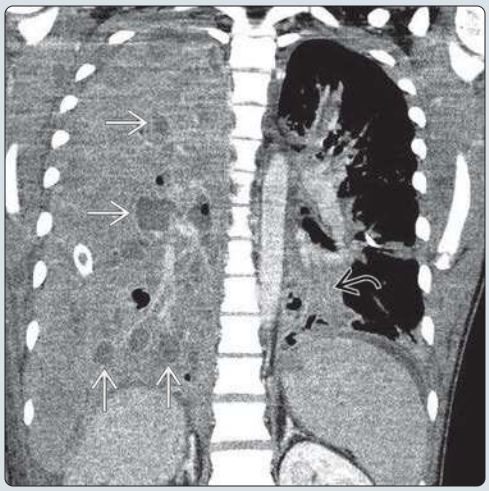
- Complication of bacterial pneumonia where dominant focus of necrosis develops in consolidated lung, resulting in variable number(s) of thin-walled cysts
- Synonyms: Necrotizing pneumonia, pulmonary gangrene
  - Abscess has thick, well-defined wall & is more commonly seen in immunocompromised children

IMAGING

- Not identified radiographically until tissue breakdown leads to communication of cavity with aerated lung/airways
- CECT shows lack of normal lung architecture, ↓ lung enhancement, & thin-walled cysts in midst of consolidation
- No clear role for percutaneous drainage in cases of cavitary necrosis in immunocompetent children

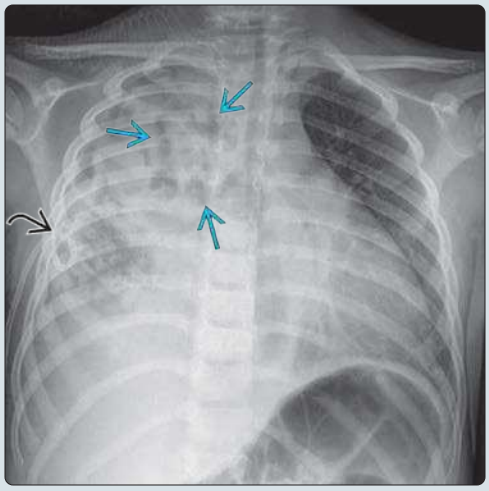
TOP DIFFERENTIAL DIAGNOSES

- Congenital pulmonary airway malformation
- Lung abscess
- Bronchopulmonary sequestration
- Bronchogenic cyst

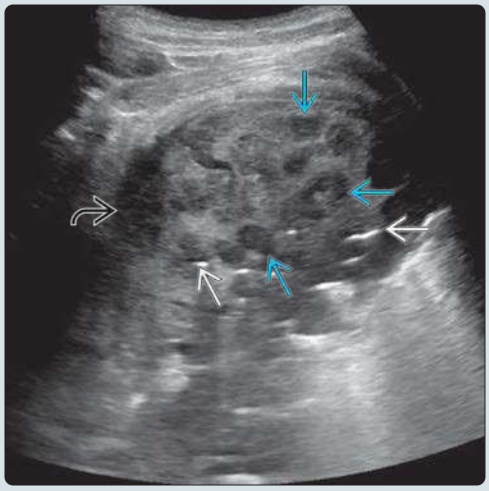


PATHOLOGY

- Increasingly identified as pediatric pneumonia complication
- *Streptococcus pneumoniae* is most common cause
  - Other organisms: MSSA, MRSA, other *Staphylococcus* & *Streptococcus* species, *Pseudomonas*, *Fusobacterium*
- May lead to bronchopleural fistula & development of pneumothorax



CLINICAL ISSUES



- Progressive symptoms (fever, respiratory distress, sepsis) in pediatric pneumonia patient despite appropriate medical management suggest complication (such as cavitary necrosis)
- Patients with cavitary necrosis tend to be intensely ill (ICU)
- Most do recover with antibiotics & nonsurgical management

(Left) *AP chest radiograph in a child with rapidly progressive symptoms shows complete opacification of the right hemithorax & partial opacification of the medial left lower lobe (LLL). There are bilateral chest tubes in place.* **(Right)** *Coronal CECT in the same patient shows heterogeneous opacification of the right lung with multiple thin-walled, fluid-containing cystic foci, consistent with cavitary necrosis. Also note the LLL opacification. Development of air in foci of necrosis allows for better visualization on radiographs.*

(Left) *Frontal view of the chest in a 7-year-old with MRSA pneumonia, empyema with chest tube in situ, & worsening clinical course demonstrates right lung consolidation with cystic lucencies concerning for associated necrosis.* **(Right)** *Longitudinal oblique ultrasound in the same patient shows consolidated lung with hypoechoic foci, compatible with areas of necrosis. Hyperechoic foci within a few of the hypoechoic areas reflect air. Note residual complex pleural fluid from the empyema.*

TERMINOLOGY

Synonyms

- Necrotizing pneumonia
- Pulmonary gangrene

Definitions

- Complication of bacterial pneumonia where dominant focus of necrosis develops in consolidated lung, resulting in variable number(s) of thin-walled cysts

IMAGING

General Features

- Best diagnostic clue
  - CECT of opacified lung shows loss of normal lung architecture with focally ↓ lung enhancement & development of thin-walled cysts ± air-fluid levels
- Location
  - More common in lower lobes
- Size
  - Variably sized cysts, typically 2-10 cm

Radiographic Findings

- Radiography
  - Poor sensitivity as cavitary lesions are initially fluid-filled & same density as surrounding consolidated lung
  - Cavitation is not detected radiographically until necrosis leads to communication with aerated lung or bronchi
    - Leads to introduction of air into cavity → cystic lucencies within lung opacified by pneumonia
  - ± pneumothorax related to bronchopleural fistula
  - Follow-up after antibiotics
    - Progressive ↓ in lung consolidation
    - Cystic lucencies eventually resolve
    - Radiographs obtained > 40 days later: Often normal or showing only minimal linear scarring

CT Findings

- CECT
  - Within area of consolidated lung
    - Loss of normal lung architecture
      - Breakdown of normal bronchogram pattern
    - ↓ enhancement
      - Noncompromised consolidated or atelectatic lung enhances
      - Nonenhancement suggests ischemia or developing necrosis
    - Multiple cystic foci filled with air &/or fluid
      - Not air-filled until communicating with aerated lung/airways
      - Walls of cyst: Thin, often nonenhancing

MR Findings

- Several studies on chest MR for evaluation of pulmonary infection in children show
  - ↑ sensitivity for detecting necrosis, abscess, & empyema compared to radiographs or radiographs + ultrasound
  - Comparable diagnostic characteristics to CECT for consolidation, necrosis/abscess, effusion
- Consolidation
  - Isointense T1 + hyperintense T2 signal relative to muscle
- Necrosis
  - Focus of T2 hypointensity within area of consolidation
  - Nonenhancing parenchyma
  - Signal void indicative of gas may be seen in necrotic areas or abscesses ± air-fluid levels

Ultrasonographic Findings

- Grayscale ultrasound
  - Ill-defined, heterogeneously hypoechoic foci in consolidated lung
    - Seen in 24% of cases imaged with both US & CT
  - Small, central areas may be more difficult to visualize
- Color Doppler
  - Characteristic appearance of consolidated pneumonia: Tree-like vascularity extending from center to periphery
  - ↓ or absent color Doppler flow within consolidated lung suggests perfusion impairment & correlates with severity of necrosis on CECT

Nonvascular Interventions

- Percutaneous drainage of lung abscesses is sometimes advocated, though creation of bronchopleural fistula may be problematic
- No clear role for percutaneous drainage in cases of cavitary necrosis in immunocompetent children

Imaging Recommendations

- Primary imaging modality of pneumonia: Radiographs
  - Insensitive to many complications
- CECT is used in minority of pneumonia cases
  - Typically in child who has not responded to appropriate therapy despite lack of clear radiographic explanation
- Follow-up
  - Patients with cavitary necrosis demonstrated on CECT do not typically need follow-up CT to document resolution
  - Radiographs obtained after 40 days are typically normal or near normal

DIFFERENTIAL DIAGNOSIS

Infected Congenital Lung Lesion

- Cavitary necrosis can appear similar to infection of underlying congenital pulmonary airway malformation (CPAM)
- Cavitary necrosis tends to be surrounded by consolidation
  - CPAM is often surrounded by aerated lung
- Children with cavitary necrosis tend to be more critically ill
- Temporal history is most helpful; favor cavitary necrosis if
  - Previously normal chest radiograph
  - Progression of lesion during illness
  - ↓ or resolving lesion after acute illness

Lung Abscess

- Suppurative complications of pneumonia represent spectrum; name given depends upon severity, distribution, & temporal relationship to development of pneumonia
  - Cavitary necrosis: Nonenhancing, poorly defined walls of cysts
  - Lung abscess: Fluid collection with well-defined, thick, enhancing wall
    - Lung abscesses rare in otherwise healthy, immunocompetent children

- Typically occur in immunocompromised children

Bronchopulmonary Sequestration

- L > R lower lobe lesion, typically solid
- Does not contain cavities unless superinfected or hybrid lesion with CPAM
- Systemic arterial supply from aorta

Bronchogenic Cyst

- Typically not air-filled but fluid density
- More commonly in perihilar region/mediastinum

PATHOLOGY

General Features

- Etiology
  - Increasingly identified as pediatric pneumonia complication
    - May be due to changing spectrum of causative organisms since introduction of pneumococcal vaccine, ↑ recognition of cavitary necrosis as distinct clinical entity, or ↑ use of CT
  - Causative organisms in large USA retrospective study
    - *Streptococcus pneumoniae* is most common, 22%
    - Others: Methicillin-sensitive & -resistant *Staphylococcus aureus*, *Pseudomonas* species, other *Staphylococcus & Streptococcus* species, *Fusobacterium*
- May lead to bronchopleural fistula & development of pneumothorax
  - In one large retrospective study, 86% had pleural effusion & 13% developed bronchopleural fistula
    - 100% of cases with bronchopleural fistula previously had chest drain in place > 7 days

Gross Pathologic & Surgical Features

- Primarily vascular process with inflammation leading to vasculitis → thrombosis of small arterioles with eventual ischemia & necrosis of consolidated lung
  - Tissue breakdown → cavity formation
  - Cavities are initially fluid-filled
  - Cavities fill with air when tissue develops communication with aerated lung
- Direct cytotoxic effects of bacterial toxins
  - Possible association with Panton-Valentine leukocidin pore-forming exotoxin & α-hemolysin seen in some strains of *S. aureus*
- Cytokine-mediated inflammatory response

CLINICAL ISSUES

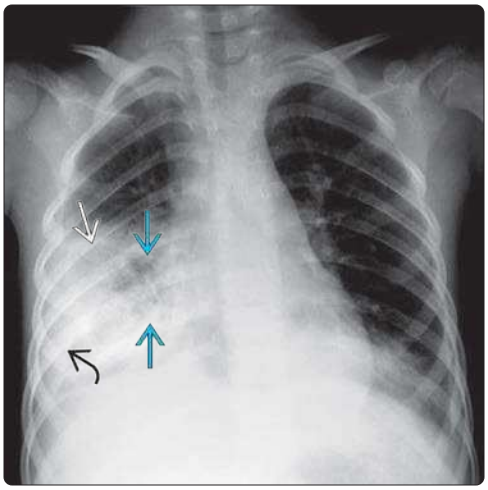
Presentation

- Most common signs/symptoms
  - Lack of clinical improvement in pneumonia symptoms despite antibiotic therapy
  - Progressive sepsis
- Clinical profile
  - When children exhibit persistent or progressive symptoms (fever, respiratory distress, sepsis) despite appropriate medical management of pneumonia, suppurative complication (such as cavitary necrosis) is usually present

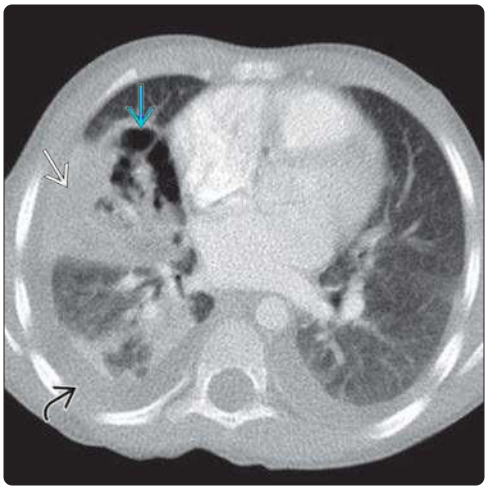
Demographics

- Age
  - May occur in children of all ages
  - Most common < 5 years old
- Epidemiology
  - ↑ incidence of complicated pneumonias in children since mid 1990s
  - Reason unclear
    - ↑ frequency of antibiotic resistant *S. pneumoniae*
    - ↑ viral infections (such as influenza A) that damage respiratory mucosa & render host susceptible to multiple infections
    - ↑ in antibiotic resistant bacteria

Natural History & Prognosis



- Patients with cavitary necrosis tend to be intensely ill
- Complications include: Bronchopleural fistula, empyema, abscess, empyema, tension pneumatocele/pneumothorax, hemolytic uremic syndrome
- Most do recover with nonsurgical management



Treatment

- Intensive support with IV antibodies
- Surgery reserved for minority of cases
  - Surgical therapy may have role for necrotic pneumonia in adults; natural history of recovery without surgical intervention in children should be stressed

(Left) *Frontal view of the chest in a 14-year-old with pneumonia demonstrates right middle lobe consolidation ➡ with areas of lucency medially ⇨, concerning for necrosis given a worsening clinical status. There is a small pleural effusion ⇨.* **(Right)** *Axial CECT in the same patient depicts the area of right middle lobe consolidation ➡ as well as gas-filled cystic foci (compatible with necrosis) ⇨ & a small right pleural effusion ⇨.*

(Left) *AP chest radiograph from a 5-year-old patient demonstrates LLL consolidation with multiple foci of radiolucency ⇨ due to cavitary necrosis. There is also right upper lobe consolidation ➡ & a left pleural effusion ⇨.* **(Right)** *Transverse lung ultrasound in the same 5-year-old shows multiple hypoechoic foci ⇨ in the consolidated left lower lobe, concerning for cavitary necrosis. The spleen is partially visualized ⇨.*

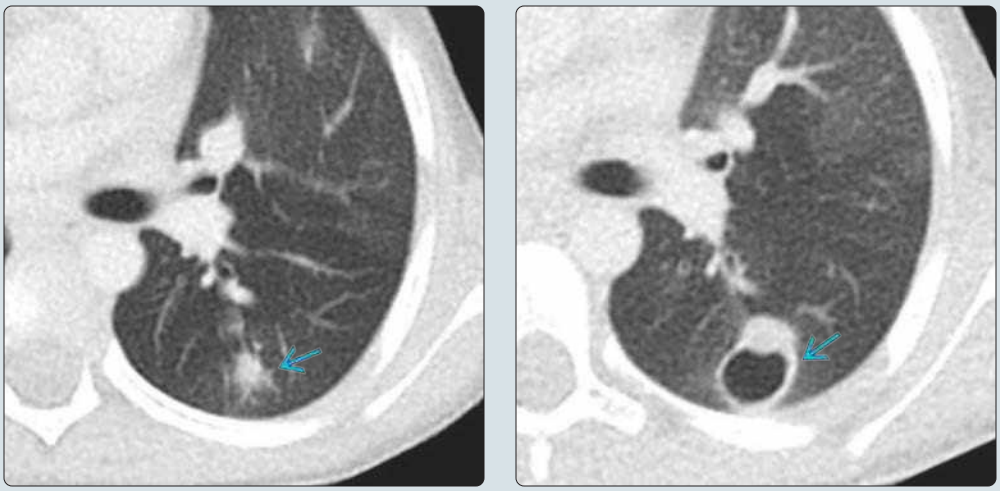
(Left) *Axial CECT in the same patient shows consolidation of the LLL with loss of the normal lung architecture & extensive tubular & cystic lucencies ⇨, consistent with cavitary necrosis.* **(Right)** *Axial CECT in an ill child shows a consolidated right lower lobe (RLL) containing a central cavity ➡ with a nonenhancing wall, consistent with cavitary necrosis. Note the large pleural effusion containing gas ➡, suggesting an underlying bronchopleural fistula.*

Fungal Pneumonia in Immunocompromised Children

KEY FACTS

TERMINOLOGY

- Causes of immunocompromised states in children
  - Immature immune system: Premature infants
  - Primary immunodeficiency: Chronic granulomatous disease, Job syndrome, severe combined immunodeficiency, Wiskott-Aldrich syndrome, DiGeorge syndrome
  - Acquired immunodeficiency: Immunosuppression, infection, chronic illness



IMAGING

- Best clue: Pneumonia that does not respond to broad-spectrum antibiotics
- Angioinvasive pulmonary *Aspergillus:* Classic findings of halo sign, air-crescent sign, & cavitation
  - Halo sign (11% of patients): Nodule with halo of ground-glass attenuation (due to hemorrhage)
  - Air-crescent sign (2% of patients): Represents retraction of necrotic lung
  - Cavitation (~ 25% of patients): Typically occurs as neutrophil counts recover (sign of recovery)
- *Candida*: Consolidation, cannot be distinguished from bacterial pneumonia
- *Pneumocystis*: Extensive ground-glass opacity with interlobular septal thickening
- Coccidioidomycosis: Unilateral consolidation, hilar adenopathy, pleural effusion, pulmonary nodules, cavitary lesions, reticulonodular opacity
- *Cryptococcus*: Pulmonary nodules (miliary or large)
- Histoplasmosis
  - Preexisting infection: Calcified pulmonary nodule(s), calcified hilar or right paratracheal lymph nodes
  - Acute infection: Mediastinal or hilar adenopathy, miliary nodules, diffuse consolidation

CLINICAL ISSUES

- Antifungal therapy depends on type of fungus

(Left) *Axial CECT of the left lung in a child with febrile neutropenia shows a poorly defined opacity ⇨ in the left lower lobe with a faint halo of ground-glass opacity. This was later confirmed to represent angioinvasive pulmonary aspergillus.* **(Right)** *Axial CECT of the chest in the same patient obtained 3 weeks later shows cavitation ⇨ of the left lower lobe opacity. In patients with neutropenia & angioinvasive pulmonary aspergillus, cavitation represents a sign of recovery as the neutrophil count ↑.*

(Left) *Axial CECT of the lungs in an immunocompromised child shows diffuse, tiny pulmonary nodules in a centrilobular distribution. The patient was confirmed to have disseminated histoplasmosis.* **(Right)** *Coronal CECT of the left upper lung in a child with a history of cystic fibrosis shows mucus-impacted bronchi ⇨ & a tree-in-bud pattern ⇨ of pulmonary nodules, which can be secondary to allergic bronchopulmonary aspergillosis.*

TERMINOLOGY

Associated Syndromes

- Causes of immunocompromised states in children
  - Immature immune system: Premature infants
  - Primary immunodeficiency: Chronic granulomatous disease & severe combined immunodeficiency
  - Acquired immunodeficiency
    - Immunosuppression: After transplant or chemotherapy, chronic corticosteroid therapy
    - Infectious: HIV/AIDS
    - Chronic illness: Cystic fibrosis, burns
- 3 types of *Aspergillus* infection
  - Invasive pulmonary *Aspergillus* affects patients with neutropenia or neutrophil dysfunction
    - Subclassified as angioinvasive or airway invasive
  - Allergic bronchopulmonary aspergillosis (ABPA) represents hypersensitivity reaction to *Aspergillus*
  - Chronic airway invasive aspergillosis is rare, indolent form of *Aspergillus* infection

IMAGING

General Features

- Best diagnostic clue
  - Pneumonia that does not respond to antibiotics in immunocompromised patient

Radiographic Findings

- Angioinvasive pulmonary *Aspergillus*
  - Tree-in-bud nodules, ground-glass opacity, & consolidation
  - Cavitary lesions & air-crescent sign are uncommon
- Airway invasive pulmonary *Aspergillus:* Patchy lower lobe consolidation & poorly defined nodules
- ABPA: Tubular opacities of mucus-impacted bronchi, bronchiectasis, & atelectasis
- Chronic airway invasive *Aspergillosis:* Consolidation → cavitation → aspergilloma & pleural thickening
- *Candida*: Perivascular pulmonary opacities may coalesce into abscess or empyema
- *Pneumocystis*: Diffuse interstitial or granular opacities
- Coccidioidomycosis: Unilateral consolidation, hilar adenopathy, pleural effusion
- *Cryptococcus*: Miliary nodules, large pulmonary nodules, large areas of consolidation, or lymphadenopathy
- Histoplasmosis
  - Acute infection: Mimics tuberculosis; mediastinal or hilar adenopathy & consolidation
  - Remote infection: Ca^{2+} of pulmonary nodule & nodes

CT Findings

- Angioinvasive pulmonary *Aspergillus*
  - Halo sign: Nodule with halo of ground-glass attenuation (due to hemorrhage)
    - Appears within 5 days from fever onset
    - Lesions can ↑ in size & number for 7-10 days
  - Air-crescent sign: Retraction of necrotic lung within consolidation → crescent of air
  - Cavitation: Typically occurs as neutrophil counts recover (sign of recovery)
- Airway invasive pulmonary *Aspergillus*: Consolidation, centrilobular nodules, & ground-glass opacity
- Allergic bronchopulmonary *Aspergillosis:* Bronchial wall thickening, bronchiectasis with mucoid impaction, tree-in-bud opacities, & consolidation
- *Candida*: Multiple pulmonary nodules; may coalesce
- *Pneumocystis*: Extensive ground-glass opacity with interlobular septal thickening
- Coccidioidomycosis: Unilateral consolidation, hilar adenopathy, pleural effusion, pulmonary nodules, cavitary lesions, reticulonodular opacity
- *Cryptococcus*: Miliary or large pulmonary nodules
- Histoplasmosis
  - Acute infection: Mediastinal or hilar adenopathy, miliary nodules, diffuse consolidation
  - Remote infection: Ca^{2+} of pulmonary nodule(s) & affected lymph nodes

Imaging Recommendations

- Best imaging tool
  - Chest radiograph is best screening test for infection
  - NECT of chest is best to diagnose & characterize parenchymal infection

DIFFERENTIAL DIAGNOSIS

Bacterial Pneumonia

- Appearance is same as in immunocompetent patients

Viral Pneumonia

- Immunocompromised patients are less likely to wheeze & more likely to develop consolidation

Pulmonary Metastases

- Usually appear as discrete, round, solid nodules

CLINICAL ISSUES

Demographics

- Epidemiology
  - *Aspergillus*
    - Biggest risk for invasive aspergillosis is neutropenia
  - *Candida*
    - Major cause of morbidity & mortality in ICU/NICU
    - Risks: Central venous catheters, invasive interventions, treatment with broad-spectrum antibiotics
  - *Pneumocystis*
    - High risk in patients with lymphoid malignancies
  - Coccidioidomycosis
    - Endemic in Southwestern United States
    - Risk for exposure ↑ with storms, high winds, earthquake, & construction
  - *Cryptococcus*
    - Endemic in Southern California
  - Histoplasmosis
    - Endemic in Ohio & Mississippi river valleys

Papillomatosis

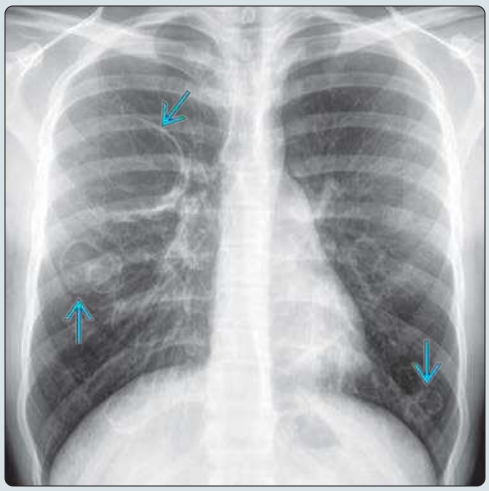
KEY FACTS

TERMINOLOGY

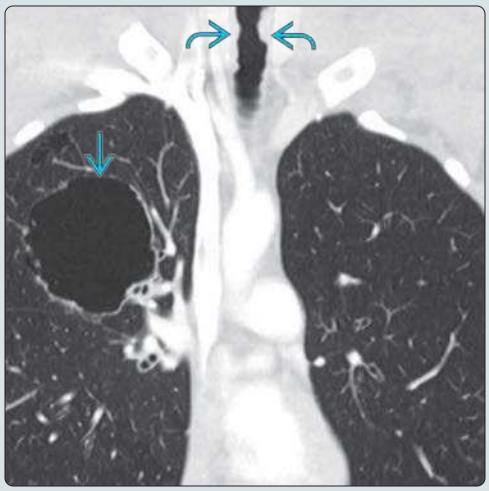
- Recurrent respiratory papillomatosis (RRP): Benign tumors of aerodigestive tract caused by infection with human papillomavirus (HPV)
  - Variable lifelong morbidity; potentially fatal course

IMAGING

- Locations: Junctional sites between respiratory & squamous epithelium
  - Larynx is most common site
  - Extralaryngeal spread in ~ 30% of patients
    - Endobronchial spread → pulmonary nodules
      - Lung parenchymal involvement in 3%
- CT appearance
  - Airway: Soft tissue nodules protruding into lumen
  - Lung: Multiple solid or cavitated nodules
    - ± postobstructive atelectasis or pneumonia
    - Malignant degeneration of pulmonary disease in 0.5%
      - Squamous cell carcinoma

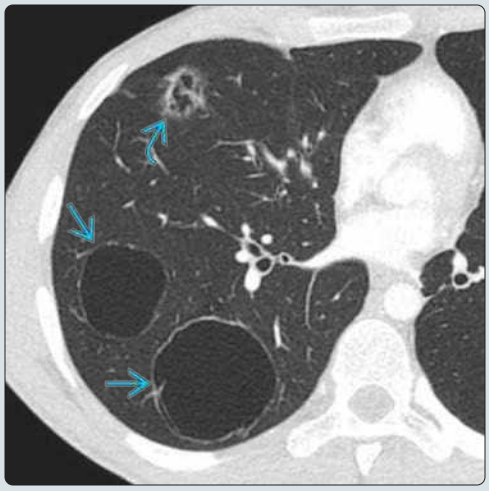


PATHOLOGY

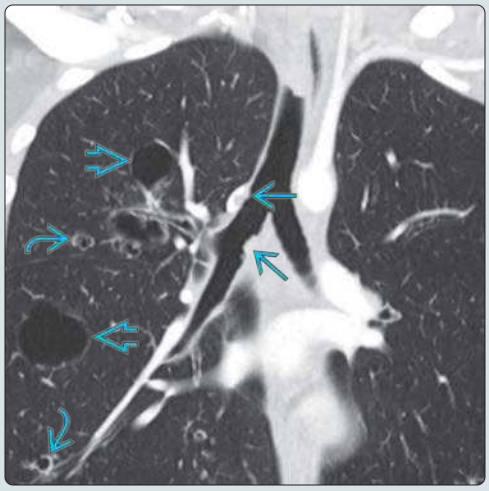


- Perinatal transmission of HPV: Infected mother → child
  - ↑ risk: Vaginal delivery, firstborn, mother < 20 years of age; delivery time > 10 hours doubles risk
- Vast majority are caused by HPV-6 & HPV-11

CLINICAL ISSUES



- Most common laryngeal tumor in children
- Most common symptoms: Hoarseness, stridor, difficulty breathing
- Mean age at diagnosis: ~ 4 years
- Disease remission can occur spontaneously at any stage
- Treatment is resection using powered microdebrider
  - Need for repeated debulking is typical
- Tracheostomy is needed in 10-15% due to airway obstruction; delayed as long as possible due to ↑ risk of distal spread
- HPV 9-valent vaccine protects against strains implicated in RRP



(Left) *PA radiograph of the chest in a young adult with respiratory papillomatosis shows multiple pulmonary cysts of various sizes. The cyst walls are irregular with variable thickness.* **(Right)** *Coronal CECT in the same patient shows a large cyst with varying wall thickness in the right upper lobe. Additional nodular foci in the tracheal lumen are typical of tracheal papillomas.*

(Left) *Axial CECT in the same patient shows cysts of various sizes in the right lung. The cyst in the right middle lobe has a thick, irregular wall.* **(Right)** *Coronal CECT in the same patient shows cysts of various sizes in the right lung. Some of the smaller cysts have thickened, irregular walls. Additional nodular intraluminal tracheal & bronchial papillomas are noted.*

TERMINOLOGY

Abbreviations

- Recurrent respiratory papillomatosis (RRP)

Definitions

- Benign tumors of aerodigestive tract caused by infection with human papillomavirus (HPV)

IMAGING

General Features

- Best diagnostic clue
  - Wart-like growth in larynx
- Location
  - Occurs at junctional sites between respiratory & squamous epithelium
    - Larynx is most common
    - Extralaryngeal spread in 30%: Oral cavity, trachea, bronchi, & esophagus
    - Tracheal or central bronchial involvement in 11%
    - Peripheral airway or alveolar involvement in 3%
      - Surgical manipulation of laryngeal papillomas ↑ risk of pulmonary dissemination
- Size
  - 1-2 mm to several centimeters
- Morphology
  - Warty lesions of larynx & tracheobronchial tree
  - Solid or cavitary pulmonary nodules

Radiographic Findings

- Radiography
  - Larynx, trachea, & main bronchi: Multifocal nodular irregularity of airway wall ± luminal narrowing
  - Lung: Multiple solid or cavitated nodules
    - As nodules enlarge, more likely to cavitate
    - Cavities may be thick- or thin-walled
    - Air-fluid levels suggest superinfection
    - Atelectasis & postobstructive pneumonia are uncommon
    - Large mass suggests malignant degeneration

CT Findings

- CECT
  - Soft tissue nodules protruding into airway ± luminal narrowing
  - Pulmonary findings
    - Nodules: May have mild enhancement
    - Cavitary lesions: Thin or thick, irregular enhancing walls
    - Malignant degeneration: Suspicious findings include heterogeneous enhancement, enlarging mass, or lymphadenopathy

Nuclear Medicine Findings

- PET/CT
  - May have areas of ↑ FDG uptake ± malignant degeneration
    - Difficult to distinguish RRP from squamous cell carcinoma
    - May help target specific lesion for biopsy

Imaging Recommendations

- Best imaging tool
  - CT is most sensitive to determine extent of disease & identify complications

DIFFERENTIAL DIAGNOSIS

Subglottic Infantile Hemangioma

- Strongly enhancing tracheal nodule on CT
- Usually presents in infancy with stridor
- Lung lesions are extremely rare

Granulomatosis With Polyangiitis

- Triad of pulmonary, paranasal sinus, & renal disease
- Pulmonary nodules may form thick-walled cavities
- Circumferential subglottic tracheal wall thickening

Septic Emboli

- Cavitated pulmonary nodules, often with thick irregular walls & surrounding lung consolidation
- Common causes: Endocarditis & septic thrombophlebitis
  - Lemierre syndrome: Septic thrombophlebitis of internal jugular vein after oropharyngeal infection → septic emboli

Metastases

- Variably sized lung nodules in patient with malignancy
- Cavitation of metastases is uncommon in children

Pneumatocele

- Transient thin-walled cyst(s) of variable size
- Usually follows known insult (trauma, infection, hydrocarbon ingestion)

Lymphangioleiomyomatosis

- Scattered thin-walled cysts of variable sizes
- Occurs in women of childbearing age
- May be sporadic or related to tuberous sclerosis complex

Langerhans Cell Histiocytosis

- Nodules &/or cysts, primarily in upper lung zones of older smokers

Invasive Aspergillosis

- Nodules have ground-glass "halo" of hemorrhage
- Immunocompromised host

PATHOLOGY

General Features

- Etiology
  - Perinatal transmission of HPV from infected mother to child
    - Risks: Active condylomata, primigravid mother, prolonged vaginal delivery, prolonged rupture of membranes, & newly acquired infection
    - 1 in 400 children delivered to women with active condylomata develop RRP
    - Still questionable if elective cesarean section is protective
  - 95% of cases of RRP are caused by HPV-6 & HPV-11
    - HPV-11 is more common & causes more severe disease

- Nearly all patients with malignant degeneration have HPV-11 infection
- Malignant transformation to squamous cell carcinoma in < 1% of RRP

Staging, Grading, & Classification

- Coltera/Derkay staging system
  - Separates aerodigestive tract into 25 subsites
  - Different sites are evaluated & scored for severity of disease

Gross Pathologic & Surgical Features

- Pedunculated mass(es) with finger-like projections

Microscopic Features

- Multiple fronds with central fibrovascular core covered by stratified squamous epithelium
- Lung & laryngeal lesions are composed of squamous cells; cavities are lined with squamous epithelium
- Squamous atypia is common even in benign lesions

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Clinical triad: Progressive hoarseness, stridor, difficulty breathing
- Other signs/symptoms
  - Dyspnea, chronic cough, recurrent upper respiratory infections, pneumonia, respiratory distress, dysphagia, & failure to thrive
  - Symptoms are often present for ~ 1 year before definitive diagnosis is established

Demographics

- Age
  - Bimodal age distribution
    - Juvenile-onset RRP (JO-RRP): Mean age at diagnosis: ~ 4 years
      - Younger age of onset = more severe disease
    - 2nd peak in adults 20-30 years of age = adult-onset RRP (AO-RRP)
      - Etiology is most likely sexual transmission of HPV
      - AO-RRP is typically less aggressive than in children
- Sex
  - M = F
- Epidemiology
  - Most common laryngeal tumor in children
  - 2nd most common cause of chronic hoarseness in children
  - In USA, RRP affects 4.3 per 100,000 children
  - Risk factors
    - Vaginal delivery, 1stborn child, & mother < 20 years of age
    - Prolonged delivery time (> 10 hours) doubles risk for development of RRP
    - Active condylomata ↑ risk 231x

Natural History & Prognosis

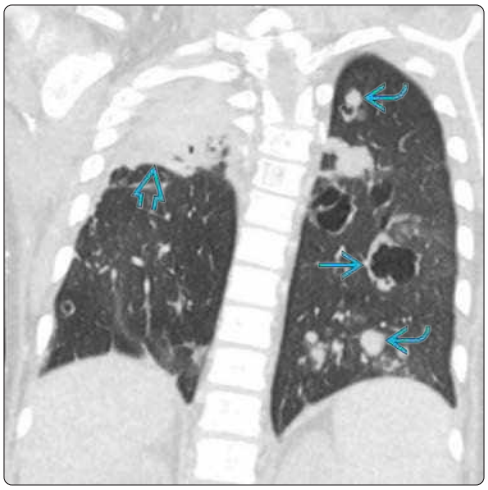
- Benign disease with varying degrees of lifelong morbidity & potentially fatal course
- Papillomas show variable growth rate
  - Overall, frequent exacerbations are typical
- Disease remission can occur spontaneously at any stage
  - Duration of remission is variable & unpredictable
  - Laryngeal disease is most likely to undergo remission
- Extralaryngeal spread in ~ 30% of patients
  - Tracheobronchial involvement in 11%
    - Tracheostomy is associated with significant morbidity
      - Papillomas coalesce at tracheotomy site
      - Distal spread is more likely
      - Tracheostomy is needed in 10-15% due to airway obstruction; delayed as long as possible
  - Lung parenchymal involvement in 3%
    - Lung nodules grow very slowly, usually measured in decades
    - May cavitate & become secondarily infected
    - May get postobstructive atelectasis & pneumonia
  - Lung cancer (squamous cell carcinoma) in 0.5%
    - High suspicion needs to be maintained
    - Malignant degeneration is more common in longstanding disease with history of prior irradiation & smoking
    - Look for increasing size of nodule on imaging
- Death due to large airway obstruction or respiratory failure
  - 57% mortality associated with pulmonary disease related to respiratory failure, infection, or malignant transformation

Treatment

- Current standard of care: Surgical resection
  - Need for repeated debulking is typical
- Laser ablation is now less commonly used
- Medical therapies are used as adjunct to surgery
  - Interferon & antiviral agents (cidofovir & acyclovir) may slow growth but are not curative
  - 3-carbinol, retinoic acid, & photodynamic therapy have variable effect
- HPV 9-valent vaccine protects against strains implicated in RRP
  - Vaccines ↓ incidence of RRP

DIAGNOSTIC CHECKLIST

Consider



- Laryngeal mass or soft tissue nodules of airway should raise suspicion for RRP

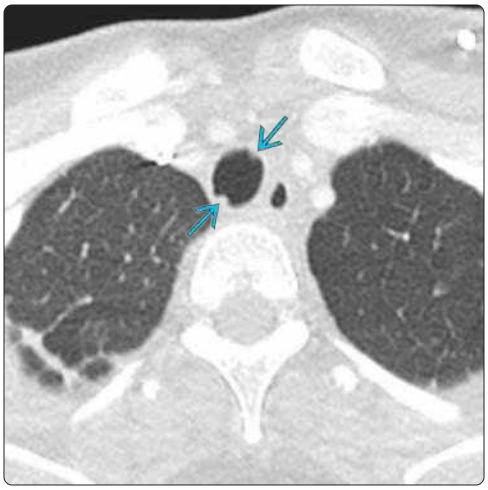


Image Interpretation Pearls

- Review parenchyma & airways in soft tissue & lung windows on multiplanar CT reconstructions

(Left) *Coronal CECT in an adolescent with respiratory papillomatosis & squamous cell carcinoma shows cysts & nodules in the left lung. The cysts have thickened, irregular walls. Consolidation is present in the right upper lobe.* **(Right)** *Axial CECT in an adolescent with respiratory papillomatosis shows nodular papillomas in the trachea.*

(Left) *Lateral radiograph of the airway in an adolescent with respiratory papillomatosis shows thickening & irregularity of the wall of the trachea, consistent with tracheal papillomas.* **(Right)** *PA radiograph of the chest in an adolescent with respiratory papillomatosis & subsequent squamous cell carcinoma shows multiple pulmonary cysts & nodules in the lungs. There is also consolidation in the left lower lobe.*

(Left) *Coronal CECT in the same patient shows multiple cysts & solid nodules. The cysts have a thickened, irregular wall. There is consolidation of the left lower lobe.* **(Right)** *Coronal F18 FDG PET image in the same patient shows multiple areas of FDG uptake in the chest. FDG uptake is not specific for malignancy. However, FDG avid lesions can help to guide biopsy in this setting.*

Lymphoma

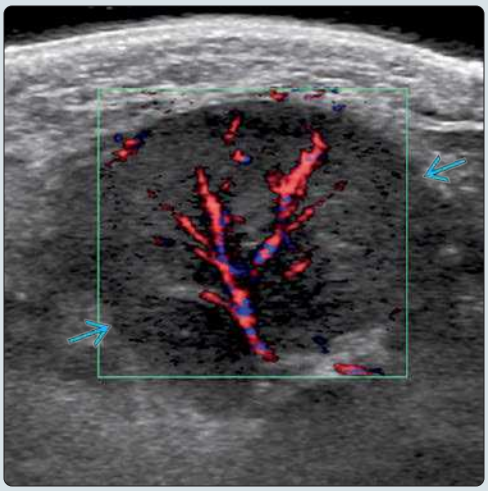
KEY FACTS

TERMINOLOGY

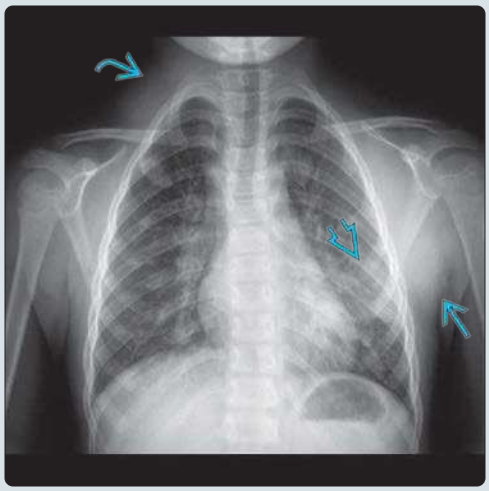
- Lymphoma: Malignant neoplasm arising from constituent cells of immune system or their precursors
- Hodgkin lymphoma (HL), non-Hodgkin lymphoma (NHL)

IMAGING

- Most common thoracic location: Anterior mediastinum
- US can help to distinguish normal thymus from abnormal thymus if nature of prominent anterior mediastinum is unclear radiographically
- CECT: Typically used for initial diagnosis
  - Enlarged & lobulated anterior mediastinal mass with fairly homogeneous soft tissue enhancement
    - Distorts, displaces, encases, & compresses adjacent structures
      - Airway compression: Associated with respiratory failure during induction of anesthesia
    - Other locations in thorax: Hilum, axilla, supraclavicular region, lungs, pleura, pericardium
- PET: Very sensitive & specific (96.5%, 100%) for lymphoma
  - Interpreted using Deauville criteria
  - Changes initial stage in 10-23% of patients compared to conventional imaging
  - Can distinguish active disease from residual inactive mass
  - Negative PET performed after 2 cycles of chemotherapy: Good prognostic factor



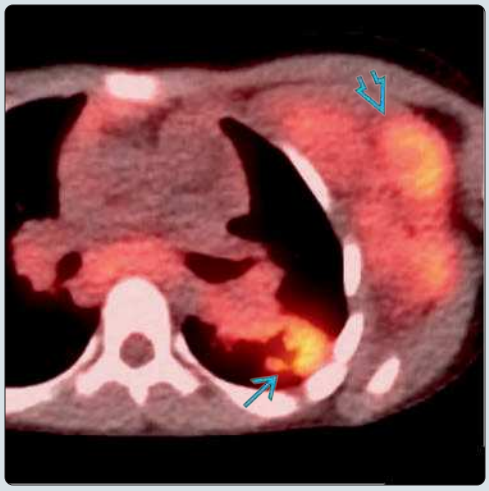
PATHOLOGY



- HL: Associated with Epstein-Barr virus in 50%
- NHL: Etiology depends on subtype, often translocation

CLINICAL ISSUES

- Lymphoma is 3rd most common pediatric malignancy
  - Accounts for 10-15% of all pediatric malignancies
- 60% of children with lymphoma have respiratory symptoms
- HL: 5-year survival = 91%
- NHL: 5-year survival = 70-76%



(Left) *Longitudinal color Doppler US of the left axilla in a teenager diagnosed with Hodgkin lymphoma shows an abnormally enlarged & rounded lymph node with loss of the typical nodal architecture. There is no surrounding fat edema. Multiple other enlarged axillary nodes were also visible.* **(Right)** *PA chest radiograph in the same patient shows ↑ soft tissue density & fullness in the left axilla & right neck with a patchy opacity in the left lung.*

(Left) *Axial CECT of the chest in the same patient shows multiple nodular opacities in the left lower lobe extending from the hilum to the lung periphery.* **(Right)** *Axial F18-FDG PET/CT fused image in the same patient shows ↑ metabolic activity in the left axillary nodal mass as well as in the left lower lobe lymphomatous infiltrate.*

TERMINOLOGY

Abbreviations

- Hodgkin lymphoma (HL), non-Hodgkin lymphoma (NHL)

Synonyms

- Hodgkin disease

Definitions

- Lymphoma: Malignant neoplasm arising from constituent cells of immune system or their precursors
  - Classic HL subtypes: Nodular sclerosis (NS), lymphocyte rich (LR), mixed cellularity (MC), lymphocyte depleted (LD)
  - NHL subtypes: Burkitt lymphoma (BL), diffuse large B-cell lymphoma (DLBCL), anaplastic large cell lymphoma (ALCL), lymphoblastic lymphoma (LBL)

IMAGING

General Features

- Best diagnostic clue
  - Anterior mediastinal mass or dominant nodal mass
- Location
  - Most common thoracic location: Anterior mediastinum
  - Other locations in thorax: Hilum, axilla, supraclavicular region, lungs, pleura, pericardium
- Size
  - Pathologic lymph nodes are traditionally considered as > 1 cm in short axis
    - Negative & positive predictive values are not 100%
  - Bulk mediastinal disease in HL: Mediastinal tumor is > 1/3 of maximal thoracic diameter on upright PA radiograph
- Morphology
  - HL
    - Mediastinal disease in 2/3 of patients
      - Most often associated with NS subtype
    - Often associated with hilar adenopathy
  - NHL
    - Anterior mediastinum is 2nd most common primary site
    - Frequency of intrathoracic involvement depends on subtype
      - 70% with LBL have mediastinal mass
      - 25% with DLBCL have primary mediastinal disease
      - Mediastinum is common location for ALCL
- Associated findings & complications
  - Superior vena cava compression/obstruction
  - Central airway compression/obstruction
  - Pleural effusion
  - Pericardial effusion
  - Pulmonary involvement

Radiographic Findings

- Anterior mediastinal mass
- Look for evidence of complications listed previously
- Tracheal displacement or narrowing → airway compression

CT Findings

- CECT
  - Diffuse thymic infiltration: Enlarged & lobulated with fairly homogeneous soft tissue enhancement
    - Distorts, displaces, encases, & compresses adjacent structures
    - Ca^{2+} is rare in untreated disease
  - Airway compression
    - > 50% reduction in area of trachea is associated with respiratory failure during induction of anesthesia
      - Biopsy can be performed semierect with mild sedation in these patients
    - Airway compromise is predicted by orthopnea, upper body edema, great vessel compression, & mainstem bronchus compression
  - Lungs involved in 5-15% in HL & < 5% in NHL
    - Pulmonary nodules ± cavitation
    - Reticular interstitial pattern from venous or lymphatic obstruction
    - Lobar or segmental consolidation
  - ± pleural or pericardial effusions

MR Findings

- STIR
  - Sensitive for detection of bone marrow & soft tissue lesions
  - Cannot distinguish normal from abnormal lymph nodes
- Whole-body DWI with background body signal suppression (DWIBS)
  - Creates images appearing similar to PET
  - Not as specific as FDG PET; requires correlation with lymph node size
    - All lymph nodes restrict diffusion; DWIBS ↑ conspicuity of nodes compared to other MR sequences
    - Must incorporate size criteria on anatomic imaging to help determine benign vs. malignant

Ultrasonographic Findings

- Grayscale ultrasound
  - Can help assess neck & axillary nodes, potentially guiding biopsy
  - Can look for pleural or pericardial effusions
  - Can help to distinguish normal thymus from abnormal thymus
    - Normal thymus: Uniform echogenic dot-dash pattern without vessel compression
    - HL/NHL: Heterogeneously hypoechoic lobular mass encasing & distorting vessels

Nuclear Medicine Findings

- PET
  - Interpreted using Deauville criteria (5-point visual scale)
    - (1) No uptake above surrounding background
    - (2)Uptake ≤ mediastinal blood pool
    - (3) Uptake > mediastinal blood pool but ≤ liver
    - (4) Moderately ↑ compared to liver
    - (5) Markedly ↑ compared to liver
  - Very sensitive & specific (96.5%, 100%) for detection of disease
  - Changes initial stage in 10-23% of patients compared to conventional imaging
  - Can help to provide prognostic information
    - Negative PET performed after 2 cycles of chemotherapy: Good prognostic factor
  - Can distinguish active disease from residual inactive mass

- PET/MR shows promise due to combination of functional imaging, anatomic imaging, DWI, & ↓ radiation

Imaging Recommendations

- Best imaging tool
  - CECT is most commonly used for diagnosis
  - PET/CT is used for staging & follow-up
- Protocol advice
  - Beware of placing patient in prone position or using sedation if there is compression of airway

DIFFERENTIAL DIAGNOSIS

Normal Thymus

- Large normal thymus occurs in children < 5 years of age
- Undulating margins; does not displace/compress airway or vessels
- Echogenic dot-dash pattern throughout on US

Germ Cell Tumor

- Often heterogeneous with cystic, fatty, &/or calcific foci

Lymphatic Malformation

- Multicystic mass of neck & mediastinum present since birth

Neuroblastoma

- Paraspinal mass ± Ca^{2+} in child < 10 years of age

Thymoma

- Very uncommon in children

PATHOLOGY

General Features

- Etiology
  - HL: Associated with Epstein-Barr virus (EBV) in 50%
    - Other risks: Immunocompromised, ↓ socioeconomic status, small family size, early birth order
  - NHL: Etiology depends on subtype
- Associated abnormalities
  - Down syndrome has higher incidence of leukemia/lymphoma

Staging, Grading, & Classification

- HL subtypes (frequency): NS (70%), MC (20%), LR (5%), LD (5%)
- HL staging: Lugano classification
  - Stage I: Single lymph node or group of nodes
  - Stage II: 2 or more lymph node groups on same side of diaphragm
  - Stage III: Nodal involvement on both sides of diaphragm or nodal involvement in chest & splenic involvement
  - Stage IV: Extranodal involvement
  - Designations applicable to any stage
    - A: Asymptomatic
    - B: Symptoms of fever, night sweats, weight loss > 10%
- NHL subtypes (frequency): BL (30%), DLBCL (10-20%), ALCL (10%), LBL (30%)
- NHL staging: International Pediatric Non-Hodgkin Lymphoma Staging System
  - Stage I: Single nodal area outside abdomen & mediastinum
  - Stage II
    - Single extranodal tumor with regional node involvement
    - ≥ 2 nodal areas on same side of diaphragm
    - Primary gastrointestinal tract tumor that is completely resectable
  - Stage III
    - ≥ 2 extranodal tumors
    - Nodal tumor above & below diaphragm
    - Any intrathoracic tumor (mediastinal, hilar, pulmonary, pleural, or thymic)
    - Intraabdominal & retroperitoneal disease, including liver, spleen, kidney, or ovary
    - Any paraspinal or epidural tumor
    - Single bone lesion with concomitant involvement of extranodal &/or nonregional nodal site
  - Stage IV: Bone marrow or CNS disease

CLINICAL ISSUES

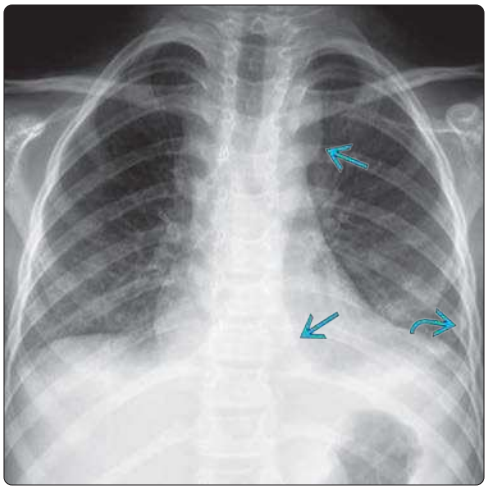
Presentation

- Most common signs/symptoms
  - 60% of children have respiratory symptoms
  - HL may present with painless adenopathy
- Other signs/symptoms
  - HL: B symptoms of fever, night sweats, weight loss
  - NHL: Can have life-threatening symptoms due to compression of trachea or superior vena cava or large pleural or pericardial effusion

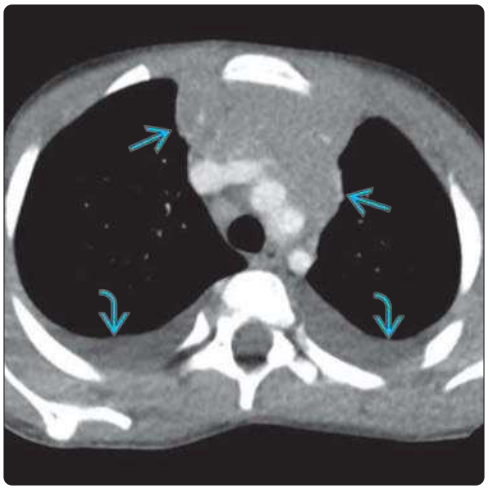
Demographics

- Age
  - Much more common in 2nd decade of life
  - Prevalence of NHL ↑ with age
- Sex
  - HL: M > F under 15 years old; F > M over 15 years old
  - NHL: M > F
- Epidemiology
  - Lymphoma: 3rd most common pediatric malignancy
    - Accounts for 10-15% of all pediatric malignancies

Natural History & Prognosis



- HL: 5-year survival = 91%
- NHL: 5-year survival = 70-76%



Treatment

- HL: Chemotherapy ± radiation
- NHL: Chemotherapy ± bone marrow transplantation or radiation therapy

(Left) *PA radiograph of the chest in a teenager with Burkitt lymphoma shows a mediastinal mass extending from the superior mediastinum to the lower chest. A small left pleural effusion is also present.* **(Right)** *Axial CECT in the same patient shows a slightly heterogeneous anterior mediastinal mass & small bilateral pleural effusions. The volume of tissue & lobulated contours of the mass would be atypical for residual thymus in a teenage patient.*

(Left) *Sagittal CECT in the same patient with Burkitt lymphoma shows the superior to inferior extent of the anterior mediastinal mass. Again note the pleural effusion.* **(Right)** *Coronal image from an F18-FDG PET in the same patient shows ↑ metabolic activity within the mediastinal mass as well as scattered lymph nodes.*

(Left) *PA radiograph of the chest in a child with Hodgkin lymphoma shows a large anterior mediastinal mass with lobulated contours. Note the left pleural effusion.* **(Right)** *Axial fused F18 FDG PET/CT in the same patient shows uptake at the periphery of the large anterior mediastinal mass. The central area without FDG uptake was necrotic.*

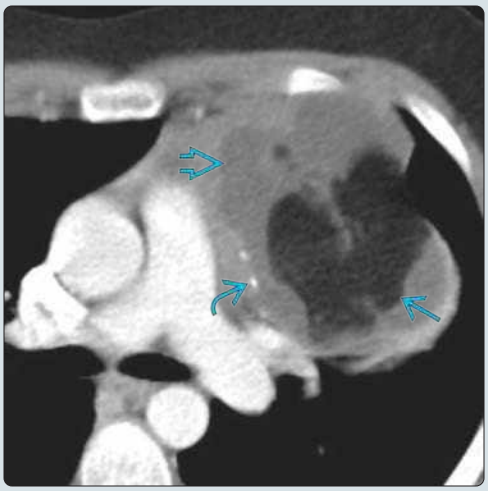
Germ Cell Tumors

KEY FACTS

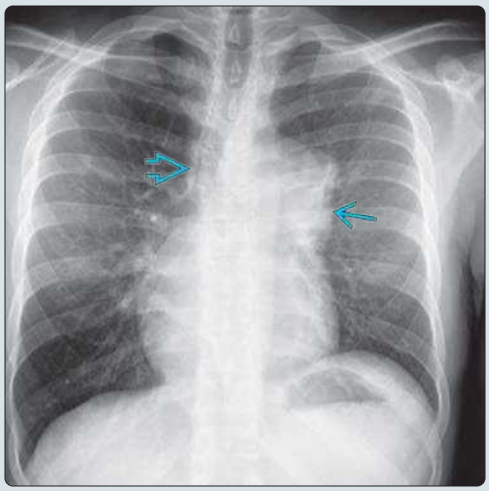
TERMINOLOGY

- Germ cell tumor (GCT) types: Teratoma, seminoma, nonseminomatous germ cell tumor (NSGCT)
  - Teratoma: Mature, immature, malignant
  - Seminoma: Germinoma & dysgerminoma
  - NSGCT: Embryonal cell, yolk sac tumor, choriocarcinoma, & mixed GCT
- Derived from primordial germ cells that differentiate into embryonic & extraembryonic structures

IMAGING

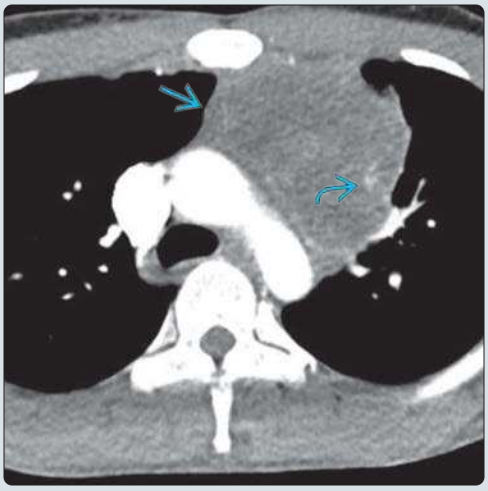


- Best clue: Heterogeneous anterior mediastinal mass arising within or adjacent to thymus
  - Less common locations: Posterior mediastinum, heart, pericardium
- Teratoma
  - Mostly cystic + soft tissue, fat, & calcium
    - 1 or more cysts; 20-40% calcify; 93% contain fat
    - CECT is sensitive for these components
- Seminoma
  - Homogeneous, lobulated, bulky soft tissue mass
  - Often straddles midline & has mass effect
- NSGCT
  - Heterogeneous mass with hemorrhage & necrosis
  - Irregular margins: Obliterated fat planes & lung invasion
- Pericardial lesions often cause pericardial effusion
- Beware of potential airway collapse from tumor compression during sedation/general anesthesia



PATHOLOGY

- 50-300x ↑ risk of mediastinal GCT with Klinefelter syndrome



CLINICAL ISSUES

- Dyspnea, chest pain, cough, superior vena cava syndrome, hoarseness, fever, weight loss
- Asymptomatic in 50-60% of teratomas, 38% of seminomas, & 10% of NSGCTs

(Left) *Axial CECT shows an anterior mediastinal mass containing fat, fluid, & calcification. This combination of densities in a mass is characteristic of a teratoma.* **(Right)** *PA chest radiograph in a young adult shows a lobulated left mediastinal mass. Note the rightward tracheal deviation & the elevation of the left hemidiaphragm. This latter finding raises concern for involvement of the left phrenic nerve.*

(Left) *Axial CECT in the same patient shows the soft tissue density anterior mediastinal mass. Multiple small vessels extend through the mass. No fat or calcification was identified in the lesion.* **(Right)** *Axial fused F18 FDG PET/CT in the same patient shows radiopharmaceutical uptake within portions of the mediastinal mass. At pathology, this mass was confirmed to be a germ cell tumor with sarcomatous & neuroblastic components.*

TERMINOLOGY

Synonyms

- Teratoma, seminoma, nonseminomatous germ cell tumor (NSGCT)

Definitions

- Germ cell tumor (GCT): Tumor derived from primordial germ cells
- Teratoma: 3 major types
  - Mature teratoma: Characterized by mixture of adult-type tissues derived from 3 germinal layers
  - Immature teratoma: Contains embryonic or fetal tissue, often neuroepithelial structures
  - Malignant teratoma: Contains foci of malignant transformation
- Malignant GCT: Seminoma & NSGCT
  - Seminoma: Germinoma & dysgerminoma
  - NSGCT: Embryonal cell, yolk sac tumor (YST), choriocarcinoma, & mixed GCT

IMAGING

General Features

- Best diagnostic clue
  - Heterogeneous anterior mediastinal mass arising within or adjacent to thymus
- Location
  - Anterior mediastinum is most common
  - Less common locations: Posterior mediastinum, heart, pericardium
- Size
  - Average size for NSGCT: 9 cm; seminoma: 5 cm
- Morphology
  - Teratoma: Mostly cystic with soft tissue, fat, & calcium elements
  - Seminoma: Homogeneous, lobulated, bulky mass
  - NSGCT: Heterogeneous soft tissue mass with hemorrhage & necrosis

Radiographic Findings

- Teratoma: Round, sharply marginated, anterior mediastinal mass
  - 20-40% calcify
- Seminoma: Bulky, lobulated, anterior mediastinal mass
- NSGCT: Large, anterior mediastinal mass
  - Pleural or pericardial effusions may be present

CT Findings

- NECT
  - Teratoma: Sharply marginated anterior mediastinal mass
    - Extends to 1 side of midline
    - Fatty, cystic/solid soft tissue, & calcified components are often visible
      - 93% contain fat
  - Seminoma: Large solid mass with homogeneous density
    - Straddles midline; mass effect on adjacent structures
  - NSGCT: Large, heterogeneous mass
    - Central area of hemorrhage or necrosis
    - Irregular margins with obliterated fat planes
    - May invade lung, chest wall, & diaphragm
    - Metastasizes to lymph nodes, lung, & liver
- CECT
  - Better defines extent of lesion & invasion
    - Look for compression of vessels & airway
  - More clearly differentiates solid & cystic components
  - Teratoma: Enhancement of rim & septations
  - Seminoma: Mild enhancement
  - NSGCT: Enhancement of peripheral soft tissue around central necrotic region

MR Findings

- T1WI
  - Teratoma: Well-circumscribed lesion
    - Varied signal of fat, soft tissue, calcium, & fluid
      - Fluid varies in signal due to protein content
- T2WI
  - Teratoma: Signal depends on tissue types in lesion
    - Fluid has high signal
    - Look for signal drop-out on fat-saturated images

Imaging Recommendations

- Best imaging tool
  - CECT demonstrates differing tissue components, extent of disease, & complications
  - Beware of potential airway collapse from tumor compression during sedation/general anesthesia

DIFFERENTIAL DIAGNOSIS

Normal Thymus

- Large, quadrilateral-shaped, homogeneous tissue in 1st few years of life
- No mass effect on vessels or airway
- Uniform dot-dash pattern of echoes on US

Lymphoma

- Bulky, lobulated, homogeneous mass compressing & displacing airway & vessels
- Rarely calcifies before treatment

Lymphatic Malformation

- Congenital multicystic mass of neck & chest
- May have soft tissue attenuation following hemorrhage

Thymic Cyst

- Usually unilocular, may be bilobed with neck & mediastinal components
- Often asymptomatic but can compress adjacent structures

Thymoma

- Rare in children
- Associated with paraneoplastic syndromes

PATHOLOGY

General Features

- Etiology
  - Most common theory: Local transformation of primordial germ cells misplaced during embryogenesis
- Associated abnormalities
  - 50-300x ↑ risk of mediastinal GCT with Klinefelter syndrome
  - Possible relationship to Li-Fraumeni syndrome & Down syndrome

- NSGCT is associated with hematologic malignancies, most commonly acute megakaryoblastic leukemia

Gross Pathologic & Surgical Features

- Teratoma: Well-encapsulated, predominantly cystic
  - Cystic component is usually unilocular
  - May be adherent to mediastinal structures
- Seminoma: Unencapsulated, well circumscribed, large
  - Usually has solid, uniform appearance with focal areas of necrosis or hemorrhage
- NSGCT: Unencapsulated, irregularly marginated, heterogeneous large mass
  - Large areas of necrosis, hemorrhage, & cysts
  - Invades local structures

Microscopic Features

- Teratoma
  - Admixture of adult-type tissues
  - Derived from 3 germinal layers
  - Most common components: Skin & appendages, pancreatic, bronchial, neural, gastrointestinal, muscular, fatty, & cartilaginous elements
- Seminoma
  - Sheets of round or polygonal cells surrounded by septa of connective tissue infiltrated by lymphocytes
  - Prominent eosinophilic nucleoli with characteristic spiked appearance
- NSGCT
  - Embryonal: Large malignant cells arranged in sheets or tubular/acinar patterns
  - YST: Reticular pattern with cords of tumor cells embedded in myxoid stroma is most common
  - Choriocarcinoma: Mix of syncytiotrophoblast, cytotrophoblast, & intermediate trophoblast

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic in 50-60% of teratomas, 38% of seminomas, & 10% of NSGCTs
  - Dyspnea (25-85%), chest pain (10-52%), cough (10-24%), superior vena cava syndrome (6-40%), hoarseness (1-14%), fever (13%), weight loss (11%)
  - α-fetoprotein is elevated in 74% of patients with NSGCT; β-HCG is elevated in 38%
- Other signs/symptoms
  - Gynecomastia, testicular atrophy, facial fullness, precocious puberty
  - If teratoma contains endocrine pancreas, can cause hyperinsulinism & hypoglycemia
  - Rare rupture of cystic component of teratoma → erosion into tracheobronchial tree followed by expectoration of sebaceous material & hair

Demographics

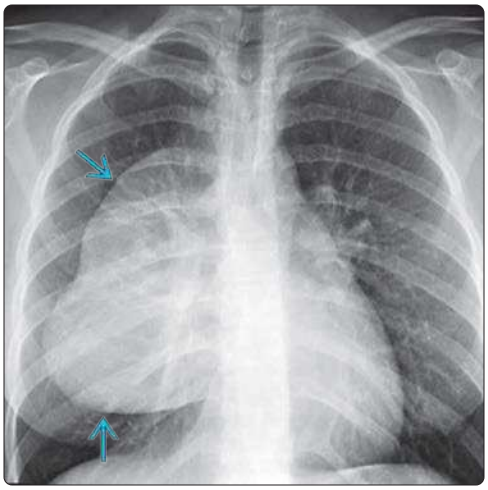
- Age
  - Separated into prepubertal & postpubertal due to differences in genetics & clinical behavior
- Sex
  - Mature teratoma: M = F
  - Malignant GCTs
    - Children: M = F [except in YST where F > M (4:1)]
    - Teenagers & adults: M > F (5:1)
- Epidemiology
  - GCT is 3rd most common mediastinal tumor in children
  - Mature teratoma: 19-24% of anterior mediastinal tumors in children
    - Teratoma: 44% of mediastinal GCT
    - Seminoma: 16-37% of mediastinal GCT
    - NSGCT: 14% of mediastinal GCT
    - Mixed GCT: 13-25% of mediastinal GCT

Natural History & Prognosis

- Prognosis is dependent on multiple factors
  - Age < 30 years is associated with better prognosis
  - Histological type
    - Mature teratoma: Benign (80% of mediastinal GCT)
    - Immature teratoma: Good prognosis, no risk of recurrence or metastasis
    - Teratoma with component of malignant GCT: Prognosis depends on malignant component
    - Seminoma: 5-year survival rate = 90%
    - NSGCT: 5-year survival rate = 48%
  - Presence of metastases (most common in lungs or bone)
  - Stage: In children, prognosis is related to stage
  - Status of resection: Complete resection is strongest prognostic indicator
  - Tumor markers: α-fetoprotein > 10,000 ng/mL = worse prognosis; ↑ β-HCG = worse prognosis in adults

Treatment

- Mature teratoma: Surgery
- Seminoma: Chemotherapy followed by surgery for residual disease
- Nonseminomatous: Chemotherapy & surgery



DIAGNOSTIC CHECKLIST

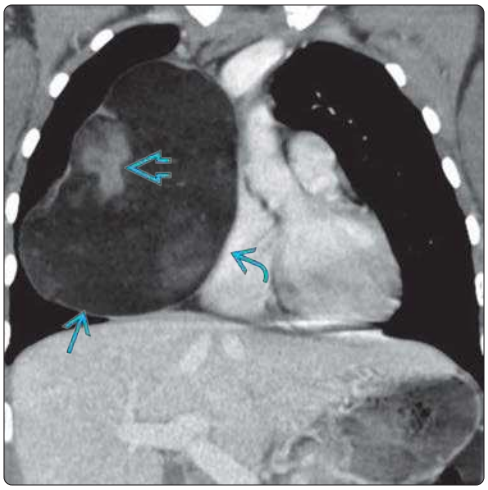


Image Interpretation Pearls

- If Ca^{2+} is present, mass = teratoma until proven otherwise
- NSGCT invades surrounding structures
- Large mediastinal masses have risk of cardiopulmonary arrest at induction of anesthesia in patients with tracheal or vascular compression

(Left) *PA radiograph of the chest shows a large, lobulated right-sided anterior mediastinal mass.* **(Right)** *Coronal CECT in the same patient shows that the large mediastinal mass is mostly composed of fat. The mass compresses the right atrium, & there is a soft tissue component within the mass.*

(Left) *Axial CECT in the same patient shows that the large mediastinal mass is mostly composed of fat. Note the marked mass effect on the superior vena cava.* **(Right)** *PA radiograph of the chest in an infant shows a large mediastinal mass displacing the heart, trachea, & mediastinum to the right. There are faint Ca^{2+} within the mass.*

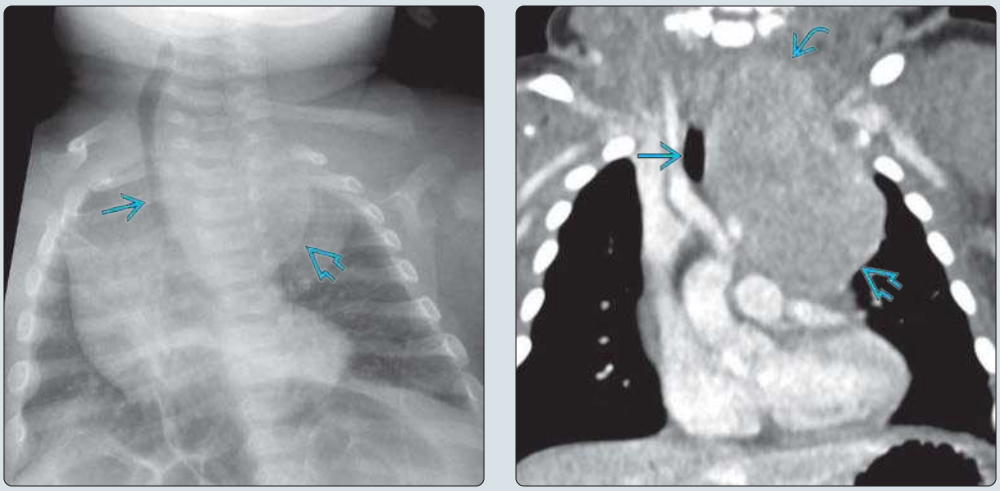
(Left) *Lateral radiograph of the chest in the same patient shows the large mediastinal mass extending posteriorly to the chest wall. Calcification is visible within the mass.* **(Right)** *Coronal CECT in the same infant shows the large mediastinal mass displacing the heart, trachea, & mediastinum to the right. The mass has fat, soft tissue, & fluid density but also contains well-formed bones with articulations, consistent with a teratoma.*

Neuroblastoma, Thoracic

KEY FACTS

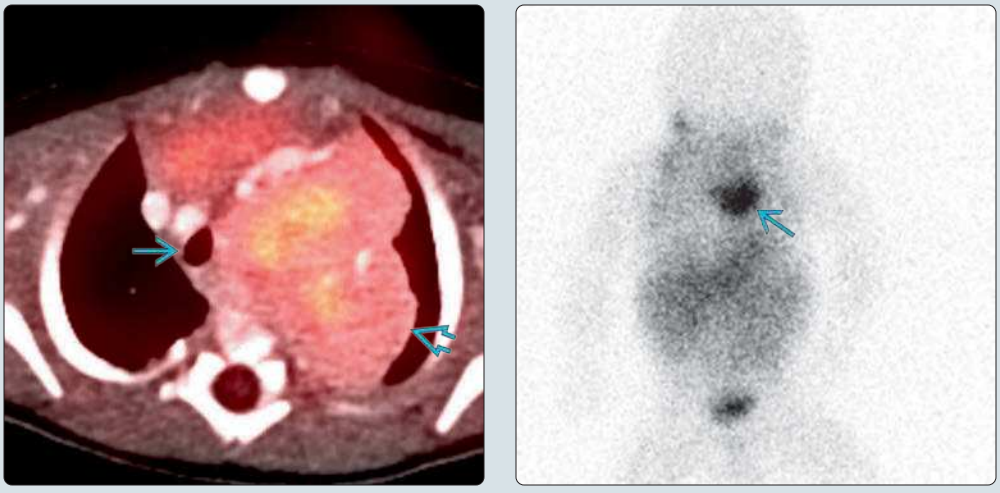
TERMINOLOGY

- Malignant tumor of primitive neural crest cells
- Continuous spectrum with more mature/benign counterparts: Ganglioneuroma & ganglioneuroblastoma



IMAGING

- Posterior mediastinal (paraspinal) mass with Ca^{2+}
  - Solid, elongated mass with paraspinal stripe widening ± rib splaying/erosion
- Tendency to invade spinal canal via neural foramen
- MR ± contrast is best imaging modality to assess local tumor (due to its ability to evaluate neural foraminal/intraspinal extension)
- MIBG scan is best for determining full extent of disease



CLINICAL ISSUES

- 3rd most common pediatric malignancy after leukemia & CNS tumors
  - Most common extracranial solid tumor in children
- Posterior mediastinum: 3rd most common site for neuroblastoma (NBL) (15-20% of cases)
  - Thoracic NBL is often asymptomatic & discovered incidentally
  - ± respiratory symptoms &/or neurologic symptoms (with cord compression)
- Mean age for thoracic presentation: 25 months
- 60-76% of patients with thoracic NBL have ↑ levels of urinary catecholamines (e.g., vanillylmandelic acid)
- Metastases are most commonly to liver & bone (including marrow)
- Treatment options: Surgical resection, chemotherapy, radiation, stem cell transplant, I-131 MIBG therapy
  - Based on anatomic stage, age, & histologic features
  - Stage 4S/MS: High rates of spontaneous regression
- Overall 5-year survival: 78%
  - Thoracic NBL is associated with higher survival rates than abdominal disease

(Left) *Frontal radiograph in an infant with thoracic neuroblastoma shows a round mediastinal mass displacing & compressing the trachea. Lesions at the apex tend to be more rounded than the elongated lower paraspinal neuroblastomas. No obvious osseous changes are visualized.* **(Right)** *Coronal CECT in the same patient shows the large mediastinal mass displacing the trachea & mediastinum to the right. The tumor extends superiorly through the thoracic inlet.*

(Left) *Axial fused F-18 FDG PET/CT in the same patient shows heterogeneous FDG uptake within the mediastinal mass. The trachea is mildly compressed & displaced to the right. Compression of the trachea is an image-defined risk factor. No intraspinal disease is identified.* **(Right)** *MIBG scan in the same patient shows uptake of the radiopharmaceutical in the mediastinal tumor. No osseous metastases were identified.*

TERMINOLOGY

Abbreviations

- Neuroblastoma (NBL)

Definitions

- Malignant tumor of primitive neural crest cells

IMAGING

General Features

- Best diagnostic clue
  - Posterior mediastinal (paraspinal) mass with Ca^{2+}
  - Invasive mass that tends to encase & displace vessels
  - Often extends into spinal canal via neural foramina
- Location
  - Posterior mediastinum arising from sympathetic chain
    - Often inferior or apical
- Morphology
  - Elongated or round solid paraspinal mass

Radiographic Findings

- Paraspinal soft tissue mass with widening of paraspinal stripe(s)
- Ca^{2+} within mass on up to 30% of radiographs
- Rib involvement is common
  - Widening/splaying of intercostal spaces
  - Mild erosion/destruction of ribs
- Neural foraminal widening from intraspinal extension
- Pleural effusion may be present
- Bone metastases are usually lucent, often subtle

CT Findings

- CECT
  - Posterior mediastinal mass, most commonly inferior
  - Mass is often heterogeneous (from necrosis & hemorrhage)
  - Ca^{2+} is seen on CT in 85-90%
  - ± local bone erosion or metastases

MR Findings

- T1WI
  - Intermediate-to-low signal paraspinal mass
- T2WI FS/STIR
  - Intermediate- to moderately high-signal paraspinal mass
  - Possible extension into neural foramen
    - Cord compression in up to 25%
  - Hyperintense bone marrow metastases
- DWI
  - May show restricted diffusion
- T1WI C+ FS
  - Variable enhancement, may be heterogeneous

Nuclear Medicine Findings

- MIBG scintigraphy
  - Avid uptake related to catecholamine production
  - 88% sensitive & 98% specific in detection of NBL
    - ~ 10% of NBL are not MIBG avid
  - Superior to PET/CT in depicting advanced disease & bone marrow metastases
  - Excellent for following therapy response
- PET/CT
  - F-18 FDG is useful in non-MIBG-avid disease
- Bone scan
  - Uptake in cortical bone metastasis &/or local bone invasion
  - Uptake in calcified primary mass (up to 74%)

Imaging Recommendations

- Best imaging tool
  - MR ± contrast: Evaluates intraspinal extension & bone marrow metastases
  - MIBG for determining full extent of disease

DIFFERENTIAL DIAGNOSIS

Widening of Inferior Paravertebral Soft Tissues

- Normal paravertebral soft tissues
  - Should not exceed adjacent pedicle in thickness or be inferolaterally oriented
  - May be more prominent in obese & supine patients
- Infectious discitis
  - Disc space narrowing, vertebral endplate irregularity
- Vertebral injury
  - Trauma & pain history are usually clear
  - Vertebral body compression or malalignment

Posterior Mediastinal Mass in Child < 3 Years of Age

- Other neuroblastic tumors
  - Ganglioneuroma
    - Most common posterior mediastinal mass in adolescents & young adults
    - Benign; similar imaging features as NBL
    - May represent mature form of NBL
  - Ganglioneuroblastoma
    - Contains both mature & immature neuroblasts
    - May represent maturing form of NBL
- Round pneumonia
  - No evidence of rib erosion or intraspinal extension
  - ± air bronchograms, parapneumonic effusion
  - Short-term follow-up radiographs after antibiotics can help confirm round pneumonia (with expected interval clearance)
- Extralobar bronchopulmonary sequestration
  - May appear similar to NBL as paraspinal mass
  - Lung relationship & feeding vessel are seen on CTA

PATHOLOGY

General Features

- Etiology
  - Malignant tumor of primitive neural crest cells
  - Continuous spectrum with more benign counterparts: NBL → ganglioneuroblastoma → ganglioneuroma
  - Most commonly arises from adrenal gland but can arise anywhere along sympathetic chain
- Genetics
  - ↑ copies of *MYCN* (n-MYC) protooncogene are associated with poor prognosis (*MYCN* amplification)
  - CD44: Glycoprotein on cell surface
    - ↑ levels: Better prognosis
- Associated abnormalities
  - Most neuroblastic tumors occur in isolation

Staging, Grading, & Classification

- International NBL Risk Group Staging System: Imaging-based staging system that requires identification of image-defined risk factors (IDRFs)
  - L1: Localized tumor confined to 1 body compartment; no IDRFs
  - L2: Local-regional tumor with ≥ 1 IDRF
  - M: Distant metastases (except stage MS)
  - MS: Metastatic disease in children < 18 months of age with metastases confined to skin, liver, &/or bone marrow
  - Thoracic-related IDRFs include
    - Tumor extension in 2 body compartments
    - Tumor encasement of carotid artery, vertebral artery, subclavian artery, aorta, celiac axis, or superior mesenteric artery
    - Tumor encasing internal jugular vein, subclavian vein, or vena cava
    - Tumor compressing trachea &/or bronchi
    - Tumor encasing brachial plexus roots
    - Lower mediastinal tumor, infiltrating costovertebral junction between T9 & T12
    - Tumor infiltrating porta hepatis
    - Tumor invading renal pedicle or touching renal vessels
    - Intraspinal tumor extension so that > 1/3 of spinal canal in axial plane is invaded, perimedullary leptomeningeal spaces are not visible, or spinal cord has abnormal signal
    - Infiltration of pericardium or diaphragm
- Bones (including marrow) in both staging systems must be clear by MIBG to qualify for stage 4S/MS (i.e., marrow disease is limited to < 10% involvement by aspiration)

Microscopic Features

- Immature, undifferentiated sympathetic cells: Small, round, blue cells
- Homer Wright rosettes: Circular groups of cells
- International NBL Pathology Classification (Shimada): Combines histiologic features & age of patient to define favorable & unfavorable histology for prognosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Thoracic NBL is often asymptomatic & discovered incidentally
  - Respiratory symptoms, including cough
  - Neurologic symptoms with cord compression
  - 60-76% of patients with thoracic NBL have ↑ levels of urinary catecholamines (vanillylmandelic acid)
- Other signs/symptoms
  - Fever, chest pain, opsoclonus-myoclonus, Horner syndrome
  - Skin mets: Blueberry muffin syndrome

Demographics

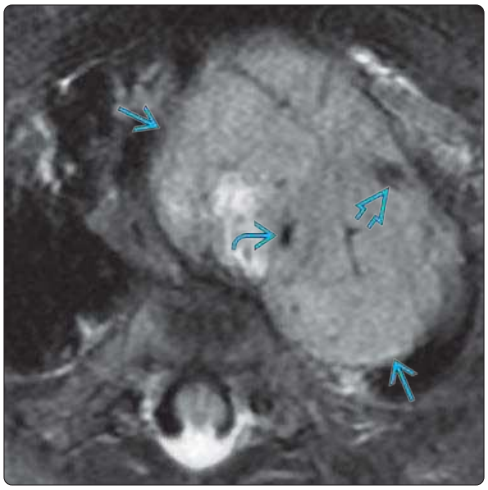
- Age
  - Mean for thoracic NBL presentation: 25 months
  - Mean for all NBL: 15-17 months
- Sex
  - F:M = 1.4:1
    - Different from other sites of NBL where M > F
- Epidemiology
  - NBL: 3rd most common pediatric malignancy after leukemia & CNS tumors
    - Most common extracranial solid tumor in children
    - 7-10% of childhood cancers
    - 10-15% of childhood cancer deaths
  - Posterior mediastinum: 3rd most common site for NBL (15-20% of cases) after adrenal & extraadrenal retroperitoneum

Natural History & Prognosis

- Thoracic NBL is associated with higher survival rates than more common NBL sites
  - Overall 5-year survival: 78%; 90% survival for stages 1, 2, 3; 29% for stage 4
- Thoracic NBL has different molecular profile than tumors of adrenal origin
  - Thoracic NBL has lower frequency of *MYCN* amplification; more likely to have numerical chromosomal alterations
- Features of NBL associated with better prognosis
  - Thoracic primary
  - Age at diagnosis < 18 months, histologic grade (Shimada system), ↓ *MYCN* amplification (copies of gene), stage MS/4S
- Metastasizes most commonly to liver, bone, & marrow
- Some lesions may spontaneously regress/mature into less malignant tumors (ganglioneuroma)

Treatment

- Options: Surgical resection, chemotherapy, radiation, stem cell transplant, biologic agents, I-131 MIBG therapy
  - Based upon stage, age, & histologic features
  - Less aggressive lesions may be treated with surgical resection alone
  - For stage 4S/MS: Some institutions advocate no treatment due to rates of spontaneous regression



DIAGNOSTIC CHECKLIST

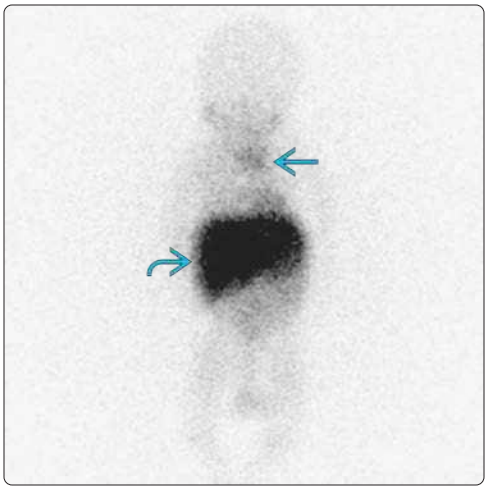


Image Interpretation Pearls

- Look for rib splaying/erosions & soft tissue Ca^{2+} when focal paraspinal mass is seen in child

(Left) *Axial T2 FS MR in a young child with neuroblastoma shows a large solid mass in the upper chest. The tumor encases the left vertebral & subclavian arteries. Neuroforaminal extension could also be seen more superiorly (not shown).* **(Right)** *MIBG scan in the same patient shows mild uptake of the radiopharmaceutic in the cervicothoracic mass. There is considerable uptake within the liver due to hepatic metastases.*

(Left) *Frontal radiograph in an infant shows an elongated left paraspinal mass with mild splaying of the left 8th-9th ribs as compared to the right intercostal space at this level.* **(Right)** *Axial T2 MR in the same patient shows a lobulated, intermediate signal intensity left paraspinal mass lifting the aorta off of the spine. The tumor surrounds 180° of the aorta but does not fully encase it. The tumor also involves the neural foramen with minimal distortion of the thecal sac.*

(Left) *Frontal radiograph shows widening of the right paraspinal stripe associated with a lobulated mass. A retrocardiac mass & speckled Ca^{2+} are noted on the left.* **(Right)** *Axial CECT of the same patient shows a large, heterogeneously calcified paravertebral neuroblastoma. The mass involves > 1/3 of the spinal canal diameter & lifts the aorta off of the spine, partially encasing it. Also note the poorly defined, hypoenhancing foci in the liver, consistent with distant metastases.*

Pleuropulmonary Blastoma

KEY FACTS

TERMINOLOGY

- Rare malignant embryonal mesenchymal neoplasm of lung & pleura that arises during organ development

IMAGING

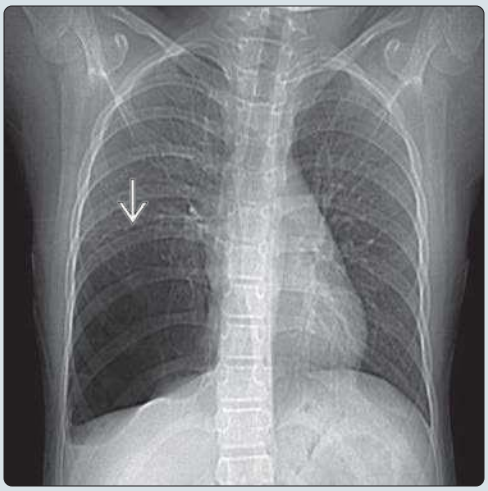
- Pleuropulmonary blastoma (PPB) appearances
  - Type 1: Air-filled, multilocular cystic mass
  - Type 2: Mixed cystic (air-filled) & solid mass
  - Type 3: Soft tissue mass; opacified hemithorax with contralateral mediastinal shift
- Pleural effusion in 77% of type 2 or 3 lesions
- Spontaneous pneumothorax at presentation in 30-65%
- Multiple lesions in 35-50%; bilateral in 11-26%
- Metastases to brain, bones, & rarely liver

TOP DIFFERENTIAL DIAGNOSES

- Congenital pulmonary airway malformation
- Congenital lobar overinflation
- Mesenchymal hamartoma of chest wall
- Sarcoma
- Spontaneous pneumothorax
- Necrotizing pneumonia

PATHOLOGY

- Clear progression from type 1 → type 2 → type 3
  - Type 1r (regressed): No cancer cells found
- *DICER1* mutation: Association of PPB, cystic nephroma (CN), thyroid & ovarian tumors
  - Germline *DICER1* mutations in 65.5% with PPB
  - 10% with PPB have CN

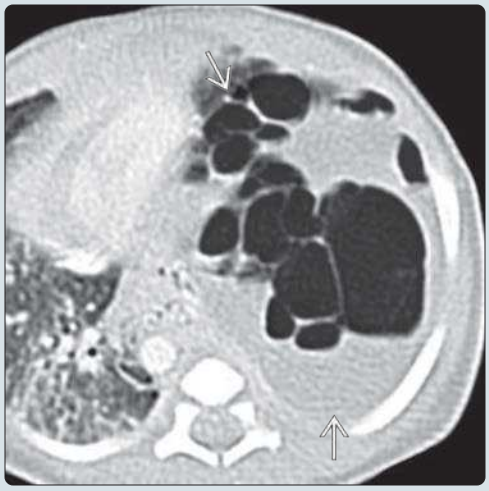


CLINICAL ISSUES

- Most common primary pulmonary malignancy of childhood
- 94% present in children < 6 years of age
- Most common presentation: Respiratory distress

DIAGNOSTIC CHECKLIST

- Consider PPB when large chest mass is seen in young child
- Imaging cannot distinguish type 1 PPB from benign cysts



(Left) *CT scanogram in an adolescent with a DICER1 mutation & pleuropulmonary blastoma (PPB) shows a cystic lesion ➡ occupying the lower 1/2 of the right hemithorax. PPB is the most common primary lung malignancy of childhood.* **(Right)** *Coronal CECT of the chest in the same patient shows a large multiseptated cystic mass ➡ of the right hemithorax. Upon resection, a type 1r PPB was confirmed.*

(Left) *Coronal T2 SSFSE fetal MR shows a hyperintense solid-appearing left lung mass ➡ that is most typical of a type 3 congenital pulmonary airway malformation (CPAM) but was found after postnatal resection to be a PPB.* **(Right)** *Axial CECT in the same patient 3 days after birth shows a large multicystic left lower lobe lesion ➡ containing air & fluid, most typical of a type 1 CPAM. A type 1 PPB was actually confirmed upon resection. Limited fetal reports of PPB have been of type 1 lesions indistinguishable from CPAMs.*

TERMINOLOGY

Abbreviations

- Pleuropulmonary blastoma (PPB)

Definitions

- Rare malignant embryonal mesenchymal neoplasm of lung & pleura that arises during organ development

Associated Syndromes

- *DICER1* mutation
  - Associated with PPB, cystic nephroma (CN), ovarian sex cord-stromal tumors (especially Sertoli-Leydig cell tumor), multinodular goiter, differentiated thyroid carcinoma, pineoblastoma, & ovarian or cervical rhabdomyosarcoma

IMAGING

General Features

- Best diagnostic clue
  - Large pulmonary cystic, solid, or mixed mass in child < 6 years old
- Location
  - Intrathoracic, located in peripheral lung adjacent to or involving visceral pleura
  - More common in right hemithorax
- Size
  - 55% of type 1 lesions are > 5 cm
  - 63% of type 2 or 3 lesions are > 10 cm
- Morphology
  - Well-defined pulmonary mass
  - 3 types
    - Type 1: Large, air-filled, multilocular cystic mass
    - Type 2: Large, air-filled, cystic & solid mass
    - Type 3: Solid pulmonary mass

Radiographic Findings

- Appearance depends on type of tumor
  - Type 1: Well-circumscribed, multilocular cystic (air-filled) mass with thin septa
  - Type 2: Cystic mass with variable soft tissue components
  - Type 3: Soft tissue mass → opacified hemithorax with contralateral mediastinal shift
- Spontaneous pneumothorax at presentation in 30-65%
- Associated with pleural effusion in 77% of type 2 or 3 lesions

CT Findings

- Type 1
  - Benign-appearing, air-filled lung cysts
  - Thin septa; no solid nodules or plaque-like thickening
  - Many different potential appearances: Unifocal (1 simple cyst), multilocular, cluster of contiguous cysts, or multifocal
- Type 2
  - Air-filled cystic mass with variable soft tissue components
- Type 3
  - Large, heterogeneous, solid mass with overall low attenuation
  - Originates from pulmonary pleura or parenchyma
  - Rarely invades chest wall
- Multiple lesions in 5-50% of patients
- Bilateral lesions in 11-26% of patients
- Metastases: Brain, bone, & rarely liver
- Imaging into upper abdomen may show associated renal tumor (i.e., CN)

Ultrasonographic Findings

- Solid heterogeneous mass (types 2 & 3)
- Pleural fluid

Imaging Recommendations

- Best imaging tool
  - Radiograph is often 1st imaging study due to respiratory symptoms
  - CECT is typically used to further characterize mass, evaluate initial extent of disease, & follow after treatment

DIFFERENTIAL DIAGNOSIS

Congenital Pulmonary Airway Malformation (CPAM)

- Type 1 CPAM: Macrocystic with large, air-filled cysts
  - ± air-fluid level on early neonatal imaging
- Type 1 CPAM is indistinguishable from type 1 PPB by imaging
  - Factors favoring CPAM: Prenatal detection (especially 2nd trimester), systemic feeding vessel (in hybrid lesion), hyperinflated lung, or asymptomatic patient

Congenital Lobar Overinflation

- Hyperinflation of affected lobe/lung
- On CT, not true cystic lesion: Lung has simplified appearance with small, widely spaced vessels

Mesenchymal Hamartoma of Chest Wall

- Intrathoracic mass of rib origin in neonate/infant
- Distortion/erosion of multiple adjacent ribs
- Ca^{2+} & fluid-fluid levels are common

Sarcoma

- Ewing/PNET, rhabdomyosarcoma, undifferentiated, others
- May be indistinguishable from type 3 PPB
- More likely to invade chest wall

Spontaneous Pneumothorax

- Should see typical patterns of lung collapse with smooth pleural line
- Septa or nodularity along suspected pleural space should suggest alternate diagnosis
  - Inserting chest tube may create bronchopleural fistula

Necrotizing Pneumonia

- Much more common than PPB
- Typically in ill child with fever

PATHOLOGY

General Features

- Genetics
  - Germline *DICER1* mutations in 70% of PPB patients
  - *DICER1* mutations are present in ~ 100% with PPB & CN
- Associated abnormalities

- Extrapulmonary lesions are identified in ~ 25% of PPB patients
- 10% are associated with CN

Staging, Grading, & Classification

- Type 1 (33%): Purely cystic
- Type 2 (35%): Cystic & solid
- Type 3 (32%): Solid

Gross Pathologic & Surgical Features

- Type 1: Cystic
- Types 2 & 3: Soft, fleshy, friable, vascular tumor

Microscopic Features

- Histologically distinct from adult pulmonary blastoma, which has malignant epithelial & mesenchymal components
  - PPB has no malignant epithelial component
- Type 1
  - Characteristic multilocular architecture with delicate septa
  - Thin cyst walls lined by alveolar-type epithelium
  - Small, primitive mesenchymal cells in stroma beneath epithelial lining
  - Focal areas of hypercellularity & hypervascularity
    - Hypercellular areas composed of hyperchromatic compact spindle cells & small round cells
  - ± foci of immature cartilage
- Type 1r (regressed): No cancer cells found
- Types 2 & 3
  - Solid components may have areas of necrosis & cystic degeneration
  - Higher grade cytologic features
    - Sheets of spindle, pleomorphic, or anaplastic cells
      - Anaplasia emerges as tumor progresses from type 1 to type 3

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Respiratory distress ± spontaneous pneumothorax
    - Pneumothorax is found at presentation in 30% of patients with type 1, 65% of patients with type 2, & 20% of patients with type 3 PPB
  - ± signs of upper respiratory tract infection
  - PPB may be incidental finding on prenatal US (in 3rd trimester) or postnatal chest radiograph

Demographics

- Age
  - 94% present in children < 6 years of age
  - Median age at diagnosis
    - Type 1: 8 months
    - Type 2: 35 months
    - Type 3: 41 months
- Sex
  - Type 1: 57% male
  - Types 2 & 3: M = F
- Epidemiology
  - PPB: Most common primary pulmonary malignancy of childhood
    - 15-25 cases of PPB diagnosed in USA/year
    - Incidence of PPB is estimated at 0.35-0.65 cases per 100,000 births

Natural History & Prognosis

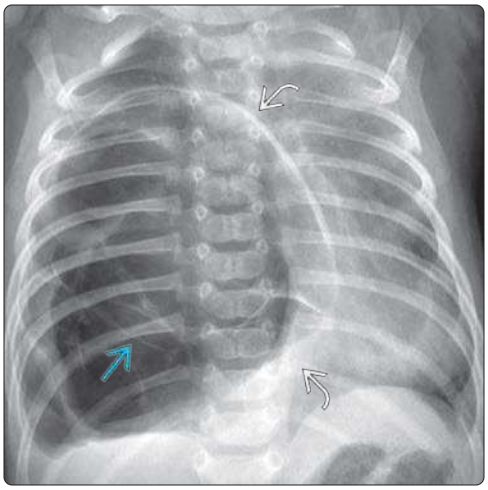
- Clear progression from type 1 → type 2 → type 3
- Type 1
  - Presents at younger age
  - Better prognosis than types 2 & 3
  - Complete surgical resection may be curative
  - Recurrent type 1 disease frequently progresses to more malignant type (2 or 3)
- Types 2 & 3
  - Presents at slightly older age
  - Multiple patients have history of pulmonary cysts preceding diagnosis of types 2 & 3 PPB
  - Worse prognosis
- 5-year survival
  - Type 1: 94%
  - Type 2: 71%
  - Type 3: 53%
- Metastasis rate
  - Type 1: No known metastases
  - Type 2: 7%
  - Type 3: 11%

Treatment

- Type 1: Complete surgical resection ± chemotherapy
- Type 2: Surgical resection + chemotherapy
- Type 3: Surgical resection + chemotherapy; consider neoadjuvant chemotherapy
- Benefit of local radiation in types 2 & 3 PPB is controversial

DIAGNOSTIC CHECKLIST

Consider



- PPB when large chest mass is seen in young child
- Type 1 PPB is radiologically indistinguishable from benign lung cysts
  - Justification for surgical excision of all cystic lung lesions found in young children

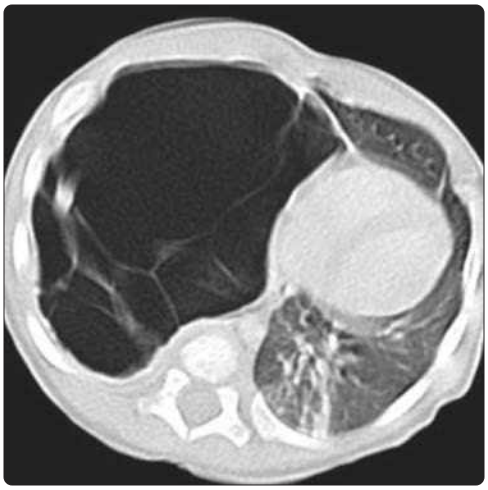


Image Interpretation Pearls

- PPB rarely invades chest wall
- Look for other *DICER1*-associated tumors

(Left) *AP radiograph of the chest shows a large, air-filled cystic mass of the right hemithorax. Numerous thin septations are seen within the mass. The mass crosses the midline & displaces the heart & mediastinum to the left.* **(Right)** *Axial CECT in the same patient further details the multiseptated, cystic mass that occupies the entire right hemithorax. A multiloculated, air-filled, cystic mass without nodular or plaque-like solid tissue is typical of a type 1 PPB (but is more commonly seen with a type 1 CPAM).*

(Left) *Frontal radiograph in an adolescent boy with a PPB shows a large soft tissue mass occupying the left hemithorax, ultimately found to be a type 3 PPB. Note the lack of adjacent rib destruction that would favor a sarcoma.* **(Right)** *Coronal CECT of the chest in the same patient shows heterogeneous enhancement of the soft tissue mass in the left lung + a small left pleural effusion. Pleural effusions are present in 77% of patients with type 3 PPB.*

(Left) *Axial CECT of the chest shows a solid well-circumscribed heterogeneous type 3 PPB of the anterior mediastinum. The mass is displacing the heart to the left. Note that the appearance is not specific & could be seen with other malignancies, such as sarcomas.* **(Right)** *Longitudinal color Doppler ultrasound of a type 3 PPB shows a solid heterogeneous mass of the right hemithorax with mild internal vascularity. A moderate pleural effusion is present.*

Pulmonary Arteriovenous Malformation

KEY FACTS

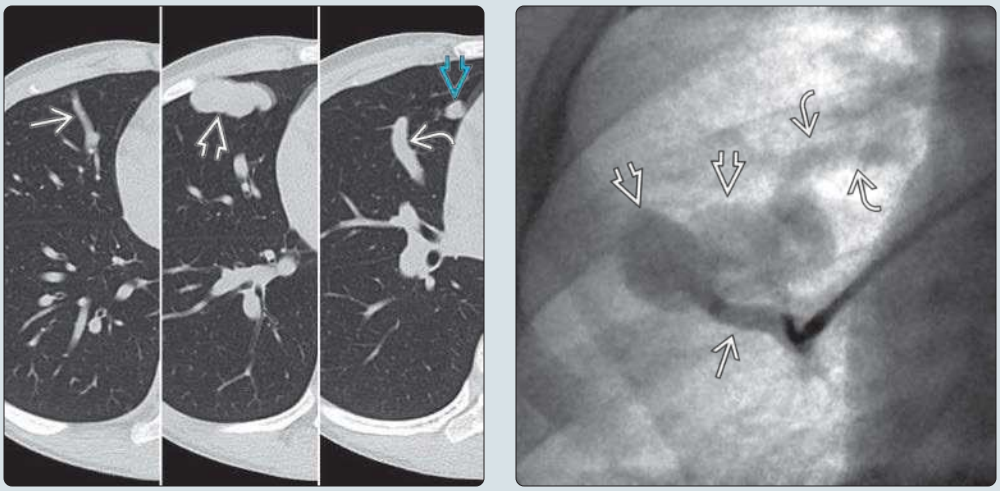
TERMINOLOGY

- Pulmonary arteriovenous malformation (PAVM): Abnormal direct communication between pulmonary artery & vein
- Associated with hereditary hemorrhagic telangiectasia (HHT), a.k.a. Osler-Weber-Rendu syndrome

IMAGING

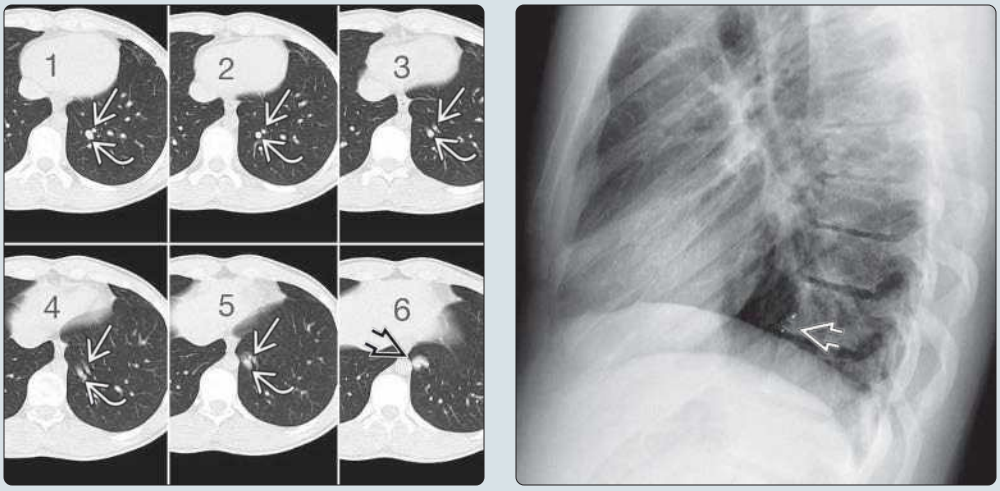
- Smoothly marginated, brightly enhancing nodule with feeding artery & draining vein; most occur in lower lobes
  - ± surrounding ground-glass opacity in telangiectatic subtype (more common in children)
- Multiplanar CTA reconstructions allow best depiction of PAVMs & planning for transcatheter embolization
  - Size of feeding artery (≥ 3 mm) & number of feeding vessels will impact therapy

TOP DIFFERENTIAL DIAGNOSES



- Granuloma
- Pulmonary varix
- Pulmonary metastasis

PATHOLOGY



- HHT accounts for up to 90% of patients with PAVMs
  - 50% of patients with HHT have PAVM
- Clinical triad of HHT: Epistaxis, telangiectasias, family history
  - AVMs of viscera: Lung, brain, spine, liver, &/or gastrointestinal tract

CLINICAL ISSUES

- Most HHT patients develop symptoms by age 20
- Consider referral to HHT Center of Excellence for endovascular treatment (coil, balloon, Amplatzer plug)
- Should screen family members of patient with HHT & PAVM: 35% incidence of PAVM
- Endovascular treatment allows embolization of multiple PAVMs at once; has very low morbidity & mortality with high success rate (permanent occlusion in > 90%)
- Untreated PAVMs can lead to neurologic complications (paradoxical emboli, abscess, stroke)

(Left) *Sequential inferior to superior (from left to right) lung CT images in a 12-year-old boy with hereditary hemorrhagic telangiectasia (HHT) show a large, lobulated pulmonary arteriovenous malformation (PAVM) in the right middle lobe. It is supplied by a single arterial feeder & has a larger caliber draining vein (which is typical). Note a 2nd smaller PAVM in the most superior image.* **(Right)** *Coned-down selective arteriogram in the same patient shows the lobulated PAVM, arterial feeder, & draining vein.*

(Left) *Sequential superior to inferior axial lung CT images (labeled 1-6) demonstrate a small PAVM in the left lower lobe with a small feeding artery & adjacent draining vein.* **(Right)** *Follow-up lateral radiograph in the same patient shows a small Amplatzer occlusion device used to treat the PAVM shown in the preceding CT.*

TERMINOLOGY

Abbreviations

- Pulmonary arteriovenous malformation (PAVM)

Definitions

- Abnormal, capillary-free vascular communication between pulmonary artery & vein, allowing R → L shunt

IMAGING

General Features

- Best diagnostic clue
  - Smoothly marginated, avidly enhancing nodule with enlarged feeding artery & draining vein on CECT
- Location
  - 50-70% are located in lower lobes
- Morphology
  - 3 typical appearances
    - Large single sac
    - Plexiform mass of dilated vascular channels
    - Dilated & tortuous direct arteriovenous connection
- Size: Most are 1-5 cm; may enlarge over time to > 10 cm

Radiographic Findings

- Radiography
  - Abnormal in almost all symptomatic patients
  - Sharply defined pulmonary nodule with uniform density; may have lobulated borders

CT Findings

- CTA is best to diagnose PAVMs (98% sensitivity)
  - Look for feeding artery & draining vein
  - Enhancement is similar to that of other vascular structures
  - Surrounding ground-glass opacity in telangiectatic subtype

Angiographic Findings

- DSA: Selective pulmonary angiography
  - Less sensitive but may be more specific than CT
  - Large feeder artery + large early draining vein

Imaging Recommendations

- Multidetector CTA allows best detection of PAVMs & planning for transcatheter embolization
- Catheter angiography is typically reserved for treatment

DIFFERENTIAL DIAGNOSIS

Granuloma

- No associated vessels; little to no enhancement
- Usually smoothly marginated but densely calcified or with central Ca^{2+}; ± associated calcified hilar & mediastinal lymph nodes

Pulmonary Varix

- Enlarged pulmonary vein, no large feeding artery or nidus
- DSA may be needed to differentiate from PAVM

Pulmonary Metastasis

- Typically not associated with large vessels
- Frequently multiple & seen in setting of known primary malignant tumor

PATHOLOGY

General Features

- Etiology
  - Congenital (most common)
    - Thought to form from incomplete resorption of vascular septa during embryogenesis
  - Acquired
    - Surgery for congenital cyanotic heart disease: Late complication of Glenn & Fontan procedures
    - Hepatopulmonary syndrome: 50% with end-stage liver disease acquire abnormal arteriovenous communications
- Associated abnormalities
  - Hereditary hemorrhagic telangiectasia (HHT), a.k.a. Osler-Weber-Rendu syndrome, accounts for up to 90% of patients with PAVMs
    - Autosomal dominant, variable penetrance
    - Clinical triad: Epistaxis, telangiectasias, family history
      - AVMs of viscera: Lung, brain, spine, liver, &/or gastrointestinal tract
    - 50% of patients with HHT have PAVM
    - Screen family members of HHT patients → 35% incidence of PAVM

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Incidental solitary pulmonary nodule on radiograph
  - Most HHT patients develop symptoms by age 20
    - Epistaxis is most common complaint
    - Findings or complications of R → L shunt: Brain abscess, embolic stroke
    - Mucocutaneous telangiectasias

Demographics

- Age: Most are congenital; 10% are detected in childhood
- Sex: M:F = 1:2
- Epidemiology: Rare, only 1:5,000

Natural History & Prognosis

- PAVMs are treated to avoid neurologic complications & heart failure
- Patients with diffuse PAVMs are almost always symptomatic

Treatment

- Options, risks, complications
  - Refer patient to HHT Center of Excellence
  - Embolization by endovascular coil, balloon, &/or Amplatzer vascular plugs
    - Traditionally reserved for feeding artery ≥ 3 mm
    - High success rate, permanent occlusion in > 98%
    - Low morbidity & mortality
    - Multiple PAVMs can be embolized at once

Child Abuse, Rib Fractures

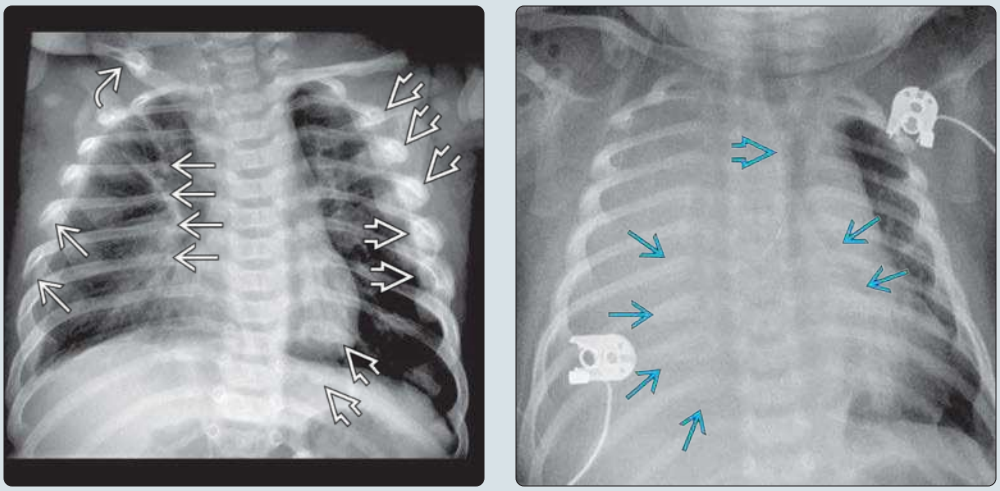
KEY FACTS

TERMINOLOGY

- Child abuse: Any act or failure to act by parent/caretaker that causes harm or imminent risk of harm to child

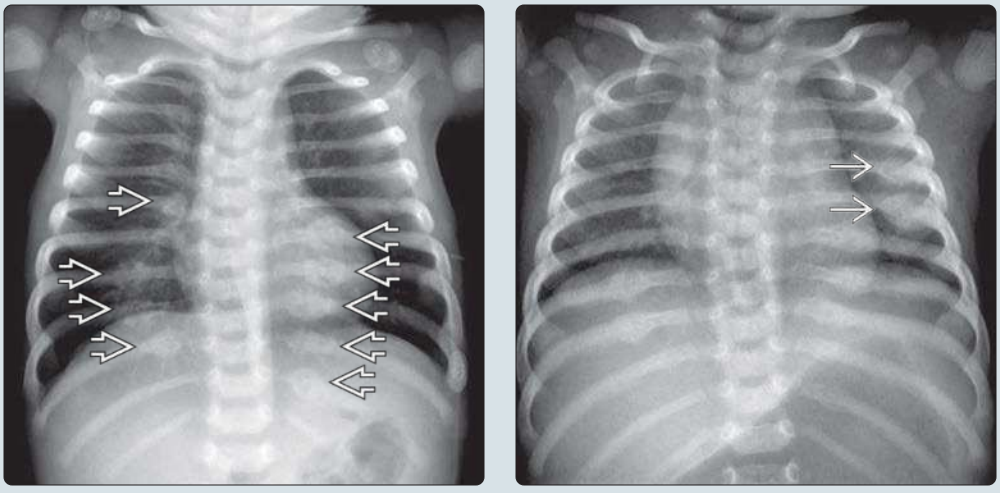
IMAGING

- Radiography
  - Linear lucency of acute fracture is often not visible
  - Callus/subperiosteal new bone formation may become visible 7-10 days after injury
    - Ranges from indistinct margins & broadening of rib → sharply marginated nodular/bulbous callus
  - Rib head fracture may appear fragmented with mixed sclerosis & lucency; often no subperiosteal new bone
  - Costochondral junction fractures appear like metaphyseal corner fractures with growth disturbance & sclerosis at healing
- Tc-99m MDP bone scan or F-18 NaF PET is complementary
  - Focal ↑ radiotracer activity within 24 hours
- CT is not advocated for identifying rib fractures but may be used to evaluate intrathoracic or intraabdominal injury
- Indications for initial radiographic skeletal survey
  - < 2 years old with suspicion of NAT
  - < 5 years old with suspicious fracture
  - Suspicion of NAT in any child unable to communicate
- Follow-up skeletal survey is obtained after 2 weeks



PATHOLOGY

- Posterior rib fractures are most common & specific for NAT
  - Adult hands squeeze child's chest → leverage posterior ribs on transverse processes → fractures



CLINICAL ISSUES

- Majority of rib fractures are not suspected on clinical exam
  - Overlying bruising in ~ 9%
  - ± clicking or popping sounds with crepitus
- Likely most common skeletal injury in NAT
  - Only radiographic manifestation of NAT in up to 29%

(Left) *AP radiograph in an infant with suspected abuse demonstrates multiple left lateral & posterior rib fractures with callus formation as well as more recent right-sided rib fractures without evidence of healing. Also note the right clavicle fracture & right pleural effusion.* **(Right)** *AP radiograph in a 5-week-old victim of physical abuse shows complete opacification of the right hemithorax due to a large chylothorax with mediastinal shift. Healing posterior rib fractures are seen bilaterally.*

(Left) *AP radiograph in a 1-month-old shows multiple healing posterior rib fractures with bulbous callus formation.* **(Right)** *AP radiograph obtained 2 weeks later in the same patient shows 2 additional healing rib fractures, which, even in retrospect, are difficult to appreciate on the initial study. Follow-up skeletal surveys should be obtained at 2 weeks with persistent suspicion based on clinical or imaging findings (or if concerning fractures are seen on the initial exam).*

TERMINOLOGY

Abbreviations

- Nonaccidental trauma or injury (NAT, NAI), child abuse, & neglect

Definitions

- Child abuse: Any act or failure to act by parent/caretaker that causes harm or imminent risk of harm to child

IMAGING

General Features

- Best diagnostic clue
  - Bulbous callus/subperiosteal new bone formation of multiple adjacent posterior ribs in infant
- Location
  - Most common distribution
    - Posterior & lateral; midrib cage (ribs 5-8); L > R

Radiographic Findings

- Acute fractures are often not visualized radiographically
  - Typically vertical/oblique linear lucency in rib short axis
  - Difficult to visualize if nondisplaced & fracture plane is oriented coronal relative to x-ray beam
  - Adjacent subpleural hematoma may be clue
- Healing fractures may become visible 7-10 days after injury
  - Callus/subperiosteal new bone formation: Ranges from indistinct margins & broadening of rib → sharply marginated nodular/bulbous callus
  - "Hole-in-rib": Radiolucency (bone resorption) surrounded by sclerosis
  - Rib head: Often without subperiosteal new bone
    - May appear fragmented with mixed sclerosis & lucency
- Costochondral junction fractures
  - Disrupt physis similar to Salter-Harris injury
  - Acute appearance is dependent on projection, similar to classic metaphyseal lesion
    - Arcuate density/bucket-handle, triangular corner fragment, fissure, or transverse lucency
  - Sclerosis or growth disturbance (flaring, nodular enlargement, or cartilage invagination) with healing
- Sensitivity 73% in one study vs. follow-up radiographs
- Sensitivity 26% in one study vs. postmortem histology

CT Findings

- Performed for suspected thoracoabdominal injury
- Not advocated for identifying rib fractures alone due to radiation exposure
- Greater sensitivity than initial skeletal survey for detection of rib fractures
- Findings similar to radiography
  - Linear lucency, often in rib short axis
  - Callus & subperiosteal new bone formation with time

MR Findings

- Whole-body MR has low sensitivity (57%) for rib fractures vs. radiographs
- May see fluid signal changes in bone marrow & soft tissues ± elevation of periosteum before fracture is evident on radiographs

Ultrasonographic Findings

- Adult studies show ↑ sensitivity of US over radiography for rib fractures, particularly of cartilaginous portion
- May show occult rib fracture in children when initial skeletal survey is negative or equivocal, though patient cooperation may be issue
- Imaging findings include discontinuity of echogenic shadowing cortex, acoustic edge shadow at margin of fracture, local hematoma with elevated periosteum

Nuclear Medicine Findings

- Tc-99m MDP skeletal scintigraphy or F-18 NaF PET is complementary to initial skeletal survey
  - Focal ↑ in radionuclide activity within 24 hours, normalizes within 6 months
  - Costochondral junction fractures (metaphyseal equivalent in anterior rib) are difficult to assess due to variable physiologic uptake
- Compared to initial skeletal survey, F-18 NaF PET shows greater sensitivity for rib fractures but lower sensitivity for classic metaphyseal lesions
- Detection of bony injury by Tc-99m MDP bone scan & initial skeletal survey from one study demonstrated
  - 60 rib fractures: 63% identified on bone scan & 73% identified on skeletal survey
  - 6 cases with solitary rib fractures: 50% identified on both modalities, remaining 50% identified only on bone scan
  - Other fractures: 33% seen on both modalities, 44% seen on skeletal survey only, 25% seen on bone scan only

Imaging Recommendations

- Initial skeletal survey
  - Indications
    - < 2 years old with suspicion of NAT
    - < 5 years old with suspicious fracture
    - Concern for NAT in any child unable to communicate
  - Images include: AP & lateral skull, lateral cervical & lumbar spine, AP & lateral & both obliques of thorax, AP pelvis, AP humeri, AP forearms, PA or shallow oblique hands, AP femurs, AP lower legs, AP feet; additional views based on clinical & imaging findings
- Follow-up skeletal survey
  - Typically 2 weeks (not < 10 days) from initial evaluation
  - Indications
    - Concerning fractures on initial study
    - Normal initial study with persistent suspicion based on clinical or imaging findings
  - Used to confirm suspected fractures & identify additional fractures
  - In one study, clarified questionable fractures or identified new fractures in 48% of cases
    - Most additional fractures were of ribs
- Tc-99m MDP bone scan or F-18 NaF PET is used as complementary & problem-solving tool
- CECT for suspected intrathoracic or intraabdominal injury

DIFFERENTIAL DIAGNOSIS

Entities Associated With Multiple Fractures

- **Osteogenesis imperfecta (OI)**
  - Type IV OI is most commonly mistaken for abuse
    - Sclera is normal in color (not blue)

- May see osteoporosis & wormian bones
- **Menkes syndrome**
  - Osteoporosis, metaphyseal spurs, brittle hair, tortuous intracranial vessels
  - Excessive wormian bone formation
- **Rickets**
  - Widening/lengthening of physes with loss of normal zones of provisional Ca^{2+} + metaphyseal fraying, cupping, & splaying
- **Leukemia**
  - Osteoporosis ± lucent metaphyseal bands, permeative destruction, aggressive periosteal new bone formation

Birth Trauma

- Rare but can occur with large babies & difficult deliveries
- No rib fractures in one study of 34,946 births

Trauma From Cardiopulmonary Resuscitation

- Rib fractures very rare in pediatric CPR (< 1%)
- Most such fractures involve anterior ribs

Accidental Trauma

- Age & history must be consistent with injury
- Rib fractures are more likely to be anterior & lateral
- Greater likelihood of intrathoracic injury & fewer fractures

Pseudoarthroses

- Typically in 1st rib
- No associated fractures or remodeling on follow-up images

Sternal Ossification Centers

- Normal ossification centers of sternum often project over posterior ribs on oblique views, mimicking callus

PATHOLOGY

General Features

- Assailant holds infant, wrapping hands around chest with finger tips at posterior ribs & thumbs situated anteriorly extending to midline
- AP compression while squeezing & shaking child results in fractures
  - Posterior rib fractures occur from leveraging posterior ribs on transverse processes
    - Most common location & most specific for abuse

CLINICAL ISSUES

Presentation

- Wide range of clinical presentations for NAT: Injury inconsistent with history, multiple injuries in various stages of healing, bruising in nonmobile infant, genitalia injury, cigarette burns, other injuries with high specificity for NAT (e.g., classic metaphyseal lesion/corner fracture)
  - Chest radiograph may be obtained with resuscitation for seizure, unresponsiveness, acute life-threatening event
- Rib fractures
  - Only radiographic finding of NAT in up to 29% of cases
  - Majority are not suspected based on clinical exam
    - Associated bruising at fracture site is rare, 9%
  - Clicking or popping sound from back or chest on physical exam, ± crepitus
  - Associated intrathoracic injury is less common than in accidental injury
    - 12.8% of NAT vs. 55.6% of accidental injuries
  - Rib fractures in children < 3 years of age are usually associated with abuse (61%)
  - Up to 82% of rib fractures in children < 1 year of age are from NAT

Demographics

- Epidemiology
  - 678,000 child maltreatment victims in 2018 in USA
    - Infants ≤ 1 year old are most at risk
  - Rib fractures are most common skeletal injury in NAT
    - In one study of abused children, 79% of all fractures involved rib cage
    - Rib fractures are present in 10-14% of skeletal surveys performed for suspected abuse

Natural History & Prognosis

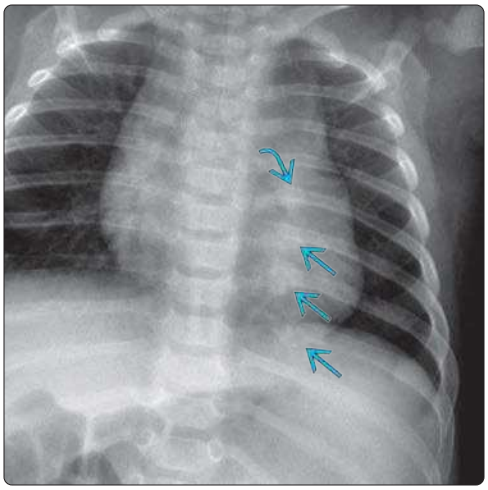
- 1,770 fatalities from child maltreatment in 2018
  - Mortality is highest in infants < 1 year old: 46.6% of deaths

Treatment

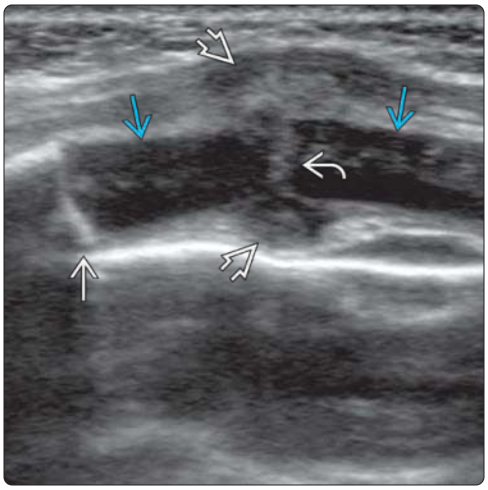
- Multidisciplinary investigation of maltreatment allegation involves physicians, social worker, Child Protective Services, legal authorities
- Ensure "at risk" child & siblings are placed in safe environment

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls



- Carefully review visible ribs on any modality in young child, regardless of study indication
  - Fractures may be incidentally noted on unrelated emergent or nonemergent exams



Reporting Tips

- Concern for child abuse based on imaging findings must be conveyed to referring clinician ASAP
- Final report represents legal document → review carefully

(Left) *AP chest radiograph from a follow-up skeletal survey of an infant with suspected fractures shows healing fractures of the 7th, 8th, & 9th ribs. A suspected 6th rib fracture was also confirmed by visualization of callus formation. The provided history was incompatible with the injuries.* **(Right)** *Transverse US demonstrates the anterior edge of an ossified rib with a fracture extending through the anterior cartilaginous rib. Note the surrounding hematoma.*

(Left) *Axial CT from a 2-year-old with blunt abdominal injuries shows a healing posterior rib fracture & an anterior rib fracture at the costochondral junction.* **(Right)** *Sagittal oblique CT from the same patient demonstrates a classic metaphyseal lesion (CML)-like appearance of the costochondral junction fractures with triangular corner fragments & bucket-handle-shaped fragments.*

(Left) *Oblique radiograph of a 2-month-old with an unexplained femur fracture demonstrates healing fractures of the posterior right 3rd to 6th ribs. Note how the rotated sternal ossification centers mimic bulbous callus of multiple left posterior ribs on this oblique view.* **(Right)** *Bone scan from the same patient confirms healing fractures at the right ribs with additional fractures identified in the medial left posterior ribs.*

Lung Contusion and Laceration

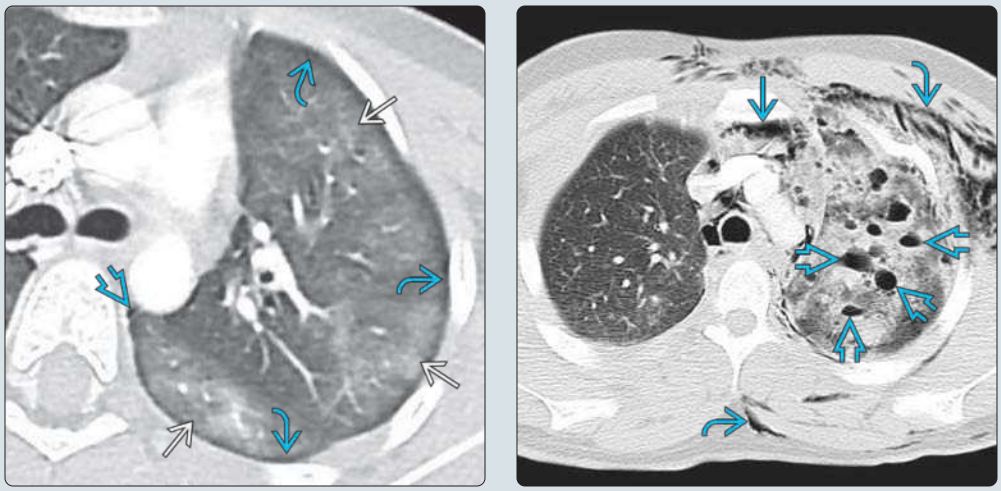
KEY FACTS

TERMINOLOGY

- Lung contusion: Hemorrhage + edema in alveoli & interstitium due to traumatic alveolar capillary damage
- Lung laceration: Frank tear of lung parenchyma

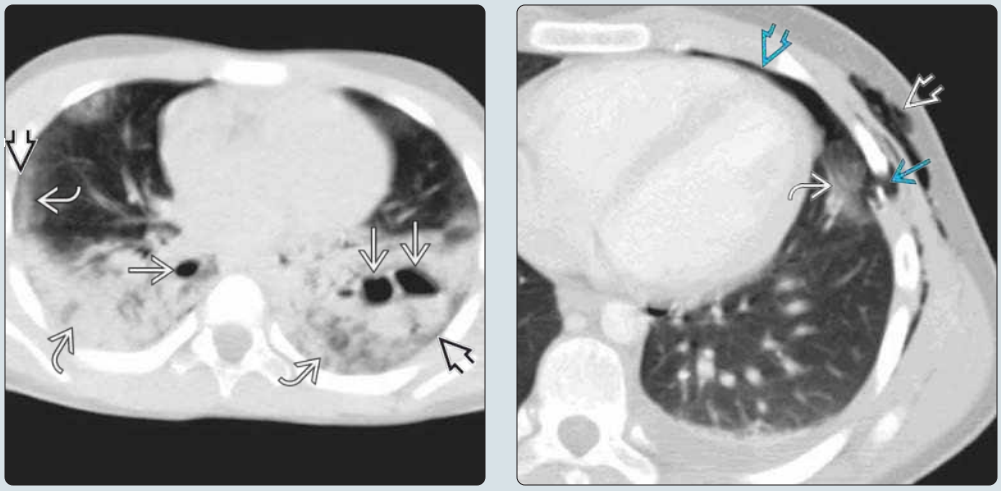
IMAGING

- Radiograph: Often sufficient for blunt chest trauma evaluation
  - Contusion: Nonsegmental patchy or diffuse opacification
    - May not be radiographically evident < 4-6 hours
  - Laceration: Round lucency ± air-fluid level
    - May be obscured by contusion initially
- CECT: Performed if strong clinical or imaging findings suggest significant thoracic injury
  - ↑ sensitivity for detecting contusion & ↑ accuracy for assessing extent compared to radiographs
    - Significance of contusions seen only on CT is doubtful → may not be associated with ↑ morbidity
  - Contusion: Confluent/nodular, crescentic/amorphous consolidative or ground-glass opacities
    - Commonly peripheral with rim of subpleural sparing
  - Laceration: Air-/fluid-filled cavity surrounded by opacity



PATHOLOGY

- Associated chest injuries
  - Pneumothorax
  - Rib fractures (less common than adults)
  - Heart & great vessels (8%), diaphragm (< 5%), tracheobronchial tree (< 3%), esophagus (< 0.1%)



CLINICAL ISSUES

- Patients with lung injuries typically have ↑ overall injury severity with multisystem trauma
  - Other systems account for high morbidity & mortality
- Consider pneumonia or acute respiratory distress syndrome (ARDS) if clinical & imaging findings worsen > 48 hours

(Left) *Axial CECT from a 6-year-old who was run over by a car shows ground-glass opacities with subpleural sparing, characteristic of pulmonary contusion. A small left pneumothorax was also present.* **(Right)** *Axial CECT of a 17-year-old after a motor vehicle accident (MVA) shows multiple air- & fluid-filled cysts throughout the left upper lobe, consistent with lung lacerations. Also note the pneumomediastinum & extensive subcutaneous emphysema.*

(Left) *Axial CECT in a trauma patient shows bilateral, primarily peripheral amorphous densities that do not respect lobar anatomy, consistent with lung contusions. There is associated subpleural sparing. The multiple fluid-containing cysts are typical of lacerations.* **(Right)** *Axial CECT in a 13-year-old after a bicycle collision shows a left 5th rib fracture, subcutaneous emphysema, a pneumothorax, & adjacent ground-glass lung opacity that is consistent with contusion.*

TERMINOLOGY

Definitions

- Lung contusion: Blunt chest trauma → alveolar capillary damage → hemorrhage + edema in alveoli & interstitium
- Lung laceration: Chest trauma (blunt or penetrating) → frank tear of lung parenchyma

IMAGING

General Features

- Best diagnostic clue
  - Crescentic or amorphous nonsegmental pulmonary opacities of mixed confluent & nodular quality
    - Subpleural sparing of overlying lung periphery
- Location
  - Posterior lung is most common

Radiographic Findings

- Contusions
  - Irregular patchy regions of poorly defined airspace consolidation (mild) vs. diffuse homogeneous consolidation (severe)
    - Due to hemorrhage & edema in alveoli & peribronchovascular interstitium
  - Located at impaction or contrecoup lung injury sites
    - Adjacent to ribs & vertebral bodies
  - Present in 30-50% of initial chest radiographs for blunt trauma
    - Radiographs underestimate volume of contusion
  - May not be evident in first 4-6 hours after trauma
    - Radiographs are negative > 6 hours in up to 33%
  - Complete clearing within 7-10 days unless other cause of opacification develops
    - Pneumonia, acute respiratory distress syndrome (ARDS)
- Lacerations
  - Thin-walled, air-filled cysts of variable size (pneumatoceles) ± air-fluid levels
    - Single/multiple, oval/spherical, uni-/multilocular
    - May fill with hematoma & subsequently expand (uncommon)
    - May be obscured by contusion initially, appearing hours or days after trauma
  - Occur at maximum impact or contrecoup injury sites
  - Persist up to 4 months; gradually ↓ in size by 1-2 cm/week
- Bronchial injury
  - Very rare
  - Persistent pneumothorax despite chest tube
  - Fallen lung sign: Lung falls away from hilum

CT Findings

- Contusions
  - Mixed confluent & nodular lung opacities (70%)
    - Crescentic (50%) or amorphous (45%) in shape
    - Posterior location (75%); lower lobes are most common
  - Subpleural sparing in up to 95% of cases
    - Thin, 1- to 2-mm crescentic rim of uniformly nonopacified subpleural lung
      - Separates lung opacity from adjacent chest wall
    - Less likely in larger contusions
  - CT is more sensitive than radiographs for contusion & more accurately determines contused volume
    - Up to 69% of contusions are underestimated (24%) or not identified (45%) on initial radiograph vs. CT
- Lacerations
  - Air- or fluid-filled cavity/cavities surrounded by parenchymal contusion
    - Due to frank tear of parenchyma (worse injury)

Ultrasonographic Findings

- High sensitivity (> 90%) & specificity (> 90%) in adults with blunt chest trauma when 2 sonographic features are present
  - Multiple B lines (comet-tail artifacts) arising from pleural line
    - Represent interstitial edema 1-2 hours after injury
    - Other processes with alveolar/interstitial involvement can appear similar (e.g., cardiogenic pulmonary edema, ARDS)
  - Peripheral parenchymal lesion with C lines, confluent consolidations (hepatization), or parenchymal disruption with effusion
    - Represents hemorrhage & debris in alveoli

Imaging Recommendations

- Chest radiographs are usually sufficient for evaluation of blunt trauma
- CT is performed in patients with strong clinical or imaging findings of significant thoracic injury
- Differentiation of contusions from other lung opacities in blunt chest trauma has relevance to child's prognosis

DIFFERENTIAL DIAGNOSIS

Aspiration

- Segmental distribution of opacities (as aspirated materials reach lungs via airways)
  - Posterior lower lobes are most common
- Absence of subpleural sparing
- Findings develop in 24-48 hours

Pneumonia

- Focal or multifocal airspace opacification
- Absence of subpleural sparing
- May be superimposed on contusion; consider if contusion worsens after 48 hours

Atelectasis

- Triangular shape with segmental distribution
- Often dependent with lack of subpleural sparing
- Signs of volume loss

Acute Respiratory Distress Syndrome

- Extensive bilateral ground-glass opacities & consolidation
- Diffuse alveolar damage in setting of pulmonary or nonpulmonary injury

Neurogenic Pulmonary Edema

- Symmetric confluent airspace opacities; normal heart size

Lung Contusion and Laceration

PATHOLOGY

General Features

- Etiology
  - Blunt trauma: 85-90% of thoracic injuries
    - Most commonly motor vehicle-related
    - Pedestrian vs. vehicle 36.5%, motor vehicle accident 31.7%, assault 11.5%, falls 9%
  - Penetrating trauma: 10-15% of thoracic injuries
    - Gunshot or stab wound, puncture from fractured rib
  - Nonaccidental trauma (NAT)
    - Thoracic injury may be more common in NAT vs. accidental trauma (17% vs. 6%)
- Associated abnormalities
  - With major chest trauma in child
    - Pneumothorax
    - Rib fractures are less common vs. adults
      - Due to elasticity of pediatric rib cage
      - Still present in 20-62% of cases
    - Uncommon injuries: Heart & great vessels (8%), diaphragm (1-5%), tracheobronchial tree (0.7-2.8%), esophagus (< 0.1%)
- Mechanism of injury
  - ↑ pliability of anterior pediatric chest wall + contrecoup forces of rapid deceleration → compression of relatively fixed posterior lung against ribs & vertebral column
  - Dispersion of forces along least mobile lung regions explains posterior location, crescentic shape, & nonsegmental distribution
  - Subpleural sparing in contusion may be due to
    - Terminal arterial branches ending prior to subpleural lung, possibly protecting this region from hemorrhage
      - Less common sign in large contusions, possibly due to extension of hemorrhage into subpleural lung
    - Compression of subpleural lung against chest wall may "squeeze" blood & edema from periphery
  - Systemic inflammatory response: ↓ surfactant production by injured alveolar tissue may lead to ARDS
  - Lung laceration: Frank tear of lung parenchyma results in cavity that fills with hemorrhage &/or air

Gross Pathologic & Surgical Features

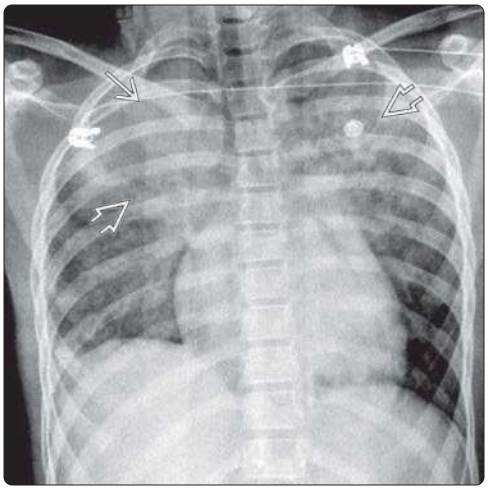
- American Association for the Surgery of Trauma injury scale
  - Grade I: Unilateral contusion < 1 lobe
  - Grade II: Unilateral contusion of single lobe or laceration → simple pneumothorax
  - Grade III: Unilateral contusion > 1 lobe, laceration with persistent (> 72 hours) air leak from distal airway, or nonexpanding intraparenchymal hematoma
  - Grade IV: Major segmental/lobar laceration with air leak, expanding intraparenchymal hematoma, or primary branch intrapulmonary vessel disruption
  - Grade V: Hilar vessel disruption
  - Grade VI: Total uncontained transection of hilar vessel

CLINICAL ISSUES

Presentation

- ↓ breath sounds, dullness to percussion, tachypnea, chest tenderness, hemoptysis (rarely)
- May present with respiratory failure in large contusions
  - Hypercarbia, hypoxia, acidosis

Natural History & Prognosis



- Children with thoracic trauma are typically more severely injured overall than those without thoracic involvement
  - Morbidity & mortality in patients with lung contusion/laceration are usually related to severity of multisystem trauma
    - Mortality rates of pediatric patients with lung contusions & lacerations are up to 34% & 43%, respectively
    - NAT mortality with thoracic injury ↑ from 15% to 50%
  - 20-37% of children with pulmonary contusion require mechanical ventilation
    - Radiographic severity of lung contusion correlates with oxygenation impairment, carbon dioxide exchange, & duration of ventilatory support
      - Radiographically occult contusions seen by CT: No ↑ in patient morbidity
    - Contusion volume > 28% on CT is predictive of need for mechanical ventilation in one study of adult & pediatric patients
      - Not reproduced in solely pediatric population
    - Contusion volume > 20% on CT is predictive of ARDS development in adults; not reproduced in children
- Complications: Pneumonia 20%, ARDS 5-20%
- Posttraumatic ARDS
  - Rare, 0.5% of all pediatric trauma cases
  - Mortality > 18% within 1 week of injury
  - Risk factors: NAT, severe injury to head or chest, pneumonia, sepsis, thoracotomy, laparotomy, transfusion

Treatment

- Supportive therapy: Pulmonary toilet, pain control, alveolar recruitment maneuvers, noninvasive positive pressure ventilation, mechanical ventilation, rarely ECMO
- Surveillance for other major organ injuries
- Observation for complications: Infection, ARDS, tension pneumothorax, hemopneumothorax, hemoptysis
- No evidence to support prophylactic broad-spectrum antibiotics (but often used)
- No proven role for corticosteroids

(Left) *Supine chest radiograph of an 11-year-old who was stepped on by a horse shows large areas of bilateral confluent ➡ & patchy ➡ opacities in the upper lung zones, compatible with contusions.* **(Right)** *Sagittal CECT from a 9-year-old after a bike accident demonstrates a confluent opacity ⇨ with adjacent extensive ground-glass opacities ⇨ in the left lung that do not respect lobar boundaries, compatible with contusions. There is extensive soft tissue emphysema ➡ & a small pneumothorax ➡.*

(Left) *Frontal radiograph of an 8-year-old after an all-terrain vehicle accident shows confluent right middle & bilateral lower lobe opacities ➡. The left lower lobe lucency is suspicious for a laceration ⇨.* **(Right)** *Axial CECT in the same patient shows a laceration with an air-fluid level in the left lower lobe ⇨. Scattered patchy & ground-glass opacities are also present in the right middle & bilateral lower lobes ➡, consistent with contusions.*

(Left) *Axial CECT of a 10-year-old who was hit by a car shows patchy densities ➡ with subpleural sparing ➡, consistent with contusion. A cavity with an air-fluid level is noted, compatible with a lung laceration ➡. There is also a left pneumothorax ⇨.* **(Right)** *Axial CECT of a 3-year-old after an MVA shows consolidation & ground-glass opacities ⇨ in keeping with contusions. Two lacerations are also seen ⇨. In addition, there are small pneumothoraces ⇨, subcutaneous emphysema ⇨, & a chest tube ⇨.*

Aortic Injury

KEY FACTS

TERMINOLOGY

- Blunt aortic injury (BAI) may manifest as intramural hematoma, intimal tear, larger intimal flap, contained pseudoaneurysm, or frank aortic rupture

IMAGING

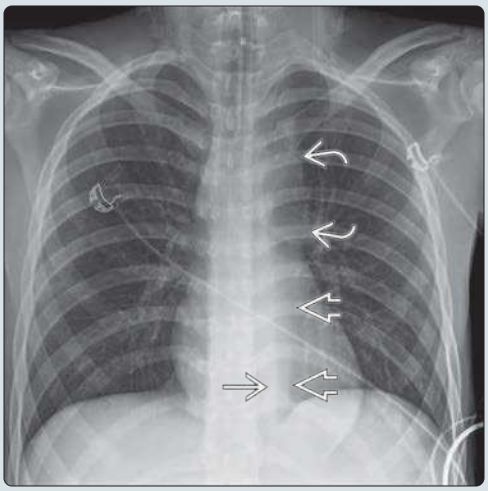
- Chest radiograph: Sensitive, not specific; high NPV (> 90%)
  - Most common findings: Indistinctness of aorta, prominent aortic knob, left apical cap
- CTA: Sensitivity & specificity 90-100%; NPV nearly 100%
  - Modality of choice: Fast, accessible, accurate; has largely replaced conventional aortography
  - Most common finding: Pseudoaneurysm, followed by intimal tear; usually near aortic isthmus

TOP DIFFERENTIAL DIAGNOSES

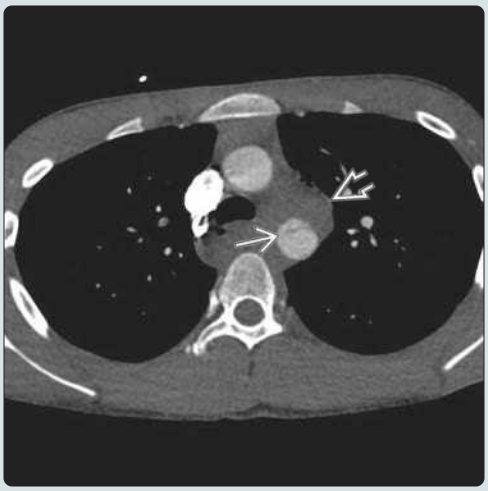
- Normal thymus
- CT artifacts
- Ductus diverticulum

PATHOLOGY

- Majority of pediatric BAIs are due to rapid & forceful deceleration injuries (motor vehicle accidents > falls, ATV crashes, & bicyclist/pedestrian vs. automobile collisions)

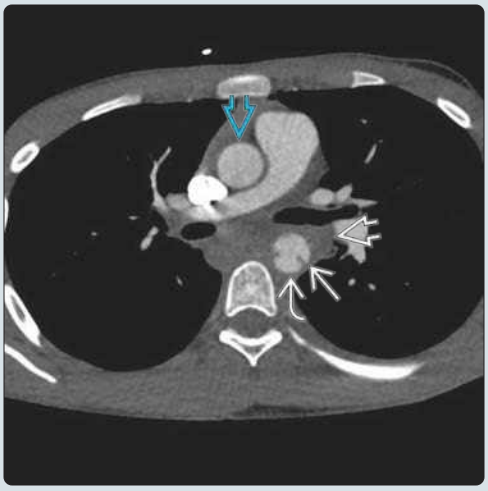


CLINICAL ISSUES

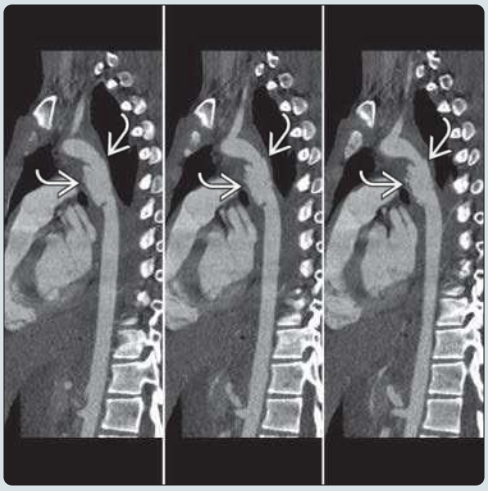


- Significant change in prognosis/treatment depending on presence or absence of aortic external contour alteration
  - Absent (intimal tears & flaps): Mortality 5-15% with treatment
  - Present: Mortality 25% for pseudoaneurysm & up to 90% for aortic rupture
- Delayed endovascular treatment is becoming more common; blood pressure control is essential in interval

DIAGNOSTIC CHECKLIST



- Look for BAI in all cases of blunt, high-energy chest trauma
- Up to 50% of pediatric BAIs lack external signs of chest trauma & have obvious CNS, abdominal, or skeletal injuries



(Left) *AP radiograph in a teenager with blunt aortic injury (BAI) after a bicycle vs. car accident reveals subtle mediastinal widening from a periaortic hematoma. Inferiorly, the hematoma creates an abnormal density parallel to the shadow created by descending aorta. Although subtle, such findings should prompt emergent CT to exclude aortic injury.* **(Right)** *Axial CTA in the same patient better shows the periaortic hematoma & clearly identifies a linear filling defect within the aorta from an intimal tear.*

(Left) *More inferior axial CTA in the same patient shows that the mediastinal hematoma & intimal tear are associated with a focal outpouching of contrast from a pseudoaneurysm. Note that the ascending aorta is normal, lacking artifact from cardiac motion that can mimic an intimal injury.* **(Right)** *Sequential sagittal CTA reconstructions in the same patient better illustrate the pseudoaneurysm as a large, irregular circumferential outpouching of contrast from the aortic lumen.*

TERMINOLOGY

Abbreviations

- Traumatic aortic injury (TAI), blunt aortic injury (BAI), blunt thoracic aortic injury (BTAI)

Definitions

- Intramural hematoma: Isolated circumferential or crescentic thickening of aortic wall without intimal injury
- Intimal tear: Small, isolated injury to intimal layer of aorta without external aortic contour abnormality → linear intimal defect &/or associated thrombus < 10 mm
- Large intimal flap: Larger intimal injury than tear but still without external aortic contour abnormality → linear intimal defect &/or associated thrombus > 10 mm
- Pseudoaneurysm: Rupture contained by adventitia → focal outpouching of aortic lumen causing external aortic contour abnormality
- Rupture: Uncontained dissection causing external aortic contour abnormality with extraluminal contrast (extravasation)

IMAGING

General Features

- Location
  - Most commonly (95%) near aortic isthmus between left subclavian & 1st intercostal arteries
  - Far less common at aortic root or diaphragmatic hiatus
  - Multiple tears are seen in small number of patients
  - May occur in abdominal aorta with seat belt injury

Radiographic Findings

- Chest radiograph is sensitive but not specific; low positive predictive value (< 20%), high negative predictive value (> 90%)
- Chest radiograph may be normal with only small mediastinal hematoma
- Radiographic signs
  - Left apical cap or left hemothorax
  - Obscured outline of descending aorta
  - Obliteration of aortopulmonary window
  - Widened mediastinum (which may be mimicked by normally prominent thymus in younger children)
  - Wide paraspinal stripe
  - Rightward shift of endotracheal &/or gastric tube(s)
  - Rightward shift of trachea
  - Depressed left main bronchus
  - Fractures of 1st &/or 2nd rib(s) &/or scapula

CT Findings

- NECT
  - Low sensitivity & specificity
  - High attenuation in aortic wall: Intramural hematoma
  - Obliteration/↑ attenuation of mediastinal fat suggests hemorrhage
  - Hematoma displacing trachea & esophagus to right
  - Hemopericardium
- CTA
  - Modality of choice: Rapid, accessible, high detail of acute thoracoabdominal injuries
    - Has largely replaced conventional aortography
  - Sensitivity 90-100%, specificity 90-100%, negative predictive value nearly 100%
  - Direct signs
    - Circumferential or crescentic thickening of aortic wall due to intramural hematoma
    - Linear filling defect (intimal flap) due to dissection
    - Intraluminal thrombus
    - Well-defined external contour abnormality of pseudoaneurysm, especially at aortic isthmus
    - Aortic wall irregularity
    - Abrupt change of aortic contour or caliber
    - Irregular, uncontained extraluminal collection of extravasated contrast
  - Indirect signs
    - Periaortic hematoma (absent in up to 20% of patients)

Ultrasonographic Findings

- Point-of-care US may reveal pericardial effusion &/or left hemothorax

Echocardiographic Findings

- May be performed in operating room; especially useful when patients go immediately to surgery
- Particularly sensitive for intimal tears
- Aortic valve regurgitation, intramural hematoma, or frank aortic rupture may be seen

Angiographic Findings

- Essentially replaced by CTA
- Used in equivocal cases or if endovascular repair is planned

Imaging Recommendations

- Best imaging tool
  - Multidetector CT angiography (at least 64 slice) is less likely to show pulsation artifact & allows thin multiplanar isotropic reconstructions
- Protocol advice
  - Quarter-/half-rotation volume data reconstructions or cardiac gating can reduce pulsation artifacts

DIFFERENTIAL DIAGNOSIS

Normal Thymus

- Prominent in young children, often accentuated by rotation or low lung volumes
- May obscure aortic contour

CT Artifacts

- Cardiac motion transmitted to aorta may mimic intramural hematoma or intimal tear
  - Rapid heart beat in children ↑ chances of pulsation artifact
- Streak artifact from contrast bolus may obscure aortic lumen or mimic intimal tear
- Atelectasis or parenchymal contusion in adjacent lung may be mistaken for aortic wall thickening

Ductus Diverticulum

- Broad-based anterior outpouching of contrast with smooth contour & obtuse margins
- Like most traumatic aortic injuries, located at aortic isthmus
- Found in up to 10% of normal population
- No hematoma, contrast leak, or intimal flap

PATHOLOGY

General Features

- Etiology
  - Majority of pediatric BAIs are due to rapid & forceful deceleration injuries
    - Mostly motor vehicle accidents (MVAs)
    - Falls, ATV crashes, & bicyclist/pedestrian vs. automobile collisions are also common
  - Sudden deceleration combined with fixation of aorta at ligamentum arteriosum → shearing, stretching, & torsional forces that injure aortic wall
  - Remainder of pediatric TAIs are due to gunshot wounds, penetrating injuries, & crushing/compression forces
- Pediatric BAI is rare compared to adults, as children have
  - Greater chest wall compliance
  - Relatively elastic vascular tissues (due to lack of atherosclerotic disease)
  - Lower body mass (thus less kinetic energy on impact)
  - Lower likelihood of MVAs

Staging, Grading, & Classification

- Society for Vascular Surgery
  - Type I: Intimal tear
  - Type II: Intramural hematoma or large intimal flap
  - Type III: Contained leak or pseudoaneurysm
  - Type IV: Transection/uncontained rupture
- Harborview criteria (newer)
  - Minimal: No external contour abnormality; intimal tear or thrombus < 10 mm
  - Moderate: External contour abnormality; intimal tear > 10 mm
  - Severe: Active extravasation or left subclavian artery hematoma > 15 mm

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hypotension, ↓ pulses in lower extremities, paraplegia
  - Up to 50% of children with BAI lack external signs of chest trauma
    - Often have more obvious neurologic, abdominal, or skeletal injuries
  - May have no signs/symptoms, or only nonspecific chest pain, dyspnea
- Other signs/symptoms
  - Associated thoracic cage injuries: Diaphragm rupture, pulmonary contusion, rib fractures
  - High association with other injuries, especially traumatic brain injury & solid abdominal organ injury

Demographics

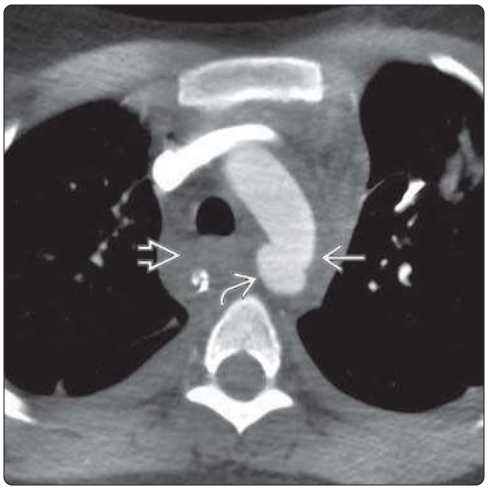
- Trauma is most common cause of death in children, but vascular trauma accounts for < 1%; BAI is even more rare
  - Retrospective review of ~ 11,000 children with severe blunt trauma showed < 0.1% sustained BAI
- Associated with high-risk recreational activities
  - Most pediatric BAIs from MVAs are in older children/teenagers

Natural History & Prognosis

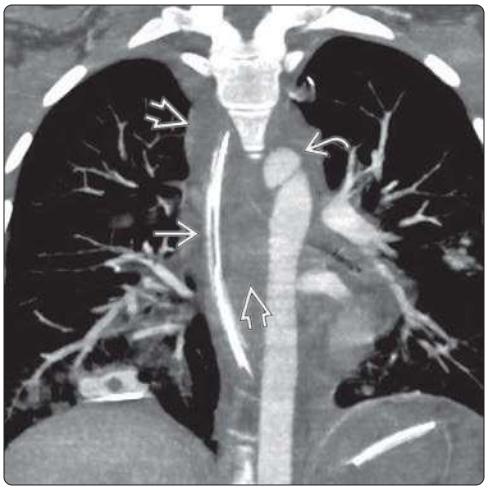
- Very low incidence, even in children involved in high-energy blunt chest trauma, but mortality rate is very high
  - ~ 80% die at scene of injury
- Survival depends on type of injury as well as time from injury to intervention
  - Injuries that do not alter external contour of aorta (intimal tears/flaps & intramural hematomas) have relatively good prognosis (mortality of 5-15% with treatment)
  - Injuries that do alter external contour of aorta have higher mortality (~ 25% for pseudoaneurysm & up to 90% for aortic rupture)
- Without intervention, mortality from BAI is very high (80% mortality < 1 hour & 98% mortality < 10 weeks)
- Late complications include posttraumatic pseudoaneurysm & coarctation or spinal cord ischemia → paralysis

Treatment

- Rapid recognition of diagnosis is critical
  - β-blockade for all patients if hemodynamically stable
- Society for Vascular Surgery
  - Type I: Medical management & close observation
  - Type II-IV: Surgical or endovascular repair (though II may be considered for nonoperative management)
    - Delayed endovascular repair is now favored over emergent operative treatment
      - Thoracic endovascular aortic repair (TEVAR)
    - Allows other injuries to be assessed & treated while ↓ operative complications
    - Provides time to appropriately size endograft & ensure that access sites can accommodate device
    - Short-term complications occur mainly at access site (bleeding, infection, pseudoaneurysm, etc.)
    - Long-term complications include device migration, fracture, endoleak, & arterial wall injury
    - Requires strict blood pressure control
- Harborview
  - Minimal: Follow-up
  - Moderate: Delayed repair after stabilization
  - Severe: Immediate repair



DIAGNOSTIC CHECKLIST



Consider

- Look for signs of BAI in all cases of blunt or high-energy chest trauma: Must have high index of suspicion
- Look for proxy signs of high-energy trauma, such as fractures of 1st &/or 2nd rib(s) &/or scapula
- Potential CTA pitfalls: Pulsation artifact, streak artifact, &/or periaortic focal atelectasis

(Left) *Axial CTA in a teenager who was in an MVA shows an abnormal external contour of the aorta caused by a pseudoaneurysm near the aortic isthmus. Also note the extensive mediastinal hematoma.* **(Right)** *Coronal CTA in the same patient again shows the pseudoaneurysm as a focal, rounded contour alteration of the aorta. Note how the mediastinal hematoma causes rightward deviation of the nasogastric tube; this indirect finding of BAI may be the only abnormality seen on an initial trauma radiograph.*

(Left) *AP radiograph of an 11-year-old patient who sustained an aortic tear during an MVA demonstrates a left apical cap, obscuration of the aortic contour, & a hemothorax. There is also a large tension pneumothorax on the right.* **(Right)** *Axial CTA from the same study shows active extravasation from an aortic rupture as well as a large, high-attenuation hemothorax. The aorta is focally enlarged & irregular. This child died from aortic transection.*

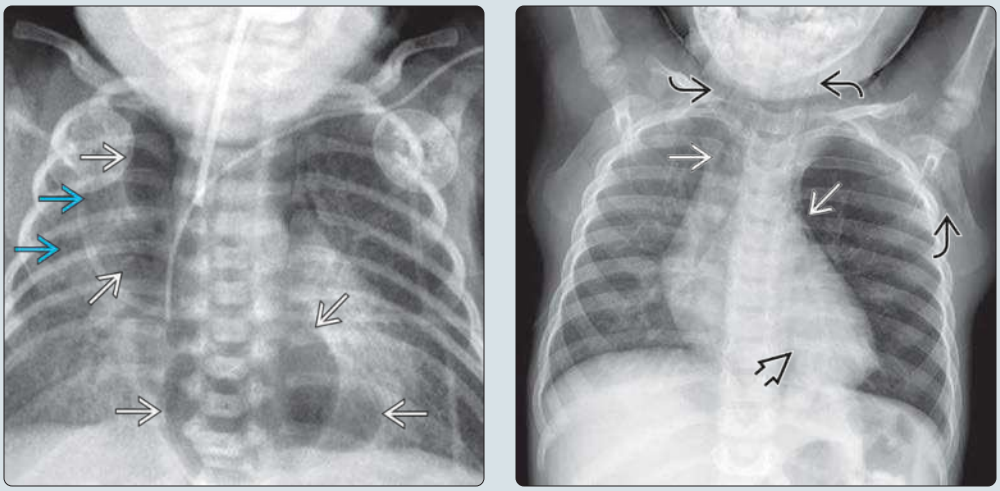
(Left) *Sequential axial CTA images in a young man who crashed his motorcycle reveal an irregular aortic filling defect as well as nonuniformity of the vessel wall caused by traumatic BAI.* **(Right)** *Oblique DSA shows placement of a conformable stent across the injury site. In clinically stable patients, a delayed endovascular repair allows time for other injuries to be assessed & treated (& results in fewer complications compared to operative management).*

Pneumomediastinum

KEY FACTS

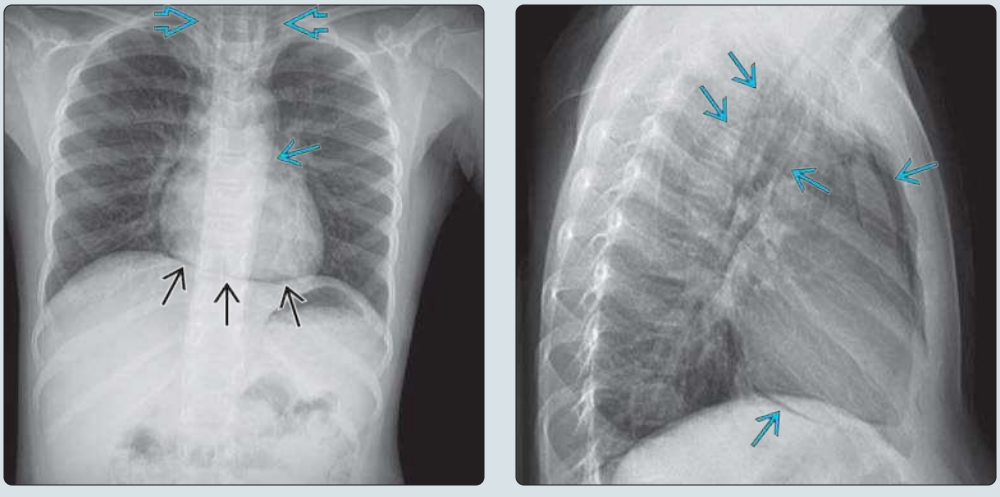
IMAGING

- Best tool for pneumomediastinum (PM): Chest radiograph
  - Pleural line lateral to main pulmonary artery & aortic arch
  - Vertical lucencies along superior mediastinum, trachea, esophagus, descending thoracic aorta
  - Continuous diaphragm sign: Air between pericardium & diaphragm results in visualization of normally obscured superior surface of central diaphragm
  - Spinnaker sail sign: Thymic elevation by mediastinal air in young child
  - Vanishing heart sign: Lucency over cardiac silhouette on supine view, posterior on lateral view
- CT or esophagram only with radiographic evidence of trauma, risk factors for aerodigestive tract injury (foreign body, surgery, mediastinitis), or respiratory distress



PATHOLOGY

- Spontaneous PM: Extension of air from ruptured alveolus into interstitium & mediastinum
  - Asthma & respiratory infection are most common
- Secondary PM: Disruption of aerodigestive tract (barotrauma, trauma, foreign body, Boerhaave syndrome), surgery, mediastinitis



CLINICAL ISSUES

- Common symptoms: Chest pain, cough, dyspnea
- Secondary PM is likely to present with rib fracture, pneumothorax, hemothorax, intracranial injury, respiratory distress, tachycardia
- Isolated spontaneous PM in stable patient: Self-limited
- Spontaneous PM with symptom progression: Further evaluate & treat underlying pulmonary cause
- Secondary PM: CT or esophagram with clinical or imaging evidence of aerodigestive tract injury
  - Widespread screening is of low yield in blunt trauma patients with otherwise normal chest radiograph
- Rarely, tension PM

(Left) *AP radiograph of a neonate with a perforated left main bronchus demonstrates a large lucency throughout the mediastinum, consistent with pneumomediastinum. The thymic tissue is displaced to the right.* **(Right)** *AP radiograph in a 2-year-old patient shows hyperinflation of the left lung with retrocardiac atelectasis & scattered foci of pneumomediastinum & subcutaneous emphysema. Subsequent bronchoscopy demonstrated an aspirated peanut in the left main bronchus.*

(Left) *Upright radiograph from a 6-year-old with chest pain after a fall shows a continuous diaphragm sign as well as subtle mediastinal lucencies, compatible with pneumomediastinum. Soft tissue emphysema is also noted.* **(Right)** *Lateral view of the chest from the same patient demonstrates lucencies surrounding the cardiac silhouette, aorta, trachea, & esophagus, compatible with pneumomediastinum.*

TERMINOLOGY

Definitions

- Pneumomediastinum (PM): Extraluminal mediastinal gas

IMAGING

Radiographic Findings

- Central lucencies with pleural line lateral to main pulmonary artery & aortic arch
- Vertical lucencies tracking on either side of superior mediastinum into neck
- Spinnaker sail sign: Elevation of thymus by mediastinal air in young child
- Vanishing heart sign: Lucency over cardiac silhouette seen on frontal view, posteriorly on lateral view due to posterior PM
- Continuous diaphragm sign: Air between pericardium & diaphragm results in visualization of normally obscured superior surface of central diaphragm
- Naclerio V sign: Air outlines lateral margin of descending aorta & extends laterally along left hemidiaphragm

Fluoroscopic Findings

- ± esophageal leakage of contrast into mediastinum

CT Findings

- Extraluminal gas in mediastinal space
- May depict underlying disruption of tracheobronchial tree

Imaging Recommendations

- Chest radiograph as initial modality
- CT or esophagram in setting of risk factors for aerodigestive tract injury (foreign body, surgery, mediastinitis, definite thoracic injury) or respiratory distress

DIFFERENTIAL DIAGNOSIS

Pneumothorax

- Upright & decubitus views can help determine whether air is localized in mediastinum vs. freely mobile in pleural space

Pneumopericardium

- Round lucency with continuous outline of heart margins; displaces pericardium outward
- Air in pericardial space changes with patient position
- Air does not extend into superior mediastinum
- Much less common than PM

Paramediastinal Pneumatocele

- ± internal fluid-fluid level or "claw" of lung parenchyma

Hernia of Stomach

- Paraesophageal or Morgagni types

PATHOLOGY

General Features

- Spontaneous PM: Pressure gradient between alveolus & surrounding tissue causes rupture with extension of air into interstices & mediastinum
  - Asthma, respiratory infection > straining against closed glottis, surfactant deficiency, meconium aspiration, inhalation drug use, forceful coughing
- Secondary PM: Disruption of aerodigestive tract (trauma, foreign body, Boerhaave syndrome, barotrauma), surgery, mediastinitis
  - Aerodigestive tract injury is rare in pediatric population (4.1% of traumatic PM)
- Extension of air from peritoneum or retroperitoneum

CLINICAL ISSUES

Presentation

- Most common: Chest pain, cough, shortness of breath
- ± crepitus in neck or chest (subcutaneous emphysema)
- Secondary PM is likely to present with rib fracture, pneumothorax, hemothorax, intracranial injury, respiratory distress, tachycardia

Natural History & Prognosis

- Spontaneous PM: Self-limited; recurrence is rare
  - Morbidity related to underlying pulmonary condition
- Secondary PM: Mortality related to other injuries
- Complications are uncommon but can include tension PM & cardiac tamponade, mediastinitis, pneumothorax

Treatment

- Isolated spontaneous PM in stable patient
  - Supportive care, emergency department observation
  - No evidence to support further studies
- Spontaneous PM with symptom progression
  - Evaluate & treat underlying pulmonary condition
- Secondary PM
  - CT or esophagram if underlying aerodigestive tract injury is specifically suspected
  - Treat underlying condition

DIAGNOSTIC CHECKLIST

Consider

- Widespread screening (especially with esophagram) is low yield in blunt trauma patients with otherwise normal chest radiograph
  - Selective investigation with high suspicion (e.g., rib fracture, effusion, pneumothorax)

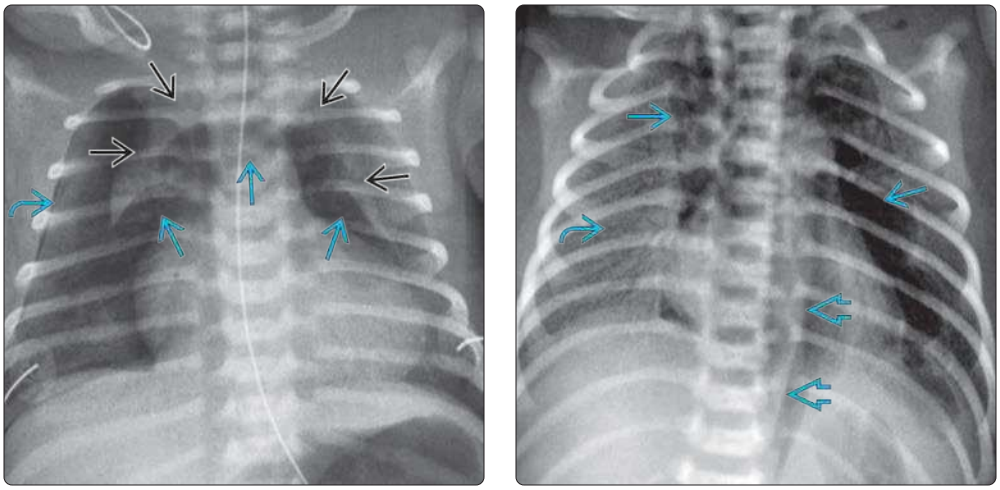


Image Interpretation Pearls

- In toddler with no history of asthma or trauma, consider aspirated foreign body

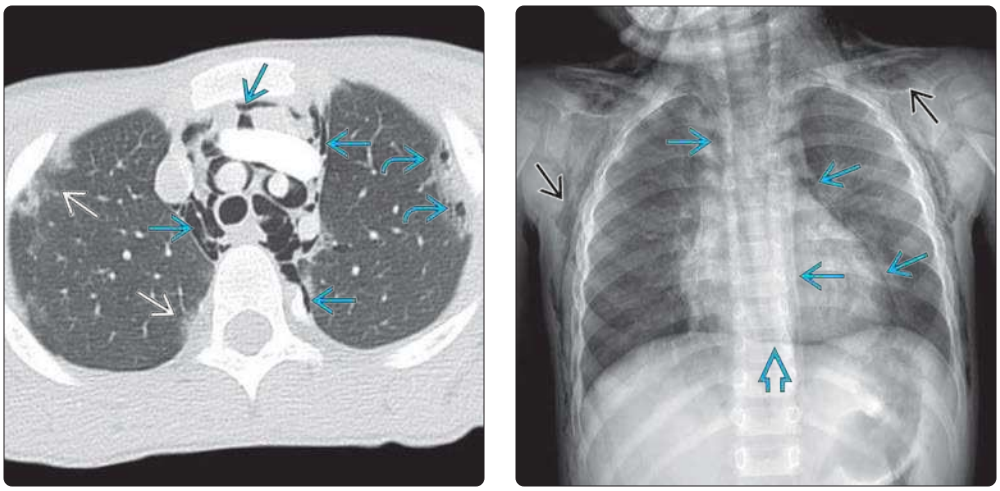
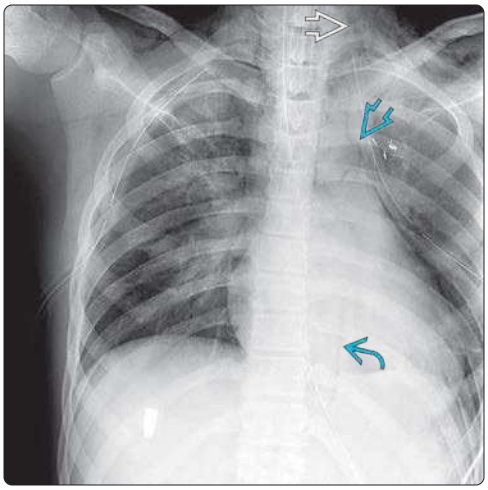
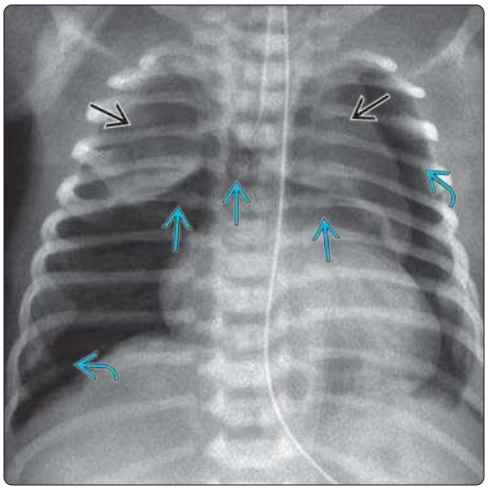
7. Bejvan SM et al: Pneumomediastinum: old signs and new signs. AJR Am J Roentgenol. 166(5):1041-8, 1996

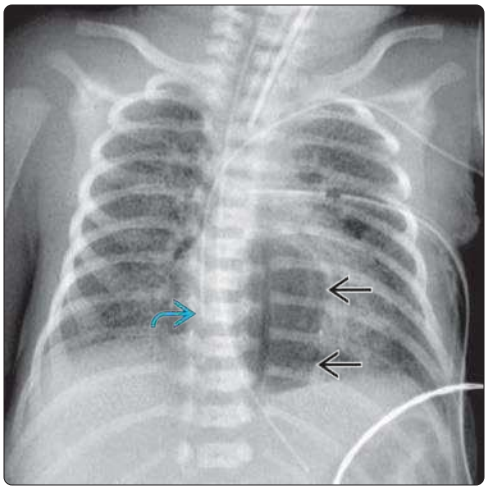


(Left) *Supine frontal view of the chest in this newborn demonstrates lucency elevating the thymus, compatible with pneumomediastinum. A small right pneumothorax is also present.* **(Right)** *Supine chest radiograph in a neonate shows extensive lucencies of pneumomediastinum displacing the lungs laterally & outlining the descending thoracic & upper abdominal aorta. Diffuse granular opacities with air bronchograms relate to the patient's surfactant deficiency.*

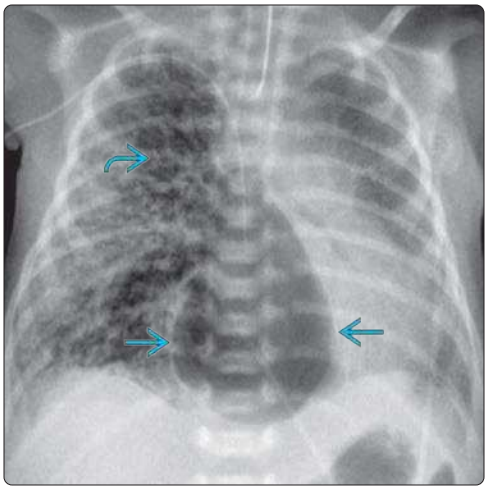


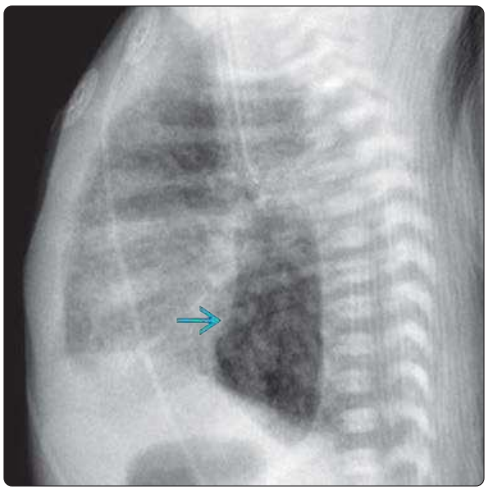


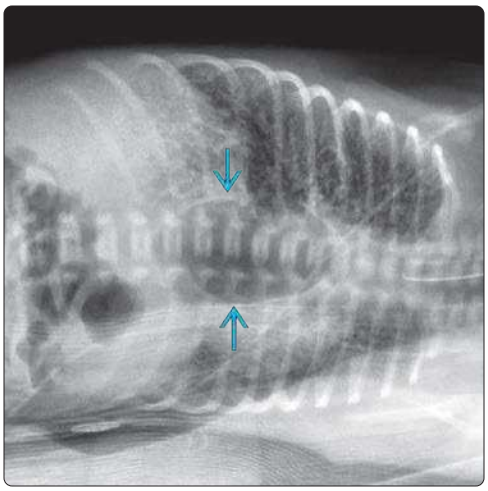
(Left) *Frontal upright radiograph of a 9-year-old who presented with shortness of breath shows curvilinear lucencies outlining the mediastinum & mildly elevating residual thymic tissue. Note also the soft tissue emphysema in the neck.* **(Right)** *Lateral upright view of the chest from the same patient again depicts pneumomediastinum with prominent anterior mediastinal lucencies.*



(Left) *Axial CECT in the same patient shows extensive pneumomediastinum. Additionally seen are subpleural ground-glass densities & cystic changes relating to the patient's history of dermatomyositis.* **(Right)** *Supine radiograph of a 3-year-old presenting with cough, fever, & facial swelling shows extensive subcutaneous emphysema & pneumomediastinum. Note the continuous diaphragm sign in this patient with RSV.*







(Left) *Supine radiograph of a 17-year-old with gunshot wounds demonstrates pneumomediastinum with air outlining the aortic arch & descending aorta. Also seen are scattered contusions & subcutaneous emphysema*. **(Right)** *Supine radiograph from a 1-day-old shows pneumomediastinum with lucency underlying/elevating the thymus. Pneumothorax is best seen at the right lung base.*

(Left) *AP radiograph in a neonate with surfactant deficiency shows a relatively large lucent collection inferiorly, typical in appearance for retrocardiac pneumomediastinum. Note also the low position of the left arm PICC in the right atrium.* **(Right)** *Supine radiograph in a 2-day-old with surfactant deficiency shows a round lucent collection projecting over the inferior midline, consistent with pneumomediastinum. Associated right pulmonary interstitial emphysema (PIE) is noted.*

(Left) *Lateral chest radiograph in the same patient localizes the pneumomediastinum to the retrocardiac region.* **(Right)** *Left decubitus view of the chest in the same patient was obtained to assess the mobility of the lucent collection (& ensure that this did not represent mobile air from a pneumothorax). The lucency did not move & was self-limited, resolving in 5 days. These features are consistent with retrocardiac pneumomediastinum.*

Neuroendocrine Cell Hyperplasia of Infancy

KEY FACTS

TERMINOLOGY

- Neuroendocrine cell hyperplasia of infancy (NEHI): Form of childhood interstitial lung disease (chILD) associated with neuroendocrine cell hyperplasia

IMAGING

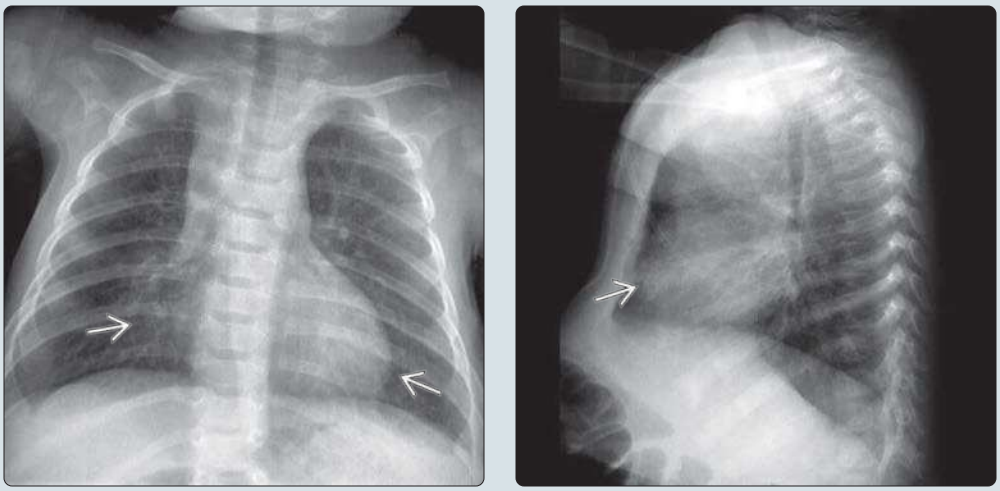
- Best test: HRCT (with inspiratory & expiratory images)
  - ~ 80% sensitive; ~ 100% specific with characteristic imaging pattern & clinical presentation
- Characteristic appearance
  - Central-predominant ground-glass opacification (GGO), especially of right middle lobe & lingula
    - Affects ≥ 4 lobes (counting lingula) in > 90% of cases
  - Diffuse mosaic air-trapping
  - No other abnormalities in 57-65% of cases

TOP DIFFERENTIAL DIAGNOSES

- Bronchiolitis obliterans (constrictive bronchiolitis)
- Asthma
- Surfactant dysfunction disorder

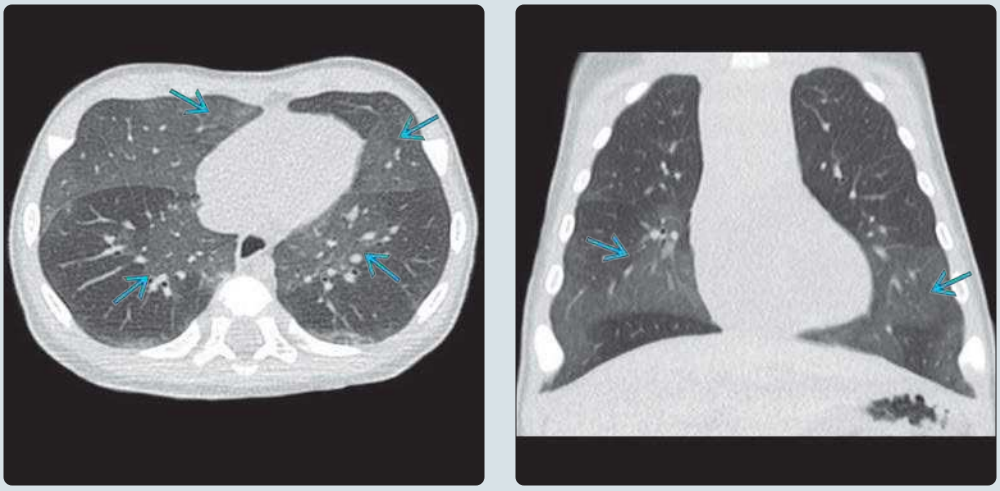
PATHOLOGY

- ↑ number of bombesin-immunopositive pulmonary neuroendocrine cells (PNECs) in distal respiratory bronchioles & alveolar ducts; etiology is unknown



CLINICAL ISSUES

- Typically presents in first 6-12 months of life with persistent retractions, tachypnea, crackles, hypoxemia, &/or failure to thrive
- Not responsive to steroids (unlike other chILDs)
- Does not progress to respiratory failure; gradually improves



DIAGNOSTIC CHECKLIST

- Important to suggest NEHI as diagnostic possibility
  - Immunostaining for bombesin is not routinely performed
  - If NEHI is not suggested by radiologist, diagnosis is likely to be missed by histopathology

(Left) *AP chest radiograph in a 4-month-old boy with an oxygen requirement & failure to thrive shows subtle, hazy, or ground-glass opacification (GGO) ➡ in the right middle lobe & lingula + mild overall hyperinflation.* **(Right)** *Lateral chest radiograph in the same patient shows the GGO ➡ in the middle lobe/lingula.*

(Left) *Axial inspiratory HRCT of the chest in the same patient with an oxygen requirement & failure to thrive shows central-predominant GGO ⇨ in the lower lobes, lingula, & middle lobe.* **(Right)** *Coronal inspiratory HRCT in the same 4-month-old boy shows the middle lobe & lingular distribution of GGO ⇨. The imaging findings are sufficient, along with the clinical history, to make the diagnosis of neuroendocrine cell hyperplasia of infancy (NEHI) without biopsy.*

TERMINOLOGY

Abbreviations

- Neuroendocrine cell hyperplasia of infancy (NEHI)

Definitions

- Form of childhood interstitial lung disease (chILD) associated with neuroendocrine cell hyperplasia

IMAGING

General Features

- Best diagnostic clue
  - Characteristic ground-glass opacification (GGO) pattern in central lungs, especially right middle lobe & lingula, with mosaic air-trapping

Radiographic Findings

- Nonspecific radiographic findings
- Perihilar opacities & hyperinflation may be similar to viral or reactive airways disease
  - Bronchial wall thickening is typically absent

CT Findings

- HRCT
  - Geographic GGO
    - Central-predominant distribution
      - Does not change with patient position (supine vs. prone)
    - Most pronounced in right middle lobe & lingula
  - Diffuse mosaic air-trapping
  - No other abnormalities in 57-65% of cases
  - Imaging findings may confirm but do not exclude diagnosis of NEHI
    - Misdiagnosis is more likely when other abnormalities are present & distribution of GGO is not classic

Imaging Recommendations

- Best imaging tool
  - HRCT ~ 80% sensitive; specificity approaches 100% with characteristic CT pattern & clinical presentation
- Protocol advice
  - Routine HRCT, including inspiratory & expiratory images
  - May use low-dose technique (e.g., 50 mAs) if evaluation of mediastinum is not needed

DIFFERENTIAL DIAGNOSIS

Surfactant Dysfunction Disorder

- GGO is more diffuse than in NEHI
- Associated with septal thickening, unlike NEHI

PATHOLOGY

General Features

- Etiology
  - Unknown

Staging, Grading, & Classification

- Form of chILD
- Considered in class of disorders of unknown etiology
  - Pulmonary interstitial glycogenosis (PIG) is also in this category

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Persistent retractions, tachypnea, crackles, hypoxemia
- Clinical profile
  - Pulmonary function tests
    - ↓ forced expiratory volume (FEV), ↑ functional residual capacity (FRC), ↑ residual volume (RV)

Demographics

- Age
  - Typically diagnosed in first 12-18 months of life
    - Mean age at presentation to pulmonologist: 7 months
    - Mean age at diagnosis: 12 months
    - Age of presentation is older than other chILDs, which present in early infancy
- Sex
  - Slight male predominance in original series of 15 cases

Natural History & Prognosis

- Long-term prognosis is unclear
  - Most children gradually improve over time but may persist into adulthood
- NEHI exacerbation
  - Episodes of ↑ air-trapping in children with NEHI who had previously experienced significant clinical improvement

Treatment

- Unlike other chILDs, NEHI not responsive to steroid therapy
  - Important to differentiate NEHI from other chILDs to avoid unnecessary side effects of steroids
- Treatment supportive
  - Oxygen supplementation
  - Nutrition optimization to prevent failure to thrive

DIAGNOSTIC CHECKLIST

Consider

- NEHI in older infants with persistent tachypnea
- Expiratory images may be helpful for diagnosis (due to air-trapping)

Image Interpretation Pearls

- Characteristic CT appearance
  - Geographic GGO pattern in central lungs, especially right middle lobe & lingula
  - Mosaic air-trapping

Pulmonary Interstitial Glycogenosis

KEY FACTS

TERMINOLOGY

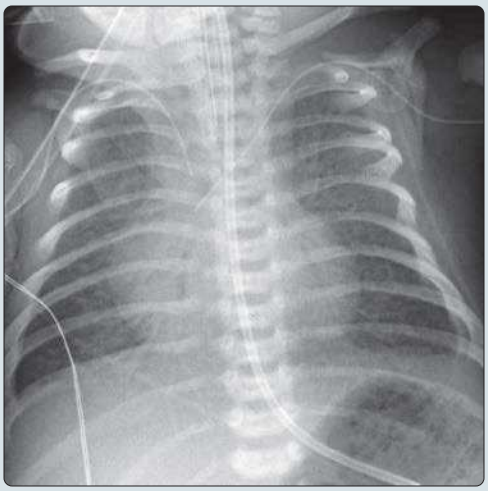
- Specific disorder of unknown etiology in childhood interstitial lung disease (chILD) classification system
- More accurate term: Neonatal pulmonary interstitial glycogen accumulation disorder

IMAGING

- Nonspecific imaging findings of diffuse or patchy hazy/ground-glass opacities, interstitial thickening, & hyperinflation
  - Appearances largely could be attributed to alveolar growth abnormalities, which pulmonary interstitial glycogenosis (PIG) often accompanies histopathologically
  - Other lung diseases, including infection & surfactant dysfunction disorders, could also show similar findings

TOP DIFFERENTIAL DIAGNOSES

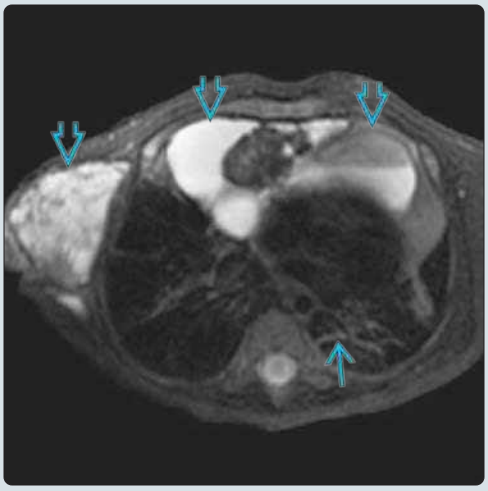
- Alveolar growth abnormality (AGA)
  - PIG is commonly associated with AGA (which confounds assessment of imaging appearance of "pure" PIG)
- Diffuse lung developmental disorders
  - Profound impairment of gas exchange
  - Death usually < 1 month of age (unless ECMO bridges to lung transplantation)
- Disorders of surfactant
  - Surfactant deficiency in premature neonates & genetic disorders affecting surfactant metabolism
- Neonatal pneumonia
  - Pleural effusion is frequent



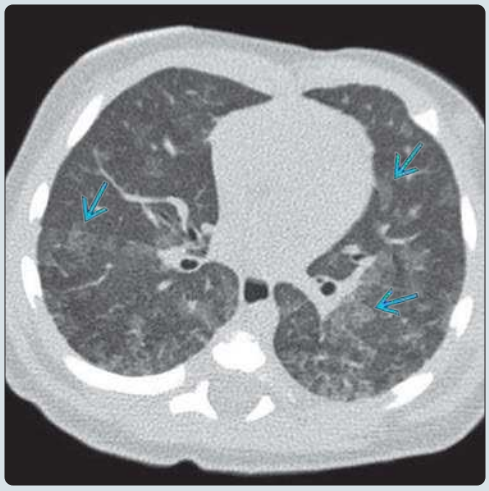
PATHOLOGY

- Infiltration & expansion of alveolar interstitium/septa by glycogen-laden immature mesenchymal cells

CLINICAL ISSUES



- PIG affects neonates & young infants
- Prognosis appears favorable without concurrent disease



(Left) *AP radiograph in a term neonate with Turner syndrome & respiratory failure reveals hyperinflation with diffuse ground-glass opacities & septal thickening.* **(Right)** *Axial HRCT from the lower lobes in the same patient with Turner syndrome shows septal thickening & areas of patchy ground-glass opacity. Biopsy revealed diffuse h pulmonary interstitial glycogenosis (PIG).*

(Left) *Axial T2 FS MR shows course interstitial markings in the lungs due to PIG. Note the multiple lymphatic malformations of the mediastinum & axilla.* **(Right)** *Axial HRCT from an 11-day-old neonate at the level of the middle & lingular bronchi confirms patchy areas of ground-glass opacity. Biopsy revealed a mild alveolar growth abnormality with patchy PIG.*

TERMINOLOGY

Abbreviations

- Pulmonary interstitial glycogenosis (PIG)

Synonyms

- Infantile cellular interstitial pneumonitis (former name)
- Neonatal pulmonary interstitial glycogen accumulation disorder

Definitions

- Specific disorder of unknown etiology in childhood interstitial lung disease (chILD) classification system
- Results from infiltration & expansion of alveolar interstitium/septa by glycogen-laden mesenchymal cells

IMAGING

General Features

- Best diagnostic clue
  - Patchy or diffuse ground-glass opacity & interstitial thickening described
  - However, coexistent lung disease (e.g., alveolar growth abnormality) likely impacts imaging appearance
- Location
  - No specific lung zonal predilection; opacities may be diffuse or heterogeneous

Radiographic Findings

- Interstitial thickening
- Diffuse or patchy hazy/ground-glass opacities
- Hyperinflation

CT Findings

- Ground-glass opacities (up to 86%)
- Hyperlucent foci ("cysts" vs. regions of alveolar simplification)
- Reticular opacities
- Architectural distortion

Imaging Recommendations

- Best imaging tool
  - HRCT

DIFFERENTIAL DIAGNOSIS

Alveolar Growth Abnormality

- PIG is commonly associated with alveolar growth abnormality (AGA), which confounds assessment of imaging appearance of "pure" PIG

Diffuse Lung Developmental Disorders

- Death usually occurs within 1st month of life without ECMO bridging to lung transplantation
- Acinar dysplasia, congenital alveolar dysplasia, alveolar capillary dysplasia with misalignment of pulmonary veins

Surfactant Dysfunction Disorders

- Abnormal proteins (SP-B, SP-C, ABCA3, & TTF-1) are important in surfactant production & function

Neonatal Pneumonia

- Pleural effusions are frequent

PATHOLOGY

Microscopic Features

- Infiltration & expansion of alveolar interstitium/septa by glycogen-laden immature mesenchymal cells, which stain positive for vimentin
  - Accumulation of glycogenated mesenchymal cells often accompanies other conditions, particularly AGA
- Little to no inflammatory change
- Diffuse or patchy involvement of pulmonary parenchyma
  - Patchy form is more common in patients with AGA

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Severity of presentation is highly variable
    - Respiratory failure with pulmonary hypertension
    - Tachypnea

Demographics

- Age
  - Neonates or young infants
    - Typically < 6 months of age

Natural History & Prognosis

- Most improve in absence of concurrent disease
  - Most require either no support vs. supplemental oxygen
- Mortality is reported with presence of comorbidities, such as AGA, congenital heart disease, & pulmonary hypertension

Treatment

- Possible benefits from corticosteroids

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- No specific imaging appearance
- Published reports of PIG imaging findings describe appearances that largely could be attributed to AGA (which PIG often accompanies histopathologically)

Reporting Tips

- Caution during HRCT interpretation, as nonspecific findings of septal thickening & diffuse ground-glass opacities can overlap with other disorders, including infection or disorders of surfactant

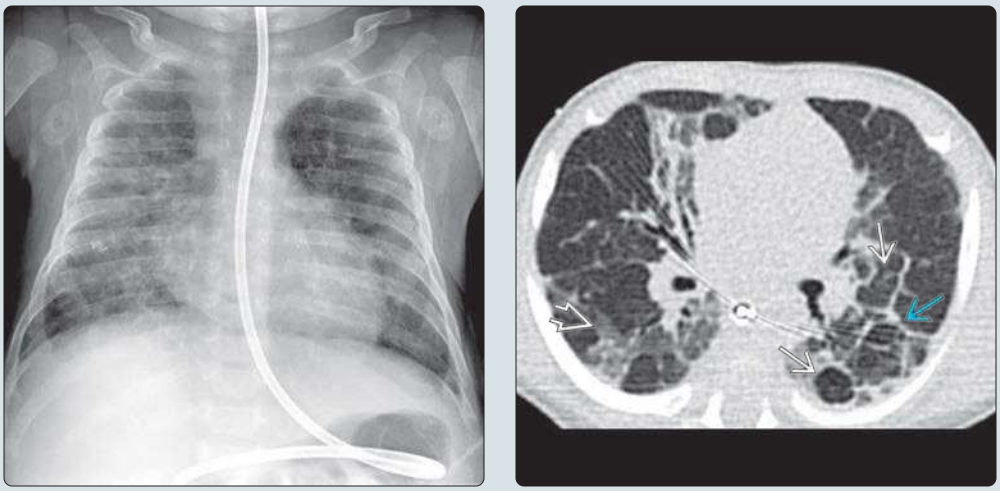
Alveolar Growth Abnormality

KEY FACTS

TERMINOLOGY

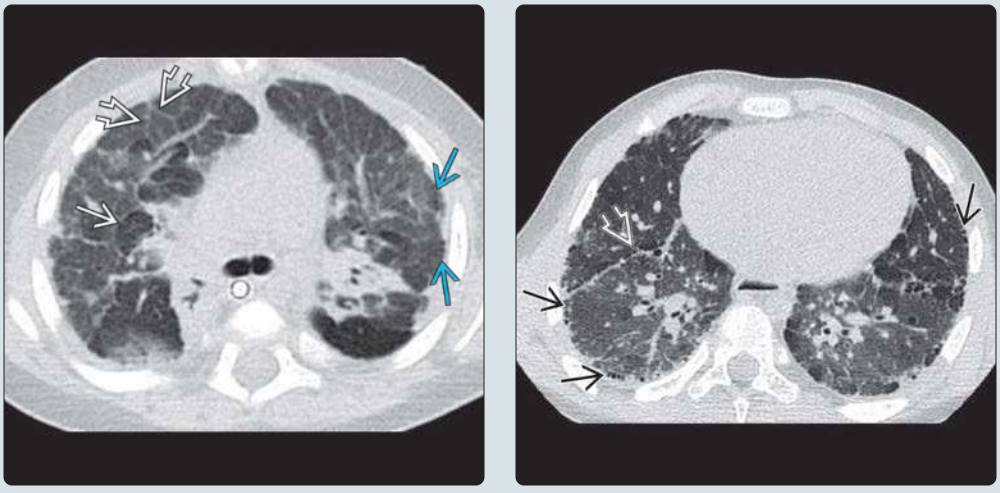
- Alveolar growth abnormality (AGA): Pathologic pattern of enlargement & simplification of alveoli with concomitant underdevelopment of pulmonary vasculature
- Synonyms: Alveolar growth disorder, alveolar simplification

IMAGING



- Radiologic findings range from near normal to
  - Variably sized but often large, secondary pulmonary lobules with vascular rarefaction
  - Subpleural & perilobular reticular opacities
  - Ground-glass opacities
  - Discrete subpleural/subfissural cysts (often in trisomy 21)
  - Hyperlucent regions that can resemble cystic change

PATHOLOGY



- Enlarged alveolar spaces with few alveoli + deficient vascular & alveolar septal development
  - ± concurrent pulmonary interstitial glycogenosis
- AGA is often secondary; seen in wide variety of diseases
  - Prenatal conditions
    - Restriction of thoracic space, ↓ or absent breathing movements, cardiac anomalies limiting pulmonary blood supply, chromosomal abnormalities
  - Postnatal conditions
    - Prematurity → bronchopulmonary dysplasia
    - Term infants with early postnatal lung injury

CLINICAL ISSUES

- Most common chronic diffuse lung disease in infancy
- Respiratory difficulties occur in neonatal period but natural history variable
  - Slow improvement or worsening with time depending on underlying disorder, AGA extent, ability to develop new alveoli, & presence of pulmonary hypertension
  - Filamin A (*FLNA*) mutations: Particularly severe AGA with periventricular gray matter heterotopia, cardiovascular anomalies, & connective tissue anomalies

(Left) *AP chest radiograph of a former 23-weeks-premature infant at 10 weeks of age shows bilateral hyperinflation with coarse parenchymal opacities.* **(Right)** *Axial HRCT in the same infant at 10 weeks of age shows disordered, secondary pulmonary lobules of variable shape with ground-glass opacities & thick, perilobular opacities, typical of chronic lung disease of prematurity with alveolar growth abnormality.*

(Left) *Axial NECT in an infant with congenital heart disease (atrial septal defect & ventricular septal defect) shows large, secondary pulmonary lobules, perilobular, reticular opacities, & subtle, subpleural cysts, typical of alveolar growth abnormality.* **(Right)** *Axial HRCT in a child with trisomy 21 shows large, secondary pulmonary lobules & subpleural/perilobular, reticular opacities with subpleural & subfissural cysts.*

TERMINOLOGY

Definitions

- Alveolar growth abnormality (AGA): Pathologic pattern of enlargement & simplification of alveoli with concomitant underdevelopment of pulmonary vasculature

IMAGING

General Features

- Best diagnostic clue
  - Large, secondary pulmonary lobules + vascular rarefaction
    - Imaging findings range from severe to near normal
- Location
  - Variable; cystic changes are often most conspicuous in subpleural & subfissural lungs
  - Unilateral in certain congenital cases with in utero ipsilateral mass effect (e.g., lung lesion, diaphragmatic hernia, chylothorax)
- Size
  - Variable ↑ size of secondary pulmonary lobule(s)

Radiographic Findings

- Hyperinflation with pulmonary vascular rarefaction & generalized lucency of parenchyma
- Coarse, reticular opacities

CT Findings

- Variably sized (but often large), secondary pulmonary lobules with vascular rarefaction
- Perilobular & subpleural linear opacities, parenchymal bands, ground-glass opacities
- Subpleural/subfissural cysts (often in trisomy 21)
- Hyperlucent regions that can appear cystic

Imaging Recommendations

- Best imaging tool: CT
  - Generally most conspicuous on inspiratory images
  - Expiratory images are helpful if clinical &/or pulmonary function test (PFT) findings suggest obstructive airways disease/air trapping
- Protocol advice: Maximize lung recruitment if patients are under sedation/anesthesia

DIFFERENTIAL DIAGNOSIS

Parenchymal Lung Diseases That May Result in Widespread Architectural Distortion

- Meconium aspiration syndrome
- Chronic aspiration
- Bronchopulmonary dysplasia (BPD)

PATHOLOGY

General Features

- Most common chronic diffuse lung disease in infancy
- AGA is often secondary; seen in wide variety of diseases
  - Prenatal conditions
    - Restriction of thoracic space, ↓ or absent breathing movements, cardiac anomalies limiting pulmonary blood supply, chromosomal abnormalities
  - Postnatal conditions
    - Prematurity (most common) with BPD
    - Term infants with early postnatal lung injury

Microscopic Features

- Reduced radial alveolar count
- Enlarged alveolar spaces with fewer alveoli & deficient vascular & alveolar septal development
- ± concurrent pulmonary interstitial glycogenosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Respiratory difficulties in neonatal period
- Other signs/symptoms
  - Filamin A (*FLNA*) X-linked genetic mutations have particularly severe AGA
    - Pulmonary hypertension & respiratory decline

Natural History & Prognosis

- Slow improvement or worsening with time depends on underlying disorder, AGA extent, ability to develop new alveoli, & presence of pulmonary hypertension
- With prematurity
  - Advances in neonatal care (improved ventilation equipment/strategies, antenatal corticosteroids, surfactant, nutrition) → shift from classic BPD (airway obstruction & fibrosis) to "new BPD" (impaired alveolar development)
    - ↓ lung injury from oxygen toxicity & barotrauma
  - Unclear how "new BPD" patients remodel alveoli & pulmonary microvasculature with age & growth
    - All extremely low birth weight infants have some degree of abnormal lung development

Treatment

- Supportive measures: Supplemental oxygen, nutrition, & prevention of RSV
- Lung transplantation in most severely affected

DIAGNOSTIC CHECKLIST

Reporting Tips

- Clinical history is important to prevent reporting all cases as chronic lung disease of prematurity/BPD
- Bilateral findings without prematurity could indicate genetic cause (trisomy 21, filamin A mutation) or peripartum condition resulting in impaired pulmonary parenchymal development

Surfactant Dysfunction Disorders

KEY FACTS

TERMINOLOGY

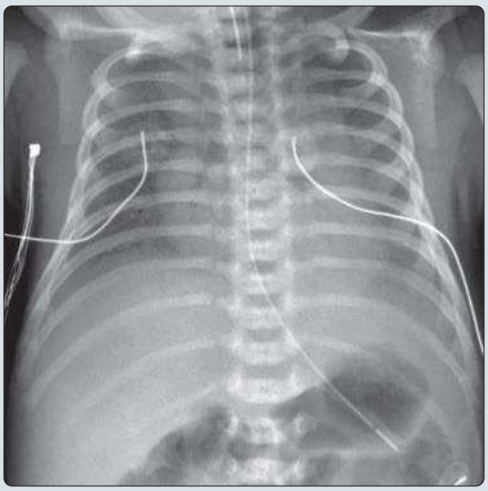
- Group of rare lung diseases caused by mutations/deletions of genes affecting surfactant homeostasis
- Most frequent surfactant dysfunction disorders
  - Surfactant protein B (SP-B): *SFTPB* gene
  - Surfactant protein C (SP-C): *SFTPC* gene
  - ATP-binding cassette transporter A3: *ABCA3* gene
  - Receptors for GM-CSF: *CSF2RA*, *CSF2RB* genes
    - Congenital alveolar proteinosis
  - Thyroid transcription factor: *TTF1/NKX2-1* genes
    - Brain-lung-thyroid syndrome

IMAGING

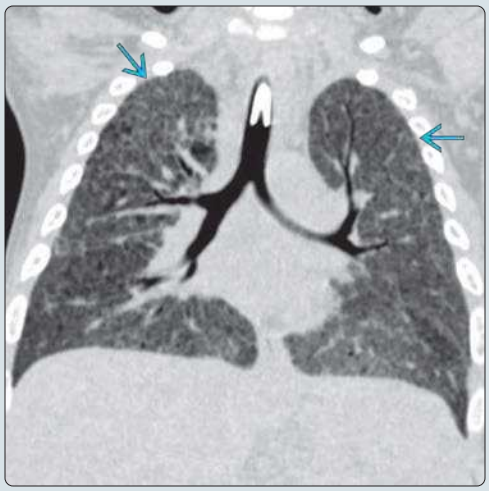
- Radiographs: Bilateral granular opacities in term neonate
- CT: Diffuse ground-glass opacification & thickened interlobular septa: Crazy-paving pattern
  - Can progress to fibrotic changes with persistent interlobular septal thickening, cysts

TOP DIFFERENTIAL DIAGNOSES

- Surfactant deficiency related to prematurity
- Neonatal pneumonia
- Transient tachypnea of newborn
- Alveolar growth abnormalities

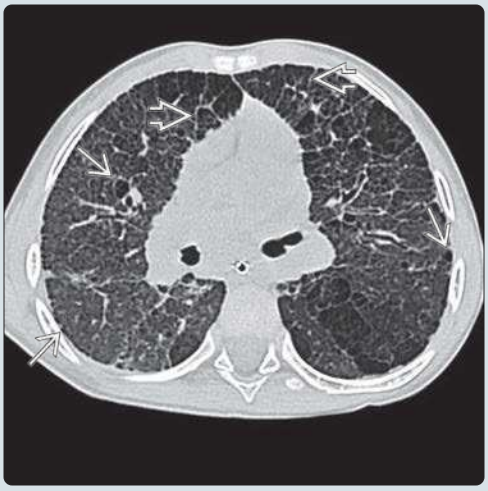


PATHOLOGY



- Pulmonary surfactant: Complex mixture of lipid (90% by weight) & protein lining alveolar surface
  - Prevents end-expiratory atelectasis

CLINICAL ISSUES



- Acute respiratory distress in full-term infants at birth
- SP-B: Progressive & usually fatal by 3-6 months of age with lung transplantation as only effective treatment
- SP-C, ABCA3: More commonly associated with diffuse lung disease in older infants, children, & adults
  - Onset of symptoms is highly variable

(Left) *AP radiograph in a term neonate presenting with respiratory distress secondary to an ABCA3 gene mutation shows low lung volumes with widespread granular opacities resembling surfactant deficiency of prematurity.* **(Right)** *Coronal HRCT in the same neonate with an ABCA3 mutation shows diffuse ground-glass opacification with areas of interlobular septal thickening.*

(Left) *Axial HRCT from an older infant with a surfactant protein C mutation shows areas of mild ground-glass opacity, numerous parenchymal cysts, & foci of interlobular septal thickening.* **(Right)** *Axial HRCT from a 17-year-old with a known ABCA3 mutation shows areas of ground-glass opacity with concomitant reticulation & traction bronchiectasis, indicating fibrosis.*

TERMINOLOGY

Definitions

- Group of rare lung diseases caused by mutations/deletions of genes affecting surfactant homeostasis
  - Differs from prematurity-related surfactant deficiency & secondary surfactant deficiency
- Most frequent surfactant dysfunction disorders
  - Surfactant protein B (SP-B): *SFTPB* gene
  - Surfactant protein C (SP-C): *SFTPC* gene
  - ATP-binding cassette transporter A3 (ABCA3): *ABCA3* gene
  - Receptors for GM-CSF: *CSF2RA*, *CSF2RB* genes
    - Congenital alveolar proteinosis
  - Thyroid transcription factor: *TTF1*/*NKX2-1* genes
    - Brain-lung-thyroid syndrome
- Pulmonary alveolar proteinosis of adults & older children
  - GM-CSF autoantibodies
  - Alveolar macrophage dysfunction

IMAGING

General Features

- Best diagnostic clue
  - Term infant with radiographic presentation similar to surfactant deficiency of prematurity

Radiographic Findings

- Diffuse or patchy granular opacities

CT Findings

- SP-B
  - Diffuse ground-glass opacification & thickened interlobular septa: Crazy-paving pattern
  - Can progress to fibrotic changes with persistent interlobular septal thickening
  - Rarely imaged with CT during severe neonatal presentation due to fragile clinical state
- SP-C or ABCA3
  - Infants
    - Diffuse ground-glass opacification or consolidation with interlobular septal thickening: Crazy-paving pattern
  - Older infants & children
    - Ground-glass opacities that ↓ in extent with age
    - Parenchymal cysts that ↑ in number & size with age
    - Interlobular septal thickening
    - Pectus excavatum

DIFFERENTIAL DIAGNOSIS

Surfactant Deficiency Related to Prematurity

- Differentiated clinically based on gestational age
  - Affects ~ 60% born < 28-weeks gestation
  - Affects ~ 5% born at term

Neonatal Pneumonia

- Can be acquired antenatally, perinatally, or postnatally
- Etiologies vary depending on timing of disease acquisition
- Pleural effusion is common

Transient Tachypnea of Newborn

- Self-limited illness due to delay in clearance of fetal lung fluid

Alveolar Growth Abnormalities

- Commonly due to prematurity but also observed in congenital heart disease & genetic disorders (e.g., trisomy 21)

PATHOLOGY

General Features

- Etiology
  - Pulmonary surfactant: Complex mixture of lipid (90% by weight) & protein lining alveolar surface
    - Prevents end-expiratory atelectasis

CLINICAL ISSUES

Natural History & Prognosis

- SP-B
  - Acute respiratory distress in full-term infants at birth
  - Transient or modest improvement with surfactant replacement &/or corticosteroid therapy
  - Progressive & usually fatal by 3-6 months of age with lung transplantation as only effective treatment
- SP-C
  - More commonly associated with diffuse lung disease in older infants, children, & adults
  - Onset of symptoms is highly variable: Influenced by mutation as well as environmental factors (e.g., viral infections)
    - Average onset of 2-3 months of age
      - 10-15% present in 1st month of life
      - Presentation in full-term neonates: Similar to surfactant deficiency of prematurity; may be fatal
      - Presentations in older infants: Tachypnea, retractions, hypoxemia, digital clubbing, & failure to thrive
  - Wide ranging long-term clinical status: From no supplemental oxygen requirement to death while awaiting transplant
  - Older adults often present with pulmonary fibrosis
- ABCA3
  - Variable: Associated with above phenotypes

Treatment

- SP-B
  - Almost always fatal without lung transplant
  - Rare cases of surviving children with partial defects in SP-B production
- SP-C & ABCA3
  - Treatment varies based on phenotypic manifestations
    - Lung transplant in infancy in severe cases

Swyer-James Syndrome

KEY FACTS

TERMINOLOGY

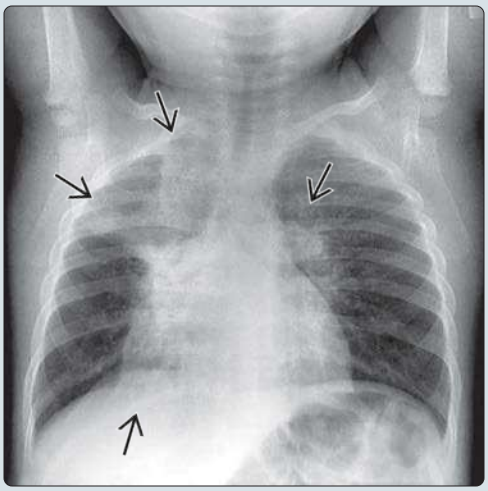
- Acquired unilateral pulmonary hypoplasia thought to result from childhood viral infection [postinfectious bronchiolitis obliterans (BO)]
- Results in small, hyperexpanded lung with relative ↓ in vascularity

IMAGING

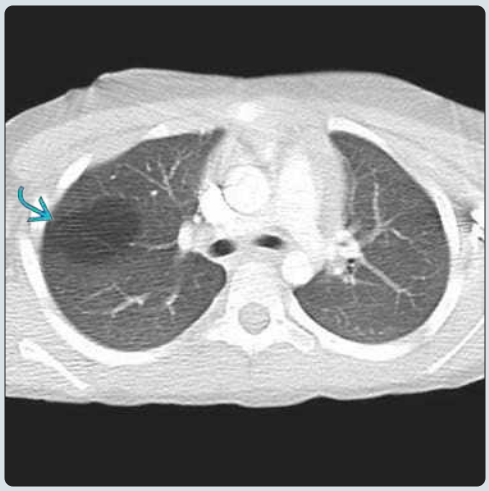
- Radiograph
  - Asymmetric hyperlucent lung with diminished number & caliber of vessels
  - May simulate pneumothorax
- HRCT
  - Air-trapping in affected lung
  - Small central & peripheral pulmonary arteries
  - Occasional bronchiectasis with minor subpleural scarring
  - Bronchial wall thickening, usually mild

TOP DIFFERENTIAL DIAGNOSES

- Foreign body aspiration
- Obstructive endobronchial lesion
- Congenital lobar overinflation
- Unilateral absence of pulmonary artery
- Poland syndrome

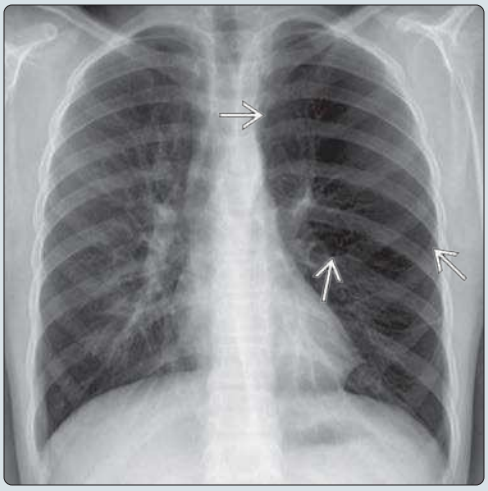


PATHOLOGY

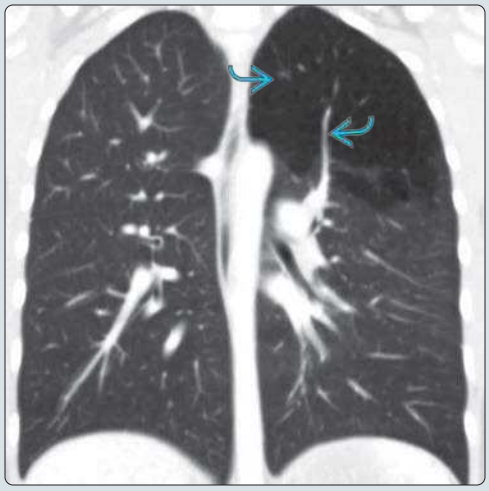


- Inflammation & fibrosis of walls & contiguous tissues of membranous & respiratory bronchioles
- Do not confuse BO with bronchiolitis obliterans organizing pneumonia (BOOP)

CLINICAL ISSUES



- Frequent respiratory infections in infancy or childhood
- Chronic cough, wheezing, recurrent pneumonia
- Variable presentation depending on severity of disease
- Prognosis is usually good
- Treatment is supportive



(Left) *Frontal upright radiograph shows a 13-month -old with typical symptoms & radiographic findings of viral airway disease, a risk factor for later developing Swyer-James syndrome (SJS). Note the asymmetric geographic areas of air-space opacity & volume loss that mostly involve the right lung.* **(Right)** *Follow-up CT in the same patient 8 years later shows a focal hyperlucency in the affected area of the right lung; note the presence of attenuated vessels coursing through the involved area.*

(Left) *Frontal chest radiograph in a previously healthy 8-year-old after a viral illness while traveling abroad demonstrates asymmetric lucency & mild hyperexpansion in the left upper lobe.* **(Right)** *Coronal CT reconstruction in the same patient shows the presence of narrow caliber vessels in the affected area. Bronchi were normal (as opposed to bronchial atresia), & there is no mass effect (as seen with congenital lobar overexpansion, which also presents earlier in life).*

TERMINOLOGY

Abbreviations

- Swyer-James syndrome (SJS)

Synonyms

- Swyer-James-MacLeod syndrome, Brett syndrome, postinfectious bronchiolitis obliterans (BO)

Definitions

- Acquired unilateral pulmonary hypoplasia thought to result from childhood viral infection
- Results in small, hyperexpanded lung with relatively ↓ vascularity & (rarely) bronchiectasis
- Imaging findings may appear as early as 9 months after initial infectious insult

IMAGING

General Features

- Best diagnostic clue
  - Asymmetric hyperlucent lung with diminished number & caliber of vessels
  - Classically unilateral but usually multifocal

Radiographic Findings

- Radiography
  - Pronounced patchy unilateral or unilobar hyperlucency (due to oligemia of involved segments)
    - May simulate pneumothorax on radiographs
  - Possible reduced lung volume on inspiration with air-trapping on expiration

CT Findings

- HRCT
  - Mosaic pattern of attenuation
  - Inspiratory: Affected lung volume is small or normal-sized
  - Expiratory: Air-trapping in affected lung
  - Small central & peripheral pulmonary arteries
  - Bronchiectasis with minor subpleural parenchymal scarring, especially in older patients
  - Bronchial wall thickening, usually relatively mild

Imaging Recommendations

- Protocol advice
  - Important to do HRCT with expiratory images

DIFFERENTIAL DIAGNOSIS

Foreign Body Aspiration

- Acute presentation, often with supportive history (e.g., recent choking on peanuts)
- Endobronchial foreign body may be visible on CT

Obstructive Endobronchial Neoplasm

- Enhancing endobronchial filling defect on CT
- More common in older teenagers & adults

Congenital Lobar Overinflation

- Congenital abnormality of lower airways that results in progressive overexpansion of pulmonary lobe
- Most commonly presents in newborn period
- Expanding hyperlucent lung tissue exerts mass effect

Unilateral Absence of Pulmonary Artery

- Also presents as unilateral small, hyperlucent, oligemic lung
- No air-trapping on expiration (as in SJS)
- All prior chest radiographs will be abnormal (as opposed to previously normal in SJS)

Poland Syndrome

- Congenital unilateral absence of pectoralis muscles & hypoplasia of ipsilateral breast soft tissues
- Radiographs: Unilateral, hyperlucent hemithorax
- CT: Normal lung parenchyma but absent/↓ extrathoracic soft tissues on affected side

PATHOLOGY

General Features

- Inflammation & fibrosis of walls & contiguous tissues of membranous & respiratory bronchioles
  - Postobstructive hyperexpansion of terminal air sacs
  - Compensatory ↓ perfusion
- Result: Underdevelopment of alveoli & pulmonary arteries
- Main histopathological finding: Constrictive bronchiolitis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Frequent respiratory infections in infancy or childhood
    - Most common infections: Adenovirus, RSV, influenza A, *Mycoplasma* pneumonia
  - Chronic cough, wheezing, recurrent pneumonia
- Other signs/symptoms
  - Variable presentations: Range from severe to asymptomatic
  - Restrictive pattern on pulmonary function tests

Demographics

- Age
  - Usually presents in infancy or childhood
  - Less severe cases may be missed until adulthood (often found incidentally on radiographs)

Natural History & Prognosis

- ~ 1% of adenovirus-induced bronchiolitis progress to BO
- If insult occurs before alveolar maturation (8 years), may affect number of alveoli & pulmonary vessels
- Prognosis is usually good

Treatment

- Pneumonectomy is reserved for intractable recurrent infections

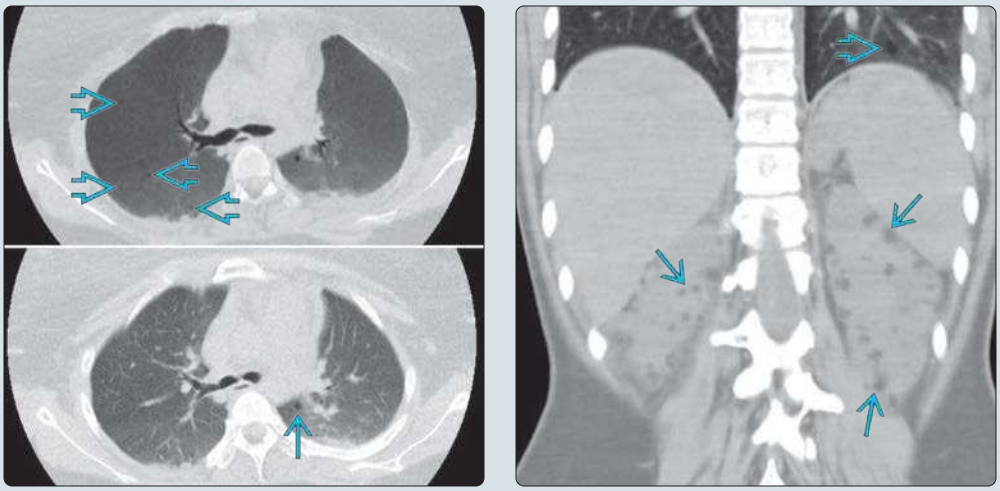
Lymphangioleiomyomatosis

KEY FACTS

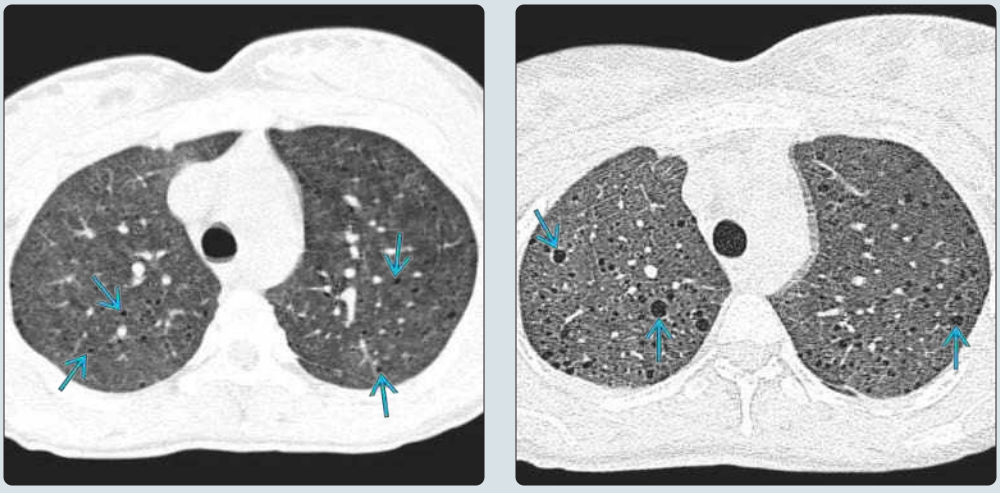
TERMINOLOGY

- Cystic disease of lungs & thoracic/retroperitoneal lymphatics due to proliferation of lymphangioleiomyomatosis (LAM) cells
  - LAM cells: Low-grade neoplastic smooth muscle-like cells that are metastatic from unknown primary tumor
- 2 subtypes are nearly identical by histology & imaging
  - Tuberous sclerosis complex associated (TSC-LAM)
  - Sporadic (S-LAM)



IMAGING

- Chest radiograph
  - Normal to ↑ lung volumes
  - Diffuse bilateral fine reticular opacities
  - ± pneumothorax, pleural effusion
- Lung CT
  - Numerous randomly distributed, thin-walled cysts
    - Range from few scattered cysts to complete lung parenchymal replacement
    - Variable size: Usually 2 mm to 2 cm (may be larger)
      - Expiratory & minIP images are more sensitive for small cysts
  - Normal intervening parenchyma
    - Small scattered nodules in minority of patients
  - CT underestimates early functional impairment



CLINICAL ISSUES

- S-LAM: Occurs nearly exclusively in females
  - Mean age of diagnosis: 35 years
- TSC-LAM is higher in women than men (42% vs. 13% of TSC cases, respectively)
  - TSC-LAM cysts may be seen in childhood
  - 22% are affected by age 20; 80% by age 40
- Most common presentations: Dyspnea on exertion, recurrent pneumothorax
- Gradual pulmonary function deterioration from slowly advancing disease
- Treatments include mTOR inhibitors, lung transplant

(Left) *Axial expiratory lung CT minIP (top) & standard (bottom) images in a 23-year-old woman with TSC show changes of LAM. Only a single, 4-mm cyst is visible on the standard reconstruction, while numerous additional smaller cysts are seen on the minIP image.* **(Right)** *Coronal NECT in a 14-year-old patient with TSC shows a small lung cyst in the left lower lobe. Despite the lung window settings, numerous fat-containing lesions can be seen throughout the kidneys, typical of renal angiomyolipomas.*

(Left) *Axial expiratory lung CT in a 22-year-old patient with TSC-LAM shows numerous scattered, 1- to 2-mm, round, thin-walled cysts with normal intervening lung parenchyma.* **(Right)** *Axial expiratory lung CT obtained 3 years later in the same patient shows that the cysts have ↑ in both size & number. The intervening parenchyma remains normal.*

TERMINOLOGY

Definitions

- Lymphangioleiomyomatosis (LAM): Disease characterized by abnormal proliferation of LAM cells in lungs & thoracic/retroperitoneal lymphatics
  - Occurs almost exclusively in women of childbearing age
- 2 main forms: Tuberous sclerosis complex-associated LAM (TSC-LAM); sporadic LAM (S-LAM)

IMAGING

General Features

- Best diagnostic clue
  - Bilateral, randomly distributed, thin-walled pulmonary cysts surrounded by normal intervening parenchyma

Radiographic Findings

- Chest radiograph is normal in early stages of LAM
- Eventual development of diffuse, fine reticular opacities
- Normal to ↑ lung volumes; ± pneumothorax (39-53%), pleural effusion (10-44%)
  - May precede visible parenchymal abnormalities

CT Findings

- Numerous thin-walled cysts with uniform distribution
  - Variable size: Usually 2 mm to 2 cm (may be larger)
    - Cyst sizes correlate with extent of disease
  - Variable number: From few scattered cysts to complete replacement of lung parenchyma
    - Small cysts are best seen on expiratory & minimum intensity projection (minIP) images
- Normal intervening lung parenchyma in majority
- Solid or ground-glass, 1- to 10-mm nodules in 3-20%; predominantly upper lobe & peripheral
  - Multifocal micronodular pneumocyte hyperplasia
- ± pleural effusion, pneumothorax, thoracic duct enlargement
- Quantitative CT analysis detects early emphysematous change surrounding cysts; high correlation with lung function: Threshold of -900 vs. -950 HU

MR Findings

- Hyperpolarized Xe-129 scans show ventilation defects, even with minimal cysts by CT & normal pulmonary function tests; elevated ADC values correspond to ↑ alveolar size

DIFFERENTIAL DIAGNOSIS

Langerhans Cell Histiocytosis

- Small pulmonary nodules ± cysts

Cystic Fibrosis

- Central & peripheral bronchiectasis, greatest in upper lobes

Bronchopulmonary Dysplasia

- History of prematurity + prolonged oxygen requirement

Papillomatosis

- Due to vertical transmission of human papillomavirus

PATHOLOGY

General Features

- Etiology
  - Abnormal neoplastic smooth muscle-like cell (LAM cell)
  - Evidence supports LAM cell metastases as cause for pulmonary manifestations
- Genetics
  - TSC-LAM: 2-hit Knudson hypothesis (sporadic superimposed on inherited germline) of mutations causing complete functional loss of *TSC1* or *TSC2* genes
    - *TSC1* gene product: Hamartin protein
    - *TSC2* gene product: Tuberin protein
    - Hamartin & tuberin are necessary for functioning mTOR signaling pathway
  - S-LAM: 2 sporadic somatic hits to *TSC2*

Extrapulmonary Findings

- S-LAM: Renal angiomyolipomas (AMLs) in 30% (usually small)
  - Chylous ascites, uterine leiomyomas, liver & pancreas cysts, abdominal/pelvic cystic lymphangioleiomyomas
- TSC-LAM: Renal AMLs in 80% (usually larger than in S-LAM) + renal cysts; hepatic & pancreatic lesions, PEComas
  - Cardiac rhabdomyomas (majority involute over time)
  - Cerebral > cerebellar cortical/subcortical tubers, white matter lesions, subependymal nodules, subependymal giant cell astrocytomas
  - Other: Retinal astrocytomas/hamartomas, facial angiofibromas, ash leaf spots, shagreen patches, subungual fibromas, cystic & sclerotic bone lesions

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Progressively worsening dyspnea on exertion in women of childbearing age
  - Spontaneous pneumothorax, often recurrent

Demographics

- Age: S-LAM mean age of diagnosis: 35 years
  - TSC-LAM lung disease can be seen on CT in childhood; 22% are affected by age 20; 80% by age 40

Natural History & Prognosis

- Progressive pulmonary function deterioration from slowly advancing lung disease; 10-year survival: 79-91%

Treatment

- Primarily symptomatic (e.g., evacuating pleural effusion, pneumothorax; bronchodilators)
- Sirolimus/rapamycin (mTOR inhibitor)
- Lung transplant

Langerhans Cell Histiocytosis, Pulmonary

KEY FACTS

TERMINOLOGY

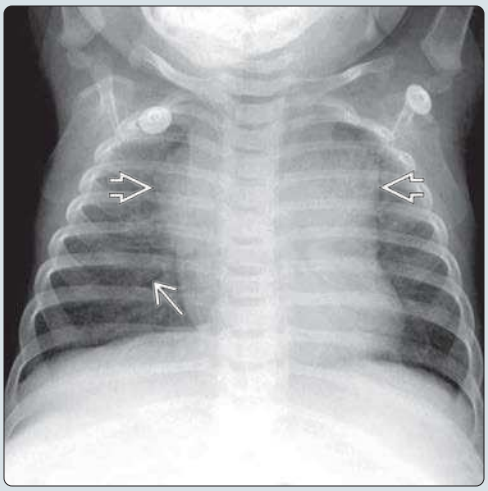
- Neoplastic proliferation of monoclonal Langerhans cells leading to formation of destructive granulomas

IMAGING

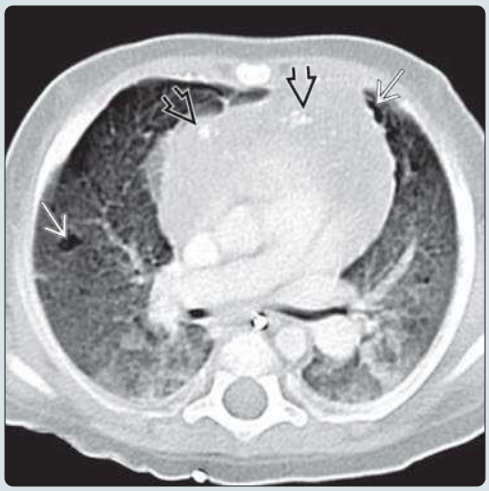
- Diffuse lung involvement is typical in children
  - Classic sparing of lower lungs/costophrenic sulci applies to adult pulmonary Langerhans cell histiocytosis (LCH)
    - Should not be used as diagnostic criterion in pediatrics
- Radiographs: Reticulonodular pattern of opacities
- CT: Combination of small nodules & cysts
  - Irregularly shaped nodules in centrilobular, peribronchial, or peribronchiolar locations
  - Cysts with variable wall thickness
- Chronic LCH: Fibrosis & traction emphysema
- May also see osseous, thymic, hepatic, & splenic involvement on chest imaging
  - High likelihood of multisystem LCH if lung disease is present in child

TOP DIFFERENTIAL DIAGNOSES

- Cystic fibrosis
- Papillomatosis
- Lymphangioleiomyomatosis
- Sarcoidosis

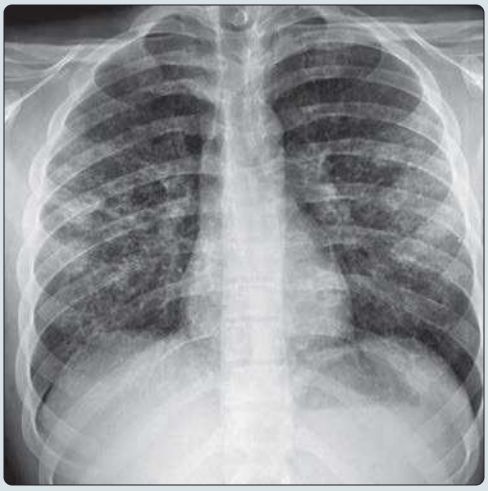


CLINICAL ISSUES

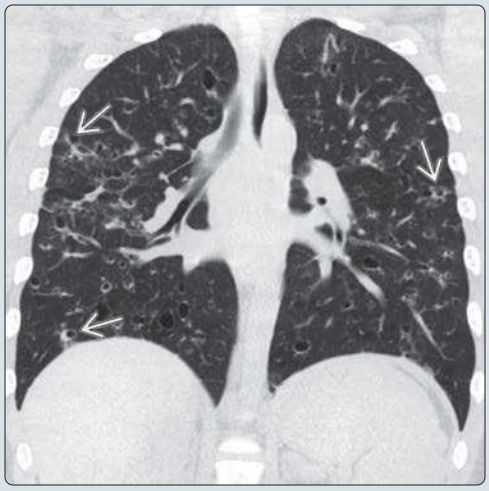


- May present at any age in childhood
- Typically occurs with multisystem disease in children
  - Lung is no longer considered risk organ for worse prognosis in LCH
- Leads to end-stage lung disease in 10-27% of cases
- HRCT is helpful to follow disease progression in young children, as pulmonary function tests are less reliable

DIAGNOSTIC CHECKLIST



- Pediatric LCH should not be confused with adult pulmonary LCH (which is typically single system disease associated with smoking)



(Left) *AP chest radiograph in a 7-month-old girl shows diffuse, hazy lung opacity with areas of linear lucency. The mediastinum is widened.* **(Right)** *Axial HRCT in the same patient shows bilateral pulmonary cysts within diffuse ground-glass opacities. The thymus is also involved by Langerhans cell histiocytosis (LCH), resulting in scattered thymic Ca^{2+}. Follow-up CT imaging (not shown) demonstrated clear lungs & resolved cysts after systemic therapy.*

(Left) *PA chest radiograph in a 14-year-old boy with pulmonary LCH shows nodular opacities intermixed with reticulation secondary to peribronchovascular cysts.* **(Right)** *Coronal CT in the same patient with pulmonary LCH shows both nodules & cysts. Note the peribronchovascular distribution of cysts, reflecting the bronchiolocentric nature of the disease.*

TERMINOLOGY

Definitions

- Langerhans cell histiocytosis (LCH): Neoplastic proliferation of monoclonal Langerhans cells in 1 or more organ systems
  - Leads to formation of destructive granulomas

IMAGING

General Features

- Best diagnostic clue
  - Combination of small pulmonary nodules & cysts

Radiographic Findings

- Early findings
  - Characteristic reticulonodular pattern (due to summation of nodules & thin-walled cysts)
  - Lung volumes are normal or ↑ (unlike many other interstitial diseases)
- Late findings
  - Honeycomb-like pattern with architectural distortion (due to summation of air-filled cysts)
- ± pneumothorax, pneumomediastinum, pleural effusion

CT Findings

- HRCT
  - Progression: Nodules → cavitary nodules → thick-walled cysts → thin-walled cysts → confluent cysts
    - Irregularly shaped nodules in centrilobular, peribronchial, or peribronchiolar locations
    - Cysts show variable wall thickness
  - Diffuse disease is common in children
    - Classic sparing of lower lungs/costophrenic sulci should not be used as diagnostic criterion in pediatrics
  - Chronic LCH: Fibrosis & traction emphysema
  - May also see osseous, thymic, hepatic, & splenic involvement on chest CT

DIFFERENTIAL DIAGNOSIS

Cystic Fibrosis

- Patchy, upper lobe-predominant disease
- Cylindrical to cystic bronchiectasis
- Bronchial wall thickening, mucous plugging

Papillomatosis

- Nodules intermixed with thick-walled cysts
- Nodules of larynx & trachea are more common than lung involvement

Lymphangioleiomyomatosis

- Small, round, thin-walled cysts with normal surrounding parenchyma
- No nodules (unless multifocal micronodular pneumocyte hyperplasia is present)

Sarcoidosis

- Apical predominant disease with ground-glass opacities, fibrotic change, subpleural honeycombing
- Hilar adenopathy is typical

PATHOLOGY

General Features

- Pulmonary LCH: Proliferation of Langerhans cells in bronchial/bronchiolar epithelium
  - Cavitating granulomas adjacent to small airways
    - Lead to airway obstruction, air-trapping, cystic change
- Diagnosed by bronchoalveolar lavage, possible biopsy
- Electron microscopy: Birbeck granule in cytoplasm of 40% of Langerhans cells
  - Classic "tennis racquet" organelle
- Immunostaining: CD1a, CD207, S100 protein positive
- Genetic mutations include *BRAF* V600E (55%), *MAP2K1*

Staging, Grading, & Classification

- Multisystem LCH
  - Pulmonary involvement in 23-50%
  - Most pediatric pulmonary LCH occurs in multisystem disease
    - Typically young children ± risk organ involvement
  - Lung disease no longer denotes risk organ involvement with worse prognosis
- Single system LCH
  - Pulmonary involvement in ~ 10% of pediatric patients
  - Typically adolescents

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Tachypnea, dyspnea, wheezing
- Clinical profile
  - Not associated with smoking (unlike adult LCH)

Natural History & Prognosis

- Leads to end-stage lung disease in 10-27% of patients with lung involvement
- < 65% 5-year survival if lung disease is severe

Treatment

- Corticosteroids & other chemotherapeutic agents
- Targeted: BRAF- or MEK-inhibitors (depending on underlying mutation)

DIAGNOSTIC CHECKLIST

Consider

- Pediatric LCH is not to be confused with adult pulmonary LCH
- Recommend chest radiography when LCH is discovered in any body system
- Degree of pulmonary involvement on CT correlates with functional impairment
  - HRCT is helpful to follow disease progression in young children, as pulmonary function tests are less reliable

Pectus Excavatum

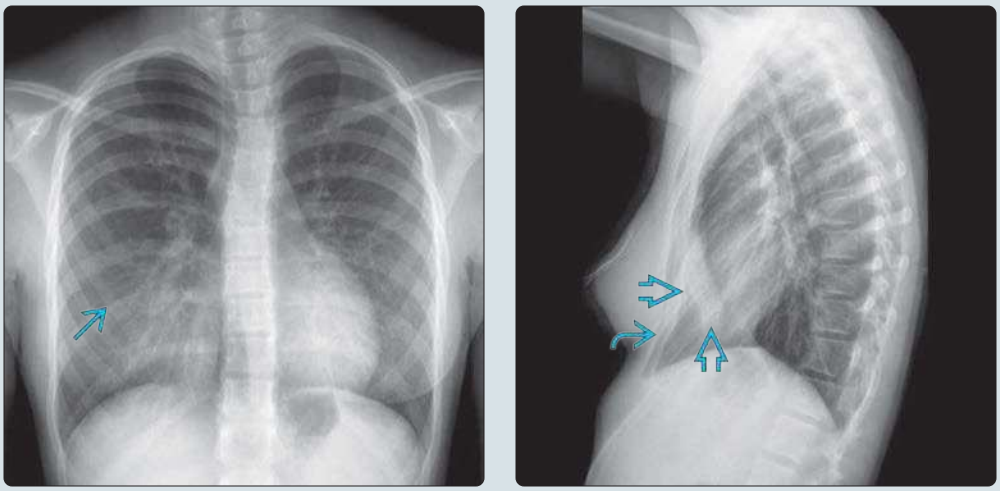
KEY FACTS

TERMINOLOGY

- Depression of sternum posteriorly → sunken appearance of midline anterior inferior chest wall

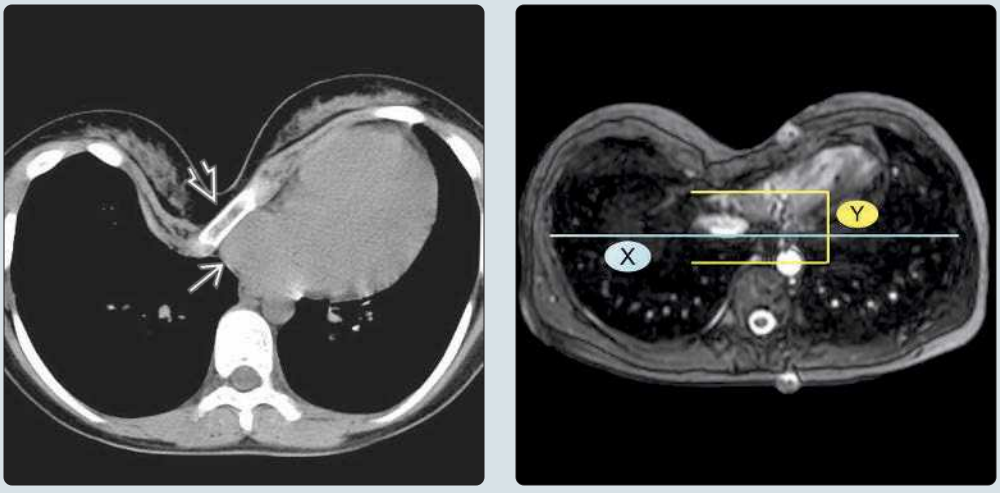
IMAGING

- Radiographs: Right heart border blurring with vertical anterior ribs; degree of depression is best seen on lateral view
- Pre-Nuss procedure evaluation with CT/MR
  - Haller index
    - Ratio of transverse (left-right) diameter divided by sagittal (anterior-posterior) diameter of chest
    - Haller index > 3.25 is considered enough deformity for surgical candidacy (by most insurance agencies)
    - Consider reporting correction & depression indices to capture patients with clinically significant deformities but possibly "normal" Haller indices
  - CT: Noncontrast, low mA images
  - MR: Single cardiac MR can replace echocardiogram & CT
    - ↓ right ventricular ejection fraction & hemodynamically insignificant pericardial effusion are common
- Post-Nuss procedure
  - Assess for complications → bar displacement/rotation, pneumothorax, pleural effusion, sternal infection



TOP DIFFERENTIAL DIAGNOSES

- Pectus carinatum
- Chest wall aggressive lesions
- Chest wall vascular malformations
- Palpable normal variants of chest wall



CLINICAL ISSUES

- Minimally invasive pectus repair (Nuss procedure)
  - Transverse curved metal bar surgically inserted internal to sternum & ribs
  - Excellent results in > 85% of patients

(Left) *Frontal radiograph shows a silhouette sign with an apparent opacity obscuring the right heart border (mimicking right middle lobe disease). Note the vertically oriented anterior ribs.* **(Right)** *Lateral radiograph in the same patient shows posterior positioning of the sternum as compared to the anterior ribs, consistent with pectus excavatum. There is no middle lobe pathology.*

(Left) *Axial NECT of the chest shows marked pectus excavatum with posterior displacement & rotation of the sternum as compared with the anterior chest wall. Note the position of the right atrium immediately behind the sternum.* **(Right)** *Axial SSFP MR shows the landmarks used to calculate the Haller index. The left-to-right (blue line) & anterior-to-posterior (sagittal yellow line) diameters are measured, & the ratio is calculated as X/Y.*

TERMINOLOGY

Definitions

- Deformity of chest wall characterized by sternal depression

IMAGING

General Features

- Imaging metrics
  - Haller index (HI)
    - Most frequently used metric to determine severity of pectus deformity; serves as indicator for Nuss procedure candidacy
    - Ratio of transverse (left-right) diameter divided by sagittal (anterior-posterior) diameter of inner aspects of osseous chest wall
    - HI > 3.25 is requirement of many insurance companies to qualify for payment of surgical correction
    - Most accurate location is caudal end of corpus sterni
  - Correction index (CI)
    - Percentage of chest depth missing from patient (i.e., percentage to be corrected by bar placement)
    - Eliminates importance of chest width
      - Narrow chest ↓ HI regardless of severity of defect
      - CI is not dependent on width; rather, CI defines distance of sternum from goal position
  - Depression index (DI)
    - Measurement of severity independent of thoracic diameters

Radiographic Findings

- Right heart border blurring with vertical anterior ribs ± obliteration of descending thoracic aortic interface
- Degree of depression is best seen on lateral radiograph
- Post-Nuss procedure
  - Nuss bar: Transverse metal bar with T-shaped stabilizer at one end
  - Potential complications: Bar displacement/rotation, pneumothorax, pleural effusion, sternal infection, cardiac injury
  - Lateral radiograph: Best view for migration of bar

CT Findings

- Pre-Nuss procedure evaluation with CT
  - Imaging metrics: HI, CI, DI, sternal tilt
  - Heart position (for surgical planning)
  - Central airway compression

MR Findings

- Expiratory axial slices with cardiac MR: Chest wall metrics + functional data (e.g., right ventricular ejection fraction, valve function)
- Right ventricle dysfunction due to extrinsic compression
- Hemodynamically insignificant pericardial effusion is common

DIFFERENTIAL DIAGNOSIS

Pectus Carinatum

- Anterior chest is convex outward: "Pigeon chest"

Chest Wall Aggressive Lesions

- Firm, painful mass ± rib destruction, pleural effusion

Chest Wall Vascular Malformations

- Soft, compressible mass; may fluctuate in size

Palpable Normal Variants of Chest Wall

- Rib anomalies may mimic sternal tilting/depression

PATHOLOGY

General Features

- Associated abnormalities
  - Connective tissue abnormalities
  - Neuromuscular disease
  - Genetic conditions
  - Pulmonary conditions

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Concerns about physical appearance are common
  - Exercise intolerance (82%), chest pain (68%), poor endurance (67%), shortness of breath (42%)
- Other signs/symptoms
  - Cardiac (pulmonic murmur, mitral valve prolapse, syncope, Wolff-Parkinson-White syndrome), restrictive lung disease, central airway compression
  - Palpable bony asymmetry associated with mild pectus deformity may be mistaken for soft tissue mass

Demographics

- Epidemiology: Accounts for up to 90% of anterior chest wall disorders

Treatment

- Conservative management for mild cases
- Minimally invasive repair (Nuss procedure): Transverse curved metal bar is inserted deep to sternum & rib cage
  - Excellent results in > 85% of patients

Minimally Invasive Pectus Repair Appearance

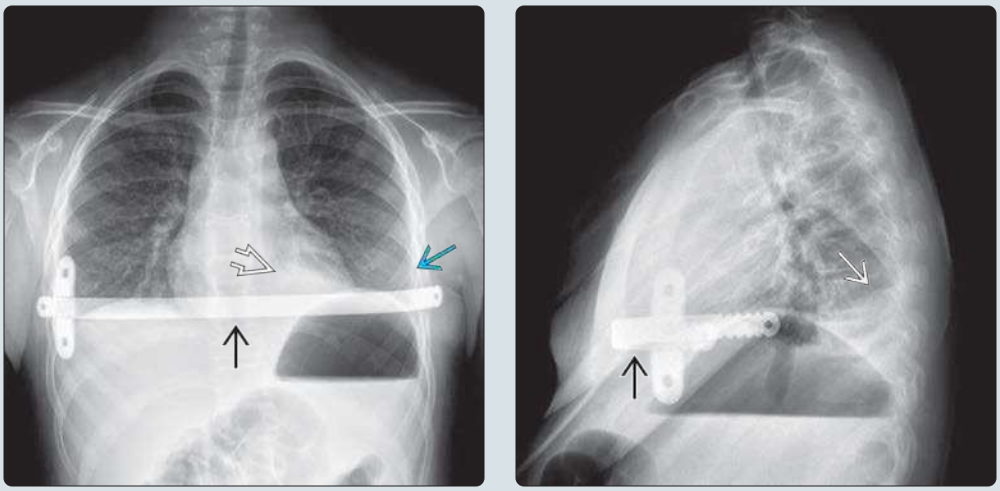
KEY FACTS

TERMINOLOGY

- Minimally invasive Nuss procedure has replaced open surgeries to repair pectus excavatum
  - Introducer is tunneled posterior to sternum
  - Convex stainless steel bar is passed (with convexity down) through 2 incisions, then flipped & fixed in place
    - Immediate cosmetic improvement
  - Bar remains in place 2-4 years

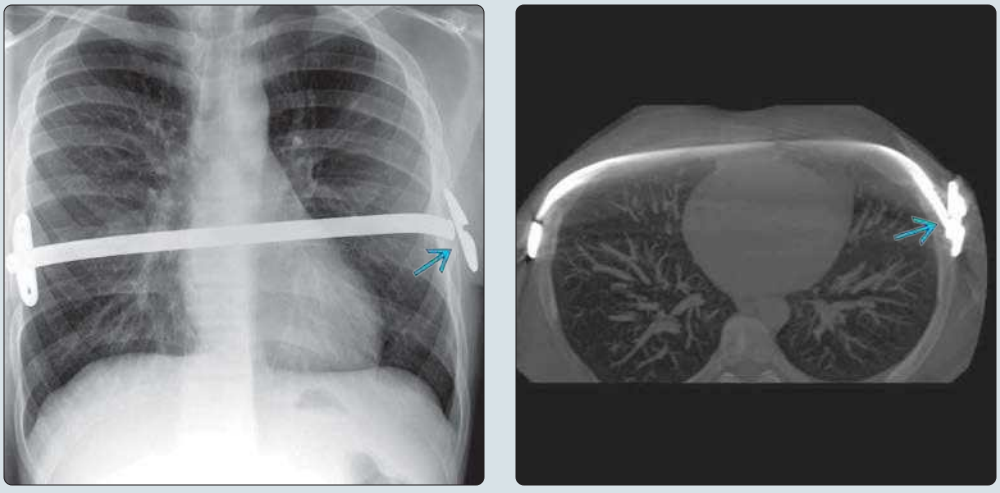
IMAGING

- Postoperative radiographs
  - AP & lateral views to evaluate Nuss bar position & improvement in pectus deformity
- Early postoperative complications
  - Pneumothorax, pneumomediastinum
  - Atelectasis, pneumonia
  - Hemothorax, pleural effusion
    - If lasts > 4 days, should be cultured
    - May also be due to nickel allergy
- Late postoperative complications
  - Bar displacement
    - May rotate, requiring surgical revision
    - Apex of bar may slip from deepest portion of sternal depression, causing unsatisfactory contour change
      - 2 bars may be placed in these patients
      - Typically no intervention if slippage is < 20%
    - Displacement is more likely in postpubertal patients



CLINICAL ISSUES

- Ideal age for repair: Just before puberty
  - May be performed earlier in cases of cardiac/pulmonary compression
  - Can also be performed after puberty with good outcomes



DIAGNOSTIC CHECKLIST

- Small postoperative pneumothoraces are common; may be managed conservatively

(Left) *PA chest radiograph in a 10-year-old girl following a minimally invasive pectus excavatum repair shows the stainless steel bar ⇨ in satisfactory position. Note the small left postoperative pleural effusion ⇨ & passive left lower lobe atelectasis ➡.* **(Right)** *Lateral chest radiograph in the same patient shows the stainless steel bar ⇨ passing posterior to the sternum at the point of maximum sternal concavity. Note the posterior pleural fluid & atelectasis ➡.*

(Left) *PA chest radiograph after a Nuss procedure shows disruption at the junction of the pectus bar & left stabilizer ⇨. The bar remains appropriately engaged with the right stabilizer.* **(Right)** *Volume-rendered axial CT in the same patient shows disruption at the junction of the pectus bar & left stabilizer ⇨.*

Askin Tumor/Ewing Sarcoma of Chest Wall

KEY FACTS

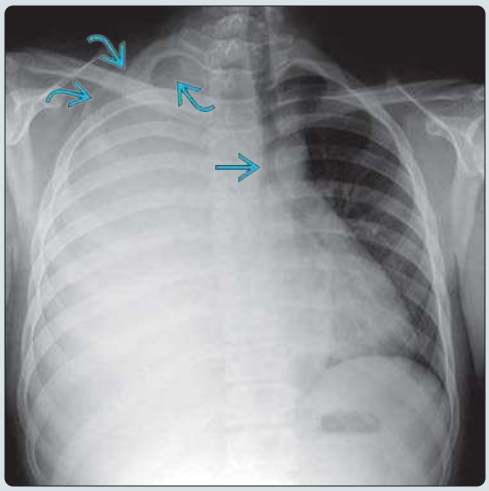
TERMINOLOGY

- Askin tumor: Extraskeletal Ewing sarcoma of chest
  - Ewing sarcoma & Askin tumor are closely related: Ewing sarcoma family of tumors (ESFT)
  - Soft tissue primitive neuroectodermal tumor (PNET) is now termed extraskeletal Ewing sarcoma by WHO

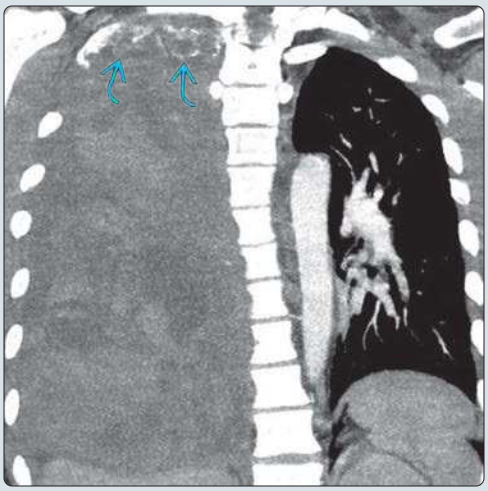
IMAGING

- Unilateral thoracic opacification
  - Large, lobular mass may occupy most of or entire hemithorax, especially with pleural effusion
  - Rib destruction is common (> 50%)
  - Ca^{2+} is uncommon
- Mildly heterogeneous enhancement on CT & MR
- Mass effect on mediastinal structures
  - Vessels & airway are typically compressed & shifted rather than encased or invaded
- Mediastinal lymphadenopathy: 25% at presentation
- Pulmonary metastasis: 38% at presentation
- CT & MR can be complimentary
  - CT better detects small pulmonary metastases
  - MR better evaluates involvement of chest wall

PATHOLOGY

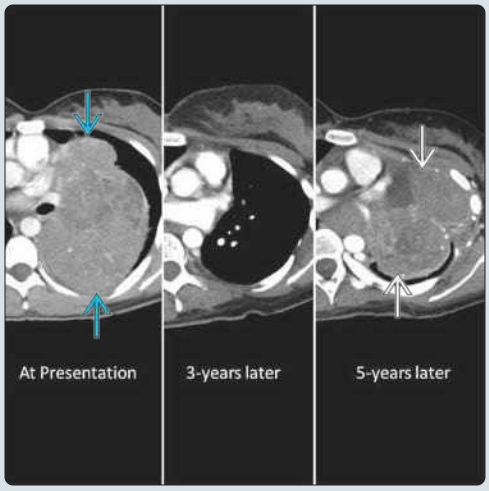


- Identical to other Ewing sarcomas
  - Small round blue cells
  - Positive immunohistochemical stain for *CD99* (MIC2) gene product: 90%
  - Chromosomal translocation [t(11;22)(q24;q12)]: 85-95%

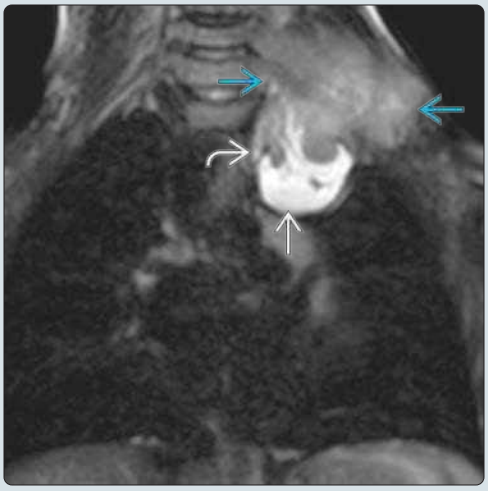


CLINICAL ISSUES

- Median age: ~ 15 years
- Prognosis: 5-year survival rate = 50-60%



DIAGNOSTIC CHECKLIST



- On posttherapy surveillance CT, look closely for
  - Local recurrence in chest wall
  - Mediastinal & chest wall lymphadenopathy
  - Pulmonary metastases

(Left) *PA radiograph in a 15-year-old girl with a chest wall Ewing sarcoma shows complete opacification of the right hemithorax with mass effect on the mediastinum. Note the lucency, expansion, permeation, & erosion of the right 2nd rib.* **(Right)** *Coronal CECT in the same patient shows a heterogeneous mass filling the right hemithorax with expansion & destruction of the right 2nd rib.*

(Left) *Initial axial CECT in a girl with an Askin tumor at presentation (L) shows a large, heterogeneous mass in the left upper hemithorax. After chemotherapy, resection, & radiation, no tumor was detectable on the 3-year follow-up CT (M). Tumor recurrence is present at 5 years (R).* **(Right)** *Coronal T2 FS MR shows a 3-year-old patient with an Askin tumor. A heterogeneous mass in the left upper hemithorax is partly cystic & extends into the soft tissues of the left lower neck.*

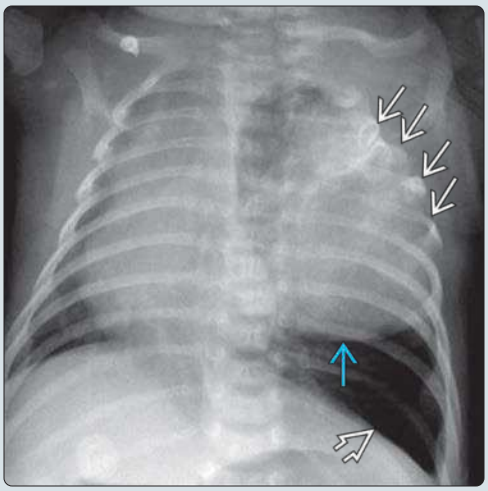
Chest Wall Hamartoma

KEY FACTS

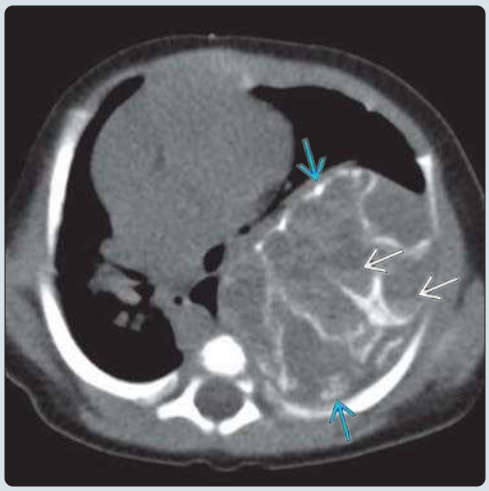
TERMINOLOGY

- Mesenchymal hamartoma of chest wall (MHCW) = benign infantile lesion of proliferating skeletal elements arising from central/internal surfaces of rib(s)

IMAGING

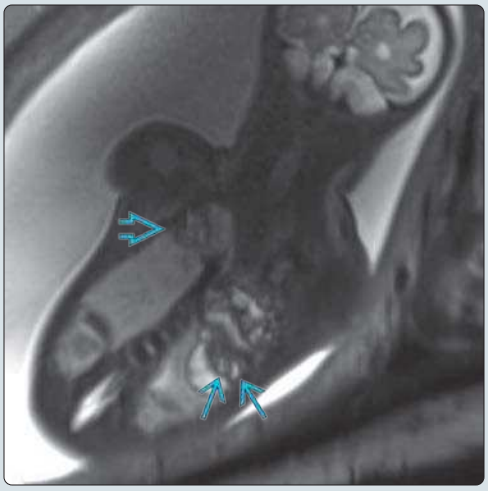


- Partially calcified soft tissue mass of chest wall
  - Chondroid > > osteoid mineralization (100% by CT)
- Multiple internal compartments containing fluid-fluid levels
  - Secondary aneurysmal bone cysts (60-80%, CT vs. MR)
- Bizarre remodeling/distortion & erosion of multiple adjacent ribs
- Prenatal US may show chest wall mass with echogenic rim ("capsule")
  - ± polyhydramnios, pleural effusion
- Typical locations
  - Extrapleural posterior > anterior chest wall
  - Multifocal (unilateral or bilateral) in < 20%

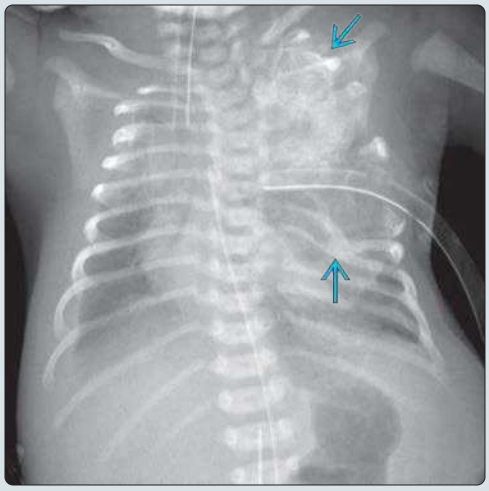


PATHOLOGY

- Hemorrhagic cavities intermixed with cartilage & bone



CLINICAL ISSUES



- 1 in 3,000 primary bone tumors
- Typically detected prenatally or within first 6 months of life
- Classic presentations: Congenital chest wall mass/deformity, respiratory distress
- No known risk of malignant degeneration, local invasion, or metastasis
- Many reports of spontaneous regression ≥ 2 years of age
- Observation if asymptomatic with classic age, presentation, & imaging findings
  - Potential for significant hemorrhage with disruption of blood-filled cavities during biopsy or excision
- Resection in setting of respiratory, cardiovascular, or neurologic compromise
  - Scoliosis occurs with resection of multiple posterior ribs

(Left) *AP radiograph in a 1-month-old with respiratory distress shows a large soft tissue mass in the left hemithorax with bizarre remodeling & erosion of multiple adjacent ribs. There is mediastinal shift & lower lobe air-trapping due to mass effect.* **(Right)** *Axial NECT in the same patient shows rim & septal Ca^{2+} throughout the mass with numerous fluid-fluid levels due to layering blood products. Biopsy confirmed a mesenchymal hamartoma of the chest wall (MHCW).*

(Left) *Coronal SSFSE T2 MR in a 33-weeks-gestation fetus shows a large, heterogeneous, multicystic lesion of the left chest. Numerous fluid-fluid levels were visible, & other images showed distortion of multiple ribs. A 2nd smaller lesion was also seen on the right. (Courtesy L. LaForest, MD.)* **(Right)** *AP radiograph in the same neonate shows distortion of numerous left ribs by the partially calcified cystic mass, typical of an MHCW. The smaller right MHCW is much less conspicuous. (Courtesy L. LaForest, MD.)*

TERMINOLOGY

Abbreviations

- Mesenchymal hamartoma of chest wall (MHCW)

Synonyms

- Mesenchymoma, chondromatous hamartoma (antiquated terms)

Definitions

- Benign infantile lesion of proliferating skeletal elements arising from rib(s)

IMAGING

General Features

- Best diagnostic clue
  - Partially calcified soft tissue mass of chest wall in infant
    - Mineralization (100% by CT), chondroid > > osteoid
  - Multiple internal compartments containing fluid-fluid levels
    - Secondary aneurysmal bone cysts (60-80%, CT vs. MR)
  - Bizarre remodeling/distortion & erosion of multiple adjacent ribs
  - Prenatal US may show chest wall mass with echogenic rim ("capsule")
    - ± polyhydramnios, pleural effusion
- Location
  - Extrapleural posterior > anterior chest wall
    - Arises from central/internal aspect of rib
  - Multifocal (unilateral or bilateral) in < 20%
  - No invasion or metastasis

DIFFERENTIAL DIAGNOSIS

Hemangioma, Infantile or Congenital

- Solid hypervascular/high flow soft tissue mass ± characteristic cutaneous features
- Bone involvement is exceptionally rare
- Predictable life cycle

Slow-Flow Vascular Malformation, Venous or Lymphatic

- Conglomerations of multiple cysts, tubular masses, &/or abnormal vessels
- Frequently extend into multiple tissue compartments
  - May involve chest wall/ribs
- Often contain fluid-fluid levels

Infantile Myofibroma

- Soft tissue mass(es) without fluid-fluid levels or rim Ca^{2+}
- May cause chronic remodeling of subjacent bone
- May be multifocal, involving soft tissues, viscera, &/or bone; uncommonly involves thoracic cage

Congenital/Infantile Fibrosarcoma

- Uncommon solid &/or multicystic mass of infants, most common in extremities
- Bone involvement is uncommon

Teratoma

- Mixed solid & cystic mass ± Ca^{2+}
  - Multiple hemorrhagic cavities are uncommon
- Does not typically involve chest wall

Palpable Normal Variant

- Frequently due to osseous &/or cartilaginous variations of ribs (such as fusion)
  - Anterior > posterior

Ewing Sarcoma

- Older children (teenagers) with aggressive bony changes of 1 rib surrounded by large soft tissue mass, ± pleural effusion

Rib Fractures of Child Abuse

- Adjacent healing fractures can have bulbous callous
  - Ca^{2+} is not contiguous or associated with significant rib distortion or soft tissue mass

PATHOLOGY

Microscopic Features

- Hemorrhagic cavities intermixed with cartilage, bone, & fibroblasts

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Chest wall mass/deformity, respiratory distress

Demographics

- Age
  - Typically detected prenatally or within first 6 months of life
  - Rarely found outside of infancy, including adolescence & adulthood
- Epidemiology
  - 1 in 3,000 primary bone tumors; incidence of 1:1,000,000

Natural History & Prognosis

- Many reports of spontaneous regression
- No known risk of malignant degeneration, local invasion, or metastasis

Treatment

- Observation if asymptomatic with classic age, presentation, & imaging findings
  - Atypical age/clinical presentation, aggressive imaging features, &/or growth may require biopsy
    - Significant hemorrhage may occur with disruption of blood-filled cavities
- Resection with respiratory, cardiovascular, or neurologic compromise
  - Scoliosis is most likely with resection of multiple posterior ribs

Asthma

KEY FACTS

TERMINOLOGY

- Chronic, reversible, paroxysmal airway hyperresponsiveness leading to airflow obstruction
- Umbrella term for numerous phenotypes in which normally harmless environmental allergens cause airway hyperresponsiveness due to pathologic immune-mediated host response (i.e., not single disease)

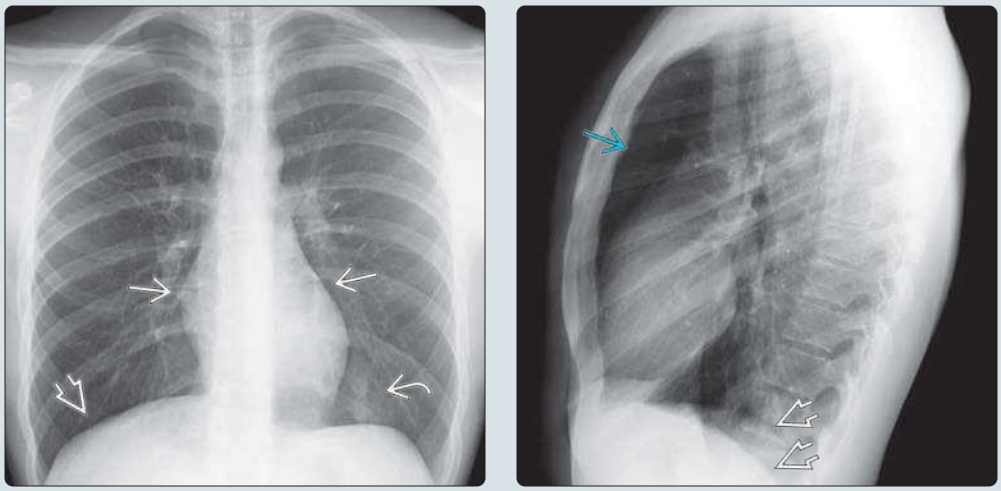
IMAGING

- Usually normal; may have symmetric hyperexpansion with flattened hemidiaphragms & ↑ retrosternal airspace
- Not necessary; helpful to identify complications & mimics
  - Consider chest radiograph if poor response to therapy

TOP DIFFERENTIAL DIAGNOSES

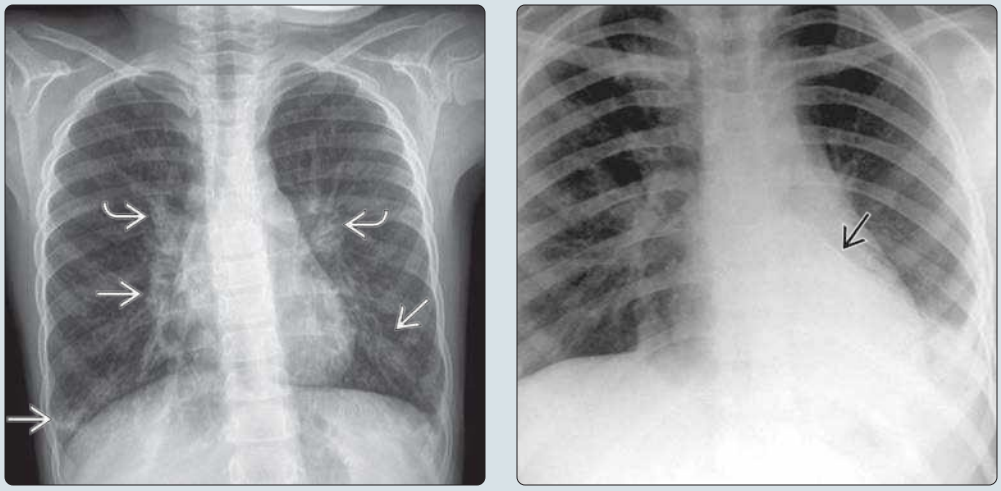
- Viral bronchiolitis: May occur in concert with & be impossible to differentiate from asthma
- Foreign body aspiration: Static, asymmetric lung volumes on bilateral decubitus or inspiratory/expiratory imaging
- Cystic fibrosis: Focal disease with bronchiectasis & mucous plugging, most common in upper lobes
- Croup: Barky cough &/or stridor (vs. wheezing in asthma) due to subglottic airway narrowing

PATHOLOGY



- Risk factors include frequent symptoms in 1st year of life, maternal smoking or history of asthma, & signs of atopy

CLINICAL ISSUES



- Intermittent wheezing before age 6 is usually benign & typically resolves within few years
- Severity of asthma symptoms between ages 7-10 years predicts persistence into adulthood

DIAGNOSTIC CHECKLIST

- Radiographs are usually normal but are indicated to exclude suspected alternate diagnosis, complication, or poor response to therapy

(Left) *Frontal radiograph in a 17-year-old during an asthma attack shows hyperexpanded lungs, resulting in a narrow cardiac silhouette & flattening of the diaphragm. Subsegmental opacity in the left lower lobe was favored to represent atelectasis.* **(Right)** *Lateral radiograph in the same patient reveals prominence of the retrosternal clear space & diaphragmatic flattening caused by air-trapping. Imaging is often near-normal in asthma patients & is best used to identify complications or alternative diagnoses.*

(Left) *Frontal radiograph in a 6-year-old with an asthma exacerbation caused by Mycoplasma pneumoniae shows peribronchial airway thickening & scattered, subsegmental opacities in the perihilar & lower lungs. Infection from M. pneumoniae is a common cause of asthma exacerbation.* **(Right)** *Frontal radiograph in a child with shortness of breath shows a dense, triangular-shaped opacity from left lower lobe collapse. Lobar collapse & atelectasis are common findings in patients with asthma exacerbation.*

TERMINOLOGY

Synonyms

- Airway hyperreactivity
- Reactive airways disease

Definitions

- Chronic disease characterized by bronchial hyperresponsiveness, reversible airway obstruction, & chronic airway inflammation
- Umbrella term for numerous phenotypes in which normally harmless environmental allergens lead to pathologic immune-mediated host response (i.e., not single disease)
- Airway hyperresponsiveness → contraction of bronchial wall smooth muscle & cascade of inflammation → acute, reversible airway narrowing & airflow obstruction
- United airway disease (UAD): Concept that upper & lower airways function immunologically as single organ
  - Overwhelming majority of asthmatics have rhinitis; less commonly, nasal polyps & other sinonasal disorders

IMAGING

General Features

- Best imaging clue
  - Symmetric lung hyperexpansion: Flattening of hemidiaphragms, ↑ retrosternal airspace

Radiographic Findings

- Not part of most acute childhood asthma algorithms; reserved for those with fever, suspected foreign body (FB) aspiration, failure to improve with treatment, or focal findings on physical exam
- Most common finding: Normal chest radiograph
- Next most common: Subtle & nonspecific signs of hyperinflation, usually symmetric
  - Flattening of hemidiaphragms
  - ↑ AP diameter of chest & retrosternal airspace
  - ± bulging intercostal spaces
- Less common findings
  - Peribronchial thickening/cuffing
    - Irregular cardiac contour ("shaggy heart")
  - Atelectasis & lobar/partial lobar collapse
  - Peripheral oligemia
- Chronic findings
  - Bronchiectasis, mucous plugging
- Complications: More frequent in younger children as smaller bronchi are more easily narrowed or occluded & more likely to have concurrent viral bronchiolitis
  - Barotrauma (pneumomediastinum, subcutaneous emphysema, &, rarely, pneumothorax)
  - Lobar collapse, segmental & subsegmental atelectasis
  - Secondary allergic bronchopulmonary aspergillosis
  - Pneumonia

CT Findings

- HRCT
  - Signs of airway narrowing
    - Bronchial wall thickening
    - Narrowing or dilation of bronchial lumen
    - Mucous plugging
  - Signs of abnormal aeration
    - Mosaic attenuation due to combination of regional air-trapping & oligemia
    - Focal peripheral air-trapping on expiratory images
  - Signs of airspace disease
    - Segmental & subsegmental atelectasis
    - Centrilobular opacities
  - Bronchiectasis suggests asthma mimics (cystic fibrosis, ciliary dyskinesias, or immune deficiencies)
- CT is generally not indicated; quantitative studies show ↑ airway thickness & ↓ mean lung density

MR Findings

- Not used clinically; hyperpolarized noble gas MR can measure ventilation volumes
- Findings also correlate with disease severity, lung function, symptom control, & level of inflammatory marker elevation

Imaging Recommendations

- Imaging is generally not recommended except in
  - Febrile children (for possible complicating pneumonia)
  - Suspected foreign body (FB) aspiration
  - Those who fail to improve with treatment
  - Suspected barotrauma or lung collapse

DIFFERENTIAL DIAGNOSIS

Viral Bronchiolitis

- Often acts as precipitating trigger for asthma & may be impossible to differentiate radiographically or clinically
- Look for preceding or concurrent symptoms of viral upper respiratory infection (e.g., nasal congestion or fever)

Foreign Body Inhalation or Ingestion

- Vast majority of aspirated FBs are not radiopaque
- Persistent air-trapping or collapse on serial radiographs, usually unilateral
- Static lung volumes on bilateral decubitus or inspiratory/expiratory imaging
- Persistent symptoms that do not respond to bronchodilator therapy

Croup

- Stridor rather than wheezing
- Barky cough
- Narrowed subglottic trachea

Cystic Fibrosis

- Early bronchial wall thickening that progresses to bronchiectasis
- Persistent hyperinflation or recurrent consolidation
- Mucous plugging of dilated bronchi
- Focal disease, most common in upper lobes

Ciliary Dyskinesias

- Situs inversus or dextrocardia (50%), paranasal sinusitis, & bronchiectasis
- Recurrent pneumonias

Immune Deficiencies

- Recurrent pulmonary infection → bronchiectasis

Vascular Sling

- Symptoms are often present from birth
- No response to bronchodilator therapy

- Abnormal impression of left pulmonary artery coursing between trachea & esophagus
- Often has associated complete cartilage rings of trachea (appearing round & narrow in cross section)

PATHOLOGY

General Features

- Etiology
  - Exact etiology is unknown; due to interplay of environmental triggers & host factors
    - Environmental associations & triggers
      - Maternal exposure to tobacco smoke, fine (< 2.5 µm diameter) particulate matter, antibiotics
      - Antibiotic use during infancy ↑ asthma risk
      - Respiratory infections, especially Mycoplasma pneumonia
      - Poor air quality: Both indoor (tobacco smoke, cockroach & pet dander, dust mites, household chemicals, molds) & outdoor (fine & course particulate matter, pollen, ozone)
      - Changes in weather, especially cold & dry conditions
    - Host factors
      - Genetic predisposition
      - Upper respiratory tract viral illnesses
      - Exercise & strong emotional states (anger, anxiety, fear)
      - Hormonal fluctuations & menses
  - Complex response to these triggers causes release of inflammatory mediators from mast cells, macrophages, eosinophils, epithelial cells, & activated T lymphocytes
    - Bronchospasm
    - Airway edema
    - ↑ mucus production
- Risk factors
  - ↑ IgE levels; often associated with seasonal allergies & eczema (atopic triad)
  - Frequent symptoms in 1st year of life
  - Family history of asthma
  - Low birthweight
  - Male sex

Gross Pathologic & Surgical Features

- Bronchial edema & wall thickening
- Mucous plugging of airway lumen

Microscopic Features

- Inflammatory cell infiltration & edema of airway wall
- Mucous gland hyperplasia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Chronic &/or recurrent cough, wheezing
  - Shortness of breath
  - Chest tightness
- Other signs/symptoms
  - ↓ peak expiratory flow rates & forced expiratory volume in 1-second (FEV_1) values
  - Symptomatic improvement with bronchodilator therapy
  - Use of accessory muscles to breathe at rest
  - Exercise limitation

Demographics

- Age
  - Prevalence peak is between 6-11 years
- Sex
  - M > F = 1.5:1.0 before puberty
  - M < F = 1.0:1.5 after puberty
- Epidemiology
  - Most common chronic disease of childhood
  - Prevalence of 1-30% worldwide
  - Positive correlation with urbanization
  - Increasing incidence worldwide with increasing mortality
  - In USA, asthma is more common in Black & Hispanic children

Natural History & Prognosis

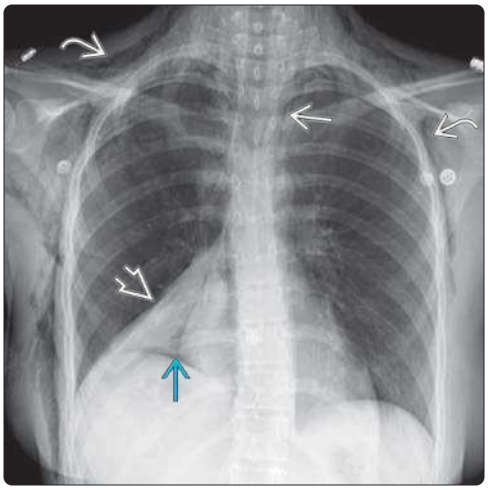
- Prognosis is usually excellent with appropriate treatment
- Wheezing before age 6 is usually benign & typically resolves within few years
- Severity of asthma symptoms between ages of 7-10 years is predictive of persistence into adulthood
  - Small subgroup (30%) of children is characterized by signs of atopy, severe & persistent symptoms at young age, & maternal history of smoking or asthma

Treatment

- Avoid exposure to known precipitating environments
- Inhaled β-agonists for bronchospasm
- Inhaled & oral corticosteroids that dampen inflammatory response
  - Used to prevent acute exacerbations & for treatment of chronic asthma
- Inhaled mast cell stabilizers that prevent release of mediators from mast cells that cause airway inflammation & bronchospasm

DIAGNOSTIC CHECKLIST

Consider



- Radiographs are usually normal but indicated with poor response to therapy, suspected complication, or concern for alternate diagnosis
- Hyperinflation with varying degrees of atelectasis
- Difficult to distinguish from viral bronchiolitis

Image Interpretation Pearls

- Look for asthma mimics & signs of complication

(Left) *Frontal radiograph in a 17-year-old with a severe asthma attack precipitated by rhinovirus infection shows extensive subcutaneous emphysema, pneumomediastinum, right pneumothorax, & right lower lobe collapse.* **(Right)** *Axial CECT in the same patient shows extraventilatory gas in the soft tissues & mediastinum as well as a small left pneumothorax & right lower lobe collapse. Barotrauma is a common complication in asthma patients.*

(Left) *Frontal chest radiograph in a young child with wheezing (who was later diagnosed with asthma) shows peribronchial airway thickening & multifocal atelectasis bilaterally.* **(Right)** *Frontal radiograph in a child with chronic asthma complicated by plastic bronchitis (which is the development of luminal casts, in this case due to inflammation) that caused bronchial occlusion & near total right lung collapse shows widespread opacity & shift of the mediastinum to the right.*

(Left) *Frontal chest radiograph in a 14-year-old with a severe asthma exacerbation shows subcutaneous emphysema in the neck & streaky lucencies in the mediastinum from pneumomediastinum.* **(Right)** *Axial sinus CT in a 14-year-old with asthma & allergic rhinitis reveals extensive sinonasal polyposis. The united airway disease hypothesis underscores how sinonasal disease & airway hyperreactivity seen in asthma are manifestations of the same inflammatory process.*

Bronchial Obstruction

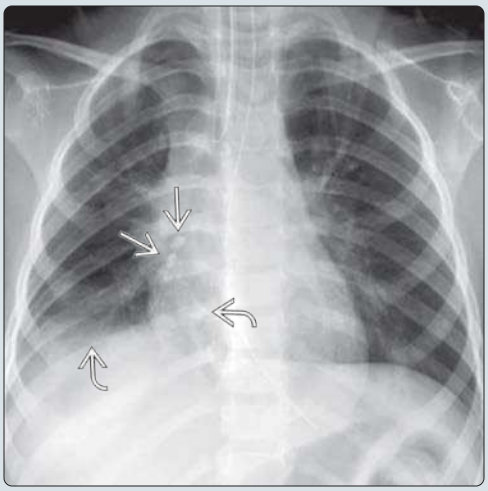
KEY FACTS

TERMINOLOGY

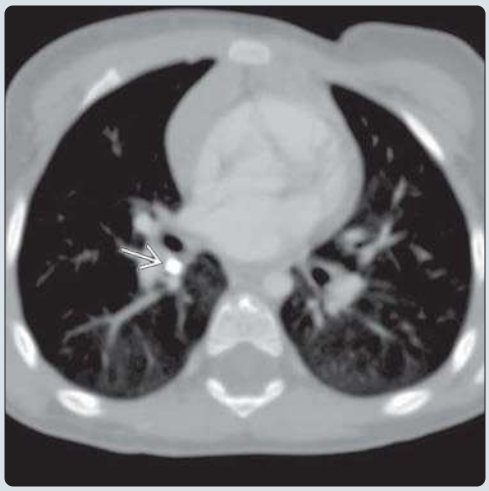
- Complete or partial bronchial occlusion by aspirated foreign body (FB)

IMAGING

- Vast majority of aspirated FBs are **not** radiopaque
- Look for unilateral static lung/lobe volume on chest radiographs
  - In uncooperative patients (most common), obtain frontal view + bilateral decubitus images: Look for lack of passive deflation of dependent lung, suggesting air-trapping
  - In cooperative patients, radiographs can be obtained at maximum inspiration & expiration: Look for expiratory air-trapping on affected side
- Volume of affected lung segments can be normal, ↑, or ↓
- Consider CT with multiplanar reconstructions & 3D virtual bronchoscopy in cases with persistent clinical suspicion & negative chest radiographs



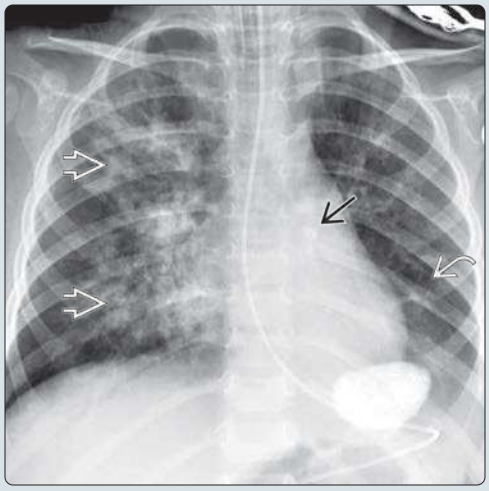
TOP DIFFERENTIAL DIAGNOSES



- Refractory asthma
  - Very common; ↑ peribronchial markings & symmetrically hyperexpanded lungs ± foci of atelectasis
- Viral lower respiratory tract infection
  - Very common; ↑ peribronchial markings & symmetrically hyperexpanded lungs ± foci of atelectasis
- Pulmonary sling
  - Much less common than FB; typically presents with respiratory distress at birth & asymmetric lung volumes
- Congenital lobar emphysema
  - Lobar hyperexpansion, generally since newborn period or early infancy

CLINICAL ISSUES

- Typically presents with wheezing, cough, sometimes fever
- More indolent symptoms if delayed presentation (10-25%)
- Delay in diagnosis is associated with ↑ complication rate
- Treatment: Bronchoscopic removal of FB



(Left) *Portable chest radiograph in a 3-year-old patient who aspirated glass fragments during a car crash shows 3 small radiopaque foreign bodies in the right lower lobe bronchus. There is resulting airspace opacity as well as volume loss causing elevation of the right hemidiaphragm & slight mediastinal shift.* **(Right)** *Axial CECT in the same child shows a square-shaped radiopaque glass foreign body in a segmental bronchus of the right lower lobe.*

(Left) *Bronchoscopic image in the same patient shows complete occlusion of the segmental bronchus by glass fragments.* **(Right)** *Portable chest radiograph of a toddler found unconscious in a debris pile after a flood shows a small, well-defined opacity in the left main bronchus. The left lower lobe is relatively hyperlucent due to air-trapping, & there are widespread patchy airspace opacities due to aspiration. The bronchial obstruction was due to a small aspirated stone.*

TERMINOLOGY

Synonyms

- Sometimes referred to as LEGO asthma

Definitions

- Complete or partial bronchial occlusion by aspirated foreign body (FB)

IMAGING

General Features

- Best diagnostic clue
  - Visualization of radiopaque FB in airway (rare)
  - Unilateral static lung volume on inspiratory/expiratory or bilateral decubitus chest radiographs
  - Airway filling defect on CT
- Location
  - Most FBs lodge in main bronchi
    - Bronchial (76%), laryngeal (6%), tracheal (4%)
    - Right bronchi (58%) > left bronchi (42%)
      - Due to straighter course & larger caliber of right vs. left main bronchi
- Size
  - Most FB: 5-12 mm

Radiographic Findings

- Radiography
  - Best direct evidence: Radiopaque FB
    - However, most FBs are **not** radiopaque
  - Best indirect evidence is static, unilateral lung volume on inspiration/expiration or bilateral decubitus imaging
  - Volume of affected lung segments can be normal, ↑, or ↓ (i.e., larger lung is not always abnormal)
    - Hyperinflation & oligemia from air-trapping
      - ± depressed hemidiaphragm, widening of intercostal spaces, mediastinal shift toward opposite side
    - Atelectasis from total bronchial obstruction, pneumonia from superinfection
      - ± elevation of hemidiaphragm, narrowing of intercostal spaces, ipsilateral mediastinal shift with atelectasis
  - Pneumothorax & pneumomediastinum from tracheobronchial laceration
  - Reported incidence of chest radiograph findings in FB aspiration (FBA)
    - Normal: 14-35%
    - Hyperinflation: 21-43%
    - Opacification/atelectasis: 18-29%
    - Mediastinal shift: 10-37%
    - Radiopaque FB: 3-23%
- Bilateral decubitus radiographs
  - Obtain frontal view + bilateral decubitus images
  - Normal, nonobstructed lung will become smaller & more opaque when dependent
  - Abnormal, obstructed lung will remain inflated & relatively lucent when dependent
  - Most appropriate maneuver for infants & toddlers who cannot cooperate with inspiratory & expiratory imaging
- Inspiratory/expiratory radiographs
  - In patients who are cooperative, radiographs can be obtained at maximum inspiration & expiration
    - Useful in minority of patients as this clinical scenario most often occurs from 1-2 years of age
  - Volume of nonobstructed lung diminishes significantly with expiration

Fluoroscopic Findings

- Child is fluoroscoped in supine frontal view
  - Normally, both hemidiaphragms will move superiorly & inferiorly in synchronous manner
  - With obstruction, lung volume in affected lung is static with ↓ or no motion of ipsilateral hemidiaphragm
- Fluoroscopy with forced expiration
  - Technique has been described where evaluator places gloved hand on child's abdomen & gently applies pressure immediately prior to & while obtaining image
  - Pressure drives diaphragms superiorly
  - Abnormal side with bronchial obstruction will remain static in volume
  - Normal side will show elevation of diaphragm as compared to initial neutral radiograph
  - Generally not recommended

CT Findings

- CT has not traditionally been utilized in imaging algorithm for suspected FB but used for
  - Persistent lung collapse or pneumonia
  - Work-up of suspected extrinsic airway compression
- Increasing amount of literature supporting low-dose, noncontrast chest CT with multiplanar reconstructions & 3D virtual bronchoscopy in cases with persistent clinical suspicion & negative initial chest radiograph
  - CT is nearly 100% sensitive for radiolucent objects (food, plastic, etc.)
  - May see FB as filling defect in bronchus ± focal hyperinflation or atelectasis
  - May prevent unnecessary negative bronchoscopy (& associated anesthesia)

Imaging Recommendations

- Best imaging tool
  - Initial chest radiographs
  - Traditional next step: Inspiratory/expiratory or bilateral decubitus radiographs or fluoroscopy (for air-trapping)
  - Current consideration: Low-dose noncontrast chest CT has much higher sensitivity/specificity for nonradiopaque FB than radiographs
    - Can also visualize air-trapping

DIFFERENTIAL DIAGNOSIS

Refractory Asthma

- Much more common than bronchial FB
- ↑ peribronchial markings
- Hyperinflation is typically symmetric
- Radiographs may be normal

Viral Lower Respiratory Tract Infection

- Much more common than FB
- ↑ peribronchial markings
- Hyperinflation is typically symmetric

Pulmonary Sling

- Much less common than FB
- Often presents with respiratory distress at birth
  - Due to associated congenital heart disease & complete tracheal rings
- Only vascular ring that results in asymmetric aeration
  - Either side may be larger

Extrinsic Tracheal Compression by Mass

- Bronchogenic cysts, lymphadenopathy, & other masses may compress bronchi & present with asymmetric aeration

Swyer-James Syndrome

- Postinfectious bronchiolitis obliterans
- Asymmetric lung hyperlucency: Lucent lung may be smaller than contralateral lung

Congenital Lobar Overinflation

- Gradually increasing symmetric lung hyperlucency confined to single lobe
- Generally presents in newborn period or early infancy

PATHOLOGY

General Features

- Etiology
  - Young children explore environment with their mouth, often putting discovered items in mouth
  - Young infants may be given FBs or inappropriate foods by older siblings
  - Self-feeding infants have ↑ risk of FBA because gag reflex is undeveloped before age 1
  - Lack of molars & poor swallowing coordination predisposes infants to FBA
  - Older children have tendency to talk, laugh, & be active while chewing
- Mechanism
  - Aspirated FB lodges in bronchus & leads to partial or intermittent obstruction
  - May have ball valve effect, leading to
    - Air-trapping & hyperinflation
    - Complete obstruction leading to atelectasis & collapse
- Typology of FBs
  - Vast majority of aspirated FBs are organic or plastic & therefore radiolucent
    - Most common: Peanuts, tree nuts, & seeds
    - Less common: Fruit, meat, plastic pieces (especially from toys), soil, other radiolucent items
    - Rare: Teeth, small hardware pieces, or other metallic items
  - Older children & teenagers more commonly aspirate nonfood items (pins, needles, paper clips, pen caps, small screws, etc.)

Gross Pathologic & Surgical Features

- FB lodged in tracheobronchial tree
  - Dried foods absorb water & may swell
  - Peanuts & tree nuts elicit airway irritation
  - Leukocyte infiltration & edema in adjacent bronchial wall
  - Chronic FB → granuloma formation/granulation tissue

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Sudden onset of coughing or choking episode
  - Classic triad of coughing, wheezing, & altered breath sounds has high sensitivity (90-95%) but low specificity (25-40%)
  - FBA may present acutely or in delayed fashion; event is often unwitnessed or not remembered until later
    - Same day (25%): Wheezing, cough, ± fever
    - Day 2-7 (45%): Indolent cough, medically refractory wheezing, dyspnea
    - Delayed by > 1 week (30%): Same as aforementioned

Demographics

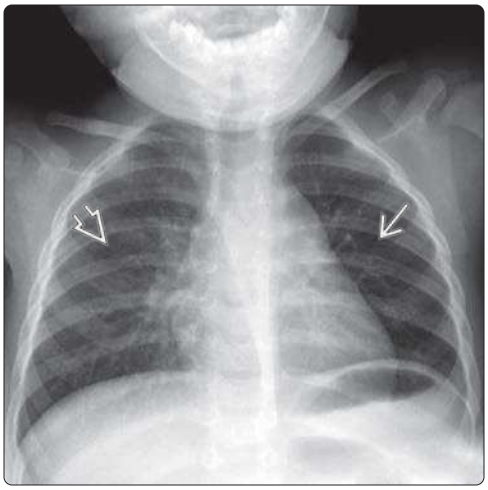
- Age
  - Most common age: 1-3 years; peak: 18 months
- Sex
  - FBA is more common in boys (2:1)

Natural History & Prognosis

- High degree of suspicion is important
- Delay in diagnosis is associated with ↑ risk of major complications
  - Incidence of major complications is low if rapidly diagnosed
  - Complications: 4% at > 4 days, 91% > 30 days
- Complications of chronic FBs
  - Bronchopulmonary fistula, bronchial rupture, damage to distal lung
- Death is rare, ~ 100 per year in USA
  - In one series of 2,165 pediatric autopsies, only 10 deaths are due to FBA

Treatment

- Endobronchial removal of FB



DIAGNOSTIC CHECKLIST

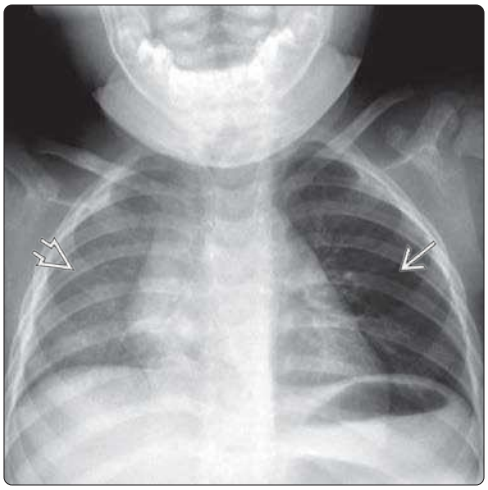


Image Interpretation Pearls

- Unilateral static lung/lobe volume at different phases of respiratory cycle is suggestive

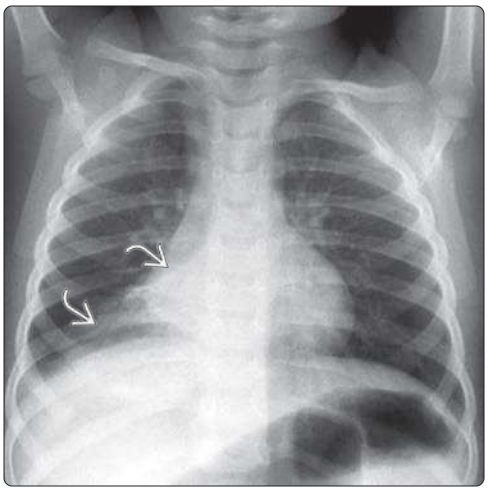
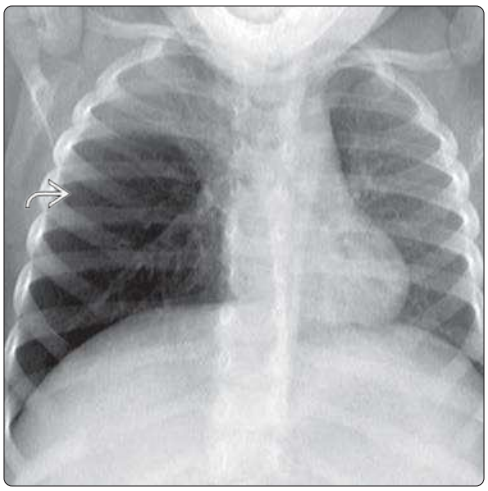
8. Hanba C et al: Consumer product ingestion and aspiration in children: a 15-year review. Laryngoscope. 127(5):1202-1207, 2017





(Left) *Inspiratory upright frontal chest radiograph in a toddler with acute respiratory distress demonstrates subtle relative lucency of the left lung compared to the right. (Right) Expiratory PA chest radiograph in the same patient demonstrates a static volume & persistent hyperlucency of the left lung compared to the right. In the correct clinical setting, static lung/lobe volume on inspiratory & expiratory or bilateral decubitus chest radiographs is very suggestive of air-trapping due to foreign body aspiration.*

(Left) *PA chest radiograph shows asymmetric hyperexpansion & lucency in the right middle & lower lobes with relative ↑ opacity in the right upper lobe & left lung. (Right) Coronal oblique CECT reconstruction in the same patient shows that the right middle lobe (RML) & right lower lobe air-trapping was due to a foreign body occluding the bronchus intermedius.*

(Left) *Frontal chest radiograph in a coughing 2-year-old patient who aspirated a peanut (unrecognized at the time) shows opacity & volume loss in the RML, presumed to be atelectasis in the setting of viral airway disease.* **(Right)** *AP radiograph in the same child 3 months later shows RML hyperlucency & oligemia due to air-trapping. During bronchoscopy, an old peanut was found in the RML bronchus. Depending on the degree of bronchial occlusion, a foreign body may cause atelectasis, hyperexpansion, or a changing picture over time.*

Cystic Fibrosis, Pulmonary

KEY FACTS

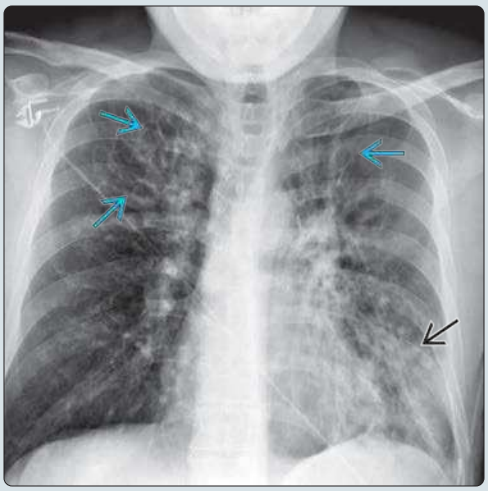
TERMINOLOGY

- Cystic fibrosis (CF): Autosomal recessive multisystem disorder caused by dysfunctional chloride ion transport across epithelial surfaces → thickening of secretions (e.g., mucus, digestive fluids, sweat)
- In lungs, abnormal mucus & degraded WBCs → chronic airway impaction → recurrent inflammation & infections → chronic airway damage (in progressively worsening cycle)

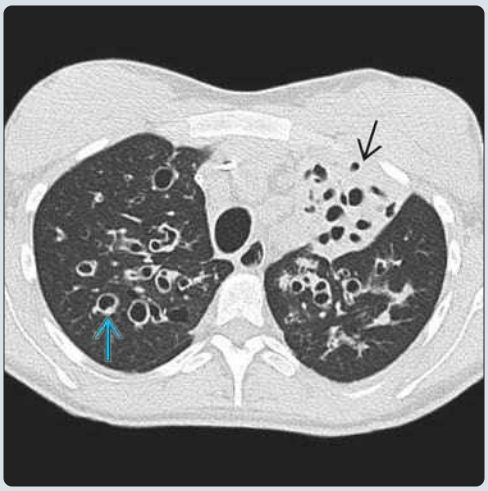
IMAGING

- Most common in upper lobes, superior lower lobes
  - Peribronchial thickening (early finding)
  - Mosaic attenuation due to air-trapping, best seen on expiratory scan
  - Bronchiectasis with signet ring sign (bronchus larger than adjacent artery)
  - Mucus plugging within dilated bronchi (finger-in-glove appearance)
  - "Tree-in-bud" centrilobular nodular opacities

PATHOLOGY

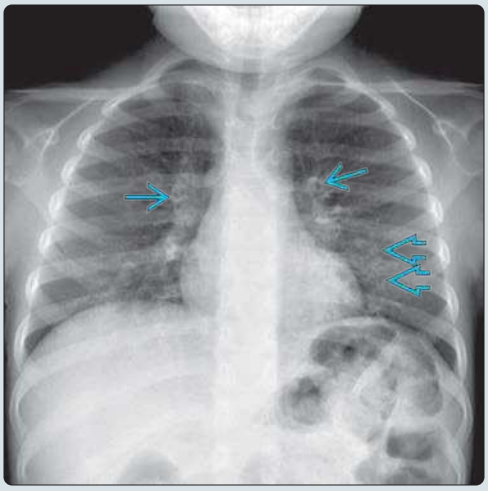


- Most common lethal genetic disorder in White patients
  - ~ 1 in 2,500 affected
- Mutation in both copies of CF transmembrane conductance regulator (*CFTR*) gene at chromosome 7q31.2 → defective chloride transport → abnormal water regulation
- > 2,000 genetic defects can result in CF; ΔF508 mutation of *CFTR* is most common (~ 90%)

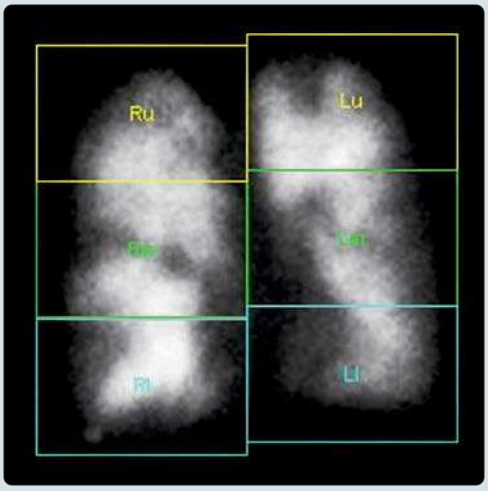


CLINICAL ISSUES

- 70% present < 1-year-old: GI symptoms are more common
- 90% by 12-years-old: Respiratory is more typical
  - Often have asthma-type symptoms
- Median survival: 41.1 years



DIAGNOSTIC CHECKLIST



- Annual chest radiograph or low-dose surveillance CT
  - CT best assesses progressive disease & predicts future exacerbations vs. pulmonary function tests, radiographs

(Left) *Frontal radiograph in a patient with cystic fibrosis (CF) shows prominent bronchiectasis in the upper lobes + left lower lobe consolidation with nodularity.* **(Right)** *Axial NECT in a CF patient shows bilateral upper lobe bronchiectasis with consolidation of the anterior segment of the left upper lobe. Note the signet ring sign (or pearl ring sign) in the right upper lobe with the dilated bronchus forming the ring & the adjacent artery forming the attached jewel.*

(Left) *Frontal radiograph in the chest in a 7-year-old with CF shows mild peribronchial thickening in the perihilar regions, an early finding of CF that is indistinguishable from common viral bronchiolitis. Additional peribronchial thickening is seen in the left base.* **(Right)** *Anterior Tc-99m MAA arterial perfusion scan in a patient with CF shows multifocal perfusion defects in the lungs bilaterally. Perfusion abnormalities may be the earliest findings in patients with CF.*

TERMINOLOGY

Abbreviations

- Cystic fibrosis (CF)

Definitions

- Autosomal recessive multisystem disorder caused by dysfunctional chloride ion transport across epithelial surfaces → thickening of secretions (e.g., mucus, digestive fluids, sweat)

IMAGING

General Features

- Best diagnostic clue
  - Upper lobe-predominant bronchiectasis & bronchial wall thickening in child with respiratory (± GI) symptoms
- Location
  - In lungs, more common in upper lobes & superior segments of lower lobes
  - Also affects sinuses, pancreas, hepatobiliary system, GI tract, & sex organs

Radiographic Findings

- Radiographs are insensitive to early changes of CF
- Late changes on radiographs include bronchiectasis, bronchial wall thickening, mucoid impaction, hyperinflation, lobar collapse, & pulmonary arterial enlargement due to pulmonary artery hypertension
- ± microcardia with chronic pulmonary hyperinflation
- ± abdominal manifestations visible on chest radiographs
  - Dilated bowel in newborn with meconium ileus
  - Ca^{2+} in newborn peritoneum if complicated meconium ileus → perforation → meconium peritonitis
  - Ca^{2+} over upper abdomen in older children & adolescents with chronic pancreatitis

CT Findings

- HRCT
  - Peribronchial thickening (early finding)
  - Bronchiectasis with signet ring sign
    - Ectatic bronchus > adjacent pulmonary artery
  - Mosaic attenuation due to air-trapping, best seen on expiratory scan
  - "Tree-in-bud" centrilobular nodular opacities
    - Bronchiolar impaction of mucus &/or infectious/inflammatory debris
  - Finger-in-glove appearance of mucus plugging within dilated bronchi
  - Other findings include: Emphysema, multifocal atelectasis, sacculations, & bullae
  - ± lymphadenopathy
- CTA
  - May show bronchial artery hypertrophy &/or aberrant/collateral arterial supply in setting of hemoptysis
  - Useful in CF patients with pulmonary hypertension to evaluate size dimensions of PA & RV

MR Findings

- Pulmonary MR ± inhaled hyperpolarized gas
  - May yield imaging results comparable to CT
  - May be able to detect early mucus plug & differentiate mucoid impaction from atelectasis
  - Phase-contrast imaging
    - Volume of flow to each lung may be calculated
    - ↑ aortopulmonary collateral flow may precede lung function decline
  - Functional cardiac information & ventricular volumes may be obtained
    - Phase-contrast imaging may be obtained to evaluate for pulmonic regurgitation from pulmonary hypertension (HTN)
    - Volumes & cine imaging to evaluate degree of RV dysfunction from pulmonary HTN

Ultrasonographic Findings

- Useful in evaluating pleural effusions
- Not helpful in lung evaluation in CF

Angiographic Findings

- Bronchial arteriography to detect (± embolize) source of pulmonary hemorrhage/hemoptysis

Nuclear Medicine Findings

- Normal chest radiograph with normal Tc-99m perfusion scan essentially excludes bronchiectasis
  - Nuclear medicine perfusion is more sensitive for detection of early disease in patients with CF
    - Multifocal perfusion defects are typically seen

Imaging Recommendations

- Best imaging tool
  - High-resolution CT with full inspiration & expiration

DIFFERENTIAL DIAGNOSIS

Asthma

- Peribronchial thickening & hyperinflation are common but without bronchiectasis

Allergic Bronchopulmonary Aspergillosis

- Findings overlap CF; allergic bronchopulmonary aspergillosis (ABPA) often complicates CF
- Other causes of ABPA include refractory asthma, tuberculosis, sarcoidosis, infectious pneumonia, Churg-Strauss syndrome

Ciliary Dyskinesia

- Abnormal ciliary movement (not abnormally thick secretions) is responsible for mucus accumulation
- Basilar predominant bronchial wall thickening, bronchiectasis
- Situs inversus & sinus disease in Kartagener syndrome

Tracheobronchomegaly (Mounier-Kuhn Syndrome)

- Rare congenital disorder with abnormal widening of upper airways

Williams-Campbell Syndrome

- Cystic bronchiectasis with bronchomalacia due to defective bronchial cartilage

PATHOLOGY

General Features

- Mutation in both copies of CF transmembrane conductance regulator (*CFTR*) gene at chromosome 7q31.2
  - > 2,000 genetic defects can result in CF; ΔF508 mutation is most common (~ 90%)
- CFTR protein malfunction → lack of chloride ion secretion → ↑ sodium retention & fluid resorption → ↑ viscosity of luminal secretions → obstruction of ducts of solid organs & hollow viscera
- In lungs, abnormal mucus & WBC degradation products (including DNA) → stasis in airways → recurrent infection & inflammation → chronic airway damage with worsening susceptibility to infection & inflammation

Gross Pathologic & Surgical Features

- Diffuse bronchiectasis & peribronchial thickening is seen on gross specimen
- Mucosal thickening of paranasal sinuses with polyposis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 1st symptoms may be delayed passage of meconium with bowel obstruction ± perforation in newborn with meconium ileus
  - In childhood, patients often look similar to asthma patients, presenting with chronic cough & wheezing
- Other signs/symptoms
  - Chronic constipation
  - Recurrent pancreatitis
  - Hepatobiliary disease
  - Clubbing of fingers & toes
- Clinical profile
  - Most detected on neonatal screening
  - After symptom development, testing by sweat chloride (> 60 mEq/mL = positive for CF)

Demographics

- Age
  - 70% present < 1 year: GI symptoms are more common
  - 90% by 12 years: Respiratory is more typical
- Epidemiology
  - Most common lethal gene defect in White patients (1 in 2,500 affected)
    - Much less common in patients with African or Asian ancestry

Natural History & Prognosis

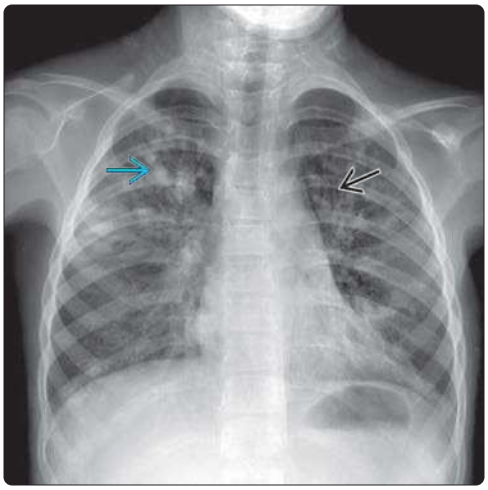
- Infancy: Often only mild or absent pulmonary symptoms
- Early childhood: Presents similar to asthma with cough, wheezing, & bronchitis
- Late childhood & adolescence: Recurrent pneumonias, bronchitis, & bronchiectasis with mucus plugging
- End-stage lung disease occurs at variable ages but often in late adolescence to early adulthood
- Exact timing of progression in CF is unpredictable
- Complications of CF lung disease
  - Recurrent infections are most common complication: > 1/2 develop infection with *Pseudomonas aeruginosa*
  - Allergic bronchopulmonary aspergillosis
  - Pneumothorax & pneumomediastinum
  - Hemoptysis
  - Bullous emphysema
  - Cor pulmonale
- Median survival: 41.1 years

Treatment

- Goal: ↓ lung damage from mucus plugging & infection
- Various internal & external airway clearance techniques
- Prophylactic antibiotics to ↓ chance of infection
- ± long-term IV (Port-a-Cath) for recurrent lung infections
- New medicines targeted at specific *CFTR* mutations
- ± lobectomy for patients with single lobe complications
- End-stage lung disease may require lung transplantation
  - Both lungs are typically transplanted to avoid infection of new lung from native lung
  - Clinical parameters typically guide transplantation

DIAGNOSTIC CHECKLIST

Consider



- Annual chest radiograph or low-dose CT surveillance of bronchiectasis complications
- Pulmonary MR is showing promise for future utility

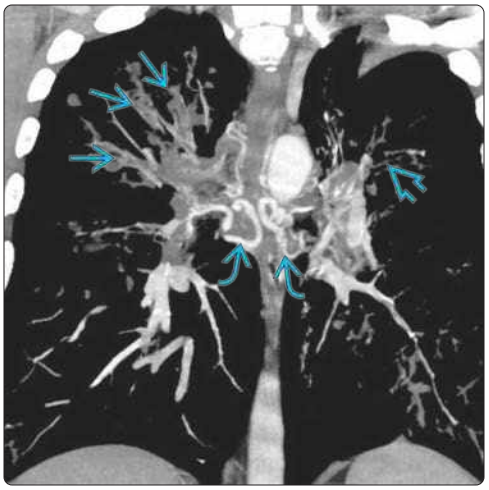


Image Interpretation Pearls

- CT is more accurate in assessing progressive lung disease than pulmonary function tests or radiographs
- CT improves with treatment of acute exacerbations
- Brody CT score predicts future pulmonary exacerbations better than initial FEV_1; scoring is based on
  - Extent of bronchiectasis
  - Size of abnormally dilated bronchi
  - Peribronchial thickening
  - Parenchymal involvement, including consolidation, ground-glass opacity, cysts, & bullae
  - Hyperinflation

(Left) *Frontal view of the chest in a 7-year-old girl with CF shows thick tubular & nodular densities in the right upper lobe. Note the bronchiectasis in the left upper lobe. Mucus impacted in the dilated bronchi is referred to as the finger-in-glove appearance.* **(Right)** *Coronal CECT MIP in a patient with CF shows mucus impacted in the dilated bronchi in the right upper lobe, which is known as the finger-in-glove appearance. Also note the bronchiectasis in the left upper lobe as well as the dilated bronchial arteries.*

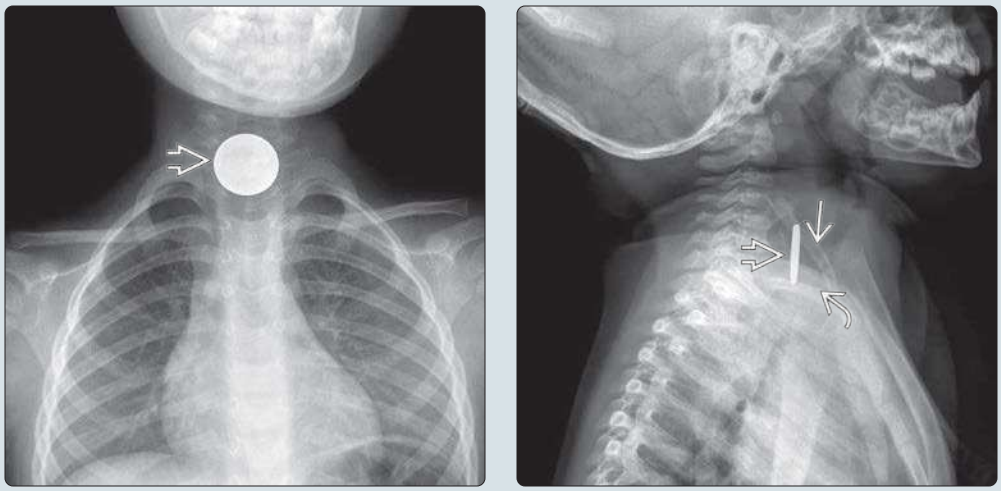
(Left) *Axial HRCT from a CF patient shows pneumomediastinum & subcutaneous emphysema. Note the prominent bronchiectasis in the upper lobes bilaterally.* **(Right)** *Sagittal SSFP bright blood MR in a patient with CF & pulmonary hypertension shows an enlarged right ventricle (RV) & pulmonary artery. There is deviation/flattening of the interventricular septum from ↑ RV pressure. Also note the dephasing artifact from the pulmonic regurgitation.*

(Left) *Coronal chest CTA in a patient with CF shows bronchiectasis & mucus-filled bronchi in the upper lobes with a left lower lobe consolidation.* **(Right)** *Color-coded, volume-rendered chest CTA in a patient with CF shows upper lobe bronchiectasis. Also note the enlarged bronchial artery collaterals arising from the descending thoracic aorta.*

KEY FACTS

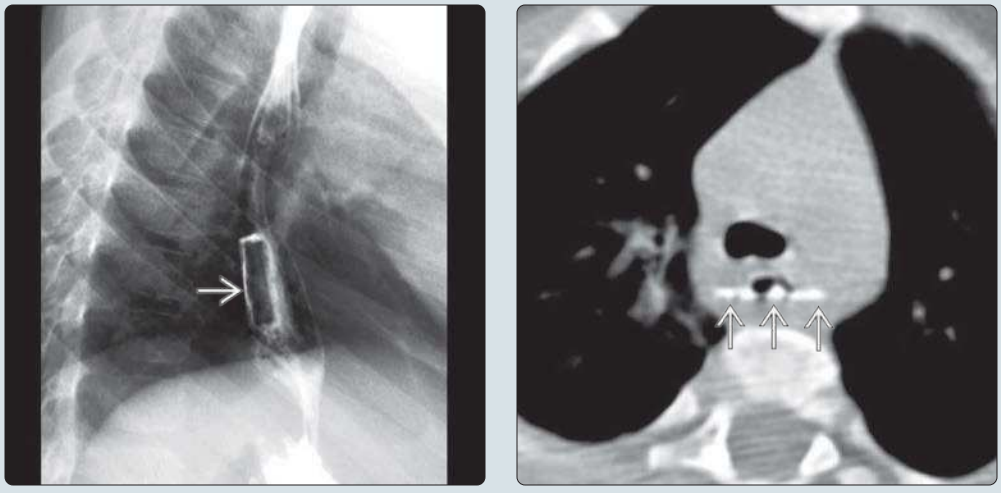
TERMINOLOGY

- Foreign body in esophagus for prolonged period of time



IMAGING

- Foreign body may or may not be radiopaque
- Airway narrowing suggests chronicity
  - Airway displaced anteriorly
  - Proximal esophagus may be dilated
- May present with complications: Abscess, pneumomediastinum, or pneumothorax
- Most common site: Upper esophagus at thoracic inlet
  - 2nd most common site: Level of carina & aortic arch
- Coins are most commonly swallowed foreign body
  - Button batteries show characteristic double-density (2-layer) periphery
- Imaging recommendations
  - Frontal & lateral chest radiographs are best initial study; include nasal cavity on lateral airway view if respiratory symptoms present
  - Esophagram for nonradiopaque foreign bodies
  - CECT vs. MR to diagnose complications, such as abscess, mediastinitis, aortic wall injury



CLINICAL ISSUES

- Respiratory/airway or feeding symptoms are most common
  - Cough, stridor, fever, wheezing
- Removal success rate is 95-100% regardless of technique
- Use endoscopy immediately for batteries in esophagus
  - Batteries quickly cause damage by pressure against wall of esophagus, leakage of caustic alkali, & generation of electrical current
  - Aortic wall inflammation can lead to delayed rupture & exsanguination; NASPGHAN guidelines recommend serial cross-sectional imaging
- Foreign bodies present for > 24 hours have ↑ risk of esophageal perforation

(Left) *AP radiograph of the chest shows a round, homogeneous metallic foreign body at the level of the thoracic inlet ➔, consistent with the history of a swallowed coin. This is the most common location for an esophageal foreign body.* **(Right)** *Lateral radiograph of the upper chest & neck shows an esophageal foreign body ➔. Note the narrowing of the trachea ➔ with soft tissue swelling around the metallic foreign body ➔.*

(Left) *Lateral esophagram shows a Scrabble piece ➔ outlined by barium in an 11-year-old who had symptoms of esophagitis for the past week. He denied swallowing anything.* **(Right)** *Axial NECT after a contrast esophagram demonstrates a localized leak ➔ into the mediastinum secondary to an esophageal perforation that occurred during the removal of coins in the esophagus.*

IMAGING

General Features

- Best diagnostic clue
  - Radiopaque object in region of esophagus
  - High suspicion for chronicity when airway is narrowed &/or anteriorly displaced
  - May present with complications: Abscess, pneumomediastinum, pneumothorax
- Location
  - Most common site: Upper esophagus at thoracic inlet
  - 2nd most common site: Level of carina & aortic arch from physiologic narrowing
  - 3rd most common site: Distal esophagus slightly above gastroesophageal junction
- Morphology
  - Coins are most commonly swallowed foreign body
    - Coins in esophagus will usually appear in coronal plane (en face) on frontal view
  - Button batteries show characteristic double-density (2-layer) shadow at periphery
    - Laterally, edges are rounded with step-off at junction of positive & negative terminals
    - Important to identify since batteries can cause caustic burn injury to esophagus in little time
  - Nonradiopaque foreign body
    - Hot dog & plastic toys are common

Radiographic Findings

- Radiography
  - Radiopaque foreign body in esophagus
    - Entirety or portion of foreign body may be radiolucent
  - Lateral view shows soft tissue thickening anterior to esophagus with displacement, bowing, & narrowing of trachea
    - Indicative of chronic inflammation & predictive of more difficult removal of foreign body

Fluoroscopic Findings

- Esophagram
  - Useful for detecting nonradiopaque foreign bodies
  - May diagnose stricture, fistula, or perforation

CT Findings

- CECT
  - Postremoval CT: Esophageal leak, diverticulum, mediastinitis/abscess; inflammation or injury of aorta if battery or sharp object is removed

MR Findings

- Some institutions use MR after battery removal rather than CECT/CTA

Imaging Recommendations

- Best imaging tool
  - AP & lateral chest radiograph is best initial study
    - Include nasal cavity with respiratory symptoms
  - Esophagram for nonradiopaque foreign bodies
  - CECT vs. MR to diagnose complications

DIFFERENTIAL DIAGNOSIS

Airway Obstruction/Inflammation

- May simulate foreign body in esophagus

Achalasia

- Failure of normal relaxation of lower esophageal sphincter

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Respiratory or airway problems are most common
    - Cough, stridor, fever, wheezing
    - Chronic upper respiratory infection or pneumonia
    - Hemoptysis, choking, cyanosis
  - GI symptoms
    - Dysphagia, drooling, vomiting, gagging
  - Chest pain when swallowing
  - Fever of unknown origin

Demographics

- Age
  - Most < 5 years; typically 8 months to 2 years

Natural History & Prognosis

- Foreign bodies present for > 24 hours have ↑ risk of esophageal perforation
- Vast majority of ingested objects pass through GI tract without problems

Treatment

- Removal success rate is 95-100% regardless of technique
- Strategy depends on type, location, & duration
- General complications prior to or without treatment
  - Most common complication: Perforation & subsequent mediastinitis
  - Rare complications include tracheoesophageal fistula & aortoesophageal fistula
- Endoscopy or surgery
  - Use urgently for sharp or irregular objects & unknown foreign bodies
    - Removal following morning after detection is acceptable
  - Use urgently for batteries in esophagus
    - Cause damage by pressure against wall of esophagus, leakage of caustic alkali, & electrical current
    - Reports of exsanguination (even delayed) due to inflammation of aortic wall by battery have led to NASPGHAN guidelines for serial cross-sectional imaging after battery removal

Sickle Cell Disease, Acute Chest Syndrome

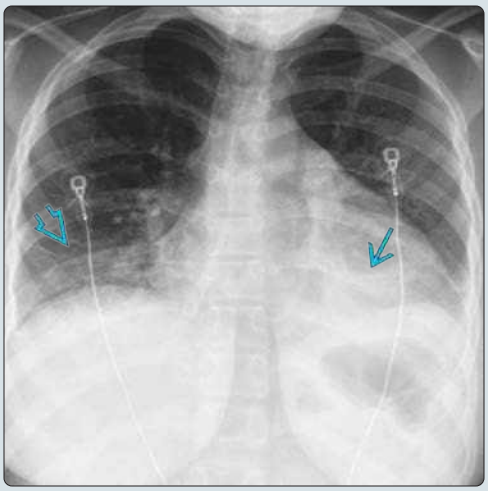
KEY FACTS

TERMINOLOGY

- New pulmonary opacity on chest radiograph + ≥ 1 additional symptom (such as fever, cough, sputum production, tachypnea, dyspnea, or hypoxia) in setting of sickle cell disease (SCD)

IMAGING

- Upper & middle lobe opacities are more common in children
- Lower lobe disease is more common in adults
- Initial chest radiograph may be normal (46%)
  - Opacity may not appear until 2-3 days after symptoms develop
- Opacities on CT may be more extensive than on radiograph

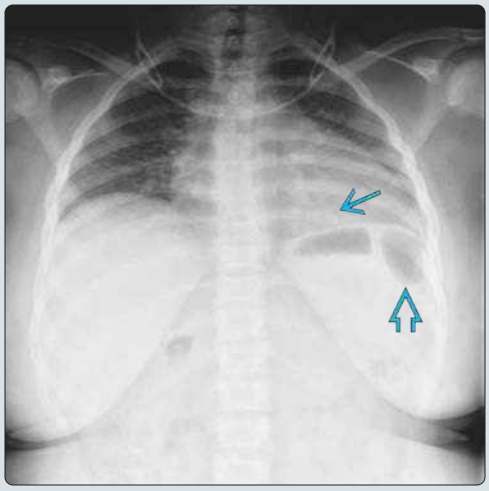


PATHOLOGY

- Potential causes: Infection (30%), pulmonary fat embolism (9%), pulmonary infarction (18%), & rib infarction

CLINICAL ISSUES

- Acute chest syndrome (ACS) is most common in patients aged 5-9 years; incidence ↓ with age
  - Fever, cough, & tachypnea are most common symptoms in patients < 10 years of age
  - Pain (chest, extremity, abdominal) is more common in adolescents & adults
- ACS is 2nd most common cause of hospitalization in patients with SCD
- ACS is most common cause of premature death in patients with SCD
  - Mortality is 4-9x higher in adults than in children
- Treatment
  - Supportive: Oxygen, antibiotics, pain control, IV fluids, incentive spirometry, & blood transfusions
  - Prevention: Pneumococcal vaccine, *Haemophilus influenzae* vaccine, & hydroxyurea



(Left) *AP radiograph of the chest in an adolescent with sickle cell disease (SCD) & acute chest syndrome (ACS) shows a poorly defined opacity in the right lower lobe with consolidation in the left lower lobe. The lungs are hypoinflated, & the heart is mildly enlarged.* **(Right)** *Axial CECT in the same patient with ACS shows consolidation in the lung bases bilaterally. Note the cardiomegaly from chronic anemia.*

(Left) *Axial CECT in lung window in the same patient shows consolidation & ground-glass opacity in right worse than left lung bases.* **(Right)** *PA chest radiograph in an adolescent with SCD & ACS shows low lung volumes with a streaky opacity in the left lower lobe. Note the cardiomegaly, cholecystectomy clips, & absent splenic shadow (replaced by bowel gas). There is also a biconcave appearance of the vertebral bodies & sclerosis of the humeral heads due to bone infarctions.*

TERMINOLOGY

Abbreviations

- Acute chest syndrome (ACS)
- Sickle cell disease (SCD)

Definitions

- New pulmonary opacity on chest radiograph + ≥ 1 additional symptom (such as fever, cough, sputum production, tachypnea, dyspnea, or hypoxia) in setting of SCD

IMAGING

General Features

- Best diagnostic clue
  - Pulmonary opacity in patient with SCD who has fever & respiratory symptoms
- Location
  - Upper & middle lobe involvement is more common in children
  - Lower lobe disease is more common in adults
- Size
  - Variable: May be segmental, lobar, or multilobar consolidation

Radiographic Findings

- Radiography
  - ACS
    - Initial chest radiograph may be normal (46%)
      - Radiograph lags behind physiological changes
      - Opacity may not appear until 2-3 days after symptoms develop
    - Opacity mimics pneumonia ± volume loss
    - Pleural effusions in > 50% of patients
  - Other findings of SCD
    - Cardiomegaly due to chronic anemia
    - Avascular necrosis/sclerosis of humeral heads
    - H-shaped or biconcave vertebrae
    - Enlarged ribs due to marrow expansion
    - Small splenic shadow (autosplenectomy) with lateralization of stomach bubble
    - Cholecystectomy clips in right upper quadrant

CT Findings

- NECT
  - Limited clinical use for ACS
  - Can have consolidation or ground-glass opacity
    - Opacities may be more extensive than on radiograph
  - Simplification of lung with ↓ vascularity
  - Pleural effusion is common
  - May see healed bone infarcts
- HRCT
  - Mosaic perfusion due to microvascular occlusion
  - Sequelae of ACS
    - Parenchymal bands & interlobular septal thickening
    - Peripheral wedge-shaped opacities
    - Architectural distortion
    - Traction bronchiectasis
- CTA
  - Pulmonary embolism is 3rd most common cause of ACS
    - Accounts for 16-17% of ACS episodes
    - Occurs in segmental or subsegmental pulmonary arteries
    - No associated lower extremity deep vein thrombosis
  - Dual energy CT can be used to make pulmonary blood volume maps
    - Higher number of iodine defects in ACS vs. controls
    - More prevalent than pulmonary opacities
    - Likely due to early microvascular changes

Nuclear Medicine Findings

- Bone scan
  - Foci of abnormal radiotracer uptake in ribs
    - ↓ or ↑ uptake: Acute or subacute bone infarcts
  - May have other bone infarcts vs. osteomyelitis
- V/Q scan
  - Limited clinical use in ACS
  - Can see perfusion defect
    - May mimic pulmonary embolism
  - Defects often resolve quickly with supportive therapy

Imaging Recommendations

- Best imaging tool
  - Chest radiograph for evaluation of pulmonary opacity
  - Pulmonary CTA if concern for pulmonary embolism
- Protocol advice
  - Routine frontal & lateral chest radiographs
  - Repeat chest radiograph in 48-72 hours if clinical concern is high as initial chest radiograph is often normal

DIFFERENTIAL DIAGNOSIS

Bacterial Pneumonia

- Clinically similar to ACS with fever, leukocytosis, pleuritic chest pain, pleural effusion, & productive cough
- Multilobar involvement & recurrent opacities are more common in SCD
- Clinical symptoms & radiographic abnormalities can be prolonged, lasting 10-12 days

Viral Chest Infection

- Viral infection causes 6-8% of ACS
  - Respiratory syncytial virus (RSV) is common

Pulmonary Infarction

- ~ 50% of cases in patients with SCD are caused by fat embolism
- Vascular occlusion by sickle cells is also important cause of ACS
- Usually diagnosis of exclusion

Asthma

- Significant comorbidity in patients with SCD; may be underdiagnosed in SCD
  - 73-78% of patients with SCD have airway hyperactivity
  - Patients diagnosed with asthma have 4-6x greater risk of developing ACS

PATHOLOGY

General Features

- Etiology
  - ACS may be multifactorial

- Infection is most common cause of ACS in children
- 50% of adult patients are initially admitted with vasoocclusive crisis causing pain

- Infection
  - Documented in 38-54% of cases
  - Most common pathogens: *Chlamydia pneumoniae* (7.2%), *Mycoplasma pneumoniae* (6.6%), RSV (6.4%)
  - Pulmonary opacity persists longer than cases where infection is not documented
- Pulmonary fat embolism
  - Cause of ACS in 9-16%
  - Etiology: Vasoocclusive crisis → edema & infarction of marrow compartment → marrow necrosis → fat cells enter venous bloodstream → embolize in branches of pulmonary artery
  - Frequently have bone pain
  - Lab findings: Thrombocytopenia, anemia; ↑ LDH, lipase, phospholipase A2, & uric acid; ↓ serum calcium
  - Diagnosis is supported by lipid-laden macrophages in bronchoalveolar lavage fluid
- Pulmonary infarction
  - Cause of ACS in 16-17%
  - Occurs in segmental & subsegmental pulmonary arteries
  - No associated lower extremity deep vein thrombosis suggests in situ thrombosis
- Rib infarction with hypoventilation from pain &/or analgesics
  - High correlation between rib infarction & pulmonary opacity
  - Pain may lead to splinting & atelectasis
  - Incentive spirometry helps prevent pulmonary complications of ACS
  - Analgesics may ↓ splinting but may cause hypoventilation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Fever, cough, & tachypnea are most common in patients < 10 years of age
  - Pain (chest, extremity, abdominal) is more common in adolescents & adults

Demographics

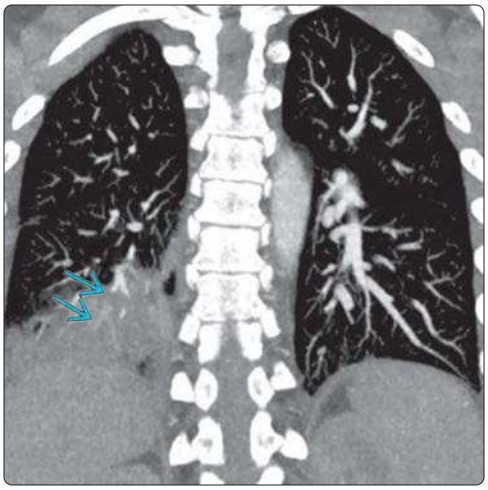
- Age
  - Most common in patients ages 5-9 years
  - Lower incidence in patients < 2 years due to higher fetal hemoglobin concentrations
  - Incidence gradually declines with age
    - Excess mortality in group with ACS
    - Fewer viral illnesses due to acquired immunity
- Sex
  - Slightly more common in males
- Ethnicity
  - In USA, almost exclusively seen in Black patients
- Epidemiology
  - Overall incidence of 12.8 episodes per 100 patient-years
  - ACS is most common cause of premature death in patients with SCD
  - ACS is 2nd most common cause of hospitalization in patients with SCD after pain crisis
    - ~ 50% of patients are admitted with diagnosis other than ACS
    - Diagnosed with ACS 2-3 days after admission

Natural History & Prognosis

- More severe in patients > 20 years
  - Mortality is 4-9x higher in adults than in children
- Features associated with poor prognosis
  - Physical exam: Altered mental status, tachycardia > 125 beats/minute, tachypnea > 30 breaths/minute, temperature > 40°C, hypotension
  - Lab findings: Arterial pH < 7.35, O_2 saturation < 88%, hemoglobin concentration ↓ by ≥ 2 g/dL, platelet count < 200,000, multiorgan failure
- Risk factors: Asthma, smoking, abdominal surgery, trauma

Treatment

- Supportive
  - Oxygen, antibiotics, pain control, IV fluids, incentive spirometry, & blood transfusions
  - Corticosteroids are controversial; may be associated with ↑ readmission rate
- Prevention
  - At higher risk for pneumonia from encapsulated organisms due to autosplenectomy
    - Pneumococcal vaccination
    - *Haemophilus influenzae* vaccination
  - Hydroxyurea
    - Reduces sickling by ↑ fetal hemoglobin level
    - Reduces incidence in patients with recurrent ACS
  - Transfusion therapy



DIAGNOSTIC CHECKLIST

Consider

- ACS in patient with SCD, chest symptoms, & pulmonary opacity

(Left) *Coronal CECT in an adolescent with SCD, acute chest pain, & ↓ right basilar breath sounds shows filling defects within subsegmental branches of the right lower lobe pulmonary artery. There is adjacent consolidation of the right lower lobe.* **(Right)** *Axial CECT in lung windows in the same patient shows consolidation in the right lower lobe.*

(Left) *Anterior & posterior projections from a bone scan in a patient with SCD show focally ↑ uptake in the left anterior 7th rib & right posterior 10th & 11th ribs, likely due to bone infarcts.* **(Right)** *Perfusion study with Tc-99m MAA in a patient with SCD shows a moderate-sized defect in the right upper lobe. Perfusion defects in SCD may represent acute or chronic infarction.*

(Left) *AP radiograph of the chest shows a poorly defined opacity in the right upper lobe of a 1-year-old with SCD presenting with fever & dyspnea. Note the elevation of the minor fissure, consistent with a degree of volume loss.* **(Right)** *AP radiograph of the chest in the same patient 12 hours later shows worsening opacification & volume loss of the right upper lobe. ACS is defined as a new pulmonary opacity in a symptomatic patient with SCD. In children, it occurs more commonly in the upper & middle lobes.*

Kaposiform Lymphangiomatosis

KEY FACTS

TERMINOLOGY

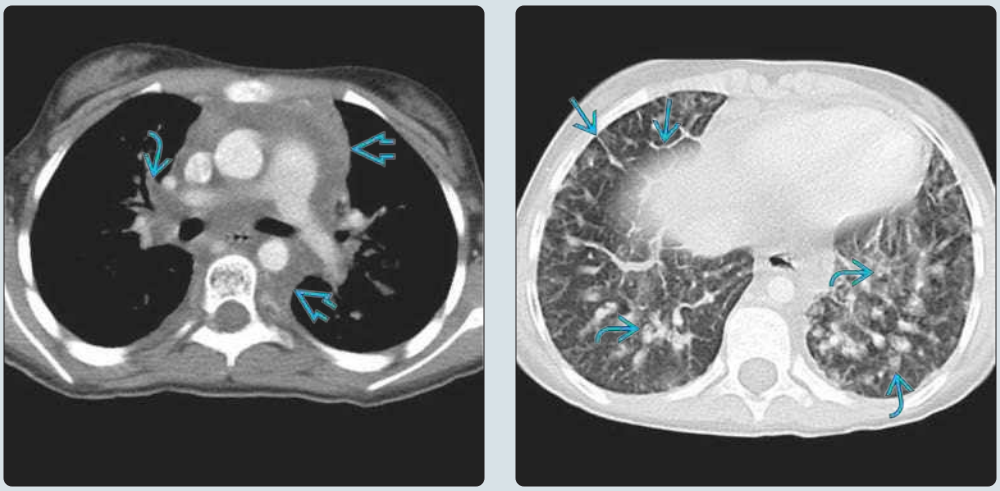
- Kaposiform lymphangiomatosis (KLA): Uncommon but aggressive lymphatic disease with poor prognosis
  - Features of both neoplasia & malformation
- Predominantly affects thorax with progressive respiratory symptoms & hemorrhages

IMAGING

- Poorly defined, infiltrative, fluid signal intensity/attenuation soft tissue lesions of mediastinum & chest wall + peribronchial & interlobular septal thickening of lung parenchyma, ± pleural & pericardial effusions
  - Enhancement of infiltrating abnormal lymphatic tissue on T1 C+ FS MR
- Location
  - Thorax: Mediastinum (100%) > lung, pleura (80-90%)
  - Subcutaneous tissues, retroperitoneum (> 50%)
  - Bone, spleen (50-60% each, typically as discrete lesions)

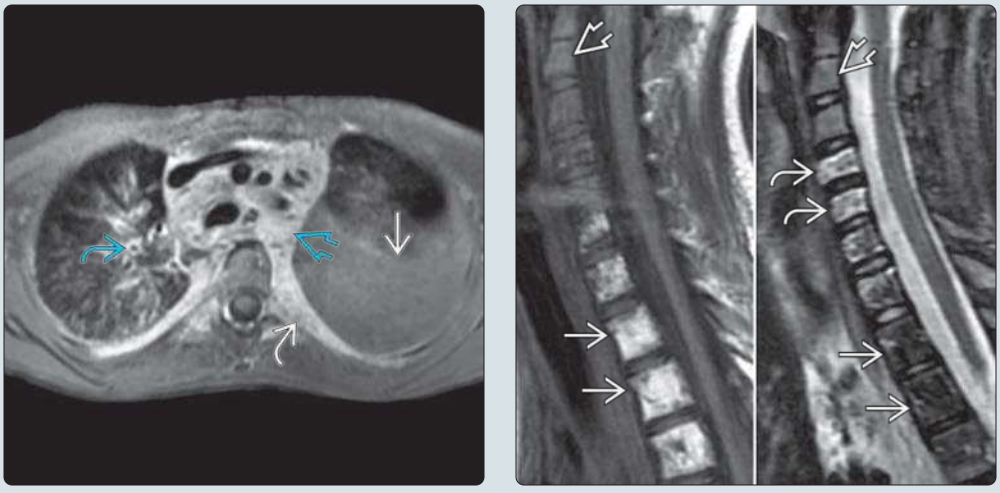
TOP DIFFERENTIAL DIAGNOSES

- Generalized lymphatic anomaly (GLA)
- Gorham-Stout disease (GSD)
- Central conducting lymphatic anomaly (CCLA)
- Kaposiform hemangioendothelioma (KHE)
- Lymphoma



PATHOLOGY

- Abnormal lymphatic channels with spindled endothelial cells; stain positive for lymphatic markers PROX1, D2-40
- Intermixed extravasated RBCs, hemosiderin



CLINICAL ISSUES

- Most common presentations
  - Respiratory (50-55%): Cough, dyspnea
  - Hemorrhage from underlying coagulopathy (50%)
  - Mass (25-35%)
- Median age of presentation: 6.5 years
- 5-year survival: ~ 50%

(Left) *Axial CECT in an adolescent girl with shortness of breath shows infiltration & expansion of the peribronchial ⇨ & mediastinal ⇨ soft tissues by poorly defined, fluid-attenuation lesions.* **(Right)** *Axial CECT in lung windows in the same patient with kaposiform lymphangiomatosis (KLA) shows extensive peribronchial ⇨ & interlobular septal ⇨ thickening.*

(Left) *Axial T1 C+ FS MR in the same patient several months later shows peribronchial thickening ⇨ with diffuse enhancement of the infiltrating mediastinal ⇨ & pleural ⇨ lesions. A large left pleural effusion ⇨ has developed.* **(Right)** *Sagittal T1 (left) & STIR (right) MR images show multifocal vertebral lesions in the same patient. Some lesions shows abnormal fatty deposition ⇨ compared to normal (for this age & sex) vertebral marrow ⇨ while other lesions show ↑ fluid signal intensity ⇨.*

TERMINOLOGY

Abbreviations

- Kaposiform lymphangiomatosis (KLA)

Definitions

- Uncommon but distinct subtype of generalized lymphatic anomaly (GLA) with poor prognosis
  - Features of both neoplasia & malformation
- Predominantly affects thorax with progressive respiratory symptoms & hemorrhages

IMAGING

General Features

- Best diagnostic clue
  - Poorly defined, infiltrative, fluid signal intensity/attenuation soft tissue lesions of mediastinum & chest wall + peribronchial & interlobular septal thickening of lung parenchyma, ± pleural & pericardial effusions
    - Microcystic lymphatic lesions are much more common than macrocystic
    - Enhancement of infiltrating abnormal lymphatic tissue on T1 C+ FS MR
- Location
  - Thorax: Mediastinum (100%) > lung, pleura (80-90%)
    - Posterior > anterior mediastinum
  - Bone (50-60%)
    - Mainly lucent lesions of vertebral bodies without cortical destruction
    - MR signal intensity is variable
      - ↑ T1, ↓ FS T2/STIR in some lesions due to unusual fatty deposition
      - ↑ fluid signal intensity (↓ T1, ↑ FS T2/STIR) in other lesions, more typical of lymphatic anomalies of bone
      - Variable enhancement with contrast
  - Abdomen (55%)
    - Retroperitoneal &/or mesenteric enhancing infiltrative tissue
    - Spleen (50%)
      - Few discrete cysts in normal size spleen vs. innumerable cysts in enlarged spleen
      - Cystic foci may enhance with contrast
    - Pancreatic & renal cysts
  - Muscles & skin (> 50%)
  - Lymphatic channels
    - Dilation with reflux of injected lymphatic contrast at many levels
- Morphology
  - Poorly defined soft tissue infiltration, usually without macrocysts
  - Discrete splenic cysts
  - Lucent bone lesions without cortical destruction

DIFFERENTIAL DIAGNOSIS

Generalized Lymphatic Anomaly

- Osseous, splenic, & pleural disease is common
- Interstitial lung disease is uncommon
- More likely to have soft tissue macrocystic disease than KLA
- Coagulopathy is not typical

Gorham-Stout Disease

- Progressive cortical bone destruction
  - Often affects multiple bones in close proximity
- Adjacent infiltrative microcystic lymphatic anomaly
- Visceral disease is less common than GLA/KLA

Central Conducting Lymphatic Anomaly

- Major lymphatic channel obstruction, malfunction, &/or leak → lymphangiectasis & chylous effusions
- MR lymphangiography demonstrates abnormal flow patterns of contrast

Kaposiform Hemangioendothelioma

- Typically presents in infancy with purpuric skin lesion & profound coagulopathy
- Unifocal infiltrative enhancing mass with greater component of spindle cells

Cat-Scratch Disease

- Regional adenopathy & fever are common
- ± osseous & splenic disease

Lymphoma

- Bulky, confluent mediastinal & hilar lymph nodes are typical
  - Mass effect is typically > with lymphatic anomalies

Langerhans Cell Histiocytosis

- Isolated or multifocal lytic bone lesions
- Systemic involvement is uncommon, typically seen in infants
- Lung disease is more common in older children & adult smokers
  - Cysts & nodules are typical

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Respiratory (50-55%): Cough, dyspnea
  - Coagulopathy &/or hemorrhage (50%)
    - Thrombocytopenia is common
  - Mass (25-35%)

Demographics

- Age
  - Median age of presentation: 6.5 years

Natural History & Prognosis

- 5-year survival of ~ 50%
- Progressive symptoms over months-years

Treatment

- No established effective long-term therapy
- Limited reports of improvement with sirolimus, vincristine
- Temporary clinical improvement with drainage procedures, including thoracentesis, pericardiocentesis/pericardial window

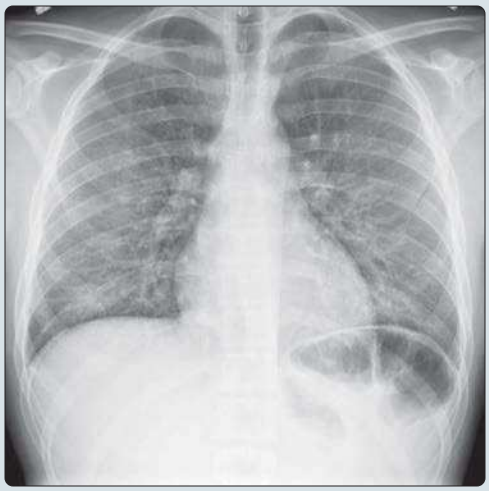
EVALI

KEY FACTS

TERMINOLOGY

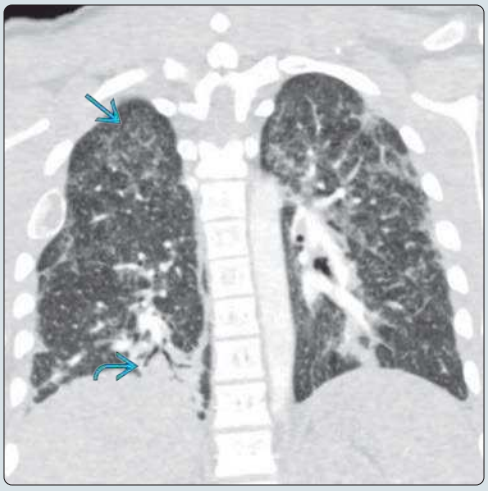
- Electronic cigarette (e-cigarette) or vaping product use-associated lung injury (EVALI)
- Bilateral, symmetric, ground-glass & consolidative opacities in patient with history of e-cigarette use or dabbing + negative work-up for pulmonary infection

IMAGING

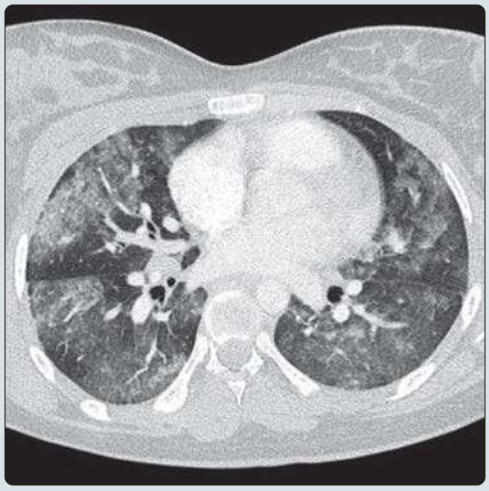


- Chest radiograph
  - Bilateral, symmetric opacities
  - May not be sufficiently sensitive in detecting lung changes from EVALI; should not be used to exclude this diagnosis
- CT
  - Most common findings: Bilateral, symmetric ground-glass & consolidative opacities
  - Also seen: Atoll or reverse halo sign, interlobular septal thickening, centrilobular nodules, subpleural &/or peribronchovascular sparing
  - Pattern of injury could follow that of cryptogenic organizing pneumonia, hypersensitivity pneumonitis, acute lung injury (diffuse alveolar damage, crazy paving), acute eosinophilic pneumonia, & lipoid pneumonia

CLINICAL ISSUES



- Respiratory symptoms are common: Cough, shortness of breath
- Many patients also present with GI symptoms, including abdominal pain, nausea, vomiting, diarrhea
  - GI abnormalities may be primary presenting symptoms
- Most recover with supportive measures & glucocorticoids
- May have progressive course with respiratory failure & death



(Left) *Axial CECT in a 17-year-old who presented with right lower quadrant pain & was worked up for possible appendicitis shows bilateral, symmetric ground-glass densities that were noted at the lung bases on the abdomen & pelvis CT. Note the relative subpleural sparing.* **(Right)** *PA chest radiograph subsequently performed in the same patient shows hazy, patchy basilar opacities. The patient was diagnosed with EVALI, as he had a history of vaping & the infectious work-up was negative.*

(Left) *Coronal CECT shows findings of EVALI in a 15-year-old with a history of e-cigarette use & shortness of breath, including subtle ground-glass densities, patchy consolidation at the right lung base, & centrilobular nodules.* **(Right)** *Axial CECT in a 16-year-old with EVALI who presented with shortness of breath & cough shows typical bilateral, symmetric opacities predominantly in the mid- to lower lung zones.*

TERMINOLOGY

Abbreviations

- Electronic cigarette (e-cigarette) or vaping product use-associated lung injury (EVALI)

IMAGING

General Features

- Best diagnostic clue
  - Bilateral, symmetric ground-glass & consolidative opacities in patient with history of using e-cigarette or dabbing + negative work-up for pulmonary infection

Radiographic Findings

- Bilateral ground-glass & consolidative opacities
- Symmetric

CT Findings

- Bilateral ground-glass & consolidative opacities
- Interlobular septal thickening & centrilobular nodules
- Subpleural & peribronchovascular sparing
- Atoll or reversed halo sign: Central ground-glass opacity (GGO) surrounded by more dense ring of consolidation
- Symmetric
- Pattern/distribution of lung findings can follow that of cryptogenic organizing pneumonia, hypersensitivity pneumonitis, acute lung injury (diffuse alveolar damage), acute eosinophilic pneumonia, & lipoid pneumonia

Imaging Recommendations

- Best imaging tool
  - Radiograph is often 1st modality but may not be sufficiently sensitive in detecting lung changes from EVALI & should not be used to exclude this diagnosis
  - CT may be necessary for further characterization

DIFFERENTIAL DIAGNOSIS

Hypersensitivity Pneumonitis

- History of other inhaled antigen

Acute Eosinophilic Pneumonia

- Bronchoalveolar lavage fluid with > 25% eosinophils

Diffuse Alveolar Hemorrhage

- Etiology may be autoimmune, drug reaction, or infectious

Acute Pulmonary Infections, Including SARS-CoV2 Infection

- Positive work-up for other infectious etiology

Other Organizing Pneumonias

- Etiology may be autoimmune, drug related, infectious, or radiation related

PATHOLOGY

General Features

- Spectrum of acute & organizing lung injury: Interstitial edema, type II pneumocyte hyperplasia, vacuolated foamy macrophages, intraalveolar fibrin, acute fibrinous pneumonitis, organizing pneumonia with airway-centered micronodular lesions, & diffuse alveolar damage with hyaline membranes
- Rarely, eosinophilic infiltrate
- Lipid-laden macrophages have been reported & are not pathognomonic for exogenous lipoid pneumonia
- No histopathologic evidence of hypersensitivity pneumonitis, even in patients with hypersensitivity pneumonitis injury pattern on CT
  - GGO centrilobular nodule CT pattern is attributed to bronchiolocentric micronodular lesions of organizing pneumonia & organizing acute lung injury
- Tetrahydrocannabinol-containing e-cigarette or vaping products are linked to most EVALI cases & are suspected to play major role in reported outbreaks
- Vitamin E acetate is also strongly linked to EVALI outbreaks
  - Found in product samples tested by FDA & state laboratories & in patient lung fluid samples tested by CDC from geographically diverse states but not in lung fluid of people without EVALI

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Respiratory: Cough, shortness of breath
  - Majority of patients also present with GI symptoms: Abdominal pain, nausea, vomiting, diarrhea
    - GI abnormalities may be primary presenting symptoms with respiratory findings noted only during work-up
  - Constitutional symptoms: Fever, weight loss

Demographics

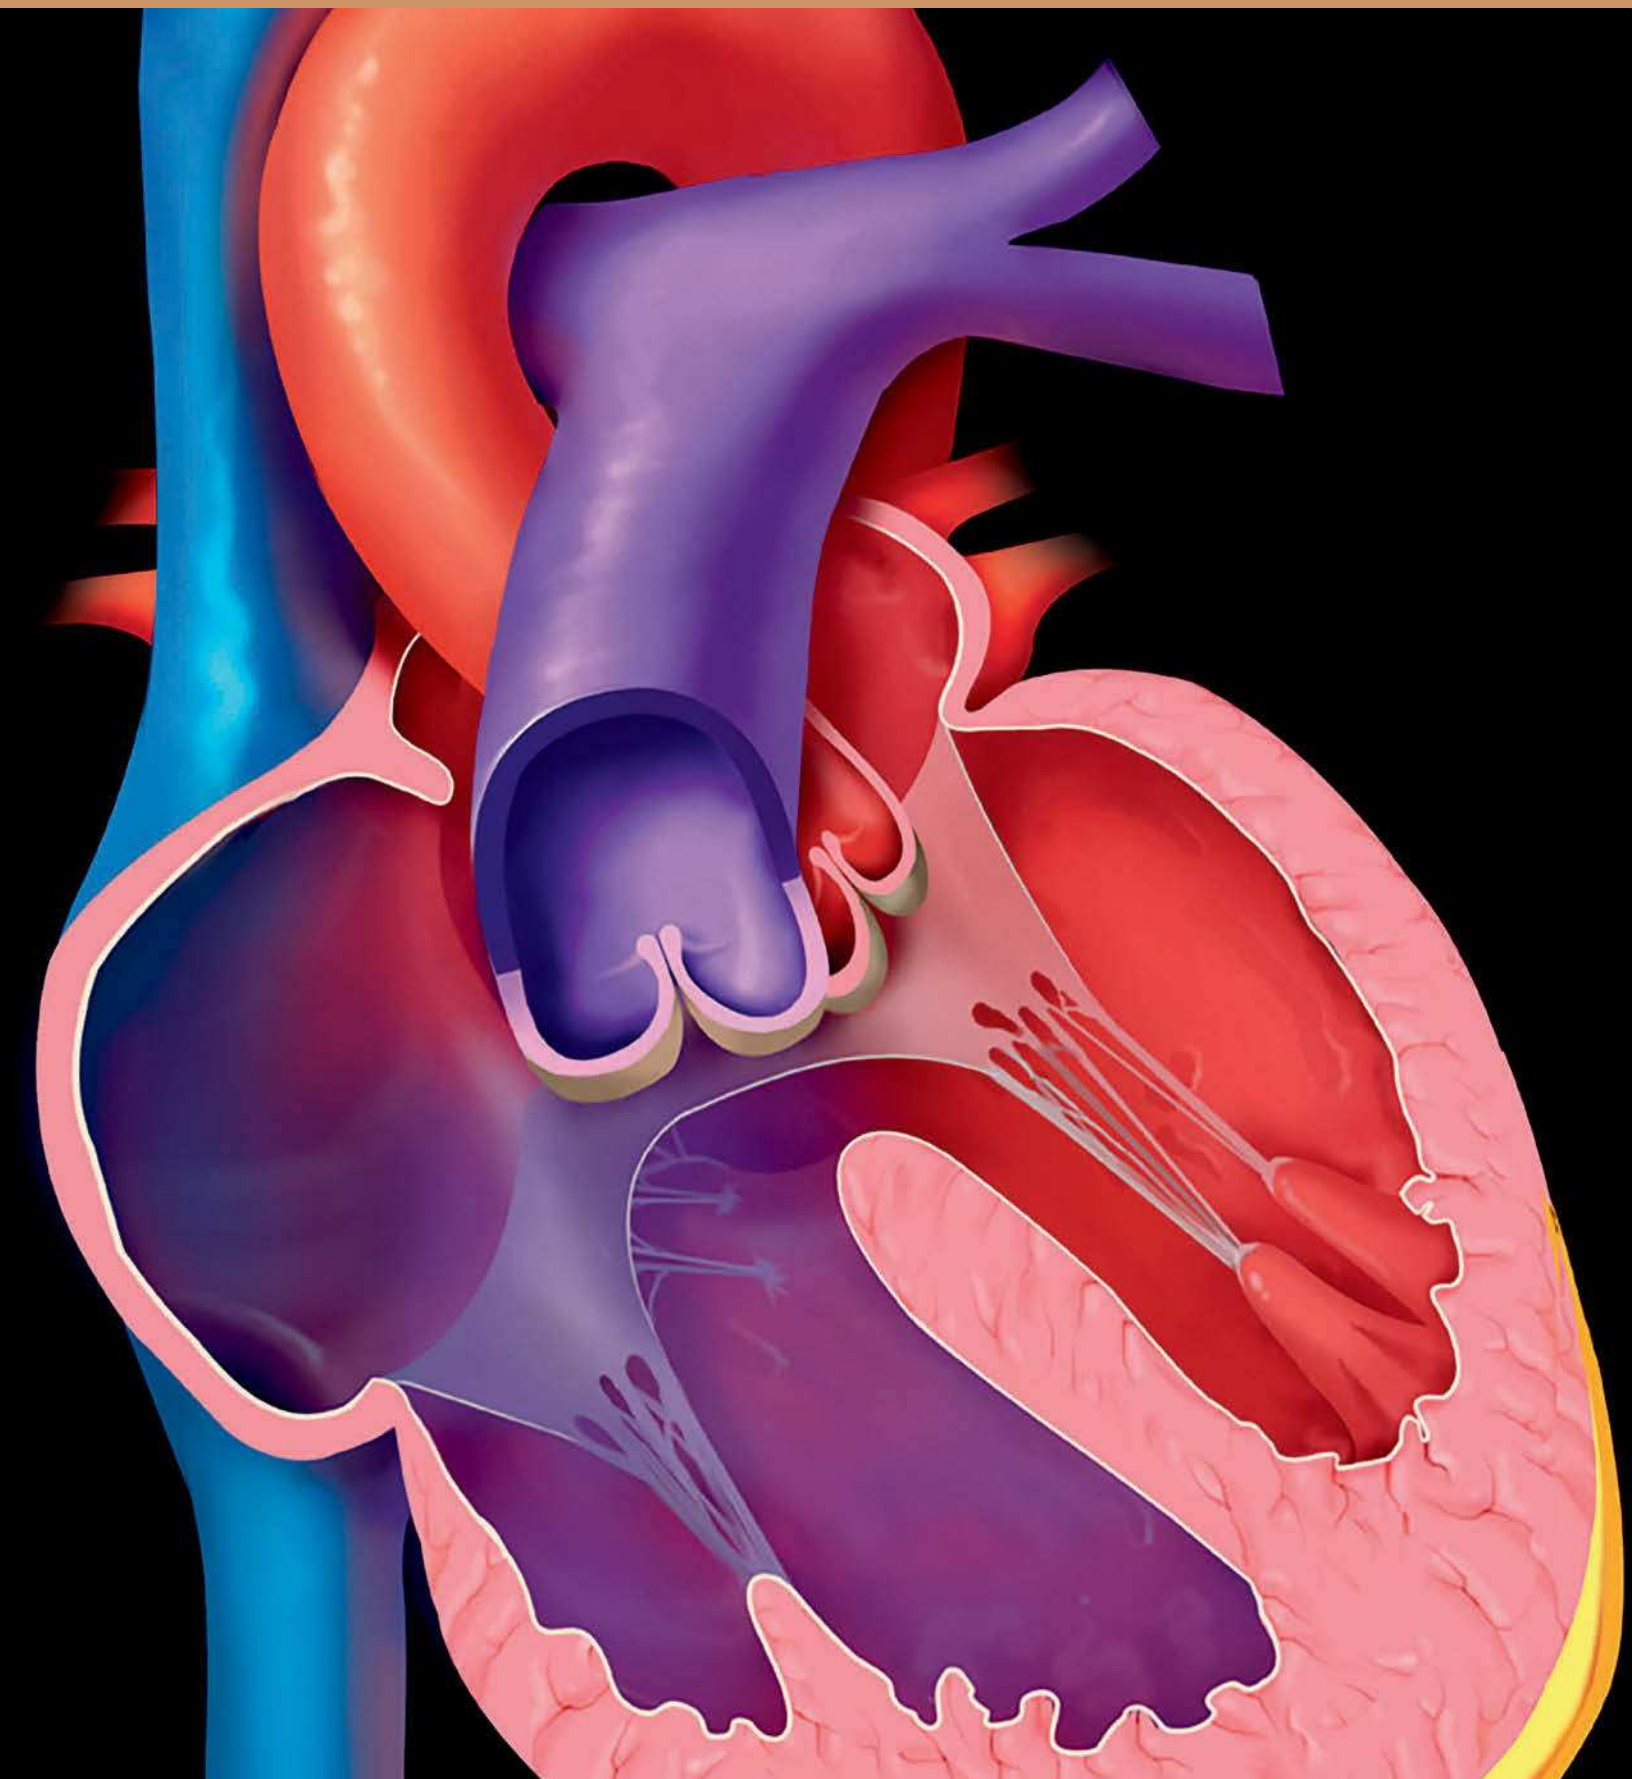
- Majority of patients < 35 years old, mean age of 24 years
- Patients < 18 years old account for 15% of hospitalizations

Natural History & Prognosis

- Most improve after cessation of vaping
- May have progression with respiratory failure & death

Treatment

- Supportive measures
- Glucocorticoids



DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Evaluation of lung bases on abdominal CT is important as many patients present with gastrointestinal symptoms

Imaging Anatomy

The days in which congenital heart disease (CHD) was characterized by chest radiography & defined by angiography are gone. Both still play some role in the diagnosis & management of CHD. However, with echocardiography, cardiac MR, & CT, we now have robust imaging modalities that can provide detailed anatomic & functional evaluation in patients with complex heart issues. A patient who undergoes a CT or MR for CHD will often have multiple findings. For example, an asplenia heterotaxy patient with right-sided isomerism may have a long list of diagnoses, such as total anomalous pulmonary venous return (TAPVR), transposition of the great arteries (TGA), patent ductus arteriosus (PDA), atrial septal defect (ASD), ventricular septal defect (VSD), single coronary artery, situs inversus, coarctation, & tracheal stenosis. This is not out of the ordinary in a complex CHD patient referred for advanced imaging (CT or MR). A systematic approach is therefore crucial in any cross-sectional imaging modality of a patient with CHD. This introduction attempts to provide a systematic approach to cardiac CT or MR in a patient with CHD.

Situs

Evaluation of situs involves the designation of an individual as normal (situs solitus), reversed (situs inversus), or some other combination (situs ambiguous). In situs solitus, the stomach, left atrium, apex of the heart, & spleen are on the left, while the right atrium, liver, superior vena cava (SVC), & inferior vena cava (IVC) are on the right. The pulmonary veins drain to the left atrium. The tracheobronchial branching in situs solitus includes a trilobed lung & main bronchus that sits posteriorly &/or superiorly to the pulmonary artery (eparterial bronchus) on the right & a bilobed lung with a main bronchus sitting below the pulmonary artery on the left (hyparterial bronchus). Situs inversus is the exact opposite of situs solitus. There are multiple variations to the above basic designation of situs. These fall into the category of situs ambiguous. Some additional observations will often be necessary. In the abdomen, besides looking at the side of the stomach, one must look for the position of the liver, absence of the spleen or presence of multiple spleens, & presence of an intrahepatic IVC (to exclude azygous continuation of the IVC). In the heart, be aware of symmetric atria & appendages in patients with heterotaxy, as these may represent 2 right atria or 2 left atria in right or left isomerism. It is usually not difficult to differentiate the ventricles based on the prominence of the trabeculations (i.e., the more trabeculated ventricle is usually the right ventricle). The right ventricle may be identified more confidently by the presence of a moderator band (muscular fibers connecting the free wall of the right ventricle to the interventricular septum). Also, pay attention to the tracheobronchial branching relative to the pulmonary arteries: It may be abnormal, bilateral, left-sided branching (hyparterial bronchi) or bilateral, right-sided branching (eparterial bronchi).

Lungs & Airways

There is an increased incidence of airway anomalies in children with CHD. These include pig bronchus, congenital stenosis, & bilateral right- or left-sided tracheobronchial branching seen with heterotaxy syndromes. More common than congenital airway anomalies is airway compression from cardiomegaly & enlarged or anomalous vasculature. The child with CHD is also susceptible to chronic lung disease from extended mechanical ventilation as well as postoperative effusions, atelectasis, tracheobronchomalacia, & infections.

Atria & Veins

It is important to make sure the venous drainage empties into the appropriate chamber of the heart. Anomalies like TAPVR & partial anomalous pulmonary venous return can easily be missed unless specifically investigated. Always look for a left SVC & a crossing innominate vein. The unsuspected presence of a left SVC may complicate cardiac surgery & cardiopulmonary bypass unnecessarily. Also, scan the atrial septum for defects. Artifact can sometimes hide or mimic ASD. As technology advances, the ability to evaluate valvular & septal structures will also improve. The atrioventricular valves should be evaluated for position, size, & thickness, but they can be difficult to evaluate if there is motion, beam hardening artifact, or a delayed contrast bolus.

Ventricles

A VSD is any communication of the right & left ventricles. These defects are most commonly in the membranous portion of the interventricular septum. In complex congenital heart patients, defects are also frequently seen in the muscular portion of the ventricular septum. Rarely, defects can also occur along the outflow tracts. Included in the evaluation of the ventricles are the right & left ventricular outflow tracts. Outflow tract evaluation includes assuring the patency (no atresias), separation (no truncus anomaly), & connection to the appropriate great vessel (no transposition).

Great Vessels

The size, course, & position of the great vessels should be evaluated by CT & MR. Basic measurements of the size of the aorta are made at the sinuses of Valsalva, aortic valve anulus, sinotubular junction of the ascending aorta, transverse aortic arch, & descending aorta. Basic measurements are made for the main pulmonary artery at the pulmonary valve anulus, midmain pulmonary artery, & proximal & distal right & left pulmonary arteries. Any other obvious stenosis or dilation should also be measured. Vascular rings, slings, & aberrant vessels should be identified. A PDA is usually present in complex congenital heart patients, & its length & width should be measured.

Coronary Arteries

The origin, course, & termination of the coronary arteries should be evaluated when possible. Visualization of the coronaries is variable depending on the type of exam performed. Generally, the coronaries are best seen with an ECG-gated cardiac CTA. It is important to note that certain coronary anomalies will alter the surgical approach. Rarely, the left (less commonly the right) coronary artery may arise from the pulmonary artery (ALCAPA). This can lead to a steal phenomenon & cause the patient to go into heart failure. Sudden death can occur in patients (typically athletes) with an interarterial (malignant) course of the coronary arteries. This is most commonly seen when the left coronary arises from the right coronary sinus or when the right coronary artery arises from the left coronary sinus. The aberrant artery then courses between the right & left ventricular outflow tracts. Some coronary anomalies are associated with certain types of CHD. This helps focus the search for the coronary anomalies. For example, patients with TGA typically have a right coronary arising from the noncoronary sinus. If the coronary anatomy is something different from the typical pattern in TGA patients,

the surgeon should be alerted, as he or she will have to translocate the coronaries during the arterial switch procedure. Coronary artery fistulas are frequently seen in patients with a hypoplastic right ventricle. It is common to see a partial interarterial course of the right coronary artery in a patient with tetralogy of Fallot since clockwise rotation of the aortic root is seen in a large percentage of these patients. Finally, for any anomaly where a coronary artery courses in front of an outflow tract, alert the surgeon so he or she can avoid severing the vessel during surgery.

Functional

Basic functional evaluation of the heart can be performed by both CT & MR cardiac exams. Routine functional evaluation includes calculating the volumes & ejection fractions of both ventricles. Indexed volumes are obtained by dividing the gross volume by the body surface area. CT & MR can also be used to evaluate the left ventricular muscle mass. Standardized data is available to compare volume & muscle mass results with other size & age matched data sets. MR has the added capabilities to evaluate & quantify flow volumes & velocities. A pulmonary to systemic flow ratio (Qp:Qs) is routinely provided by interrogating the flow from the right & left ventricular outflow tracts. In patients with pulmonic & aortic regurgitation, velocity-encoded phase-contrast imaging can be used to calculate regurgitant fractions. The regurgitant fraction is calculated by dividing the regurgitant volume by the stroke volume. Similar applications can be used to evaluate other veins, arteries, & valves as needed. Regurgitant fractions are typically followed yearly in patients with a pulmonary homograft to assess the severity of pulmonic regurgitation. When MR thresholds of end-systolic, end-diastolic, & pulmonic regurgitant fractions are met, a pulmonic valve replacement is recommended.

Anatomy-based Imaging Issues

It is crucial to know as much as possible about the patient's anatomy & postsurgical history before protocoling a cardiac CT or MR. For example, IVC (Fontan) & SVC (Glenn) shunts may introduce unopacified blood directly into the pulmonary arterial system. This can simulate a pulmonary embolism when unsuspected. Thoughtful protocoling of patients with CHD can help avoid artifacts that may simulate pathology & provide additional information to the cardiologist & cardiothoracic surgeon to better care for these patients.

Indications for Cardiac MR & CT

The routine congenital heart patient with a simple lesion (ASD, PDA, VSD) would likely never undergo an advanced imaging study, such as a cardiac CT or MR. Echocardiography provides excellent delineation of the intracardiac anatomy, great artery relationships, & function of the heart. Cardiac CT & MR are reserved for problem-solving in difficult echocardiography cases.

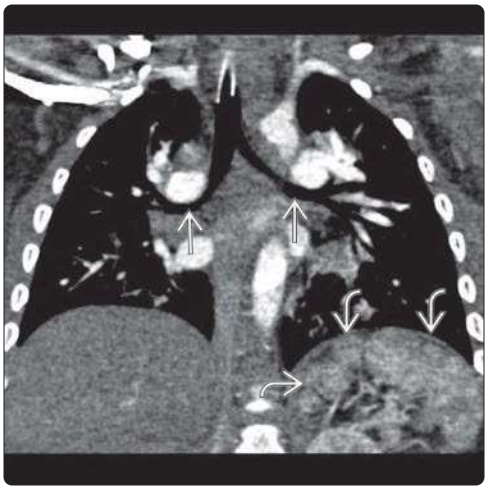
Extracardiac anatomy can be difficult to completely evaluate by echocardiography in complex cases. CT & MR are frequently done to evaluate the pulmonary veins, pulmonary arteries, systemic veins, & the aorta & its branches. Heterotaxy patients often have abnormalities involving the extracardiac anatomy & airways & may now routinely undergo cardiac CT or MR.

There are certain circumstances where the evaluation of the intracardiac anatomy can benefit from CT & MR. These include cardiac tumors, cardiomyopathies, ischemic heart disease, myocarditis, & coronary artery abnormalities. A more accurate volumetric analysis with CT or MR may be desirable in patients to evaluate the possibility of a 2-ventricle repair. MR has proven to be an effective tool to follow tetralogy of Fallot patients with pulmonic regurgitation to determine the timing of pulmonary valve replacement.

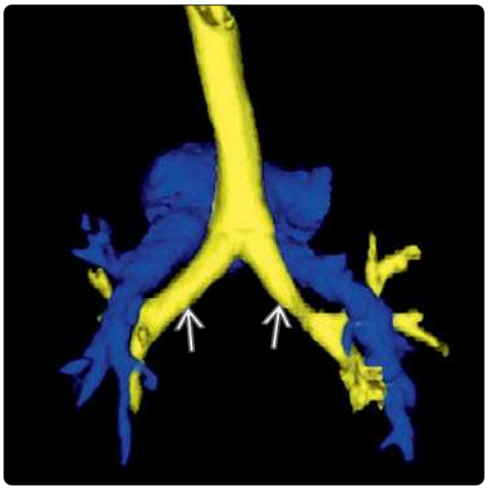
Cardiac MR vs. Cardiac CT

With higher temporal resolution, cardiac MR is superior to cardiac CT for functional imaging of the heart & evaluation of intracardiac anatomy. With higher spatial resolution, cardiac CT is superior to MR for extracardiac anatomy, airway evaluation, & coronary artery detail. There is significant overlap between the 2 modalities, as cardiac CT can provide volumetric functional evaluation, & MR gives adequate delineation of the extracardiac anatomy.

Cardiac MR requires longer sedation times than CT. Cardiac CT exposes the patient to ionizing radiation. Adjusting for size & using prospective gating, as well as other techniques, can significantly reduce the radiation dose.



Cardiac 3D Models



Segmentation of the anatomy in a patient with complex disease is often performed, & they can be exported to 3D printers to create physical models of the heart for surgical planning. 3D printers are now widely available & can print the models using a variety of flexible & nonflexible materials. Simple resin models of the heart can be printed & used in educating parents, patients, & health professionals. 3D congenital heart models are now used in the teaching of physicians in training at all levels. Patient-specific models can be printed in flexible material & be used to test devices on the patient's anatomy before performing the actual procedure. This method has also proven effective in decreasing procedure times. Examples include the coiling of aneurysms, sizing of devices for the closure of intramuscular VSD, & Melody valve placement along the pulmonary outflow tract.

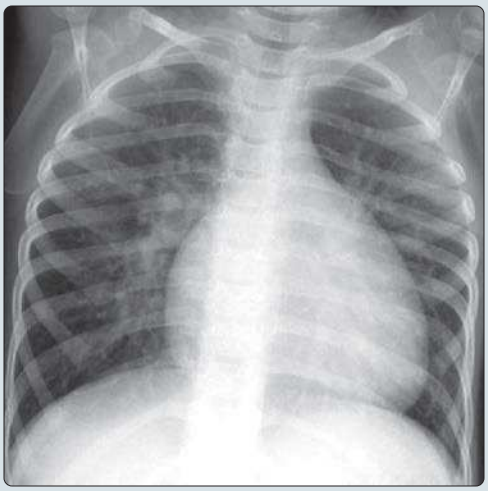
Atrial Septal Defect

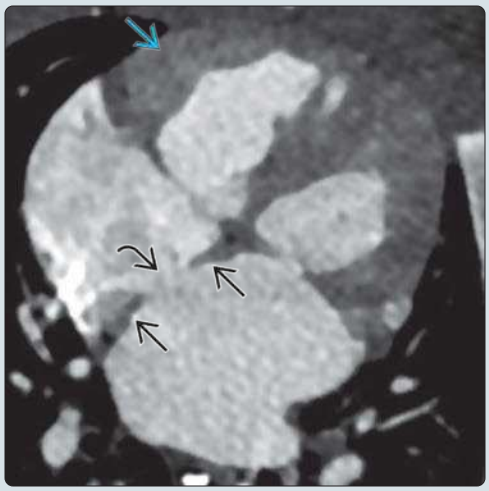
KEY FACTS

TERMINOLOGY

- ASD: Defect(s) in cardiac atrial septum; may be isolated or associated with other congenital heart disease (CHD)
- Left-to-right (LTR) shunt: Blood from left heart bypasses systemic circulation to enter right heart
  - Most ASD sequelae are related to long-term LTR shunting
- Types of ASD
  - LTR shunts: Ostium secundum (70-90%), ostium primum, sinus venosus, unroofed coronary sinus defects
  - Patent foramen ovale is normal variant & usually transient with normal atrial pressures
    - ↑ stroke risk; unclear migraine association



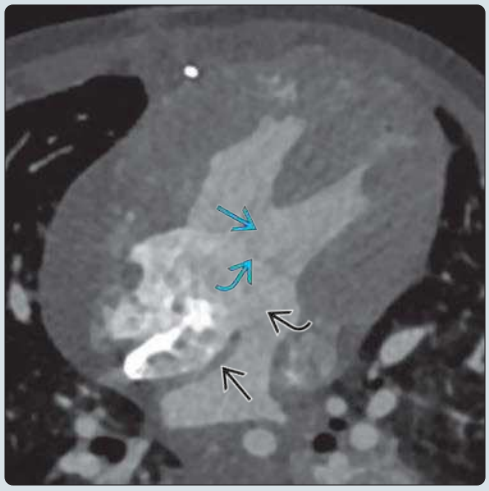
IMAGING



- LTR shunting leads to chronic volume overload of right heart, eventual enlargement of RA, RV, & PA
- Diagnosis of actual defect is primarily made by echocardiography
- Cardiac MR is accurate alternative for depiction of function, flow, & anatomy

CLINICAL ISSUES

- ASD: 10% of CHD in children, yet 30% of CHD in adults
- Secundum ASD: Majority of patients are asymptomatic
  - Spontaneous closure occurs in many children
  - Subtle symptoms are more likely in 2nd decade, though large defects frequently do not present until adulthood
    - Fatigue, exercise intolerance, syncope, shortness of breath, palpitations
    - ASD leading to severe pulmonary hypertension: Median age of detection is 51 years
  - Repair if shunt ratio > 1.5:1 or defect > 10 mm
  - Percutaneous closure with occlusion device
- Primum/atrioventricular septal defect is more severe; requires early surgical repair
- Sinus venosus ASDs also require surgery due to complex anatomy



(Left) *Frontal chest radiograph in a 4-year-old child demonstrates cardiomegaly, ↑ pulmonary vascularity, & mild pulmonary edema. The patient had a large, untreated atrial septal defect (ASD).* **(Right)** *Axial cardiac CTA in an infant with other congenital anomalies shows a defect in the midportion of the atrial septum, consistent with a secundum-type ASD. Note the hypertrophy of the right ventricle (RV).*

(Left) *Color-coded volume-rendered 4-chamber cardiac CTA shows a defect in the midportion of the atrial septum, consistent with a secundum-type ASD. Note that the interventricular septum separates the RV & left ventricle (LV).* **(Right)** *Axial cardiac CTA in an infant with an atrioventricular (AV) canal defect shows a prominent septum primum defect of the atrial septum. Note the common AV valve & the posterior ventricular septal defect (VSD).*

TERMINOLOGY

Abbreviations

- Atrial septal defect (ASD)
- Congenital heart disease (CHD)

Definitions

- ASD: Defect(s) in cardiac atrial septum; may be isolated anomaly or associated with other congenital heart lesions
- Left-to-right (LTR) shunt: Blood from left heart bypasses systemic circulation to enter right heart
  - Most ASD sequelae are related to long-term LTR shunting

IMAGING

General Features

- Best diagnostic clue
  - Defect in atrial septum seen on any imaging modality
  - Sequelae of isolated ASD are uncommon in children
- Location
  - Patent foramen ovale: Persistence of normal fetal interatrial communication that allows flow from inferior vena cava (IVC) to largely bypass right atrium (RA) & freely enter left atrium (LA) in utero
    - Most common (25-30% of adults) but considered normal variant (not generally considered with other ASDs as flap only allows flow from right to left, not LTR shunting)
      - Only occurs with elevations in right heart pressures, typically transient phenomenon
      - Main concern in this population is stroke; questionable association with migraine headaches
  - Ostium secundum ASD (70-90% of LTR shunt ASDs): Defect of fossa ovalis due to defect of septum primum
  - Ostium primum ASD (2-3%): Simplest form of atrioventricular septal (endocardial cushion) defect (AVSD); this ASD lies between anterior/inferior portion of septum & AV valves
  - Sinus venosus ASD (4-11%): Posterior to fossa ovalis; superior-type (communication of cardiac superior vena cava (SVC) & at least 1 right pulmonary vein) > inferior-type (posterior inferior right atrial wall) defects
  - Unroofed coronary sinus (least common): Defect between LA & coronary sinus roof
- Size
  - Variable
- Morphology
  - Many ASDs are irregular or complex, not circular

Radiographic Findings

- Chest radiograph findings
  - Ostium secundum ASD
    - Small to moderate defects: Normal chest radiographs
    - Large defects: Mild cardiomegaly, normal to ↑ main pulmonary artery (PA) size, shunt vascularity
  - Ostium primum ASD or AVSD
    - Young child with cardiomegaly & ↑ pulmonary vascularity
    - Volume overload of RA, right ventricle (RV), & PA
  - Sinus venosus defect, superior type
    - Horizontal position of right upper lobe (RUL) pulmonary vein as it enters SVC
  - Adults with pulmonary hypertension
    - Classic enlarged, convex main PA with peripheral ↓ in size of vessels
    - RV enlargement
      - Upturned cardiac apex on frontal view
      - Diminished retrosternal clear space on lateral view

CT Findings

- CTA
  - Defect in atrial septum
    - Large shunt is suggested with unexpected equalization of contrast between atria during cardiac CTA with saline chaser
  - Enlargement of RA, RV, PA
  - Useful to look for associated congenital heart lesions
    - Partial anomalous pulmonary venous return (PAPVR) is associated with sinus venous ASD
  - Volumetric functional information can be obtained with retrospective gating

MR Findings

- SSFP cine
  - Shunt quantification using biventricular stroke volume ratio; net shunt volume = difference in stroke volumes
  - Interrupted septum is visible on 4-chamber views & short-axis stacks
    - Shunting blood may show signal loss (dephasing) on these bright-blood sequences
- Gradient-recalled echo cine with saturation band
  - Saturation band applied across 1 atrial chamber
  - Shunting from chamber of saturated blood (dark) into chamber of unsaturated blood (bright) reveals defect
- 1st-pass gadolinium perfusion
  - Rapid dynamic imaging can show ASD by
    - Dark (unenhanced) LA blood shunting into bright (enhanced) RA, followed by bright (enhanced) LA blood shunting into less enhanced RA
- Phase contrast velocity
  - Shunt ratio (Qp;Qs) is calculated by determining velocity & flow in ascending aorta & main PA
    - Qp;Qs of 1.5:1 is typically symptomatic
  - Also used to measure ASD flow directly
  - En face evaluation accurately depicts ASD size & shape as well as rim assessment
    - Critical parameters for assessing possibility of percutaneous closure
- MR angiography
  - Depiction of anomalous pulmonary veins

Angiographic Findings

- Utilized for transcatheter percutaneous treatment with closure device

Imaging Recommendations

- Best imaging tool
  - Primary diagnosis is made by echocardiography
  - Cardiac MR is accurate alternative for depiction of function, flow, & anatomy
  - Catheterization for percutaneous closure

DIFFERENTIAL DIAGNOSIS

Normal Chest Radiograph

- Main PA can be prominent normally, particularly between ages 8-12 years

Ventricular Septal Defect

- Small shunts have normal radiographs
- Moderate or large shunts have cardiomegaly & ↑ PA flow

Pulmonary Hypertension

- Variety of causes, mostly secondary to chronic lung disease
- Enlarged main & central PA with pruning distally, mosaic perfusion on CT

PATHOLOGY

General Features

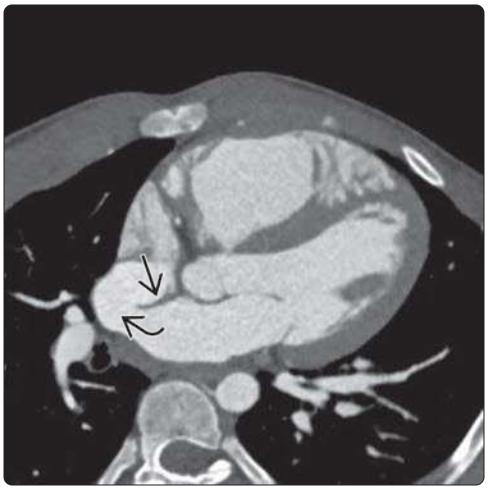
- Genetics
  - Down syndrome (trisomy 21): Up to 65% have CHD
    - Up to 45% are due to AVSD; up to 42% are due to ostium secundum ASD
  - Holt-Oram syndrome (*TBX5* gene mutation on 12q24): ASD + upper extremity anomalies
  - Various other syndromes
  - Most ASDs are sporadic
    - Mutations have been found in several genes associated with cardiac septation
- Associated abnormalities
  - Sinus venosus
    - Superior: PAPVR of RUL pulmonary vein to SVC
    - Inferior: PAPVR of right lower lobe pulmonary vein to IVC or RA
  - Ostium secundum
    - Mitral valve degeneration with regurgitation in 25%
  - Unroofed coronary sinus: Persistent left-sided SVC
- Pathophysiology: Volume overload primary issue
  - ASD: Low-pressure LTR shunt
  - VSD, AVSD: High-pressure LTR shunts
  - All eventually lead to pulmonary hypertension if untreated

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Most children with ASDs have no symptoms
    - Detected due to murmur or other medical work-up
  - Rarely present in childhood with failure to thrive, respiratory infection, tachypnea
  - Subtle symptoms are more likely in 2nd decade, though large defects frequently do not present until adulthood
    - Fatigue, exercise intolerance, syncope, shortness of breath, palpitations
  - ASD leading to severe pulmonary hypertension: Median age of detection is 51 years
  - Ostium secundum, sinus venosus: Majority of patients are asymptomatic
  - AVSD or ostium primum defects: More likely to have early symptoms
- Other signs/symptoms
  - Abnormal heart sounds
    - Crescendo-decrescendo systolic ejection murmur of 2nd left intercostal space
      - ↑ volume through pulmonic valve
    - Widely split 2nd heart sound
      - Delayed closure of pulmonic valve

Demographics



- Age
  - Congenital defect; most ASDs are asymptomatic in infancy with symptoms developing in adulthood
  - AVSD is detected prenatally or in 1st week of life
- Sex
  - Ostium secundum defects: F:M = 2:1
- Epidemiology
  - 3rd most common CHD
  - ASD: 10% of CHD in children, yet 30% of CHD in adults
  - 56-100/100,000 live births
    - True incidence may be higher as many close spontaneously (especially ostium secundum)

Treatment

- Repair indicated: Shunt ratio > 1.5:1 or defect > 10 mm
  - Repair unless child is under 2 years of age (due to rates of spontaneous closure)
- Patients with small shunts: Monitor for right heart dysfunction
- Repair is contraindicated if pulmonary hypertension has already developed
- Ostium secundum ASD
  - Spontaneous closure occurs in many children
  - If persistent, close percutaneously with catheter-placed occlusion device
  - Large defects may need patch or direct suture closure
- Ostium primum defects are not amenable to percutaneous device closure due to relationship to AV valves
  - Surgery by 3-5 years of age
- Sinus venosus defect: More complex surgical repair is required due to pulmonary vein anatomy

(Left) *Oblique axial cardiac CTA in a child shows a sinus venosus ASD with the defect in the superolateral aspect of the atrial septum.* **(Right)** *Color-coded volume-rendered 4-chamber cardiac CTA shows the sinus venosus-type defect in the superolateral aspect of the atrial septum where the blood volume in the right atrium (teal), left atrium (magenta), right ventricle (blue), & left ventricle (salmon) are also shown.*

(Left) *Right lateral view of a volume-rendered cardiac CTA shows pulmonary veins draining to the SVC, consistent with a right upper lobe partial anomalous pulmonary venous return (PAPVR) in a patient with a sinus venosus ASD. PAPVR is common in patients with this type of ASD.* **(Right)** *Axial coronary CTA shows a patent foramen ovale with a typical oblique defect & flap in the atrial septum. This is seen in 25% of the population. Note that the size of the RA is normal as left-to-right (LTR) shunting does not occur.*

(Left) *Sagittal MIP cardiac CTA in an infant shows confluence of pulmonary veins communicating with the CS, consistent with a variant of an unroofed coronary sinus type of ASD.* **(Right)** *Posterior volume-rendered cardiac CTA in an infant shows the confluence of pulmonary veins communicating with the CS, consistent with a variant of an unroofed CS type of ASD. Note also that a left SVC empties into the CS.*

Ventricular Septal Defect

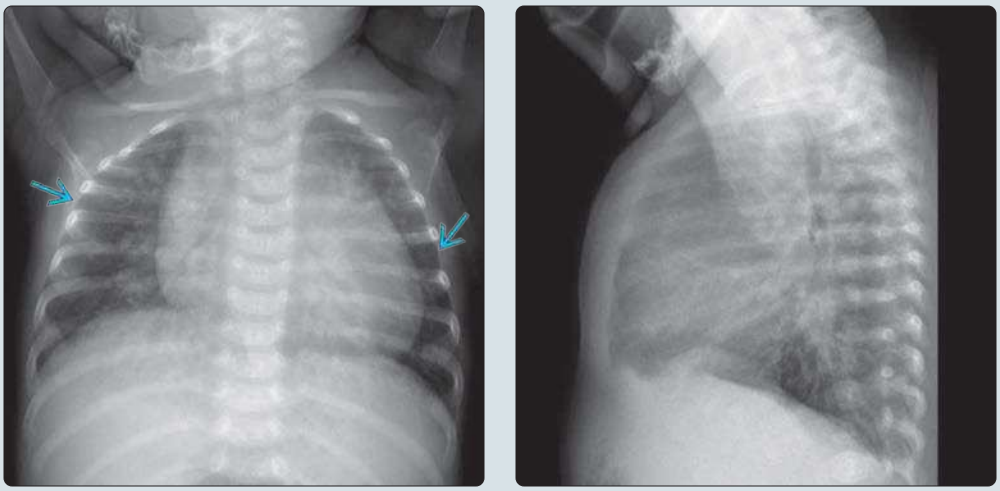
KEY FACTS

TERMINOLOGY

- Cardiac anomaly with communication(s) between left & right ventricles through septum
  - Perimembranous septal defect (80%)
  - Posterior or inlet defect associated with atrioventricular septal defect (AVSD) (8-10%)
  - Muscular or trabecular septal defect (5-10%)
  - Outlet septal defect or supracristal ventricular septal defect (VSD) (5%)
- Complex cardiac anomalies with VSD: Tetralogy of Fallot, truncus, double-outlet right ventricle (DORV)

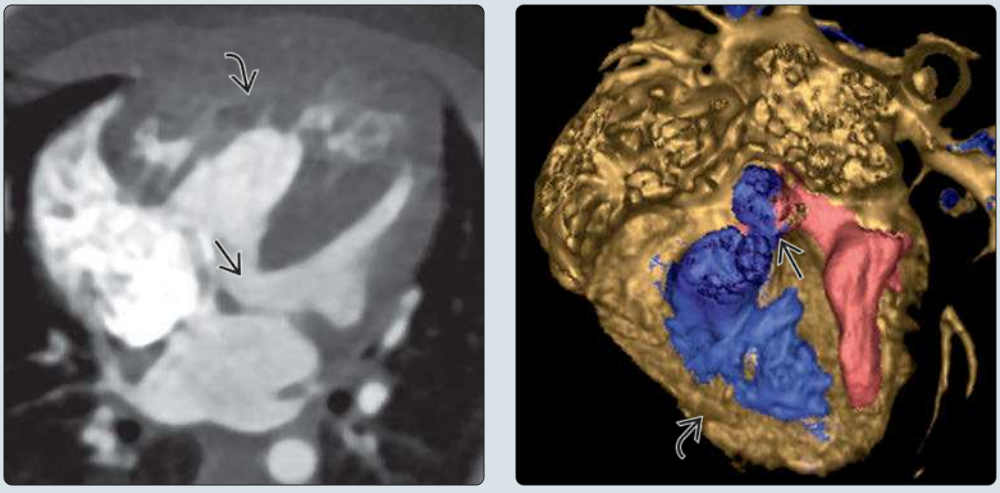
IMAGING

- Cardiomegaly with ↑ size of main pulmonary artery, ↑ pulmonary artery flow, left atrial enlargement, & usually small aorta
- Hyperinflation in large shunts from abnormal lung compliance & bronchial compression by dilated pulmonary arteries
- CT & MR delineate anatomy
  - Multiple muscular VSDs: "Swiss cheese" septum
  - Shunt volume is estimated by velocity-encoded cine MR



TOP DIFFERENTIAL DIAGNOSES

- Atrioventricular canal defects
- Patent ductus arteriosus; DORV



CLINICAL ISSUES

- Small VSD: Asymptomatic but have heart murmur
  - May close spontaneously
- Moderate or large shunts are often asymptomatic early until pulmonary vascular resistance drops
  - Children develop tachypnea, tachycardia, diaphoresis, & failure to thrive
  - Treated medically with subsequent surgical approach
    - Muscular lesions require more difficult surgical approach; VSD catheter closure devices are often used

(Left) *AP radiograph in a 2-month-old with tachypnea & poor feeding secondary to a perimembranous ventricular septal defect (VSD) shows cardiac enlargement, ↑ pulmonary vascularity, & hyperinflation with bulging of the lungs between the intercostal spaces.* **(Right)** *Lateral radiograph in the same patient redemonstrates these findings of cardiomegaly, ↑ vascularity, & hyperinflation. The hyperinflation is due to bronchial compression & poor lung compliance.*

(Left) *Axial cardiac CTA in an infant shows a perimembranous-type VSD. Note the right ventricular (RV) hypertrophy, which is due to RV compensation from ↑ left-to-right volume.* **(Right)** *Axial image color-coded surface-rendered cardiac CTA in an infant shows a perimembranous-type VSD where the RV (purple) communicates with the left ventricle (LV) (pink). Note the right ventricular hypertrophy.*

TERMINOLOGY

Abbreviations

- Ventricular septal defect (VSD)

Definitions

- Cardiac anomalies characterized by defect(s) in ventricular septum
  - Perimembranous septal defect
  - Muscular or trabecular septal defect
  - Posterior or inlet defect associated with atrioventricular septal defect (AVSD)
  - Outlet septal defect or supracristal VSD
- Complex cardiac anomalies with VSD
  - Tetralogy of Fallot, truncus arteriosus, double-outlet right ventricle
  - Associated with other congenital lesions: Coarctation, tricuspid atresia

IMAGING

General Features

- Best diagnostic clue
  - Chest radiograph with cardiomegaly (particularly left atrial enlargement) + ↑ pulmonary artery flow in small child
  - Defect in ventricular septum on any cross-sectional imaging modality
- Location
  - Membranous or perimembranous defects: 80%
    - Defects lie in outflow tract of left ventricle immediately beneath aortic valve
  - Inlet VSD: 8-10%
    - Posterior & inferior defects, beneath septal leaflet of tricuspid valve
    - Associated AVSD with usual involvement of atrioventricular valves
  - Outlet VSD occurs in 5%
    - Conal, subpulmonic, subaortic, supracristal, or infundibular
    - Malalignment defects associated with truncus arteriosus, tetralogy of Fallot, & double-outlet right ventricle
    - Supracristal defect is located about crista muscle high in ventricular outlet portion
      - May cause prolapse of aortic coronary cusp with development of aortic insufficiency & injury to aortic valve
  - Muscular or trabecular VSD occurs in 5-10%
    - Confined to muscular portion of interventricular septum
    - Central muscular, apical muscular, or marginal; may have multiple defects described as "Swiss cheese" muscular septum
- Size
  - Defects can be small, moderate, or large & involve adjacent structures

Radiographic Findings

- Small VSD
  - Normal chest radiograph does not exclude small shunt
- Moderate to large VSD
  - Cardiomegaly with ↑ size of main pulmonary artery, ↑ pulmonary artery flow, left atrial enlargement, & (usually) small aorta
    - Main pulmonary artery is high in position in infants, frequently confused with aortic knob
  - Heart failure may occur with venous edema
  - Hyperinflation is seen in large shunts due to abnormal lung compliance & possibly bronchial compression by dilated pulmonary arteries
- Supracristal VSD
  - Left-to-right shunt is usually small as anterior leaflet of aortic valve prolapses & may partially cover defect
  - May have evidence of dilated ascending aorta if aortic insufficiency is present
  - Difficult to diagnosis on chest radiographs

CT Findings

- Cardiac gated CTA
  - Delineates cardiac anatomy ± functional & volumetric evaluation
  - 3D images for planning percutaneous closure device
  - 3D printed models (made from various materials) are now occasionally used to test closure device placement before procedure
    - Simulated procedures are now performed using 3D models, virtual reality, & artificial intelligence

MR Findings

- Delineates cardiac anatomy & quantification of physiologic function
- Morphologic information is provided by ECG-gated spin-echo & cine MR imaging
- Shunt volume can be estimated by using velocity-encoded cine MR imaging
- Qp:Qs ratio (amount of blood flowing from right ventricle compared to left ventricle) may be calculated using phase-contrast imaging of right & left ventricular outflow tracts
  - Qp:Qs ratio > 1.5:1 is 1 indication for closure of VSD
- High-resolution 3D examination of vessels

Echocardiographic Findings

- Characterizes type, location, & number of septal defect(s) as well as function & hemodynamic assessment
- ECG is utilized as main diagnostic modality in infants & young children

Angiographic Findings

- Cardiac catheterization & angiography findings
  - Catheterization is utilized in complex lesions to obtain hemodynamic information & delineate anatomy

DIFFERENTIAL DIAGNOSIS

Atrioventricular Septal Defects

- Congenital defect involving atrial & ventricular septum & associated atrioventricular valves
- Chest radiograph demonstrates cardiomegaly & ↑ flow
- Presents early with clinical symptoms of large shunt
- High association with trisomy 21

Patent Ductus Arteriosus

- Persistent flow through ductus from high-pressure aorta to main pulmonary artery

- When shunt is large, chest radiograph demonstrates cardiomegaly & ↑ flow
- Presents early & has loud, continuous murmur during both systole & diastole

Double-Outlet Right Ventricle

- Both great vessels have their origins from right ventricle
- Aortic-mitral discontinuity is present with valves at similar level
- Pulmonary artery pressure is lower than systemic with significant flow into pulmonary arteries
  - Clinically & radiographically simulates large left-to-right shunt
- Complex lesion with many variants & classifications

PATHOLOGY

General Features

- Genetics
  - No specific genetic defect in majority
- Embryology
  - Complex, dependent on location of defect & associated anomalies
- Pathophysiology
  - Determinants of left-to-right shunt: Defect size, relative resistance or pressure in ventricular chambers (which may reflect systemic or pulmonary artery pressures)
  - Small defects have high resistance to flow across defect, resulting in small shunts
  - Large-sized VSDs are defined as defects that approximate size of aorta (& may have large flow)
  - ↑ flow across shunt → ↑ work of right ventricle & ↑ volume of venous return to left atrium & ventricle
  - Marked volume overload occurs → child develops tachycardia + congestive heart failure
  - Long-term ↑ in flow to pulmonary arteries is associated with vessel injury → pulmonary hypertension
    - Complex interaction between vascular endothelium & smooth muscle reaction is incompletely understood
    - May be reversible, & those with early pulmonary hypertension may need early surgical closure

CLINICAL ISSUES

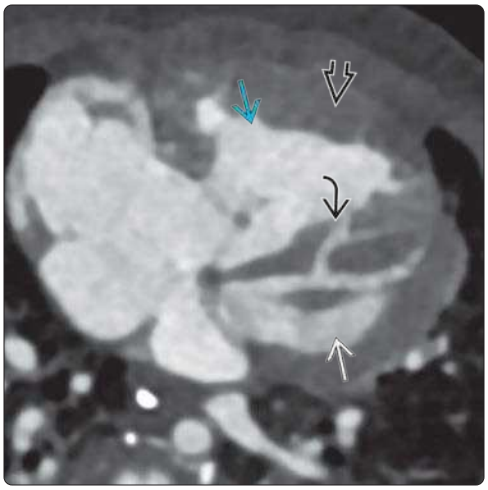
Presentation

- Most common signs/symptoms
  - Dependent on size of shunt, associated lesions, & pulmonary vascular pressure
    - Small VSD: Asymptomatic but have heart murmur
    - Moderate or large VSD: Children have tachypnea, tachycardia, diaphoresis, & failure to thrive
      - Congestive heart failure may occur
- Other signs/symptoms
  - Loud systolic murmur near left heart border

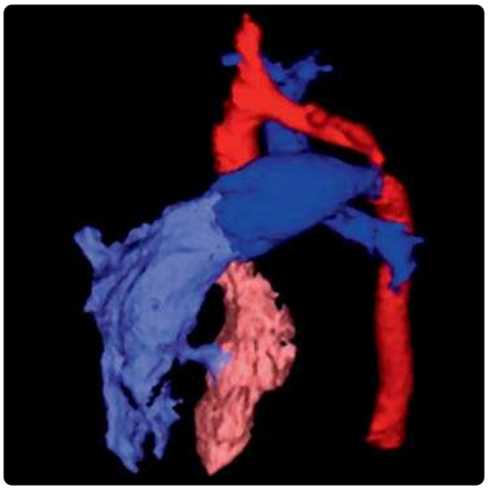
Demographics

- Age
  - Although defect is present at birth, children are not symptomatic immediately due to high pulmonary vascular resistance of newborn
  - Moderate or large shunts are usually symptomatic in 1st few months of life
- Sex
  - M = F
- Epidemiology
  - Accounts for 20% of all congenital heart lesions
  - Most common congenital lesion associated with other heart lesions

Natural History & Prognosis



- Most small muscular VSDs close spontaneously
- Untreated large shunt will develop pulmonary vascular disease
  - Reversal of shunt from right-to-left with late-onset cyanosis
- Associated cardiac anomalies determine final outcome
- Lifetime risk of bacterial endocarditis



Treatment

- Small defects may close spontaneously
  - Includes many small muscular defects
  - Aneurysm of ventricular septum may be part of spontaneous closure
- Moderate & large defects are treated medically, followed by surgical approach
  - Medical therapy with diuretics & afterload reduction
  - Many infants improve & will grow
  - Poor growth &/or congestive heart failure may be indication for early surgery
- Surgical treatment depends on site of VSD
  - Perimembranous VSD: Surgical closure of shunt lesion is usually performed with right atrial approach on bypass during 1st or 2nd year if shunt is moderate or large
  - Outlet defects (such as supracristal VSD) are closed earlier to prevent aortic sinus prolapse, injury to valve leaflet, & subsequent aortic regurgitation
  - Muscular lesions require more difficult surgical approach; VSD catheter closure devices are often used

(Left) *Axial cardiac CTA in a newborn shows an intramuscular-type VSD between the RV & LV. Note the significant RV hypertrophy.* **(Right)** *Lateral color-coded 3D reconstruction of a cardiac CTA shows a single intramuscular-type VSD between the RV (purple) & LV (pink). Note that there is only mild enlargement of the RV (purple) as the Qp:Qs ratio was only 1.2:1.*

(Left) *Oblique axial cardiac CTA shows a Swiss cheese appearance of the interventricular septum near the apex in this patient with multiple muscular-type VSDs. Note the normal position of the septum.* **(Right)** *Three-chamber view from a cine SSFP cardiac MR shows an aneurysm of the membranous ventricular septum protruding into the RV. This likely represents the spontaneous membranous closure of a previously patent VSD. This anomaly may cause RV outflow tract obstruction.*

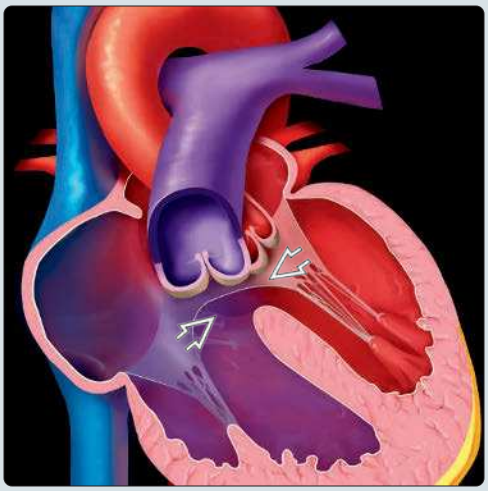
(Left) *Axial cardiac CTA in a Down syndrome patient shows a posterior-type VSD. Note the septum primum atrial septal defect (ASD) in a patient with a complete atrioventricular (AV) canal defect & common AV valve.* **(Right)** *Left lateral view from a color-coded 3D CTA in an infant shows a large posterior VSD typical of patients with AV canal defect.*

Atrioventricular Septal Defect

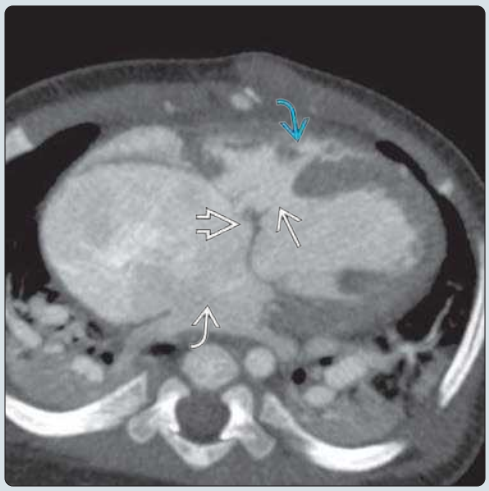
KEY FACTS

TERMINOLOGY

- Atrioventricular septal defect: a.k.a. complete atrioventricular canal (AVC) defect, endocardial cushion defect
- Broad spectrum of defects characterized by involvement of atrial septum, ventricular septum, & 1 or both atrioventricular (AV) valves
- Ostium primum defect: Considered partial AVC defect or partial AV septal defect

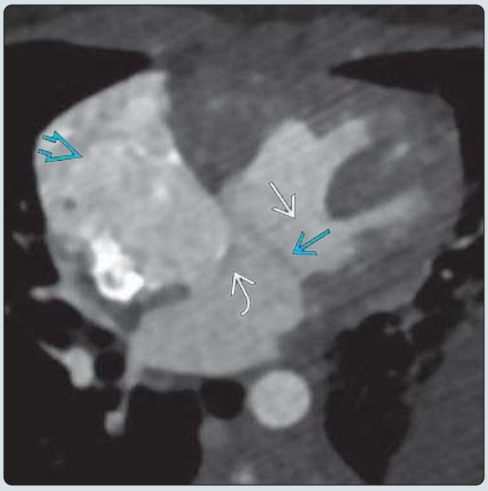


IMAGING

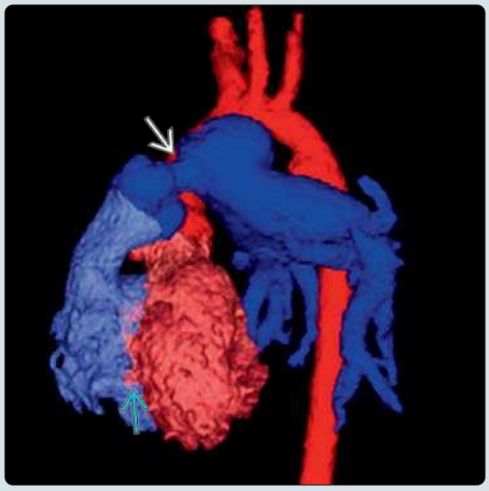


- Large right atrium, right ventricle, pulmonary artery with ↑ pulmonary artery flow
- Large defect in anterioinferior portion of atrial septum (ostium primum defect)
- Large defect in ventricular septum (posterior type is most common)
- Anterior & superior aortic position with elongation + dysplastic common 5-leaflet AV valve narrowing subvalvular LVOT → "gooseneck" deformity on angiography
- When AV valve opens toward 1 ventricle → unbalanced canal defect (right ventricular or left ventricular dominance can occur with single ventricle physiology)
- Mitral insufficiency may occur both pre- & postoperatively

CLINICAL ISSUES



- Associated with trisomy 21 in 44-48%
- Large shunts present early with tachypnea, tachycardia, & failure to thrive
- Small shunts may be well tolerated through 1st decade; children may be asymptomatic
- Single ventricle physiology may necessitate staged procedure, such as Glenn & then Fontan for unbalanced AVC
- Partial AVC is closed by pericardial patch via right atrial approach



(Left) *Graphic shows a defect in the atrioventricular (AV) septum connecting the right atrium & right ventricle to the left atrium & left ventricle.* **(Right)** *Axial cardiac CTA shows an AV septal defect (AVSD). There is a common dysplastic AV valve with an inlet-type ventricular septal defect (VSD) & a septum primum atrial septal defect (ASD). Note the enlargement of the right atrium & the small right ventricle in this unbalanced AV canal defect.*

(Left) *Axial cardiac CTA in an infant with Down syndrome shows a large VSD, septum primum ASD, & common AV valve, consistent with an AVSD. Note the large right atrium.* **(Right)** *Lateral color-coded cardiac CTA shows a large posterior-type VSD in a patient with AVSD. Postoperative changes are seen from pulmonary banding to limit pulmonary flow.*

TERMINOLOGY

Abbreviations

- Atrioventricular septal defect (AVSD)

Synonyms

- AVSD
  - Atrioventricular canal (AVC) defect
  - Endocardial cushion defect
  - Complete AVC defect
- Ostium primum defect
  - Partial AVC defect
  - Partial AVSD
  - Incomplete endocardial cushion defect

Definitions

- Broad spectrum of defects characterized by involvement of atrial septum, ventricular septum, & 1 or both AV valves
  - Complete AVSD indicates presence of both atrial & ventricular septal defects with common AV valve
  - Partial AVSD indicates atrial septal involvement with separate mitral & tricuspid valve orifices
  - Unbalanced AVSD indicates 1 ventricular chamber is hypoplastic as compared to other, depending on direction of AV valve flow

IMAGING

General Features

- Best diagnostic clue
  - Chest radiograph
    - Large heart with large main pulmonary artery & ↑ pulmonary artery flow
    - Serial radiographs to evaluate for pulmonary hypertension
    - Mitral insufficiency may occur both pre- & postoperatively
      - When mitral insufficiency is severe, left atrium can be large & cause left lower lobe collapse
    - Children with large shunts have ↑ incidence of upper respiratory infections & pneumonia
    - Pulmonary hypertension patients have abnormal lung compliance: Lungs are often hyperinflated with eversion of hemidiaphragms
- Location
  - Complete AVC
    - Large defect in anterioinferior portion of atrial septum (ostium primum defect)
    - Large defect in ventricular septum (posterior type is most common)
    - Common AV valve with variable chordal attachments to ventricle
    - When AV valve opens toward 1 ventricle → unbalanced canal defect
    - Right ventricular or left ventricular dominance can occur with single ventricle physiology (or unbalanced defect)
    - Hypoplasia of inlet & outlet septum → hypoplasia of chamber with malalignment of ventricular septum
  - Ostium primum defect
    - Defect in anterioinferior aspect of atrial septum
    - ± coexistent cleft in anterior leaflet of mitral valve
    - 5-leaflet AV valve is present with separate valve orifices to right & left ventricles
- Size
  - Broad spectrum of size of defects in AV septum & respective sizes of ventricles

Echocardiographic Findings

- Echocardiogram
  - Defines lesion in infants & young children
    - Primum defects have echo dropout in lower portion of septum, cleft in mitral valve
    - Anterior & superior displacement of aorta with elongation & narrowing of left ventricular outflow tract (LVOT)
    - 3D echocardiography can better define anatomy of valve
- Color Doppler
  - Demonstration of left-to-right shunt, severity of mitral regurgitation, & tricuspid regurgitation
    - LVOT obstruction can be quantified

CT Findings

- CECT
  - Noninvasive alternative to further depict anatomy, chamber volumes, & function
  - Large right atrium, right ventricle, & pulmonary artery

MR Findings

- Excellent noninvasive alternative for depiction of function & anatomy
- Best imaging modality for calculating complex regurgitation across common AV valve
- Most accurate assessment of ventricular hypoplasia
- Qp:Qs ratio is calculated from velocity-encoded cine MR technique

Angiographic Findings

- Conventional
  - Cardiac catheterization is not usually done to evaluate anatomy but to measure pulmonary vascular resistance
    - Left ventriculogram shows cleft in mitral valve, shunts, respective sizes of ventricles, & LVOT obstruction
    - Classic "gooseneck" deformity seen on frontal projection of left ventricular angiocardiogram
      - Dysplastic common AV valve narrows subvalvular LVOT

Imaging Recommendations

- Best imaging tool
  - Echocardiography in infants & young children: Defines lesion
    - Primum defects have echo dropout in lower portion of septum, mitral valve cleft
    - Complete AVSD demonstrates varying degrees of absence of septum, size of defect, & relative size of ventricles
- 3D CT & MR reconstructions: Useful for demonstrating complex global, coronary, & extracardiac anatomy for presurgical planning

DIFFERENTIAL DIAGNOSIS

Ventricular Septal Defect

- Most common congenital heart disease (CHD) with left-to-right shunt
- Most common CHD associated with other lesions
- Cardiac enlargement with ↑ pulmonary flow

Atrial Septal Defect

- Defect in superior portion of atrial septum
- Presents in older children who are usually asymptomatic from shunt
- Left-to-right shunt is usually not large but can cause Eisenmenger physiology in adult if unrecognized

Patent Ductus Arteriosus

- Communication between high-pressure aorta & lower pressure pulmonary artery
- Left-to-right shunt usually presents in infancy
- Closed by percutaneous occlusion devices

PATHOLOGY

General Features

- Etiology
  - Malformation occurring during 5th week of gestation
  - Abnormal or inadequate fusion of superior & inferior endocardial cushion
  - Abnormal fusion of ventricular (trabecular) portion of septum
  - Iatrogenic AVSD has been described
- Genetics
  - Associated with trisomy 21 in 44-48%
- Associated abnormalities
  - Trisomy 21 children have constellation of clinical & radiographic findings
    - Chest radiograph may show 11 ribs, double manubrial ossification center in 80%
  - Heterotaxy
  - Tetralogy of Fallot

CLINICAL ISSUES

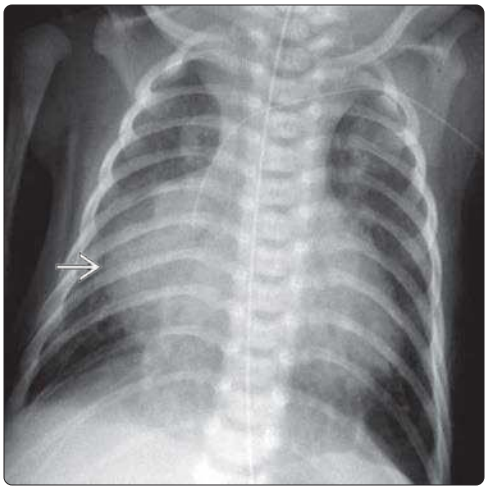
Presentation

- Most common signs/symptoms
  - Complete AVSD
    - Large shunts present early with tachypnea, tachycardia, & failure to thrive
    - Mitral insufficiency adds complexity & earlier symptoms
  - Partial AVSD
    - Small shunts may be well tolerated through 1st decade, children may be asymptomatic
    - Mitral insufficiency adds complexity & earlier symptoms
- Other signs/symptoms
  - Pathophysiology of lesions
    - Degree of left-to-right shunting is determined by size of defect & relative compliance of atria & ventricles
    - Right ventricular compliance reflects pulmonary vascular resistance
    - Infants have ↑ pulmonary vascular resistance & therefore rarely have shunts
    - As pulmonary vascular resistance ↓, left-to-right shunting ↑ with age
    - Subsequent enlargement of right atrium & right ventricle & ↑ in pulmonary vascularity
    - Cleft directs regurgitant blood through atrial defect

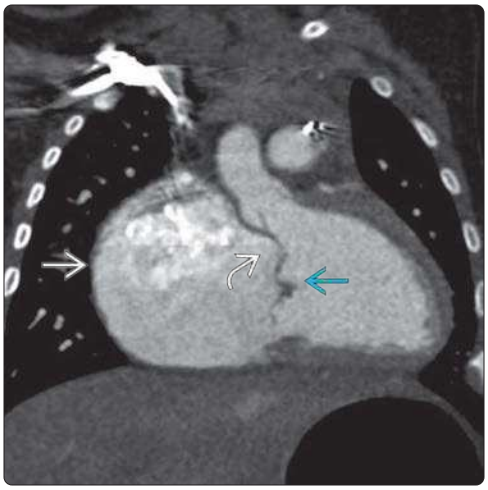
Demographics

- Epidemiology
  - 4-8:1,000 live births have congenital heart defects
  - 5-8% have AVSD
  - 44-48% of patients with Down syndrome or trisomy 21 have AVC defect

Natural History & Prognosis



- Complete AVC defect presents in infancy with symptoms
- Children assessed for surgical repair
  - Postoperative course may be complicated by mitral insufficiency
  - Pulmonary hypertension occurs in children without surgical intervention



Treatment

- Medical management until surgery (depending on lesion & severity)
- Surgical management: Partial AVSD
  - Closed by pericardial patch via right atrial approach
  - Percutaneous closure devices are not typically deployed as inferior attachment may injure AV valves
- Surgical management: Complete AVSD (mortality rate: 3%)
  - Elective repair in children 2-5 years of age unless mitral regurgitation is present
  - Complications include mitral insufficiency (which may require reoperation, valvuloplasty, or replacement)
  - Arrhythmias, such as sinus node dysfunction or heart block
- Surgical management: Complete unbalanced AVSD
  - Single ventricle physiology may necessitate staged procedure, such as Glenn & then Fontan

(Left) *Frontal chest radiograph in a 2-month-old with Down syndrome shows cardiomegaly, ↑ pulmonary vascularity, & venous congestion. Note the massive enlargement of the right atrium. (Right) Coronal CTA shows the dysplastic common AV valve narrowing the subvalvular left ventricular outflow tract (LVOT). This is the cause of the "gooseneck" deformity seen on conventional angiography in patients with AVSD. Note the enlarged right atrium.*

(Left) *Four-chamber cardiac CTA in an infant demonstrates an ostium primum defect in the atrial septum with a common AV valve. There is also a defect in the ventricular septum in this patient with an AVSD.* **(Right)** *Four-chamber 3D color-coded CTA in an infant with an AVSD demonstrates an ostium primum ASD in the atrial septum with a large defect in the ventricular septum . Note the marked thickening of the right ventricle wall.*

(Left) *Four-chamber view echocardiogram shows echo dropout in the inferior portion of the atrial septum, which is characteristic of a primum ASD. Note the intact portion of the atrial septum.* **(Right)** *Left ventricular angiogram shows a typical "gooseneck" deformity of the LVOT in a patient with AVSD. Subvalvular narrowing of the LVOT is due to the enlarged common AV valve.*

Patent Ductus Arteriosus

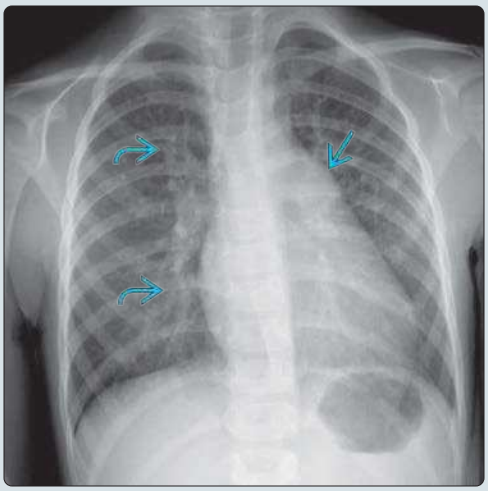
KEY FACTS

TERMINOLOGY

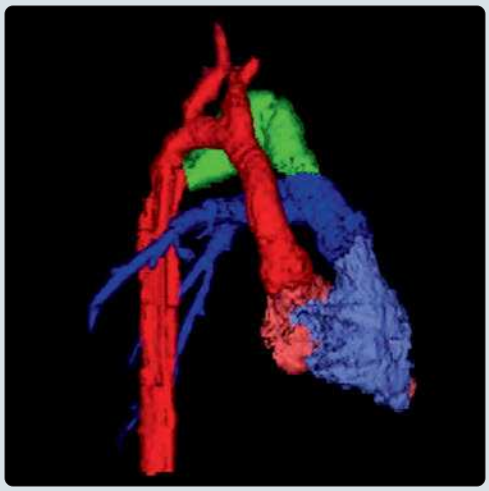
- Persistent postnatal patency of normal prenatal connection from PA to proximal descending aorta
- Hemodynamics: L-to-R shunt between aorta & PA
- PDA is frequently essential in complex congenital heart disease: L-to-R or R-to-L flow, depending on other anomalies
- PDA in persistent fetal circulation syndrome: R-to-L flow

IMAGING

- Well demonstrated by CTA & MRA: Usually linear, directed anterior to posterior, of variable size
- PDA may be tortuous vessel connecting aorta &/or innominate artery with PA
- CTA is modality of choice for showing airway compression from tortuous PDA or vascular ring

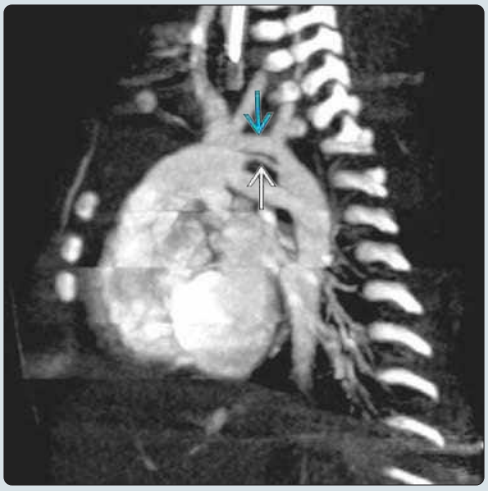


PATHOLOGY

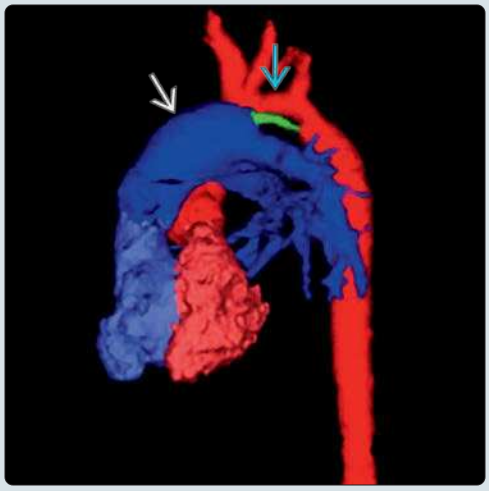


- With normal drop of pulmonary vascular resistance, L-to-R shunt to PA through PDA: Volume overload of left-sided cardiac chambers
  - Diastolic flow reversal in aorta can lead to renal & intestinal hypoperfusion → renal dysfunction & necrotizing enterocolitis
  - Pressure overload of RV eventually causes reversal of shunt (R-to-L) → cyanosis (Eisenmenger physiology)
- When closed: Forms ligamentum arteriosum, ± Ca^{2+}
- In right arch, aberrant left subclavian artery ductus completes vascular ring

CLINICAL ISSUES



- To close ductus in premature infants: Indomethacin
- To keep ductus open in cyanotic heart disease: Prostaglandin E1
- Term infants, older children: Surgical clipping or ligation vs. endovascular closure with duct occluder devices &/or coils



(Left) *Frontal view of the chest in an 8-year-old patient with a persistent patent ductus arteriosus (PDA) shows ↑ (shunt) vascularity with prominence of the pulmonary artery (PA). Chronic PDA can cause Eisenmenger syndrome.* **(Right)** *Frontal oblique 3D color-coded cardiac CTA shows a massively enlarged PDA (green) coursing between the main PA (blue) & the descending aorta (red). Note that the PDA can be larger than the aortic arch.*

(Left) *Oblique MIP cardiac CTA shows a small PDA connecting the aorta to the main PA. Note that the transverse aortic arch is mildly hypoplastic. A PDA is commonly seen in association with a left ventricular outflow tract obstruction.* **(Right)** *Oblique 3D color-coded cardiac CTA in the same patient shows a PDA (green) with a mildly hypoplastic aorta. Compare this with the previous MIP image. Note the enlarged size of the main PA caused by ↑ L-to-R shunting.*

TERMINOLOGY

Abbreviations

- Patent ductus arteriosus (PDA)

Synonyms

- Persistent arterial duct, patent ductus Botalli

Definitions

- Persistent postnatal patency of normal prenatal connection from pulmonary artery (PA) to proximal descending aorta
- Category: Acyanotic, ↑ pulmonary blood flow
- Hemodynamics: Left-to-right shunt between aorta & PA
- PDA is frequently essential part of complex congenital heart disease
  - Typical ductal-dependent lesions, including hypoplastic left heart syndrome, severe hypoplastic-type coarctation, & interruption of aortic arch: Conduit for systemic perfusion (right-to-left flow)
  - D-transposition of great arteries: Necessary for admixture between systemic & pulmonary circuits (left-to-right flow)
  - Pulmonary atresia & other severe cyanotic heart diseases with right-sided obstruction: Conduit for pulmonary perfusion (left-to-right flow)
- PDA is part of persistent fetal circulation syndrome: Right-to-left flow
  - Severe lung disease (meconium aspiration, surfactant deficiency disease, neonatal pneumonia)
  - Primary pulmonary hypertension of neonate

IMAGING

General Features

- Best diagnostic clue
  - Cardiomegaly & heart failure once pulmonary vascular resistance drops in premature infant recovering from surfactant deficiency disease

Radiographic Findings

- Cardiomegaly (left atrium & left ventricle)
- ↑ pulmonary vascularity
- Wide vascular pedicle (large aortic arch with ductus bump)

CT Findings

- CTA
  - Volume renditions of aortic arch depict PDA with associated complex anatomy
  - Excellent modality for sizing of ductus prior to cardiac catheterization for placement of occluder device or prior to stenting in hybrid procedure
  - Modality of choice for showing airway compression from tortuous PDA or vascular ring
  - Valve-like structure is often identified at PA side of PDA that should not be mistaken for endarteritis

MR Findings

- SSFP bright blood cine
  - Functional right ventricular assessment in cases with Eisenmenger pulmonary hypertension
  - Dephasing artifact is depicted in direction of PDA flow
- Double inversion recovery (black blood) sequence
  - Sagittal oblique plane through aortic arch depicts ductus
- 3D gadolinium MRA with volume rendition to depict anatomy
- Velocity-encoded cine sequences are used to calculate Qp:Qs ratio
  - Closure is usually indicated for Qp:Qs ratio > 1.7

Echocardiographic Findings

- Echocardiogram
  - Suprasternal notch view: Direct visualization of ductus
  - Size & flow across ductus in early infancy have been shown to correlate with prognosis of chronic lung disease in premature infants
- M-mode
  - ↑ left atrium:aorta ratio (> 1.2:1)
- Pulsed Doppler
  - Diastolic flow reversal in descending & abdominal aorta (ductus steal)
  - Flow acceleration across constricting ductus: Transductal velocity ratio
- Color Doppler
  - For flow direction through ductus

Angiographic Findings

- Conventional
  - Cardiac catheterization is only needed for associated complex cyanotic heart disease & to determine reversibility of pulmonary hypertension
  - Placement of PDA closure device

Imaging Recommendations

- Protocol advice
  - Treatment decisions are based only on echocardiographic findings in majority of cases
  - CTA is recommended for complex anatomy with airway compression

DIFFERENTIAL DIAGNOSIS

Other Causes of Left-to-Right Shunting

- Atrial & ventricular septal defects
- Atrioventricular canal

Persistent Fetal Circulation Syndrome

- Pulmonary hypertension (primary or secondary to severe lung disease)
- Patent foramen ovale
- PDA secondary to profound irreversible hypoxia

PATHOLOGY

General Features

- Etiology
  - Prematurity: Persistent postnatal hypoxia → failure of contraction of ductus
  - Term infant: Associated with maternal rubella
- Genetics
  - No specific genetic defect is identified in most cases of isolated PDA
- Embryology
  - Ductus originates from primitive 6th aortic arch
- Pathophysiology (for simple PDA)
  - PDA is persistence of normal prenatal structure after birth

- In normal neonate, ductus arteriosus closes functionally 18-24 hours after birth, anatomically at 1 month of age
- With normal drop of pulmonary vascular resistance, left-to-right shunt occurs to PA through PDA → volume overload of left-sided cardiac chambers
- With pulmonary hypertension, pressure overload of right ventricle causes reversal of shunt (right-to-left) → cyanosis (Eisenmenger physiology)
- Diastolic flow reversal in aorta can lead to renal & intestinal hypoperfusion → renal dysfunction & necrotizing enterocolitis

Gross Pathologic & Surgical Features

- PDA is usually wider on aortic side
  - Length: 2-8 mm; diameter: 4-12 mm
  - Makes acute angle with aorta in simple PDA, blunt angle with associated congenital heart disease
- Contractile tissue is mainly on pulmonary side: Spirally arranged muscle bundles in media
  - Prostaglandin E1 (present in fetal life) maintains relaxation
  - ↑ oxygen pressure causes constriction
- Thickening of intima with mucoid degeneration
- When closed, arterial duct forms ligamentum arteriosum
- Calcified ligamentum arteriosum is often incidentally seen on radiograph or CT
- Can be right-sided & originate from base of brachiocephalic artery or from aberrant right subclavian artery
- In right arch with aberrant left subclavian artery anatomy, ductus completes vascular ring
- Rarely ducti may be bilateral with right ductus typically originating from right brachiocephalic or subclavian & left ductus originating from undersurface of aorta
  - Double ducti anatomy may be reversed with situs anomalies
  - Spontaneous closure of ductus may help differentiate from aortopulmonary collaterals

CLINICAL ISSUES

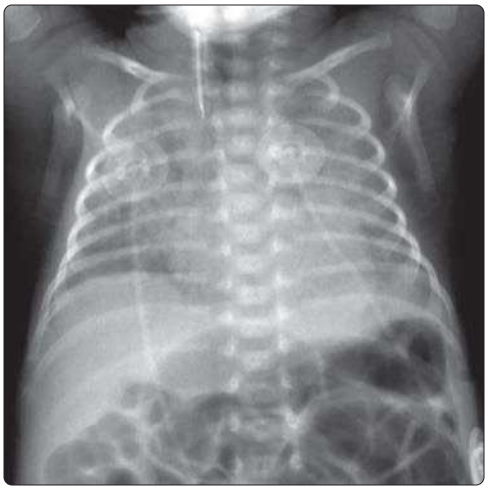
Presentation

- Most common signs/symptoms
  - Characteristic machinery-like murmur
  - Bounding peripheral pulses
  - Congestive heart failure
  - Special situation: Premature infant recovering from surfactant deficiency disease
    - ↓ in hypoxia → ↓ in pulmonary vascular resistance → ↑ shunt flow through ductus arteriosus → clinical & radiographic signs of congestive heart failure (cardiomegaly, pulmonary edema)
- Other signs/symptoms
  - Subacute bacterial endocarditis
    - Need for treatment of clinically "silent" PDA (incidentally detected with echocardiography) controversial
  - Ductal aneurysm
    - Can result from premature narrowing of ductus on pulmonary side

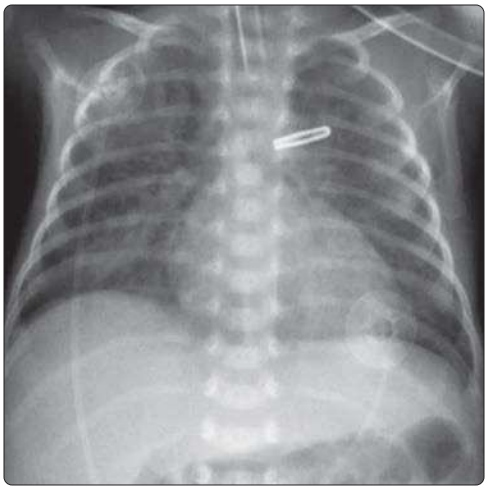
Demographics

- Epidemiology
  - 10-12% of congenital heart disease
  - 1/2,500-5,000 live births
  - Slightly more common in female patients
  - Associated with prematurity (21-35%)

Natural History & Prognosis



- Isolated PDA: Excellent prognosis with early closure
- When associated with complex heart disease, prognosis determined by underlying disorder
- Irreversible pulmonary hypertension (Eisenmenger physiology) → shunt reversal & development of cyanosis
- Persistent fetal circulation, pulmonary hypertension: Treatment with extracorporeal membrane oxygenation often necessary to disrupt vicious cycle
  - Hypoxia → pulmonary vasoconstriction → ↓ pulmonary flow → more severe hypoxia



Treatment

- To close ductus in premature infants: Indomethacin
  - Side effects: Renal failure, intestinal perforation, intracranial hemorrhage
- To keep ductus open (cyanotic heart disease): Prostaglandin E1
- Term infants, older children: Surgical clipping, ligation, or device closure of PDA
  - Can be performed at bedside under video-assisted thoracoscopic &/or robotic guidance
  - Complications: Inadvertent ligation of aortic isthmus or PA, recurrent laryngeal nerve injury
- Endovascular closure with duct occluder devices &/or coils
  - Small ductus (< 4 mm): Gianturco coils
  - Large ductus (> 4 mm): Ivalon plug, Rashkind & Amplatz duct occluders
  - Complications: Protrusion of occluder device into left PA orifice → ↓ left lung perfusion, peripheral embolization
  - Incomplete closure in 10-20%

(Left) *AP chest radiograph in a 7-day-old premature infant shows diffuse, bilateral, hazy opacification of the lungs. An echocardiogram showed a PDA with left-to-right flow.* **(Right)** *AP view of the chest in the same patient shows a surgical clip from interval ligation of a PDA with ↑ aeration of the lungs & ↓ pulmonary edema.*

(Left) *Axial MIP CTA shows a right aortic arch ⇨ with an aberrant left subclavian artery ⇨ & small PDA ⇨. Note that the small PDA completes the vascular ring around the trachea ⇨.* **(Right)** *Posterior 3D color-coded cardiac CTA shows a PDA (green) arising from the ductus bump ⇨ along the descending aorta & extending to the main PA (blue). The small PDA completes the vascular ring in this patient with a right arch. Note the impression on the esophagus (light green) at the level of the PDA.*

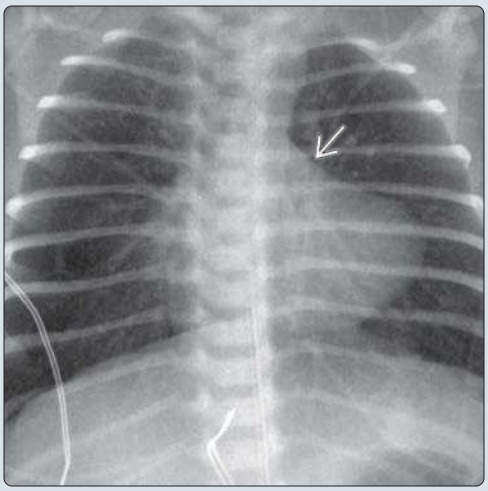
(Left) *Axial MIP cardiac CTA shows a hypoplastic aortic arch ⇨ with an enlarged PDA ⇨ connecting the PA ⇨ to the descending thoracic aorta ⇨. This constitutes a ductal-dependent lesion as the flow through the aorta is inadequate.* **(Right)** *Left posterior 3D color-coded cardiac CTA shows a hypoplastic aortic arch ⇨ with an enlarged PDA ⇨ connecting the PA ⇨ to the descending thoracic aorta ⇨. Note that there is also a focal coarctation ⇨ in this ductal-dependent lesion.*

Tetralogy of Fallot

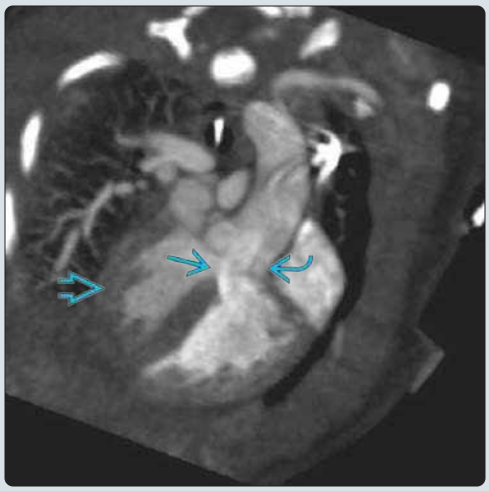
KEY FACTS

TERMINOLOGY

- Most common cyanotic congenital heart lesion
- Tetralogy: 4 heart defects from embryologic anterocephalad deviation of conoventricular septum
  - Infundibular or subpulmonary narrowing
  - Anterior malalignment ventricular septal defect (VSD)
  - Aorta overriding VSD
  - Secondary right ventricular hypertrophy (RVH)
- Spectrum of tetralogy of Fallot disease
  - "Blue tet": More subpulmonary obstruction → VSD shunts right-to-left → cyanotic appearance
  - "Pink tet": Less subpulmonary obstruction → VSD shunts left-to-right (normal) → acyanotic appearance
  - Tetralogy with pulmonary atresia & major aortopulmonary collaterals: Severe congenital heart disease
  - Tetralogy with absent pulmonary valve: To-&-fro flow in pulmonary artery (PA) leading to massively dilated branch PAs, tracheobronchial compression

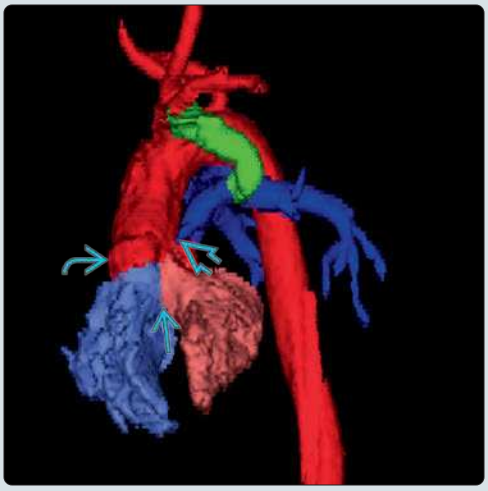


IMAGING

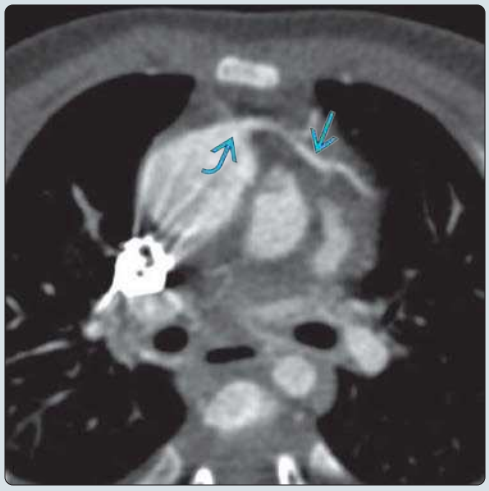


- Radiography: Normal heart size, concave PA segment, ↓ pulmonary vascularity (oligemia)
  - RVH → upturned cardiac apex → boot-shaped heart
  - Right-sided aortic arch in 25%
- Echocardiography: Initial diagnosis, often prenatal
  - Coronary artery anomalies are important for surgical planning: Left anterior descending artery arising from right coronary & crossing RVOT (4%)
- Cardiac MR: Becoming gold standard for postoperative assessment; critical biomarker data for timing of pulmonary valve replacement (PVR)

CLINICAL ISSUES



- Typical repair within 1st year to life: VSD closure, relieve RVOT obstruction (transannular patch)
- Significant PR → RV chamber dilation over time: ↓ exercise tolerance, RV dysfunction, ventricular arrhythmias
- PVR is utilized to prevent progressive RV dilation



(Left) *AP radiograph shows the classic appearance of tetralogy of Fallot (TOF) with a concave pulmonary artery (PA) segment & an upturned cardiac apex creating the "coeur en sabot" (boot-shaped heart) appearance. Note the pulmonary oligemia.* **(Right)** *LVOT MIP cardiac CTA in a patient with TOF shows a ventricular septal defect (VSD) with right ventricular (RV) hypertrophy & an overriding aorta (as the aorta "overrides the VSD").*

(Left) *Color-coded 3D surface-rendered cardiac CTA in an infant with TOF shows a prominent subaortic VSD with an overriding aorta & complete pulmonic atresia. Note the enlarged PDA (green), which provides flow to the PAs (blue).* **(Right)** *Axial cardiac CTA in a patient with TOF shows a prepulmonic left coronary artery arising from the right coronary sinus. This is critical information for presurgical planning to prevent sacrifice of the left coronary when placing a pulmonary valve homograft.*

TERMINOLOGY

Definitions

- Tetralogy of Fallot (TOF): 4 heart defects in combination
  - Obstruction to pulmonary outflow via infundibular right ventricular outflow tract (RVOT) narrowing or pulmonary valve stenosis
  - Secondary RV hypertrophy (RVH) from ↑ right ventricle (RV) pressures/fixed subpulmonary obstruction
  - Anterior malalignment ventricular septal defect (VSD)
  - Aorta overriding VSD
- Category: Cyanotic, normal heart size, ↓ pulmonary vascularity
  - Most common cyanotic congenital heart lesion
- Hemodynamics: Obstruction to pulmonary blood flow via infundibular narrowing by anterior deviation of subpulmonary conal septum
  - Spectrum: Classic "blue tet," "pink tet," TOF with pulmonary atresia & major aortopulmonary collaterals (MAPCAs), TOF with absent pulmonary valve

IMAGING

General Features

- Best diagnostic clue
  - Anterocephalad deviation of subpulmonary conoventricular septum → 4 characteristic heart defects
  - Aorta overriding large anterior malalignment VSD

Radiographic Findings

- RVH + concave pulmonary artery (PA) segment: Boot-shaped heart ("coeur en sabot")
  - RVH rotates heart, creating rounded, upturned apex
- ↓ pulmonary vascularity (oligemia) due to obstruction of pulmonary blood flow
- Normal heart size at birth
- Right-sided aortic arch (25%)

CT Findings

- CTA
  - Preoperative: Multidetector CT can diagnose coronary anomalies, obviating need for angiography
  - Postoperative: Cardiac gated cine CT can perform
    - Assessment of RV volumes & function in patients with contraindication for MR
    - CTA is also less affected by metal artifact than MR (to assess results of interventions, e.g., stents, coils)

MR Findings

- T1WI
  - Cardiac gated axial images for preoperative definition of PA anatomy, PA stenosis
  - Postoperative PA anatomy, patency of Blalock-Taussig (BT) shunts assessed by presence of flow void
- T2* GRE
  - Short-axis SSFP cine bright blood MR for RV & left ventricular (LV) volumes, ejection fraction (EF), pulmonary regurgitant fraction, branch PA differential flow
    - Functional MR: Biventricular response to exercise & recovery
    - Presence of RVOT akinesia/aneurysm & wide anulus correlates with need for pulmonary valve replacement (PVR)
- MRA
  - Gadolinium-enhanced MRA: Depiction of PA anatomy & aortopulmonary collaterals
  - Phase contrast assists with estimating RV EF & pulmonary regurgitation

Echocardiographic Findings

- Location of VSD, additional muscular VSDs
- Degree of aortic override, position of arch
- RVOT obstruction, pulmonary valve morphology
- Branch PA anatomy
- Coronary artery origin & proximal courses

Imaging Recommendations

- Best imaging tool
  - Initial diagnosis with pre- & postnatal echocardiography
- Protocol advice
  - MRA/3D whole-heart sequence or CTA for detailed PA & coronary anatomy
  - Cardiac catheterization for coronary anatomy & percutaneous interventions (RVOT or ductal stent as initial palliative procedure)
  - MR in older child/young adult with poor acoustic echocardiography windows; becoming gold standard for functional assessment of postoperative regurgitation & ventricular dysfunction prior to PVR

DIFFERENTIAL DIAGNOSIS

Double-Outlet Right Ventricle With Normally Related Great Vessels, Subaortic Ventricular Septal Defect, & Pulmonary Stenosis

- Defined as both outlets (aorta & PA) arising from RV
- Can be difficult to differentiate from TOF; therefore, secondary characteristics are often employed
  - > 50% aortic override of VSD
  - Bilateral subarterial conal septum leading to mitral-aortic fibrous discontinuity

Pulmonary Atresia With Intact Ventricular Septum

- Massive cardiomegaly with right atrial enlargement at birth

Pulmonary Valve Stenosis & Perimembranous Ventricular Septal Defect

- Significant pulmonary valve stenosis with VSD should be evaluated for conal septal deviation

Tricuspid Atresia With Normally Related Great Vessels, Subpulmonary Obstruction

- Large right atrium with obligate right-to-left atrial level shunt; subpulmonary obstruction through restricted VSD

PATHOLOGY

General Features

- Genetics
  - Chromosomal anomalies in 11% (chromosome 22)
  - Other congenital anomalies in 16%; 8% are syndromic
- Associated abnormalities
  - PA branch stenosis or hypoplasia

- Absence of pulmonary valve: Severe pulmonary regurgitation → aneurysmal dilation of PAs → tracheobronchomalacia & compression
- Pulmonary atresia & MAPCAs
  - Extreme end of TOF spectrum; severe congenital heart disease with often poor prognosis
- Patent foramen ovale vs. secundum atrial septal defect
- Right aortic arch, mirror image branching (25%)
- Coronary anomalies: Left anterior descending arising from right coronary & crossing RVOT (4%) with implications for surgical repair

- Pathophysiology: Balance between RVOT obstruction & VSD determines shunt direction
  - Classic TOF: Right-to-left shunting, ↓ pulmonary flow, cyanosis
  - "Pink" TOF: Left-to-right shunting, normal to ↑ pulmonary flow, congestive heart failure
- Embryology
  - Abnormal bulbotruncal rotation & septation
  - Primary hypoplasia of infundibular septum

Gross Pathologic & Surgical Features

- Anterior/cephalad deviation of infundibular septum, hypertrophic outlet septum, & anterior muscle bands
- Hypoplastic pulmonary valve anulus with deformed & stenosed, often bicuspid, pulmonary valve
- Large perimembranous subaortic VSD with aortic override of 15-95%

CLINICAL ISSUES

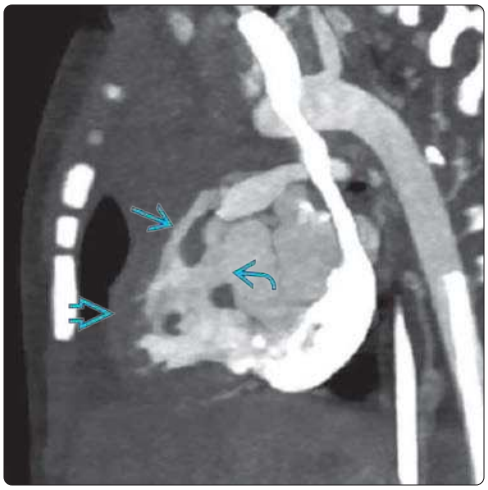
Presentation

- Most common signs/symptoms
  - Varying degrees of cyanosis at birth (most often apparent by 3 months)
  - Older child: Cyanotic spells, relieved by squatting
  - Congestive heart failure (large VSD)
- Other signs/symptoms
  - After repair: ↓ exercise tolerance, RV dysfunction
  - Severe arrhythmias, which may be fatal
    - RV chamber dilation from postoperative pulmonary regurgitation
    - Damage to conduction system during VSD closure
    - Scar from right ventriculotomy → ectopy focus
  - Bacterial endocarditis
  - Stroke due to paradoxic embolus to brain
  - Hyperviscosity syndrome due to polycythemia

Demographics

- Epidemiology
  - Incidence: 3-5 per 10,000 live births
  - 4th most common congenital heart anomaly
  - Most common cyanotic heart lesion

Natural History & Prognosis



- 10% of untreated patients live > 20 years
- Short term: Excellent results after early "complete" repair
- Long term: Determined by RV diastolic & systolic dysfunction; chronic regurgitation leading to dilation, arrhythmias, & risk of sudden death
  - Timing of PVR is determined by results of functional MR

Treatment

- Palliative shunt (needed primarily with hypercyanotic episodes or extreme desaturation)
  - Classic BT shunt: End-to-side subclavian artery to PA (opposite from aortic arch)
  - Modified BT shunt: Interposition of Gore-Tex graft
  - Central shunt: Ductus-like connection between aorta & PA
- Complete repair: Removal of RVOT obstruction, VSD closure
  - Limited transannular patch with RVOT enlargement: Postoperative pulmonary regurgitation
    - RV dysfunction, arrhythmias
  - Rastelli shunt: Valved conduit between RV & PAs in case of severe RVOT stenosis or pulmonary valve atresia
- Pulmonary valve or conduit replacement after early complete repair
  - Conduit stenosis: RV pressure overload, systolic dysfunction
  - Pulmonary regurgitation: RV volume overload, diastolic & systolic dysfunction, reciprocal left ventricle systolic dysfunction, arrhythmias
  - Timely surgery allows RV remodeling with ↓ RV size, ↑ EF, ↑ exercise capacity
- Percutaneous balloon dilation of residual pulmonary valve stenosis &/or peripheral PA stenosis (with stent placement)
- Transcatheter PVR
  - Less invasive, new option for PVR
  - Risk:benefit ratio of earlier reintervention is being evaluated compared with surgical replacement
  - Risk of bacterial endocarditis is higher compared to surgical PVR

(Left) *Sagittal MIP cardiac CTA in an infant with TOF shows narrowing of the RV infundibulum with RV hypertrophy & a VSD. **(Right)** Anterior oblique color-coded 3D surface-rendered cardiac CTA in an infant with TOF shows the narrowed RV infundibulum, VSD & overriding aorta. Note all the aortopulmonary collaterals feeding the PAs (blue).*

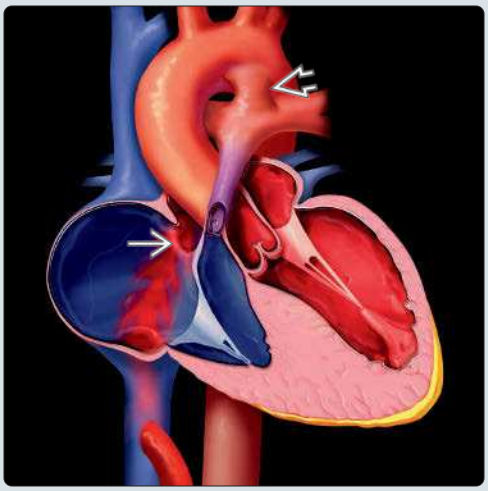
(Left) *Sagittal bright blood SSFP cardiac MR cine in a postoperative patient with TOF shows a pulmonic regurgitation signal void of dephasing artifact. Also note the enlarged RV. Pulmonic regurgitation is often well tolerated after primary repair.* **(Right)** *Four-chamber bright blood SSFP cine MR shows a typical appearance of the RV after "complete" repair. The RV often dilates from volume overload secondary to a large regurgitant fraction across the pulmonic valve.*

(Left) *Oblique axial MIP cardiac CTA shows massive enlargement of the central PAs in a patient with a TOF variant where there is absence of the pulmonic valve. Note the abrupt change in caliber of the secondary PAs.* **(Right)** *Lateral color-coded 3D surface-rendered cardiac CTA shows massive enlargement of the central PAs in a patient with a TOF variant where there is absence of the pulmonic valve. Also note the VSD.*

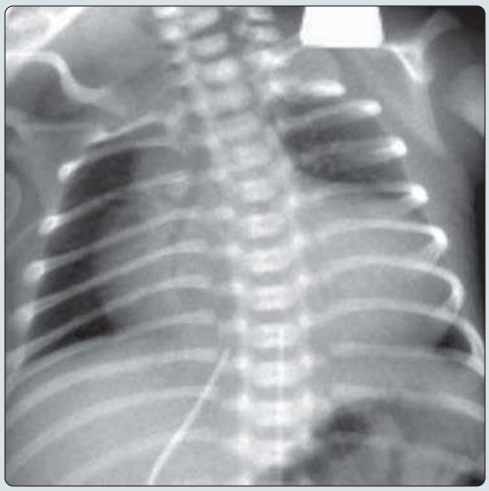
Pulmonary Atresia

KEY FACTS

TERMINOLOGY

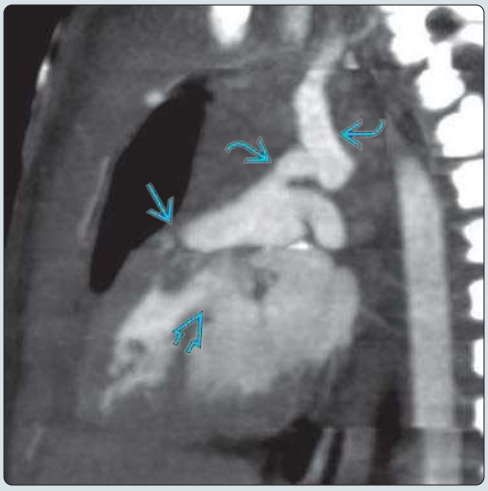


- 2 distinct entities, differentiated by presence or absence of ventricular septal defect (VSD)
  - Pulmonary atresia (PAt), intact ventricular septum (VS): Normal-sized pulmonary arteries (PAs) supplied by patent ductus arteriosus (PDA), patent foramen ovale (PFO)
  - PAt, VSD, multiple aortopulmonary collateral arteries (MAPCAs): Hypoplastic/absent PAs; MAPCAs supply 1 or both lungs
    - At extreme end of spectrum of right ventricular outflow tract (RVOT)-obstructive (Fallot-type) heart lesions with complex & highly variable PA anatomy

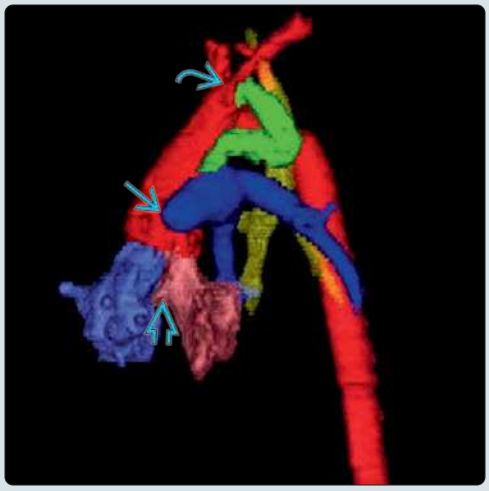


IMAGING

- Extreme boot-shaped appearance of heart
  - PAt, intact VS: Severe cardiomegaly from massive right atrial dilation
- Right-sided aortic arch is common
- Initial diagnosis with echocardiography
- Cardiac CTA delineates PAs, MAPCAs, & coronary artery fistulas & sinusoids
  - Provides roadmap for subsequent catheterization
- CT or MR postoperatively for shunt/conduit patency
- Cardiac catheterization for hemodynamic assessment, selective injection studies, & catheter-based interventions



CLINICAL ISSUES



- Progressive cyanosis after birth at closure of PDA
  - Prostaglandin E1 to maintain PDA
- Congestive heart failure with large unobstructed high-flow MAPCAs
- Treatment
  - PAt, VSD, MAPCAs: Unifocalization of MAPCAs & true PAs (if existent, to allow for PA growth)
  - PAt, intact VS: Type of repair depends on RV size & RV dependency on coronary circulation

(Left) *Graphic shows pulmonary atresia with an intact ventricular septum. Note the patent foramen ovale, dilation of the right atrium, & right ventricular (RV) hypertrophy. The pulmonary arteries (PAs) are perfused by flow from the aorta through a patent ductus arteriosus (PDA).* **(Right)** *Frontal view of the chest in a neonate with pulmonic atresia shows cardiomegaly with ↓ pulmonary vascularity. The differential diagnosis for this appearance includes pulmonic atresia, Ebstein anomaly, & tricuspid atresia.*

(Left) *Sagittal MIP cardiac CTA in an infant shows an atretic main PA with the PDA arising from the left brachiocephalic artery & inserting into the main PA. Also note the ventricular septal defect (VSD).* **(Right)** *Lateral 3D surface-rendered cardiac CTA in an infant shows the atretic PA & tortuous PDA (green) arising from the left brachiocephalic artery & inserting into the superior aspect of the main PA (blue). Also note the VSD between the RV (violet) & left ventricle (LV) (salmon).*

TERMINOLOGY

Abbreviations

- Pulmonary atresia (PAt)

Synonyms

- Sometimes referred to as truncus arteriosus type 4 or pseudotruncus (misnomer)

Definitions

- 2 distinct entities, differentiated by presence or absence of ventricular septal defect (VSD)
  - PAt, VSD, multiple aortopulmonary collateral arteries (MAPCAs): Hypoplastic/absent pulmonary arteries (PAs); MAPCAs supply 1 or both lungs
    - Type A: Normal-sized PAs with small aortopulmonary (AP) collaterals
    - Type B: Mild to moderate PA hypoplasia with multiple AP collaterals
    - Type C: Markedly hypoplastic PAs with pulmonary flow from numerous AP collaterals
  - PAt, intact ventricular septum (VS): Normal-sized PAs supplied by patent ductus arteriosus (PDA), patent foramen ovale (PFO)
    - Coronary sinusoids or fistulas are often present
- Both are characterized by underdevelopment of right ventricular outflow tract (RVOT) & pulmonary valve
  - PAt, VSD, MAPCAs: At extreme end of spectrum of RVOT-obstructive (Fallot-type) heart lesions with complex & highly variable PA anatomy
- Category: Cyanotic, cardiomegaly, ↓ &/or irregular pulmonary vasculature
- Hemodynamics: Extreme outflow obstruction of RV; (almost) entire cardiac output goes into dilated overriding ascending aorta

IMAGING

General Features

- Best diagnostic clue
  - Atresia of RVOT &/or pulmonary valve

Radiographic Findings

- Extreme boot-shaped appearance of heart
- Right-sided aortic arch is common
- Diminutive hilar shadows
- Irregular branching patterns of MAPCAs
- PAt, intact VS: Severe cardiomegaly from massive right atrial dilation

CT Findings

- CTA
  - Cardiac CTA provides detailed evaluation of PAs & MAPCAs
    - 3D images have proven helpful in planning for unifocalization
  - CTA is best used to provide anatomic roadmap for subsequent catheterization
    - Saves overall radiation, contrast, procedure time
    - Cardiac CTA provides delineation of coronary artery fistulas & sinusoids
  - CTA is excellent modality for unstable postoperative patients

MR Findings

- T1WI
  - PAt, VSD, MAPCAs: Cardiac gated axial images for preoperative definition of PA anatomy
- T2* GRE
  - Short- & long-axis SSFP cine MR for functional assessment, tricuspid regurgitation
- MRA
  - Coronal gadolinium-enhanced MRA for detailed analysis of PA anatomy & MAPCAs
- Phase-contrast imaging
  - Helpful in following RV volumes & regurgitant fractions in postsurgical patients

Echocardiographic Findings

- Echocardiogram
  - PAt, VSD, MAPCAs
    - Characterizes intracardiac anatomy, position, & size of VSD, aortic root override
    - Development of branch PAs & their confluence
  - PAt, intact VS
    - Morphology of interatrial septum: Identifies restriction to flow across PFO
    - Size of RV & tricuspid anulus (expressed as Z score), degree of tricuspid regurgitation: Important for planning of surgical repair

Angiographic Findings

- Conventional
  - PAt, VSD, MAPCAs
    - Selective injection with pressure recordings of all MAPCAs + imaging of true PAs
    - Pulmonary venous wedge injections for retrograde filling of diminutive PAs
  - PAt, intact VS
    - Suprasystemic pressure recordings in RV
    - Detailed imaging of coronary anatomy through RV & aortic root injections: RV to coronary communications, stenoses, interruptions

Imaging Recommendations

- Protocol advice
  - PAt, VSD, MAPCAs
    - Initial diagnosis with echocardiography
    - CT or MR for preoperative assessment of PA anatomy, postoperative assessment for shunt/conduit patency
    - Cardiac catheterization for hemodynamic assessment, selective injection studies, & catheter-based interventions

DIFFERENTIAL DIAGNOSIS

Tetralogy of Fallot

- At least partial patency of RVOT

Complex Cyanotic Heart Lesions With Component of (Sub-)Pulmonary Stenosis

- Double-outlet RV
- Transposition of great arteries with VSD
- Single ventricle
- Tricuspid atresia

Ebstein Anomaly

- May mimic PAt, intact VS with large tricuspid anulus & massive tricuspid regurgitation

PATHOLOGY

General Features

- Embryology (PAt, VSD, MAPCAs)
  - RVOT obstruction → hypoplasia of PAs
  - Persistence or hypertrophy of primitive arterial connections to lungs
  - Hypertrophy of bronchial arteries
- Pathophysiology of PAt, VSD, MAPCAs: Balance between flow through PAs & MAPCAs determines pulmonary perfusion
  - PA flow at subsystemic pressures, restricted by narrow caliber & eventual closure of ductus arteriosus
  - MAPCA flow leads to ↑ lung perfusion at systemic pressures (unless restricted by stenosis)
  - Degree of cyanosis is determined by intracardiac admixture & amount of pulmonary flow
  - Large amount of pulmonary blood flow through unrestricted MAPCAs → congestive heart failure
- Pathophysiology of PAt, intact VS: Obligatory right-to-left shunt through PFO
  - PAs are supplied by PDA
  - Small, heavily trabeculated RV with suprasystemic pressures
  - Depending on size of tricuspid valve anulus: Severe tricuspid regurgitation, leading to massive right atrial dilation (comparable to Ebstein anomaly)
  - Transmyocardial sinusoids connecting RV cavity with coronary artery system cause coronary flow reversal during diastole, leading to myocardial ischemia & infarction

Staging, Grading, & Classification

- PAt with VSD & MAPCAs
  - Type A: Majority of pulmonary flow from PAs with small MAPCAs
  - Type B: Equal pulmonary flow from PAs & MAPCAs
  - Type C: Majority of pulmonary flow from MAPCAs with markedly hypoplastic native PAs

Gross Pathologic & Surgical Features

- Hilar arteries = true PAs
- Presence & confluence of central portions of true PAs is important for surgical repair
- MAPCAs originate from
  - Ascending aorta
  - Brachiocephalic or intercostal arteries
  - Ductus arteriosus
  - Descending aorta (most common)

Microscopic Features

- Pulmonary vascular disease develops in vascular bed of high-flow MAPCAs → ↑ in cyanosis

CLINICAL ISSUES

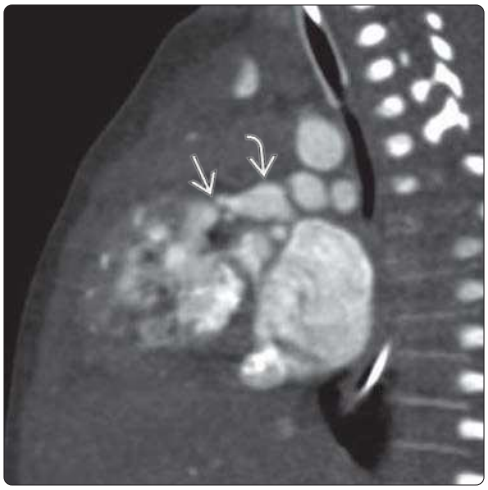
Presentation

- Most common signs/symptoms
  - Progressive cyanosis after birth with closure of ductus arteriosus
  - Congestive heart failure with large, unobstructed, high-flow MAPCAs
- Other signs/symptoms
  - Failure to thrive, polycythemia, finger clubbing

Demographics

- Epidemiology
  - Rare, congenital cyanotic heart lesions, often classified together with tetralogy of Fallot

Natural History & Prognosis



- Progressive cyanosis due to development of pulmonary vascular disease → irreversible pulmonary hypertension
- Life expectancy when untreated: < 10 years
- Survival into adulthood is now possible: Adult congenital heart disease
  - Need for lifelong follow-up with multiple imaging tests
- Prognosis is guarded, depends on feasibility of surgery

Treatment

- Prostaglandin E1 to keep ductus arteriosus open
- Palliative: Systemic-to-PA shunt (Blalock-Taussig, central), initial banding of high-flow MAPCAs
- PAt, VSD, MAPCAs: Staged complete repair
  - Unifocalization of MAPCAs & true PAs (if existent, to allow for PA growth)
  - Early 1-stage repair in infancy with incorporation of all MAPCAs in PA conduit, may be feasible
  - Complete repair with incorporation of MAPCAs & PAs in conduit, connected to reconstructed RVOT, & closure of VSD (may not be possible due to high pressure in pulmonary system from residual stenosis/hypoplasia & pulmonary vascular disease)
  - Catheter-based interventions (balloon angioplasty with stenting of stenoses, coil embolization of small superfluous &/or bleeding MAPCAs)
- PAt, intact VS: Type of repair depends on RV size & RV dependency on coronary circulation
  - Restriction in flow across PFO: Balloon atrial septostomy
  - Catheter-based or surgical pulmonary valvotomy
  - Sudden decompression of RV through valvotomy, RVOT repair, or transannular patch may lead to myocardial ischemia/infarction
  - When RV is too hypoplastic for biventricular repair: Cavopulmonary (Glenn) shunt, staged completion of univentricular repair (Fontan)

(Left) *Sagittal MIP cardiac CTA shows an atretic, thickened pulmonary valve with normal caliber PA. A PDA feeds the main PA. This patient is considered ductal dependent as survival is not possible without the PDA.* **(Right)** *Left posterior oblique 3D surface-rendered cardiac CTA shows complete pulmonic atresia with a gap seen between the RV (purple) & the PA (blue). Note the large PDA (green) that provides flow to the lungs.*

(Left) *Axial MIP cardiac CTA shows markedly hypoplastic PAs in a patient with pulmonic atresia.* **(Right)** *Superior 3D surface-rendered cardiac CTA shows markedly hypoplastic native PAs (blue). A VSD is present. Multiple aortopulmonary collaterals (green) are providing the majority of the pulmonary flow (type C pulmonic atresia).*

(Left) *Axial MIP cardiac CTA in an infant shows an atretic pulmonary valve. There were multiple coronary artery fistulas connecting to the RV in this patient with an intact ventricular septum.* **(Right)** *Posterior oblique 3D surface-rendered cardiac CTA in an infant shows an atretic pulmonary valve. There were multiple coronary artery fistulas connecting to the RV in this patient with an intact ventricular septum.*

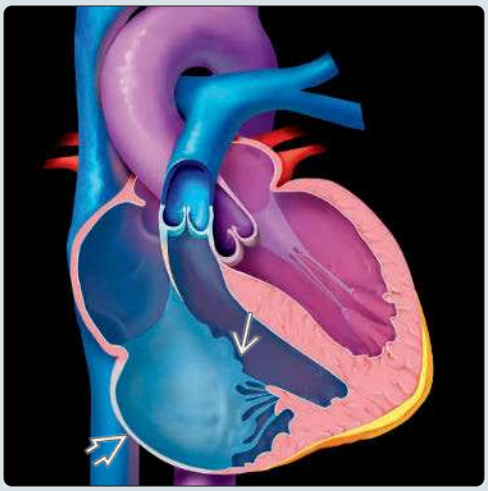
Ebstein Anomaly

KEY FACTS

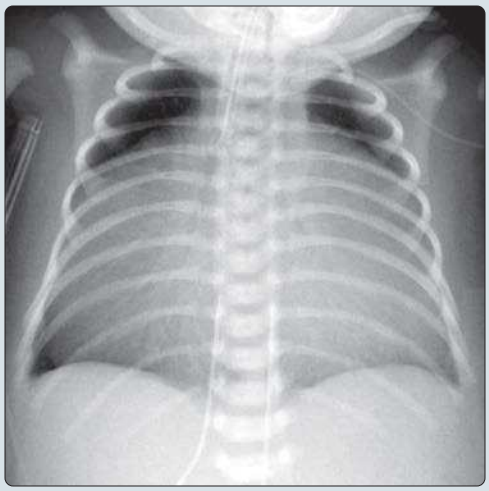
TERMINOLOGY

- Downward/apical displacement of septal & posterior leaflets of tricuspid valve with tricuspid regurgitation
- Category: Cyanotic congenital heart disease with cardiomegaly & ↓ pulmonary vascularity

IMAGING

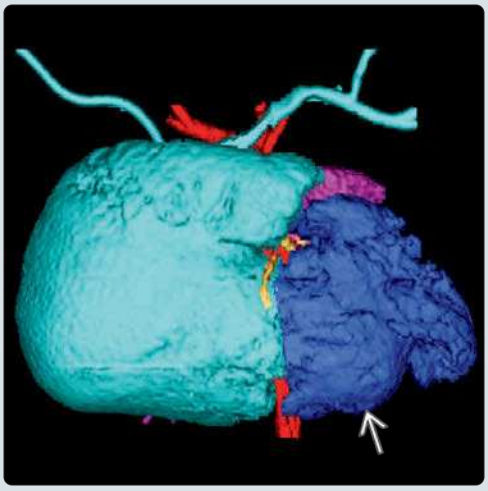


- Classic radiographic appearance: Massive right-sided cardiomegaly (box-shaped heart)
- All cross-sectional modalities can show right atrial enlargement, apical displacement of tricuspid septal leaflet, & "atrialized" portion of right ventricle (RV)
  - Apical displacement of septal tricuspid leaflet (> 15 mm in children < 14 years; > 20 mm in adults)
- MR is excellent to evaluate ventricular volumes, ejection fraction, tricuspid regurgitant fraction



PATHOLOGY

- Patent foramen ovale (PFO), secundum atrial septal defect (ASD) in 90%



CLINICAL ISSUES

- Wide spectrum of findings & ages at 1st presentation
  - Some patients are asymptomatic
- Presence of cyanosis depends on balance between right & left atrial pressures
- Prognosis depends on hemodynamic significance of tricuspid regurgitation & presence of cyanosis, arrhythmias
- Supportive treatment in cyanotic neonate
  - Oxygen, nitric oxide ventilation to lower pulmonary vascular resistance
- Tricuspid valve replacement &/or reconstruction (valvuloplasty)
  - Definitive repair procedure

(Left) *Anterior graphic depicts downward displacement of the tricuspid posterior valve leaflet ➡, which has become incorporated into the right ventricular (RV) wall ➡, leading to "atrialization" of the inflow portion of the RV.* **(Right)** *Single frontal view of the chest in a newborn shows massive cardiomegaly (the box-shaped heart) with ↓ pulmonary vascularity, typical of patients with Ebstein anomaly.*

(Left) *Frontal view 3D color-coded cardiac CTA shows massive dilation of the right atrium (RA) (ight blue). Note the smooth portion of the RV wall ➡ that has become "atrialized."* **(Right)** *Axial cardiac CTA shows a massively dilated RA ➡ with the septal leaflet ➡ of the tricuspid valve deviated toward the apex of the heart. Note the atrialized (smooth) RV wall ➡.*

TERMINOLOGY

Definitions

- Downward/apical displacement of septal & posterior leaflets of tricuspid valve → tricuspid regurgitation
- Classic radiographic appearance: Massive right-sided cardiomegaly (box-shaped heart)
- Category: Cyanotic, (severe) cardiomegaly, normal or ↓ pulmonary vascularity
- Hemodynamics: Determined by severity of tricuspid valve regurgitation
  - Volume overload to right heart
  - Right-to-left shunting through patent foramen ovale (PFO) → cyanosis

IMAGING

General Features

- Best diagnostic clue
  - Downward/apical displacement of septal tricuspid leaflet (≥ 8-mm/m² body surface area)
- Location
  - Tricuspid valve

Radiographic Findings

- Severe right-sided cardiomegaly: May mimic large pericardial effusion
  - Heart size ranges from near normal in newborn period to massively enlarged
  - Heart ↑ gradually in size over time, reaching massive proportions in untreated cases during adulthood
  - Cardiothoracic ratio is used as parameter for follow-up
- Small vascular pedicle

CT Findings

- Cardiac CT can be used to obtain volumes & functional analysis of ventricular contraction
  - Also useful in defining associated complex extracardiac anomalies

MR Findings

- MR cine
  - Cardiac gated steady-state free precession bright blood MR
    - Apical displacement of septal tricuspid valve leaflet
    - Smooth "atrialized" component of right ventricle (RV)
    - Dephasing signal void from tricuspid regurgitation
    - Can calculate ventricular volumes, ejection fraction (EF), tricuspid regurgitation fraction
      - Left ventricular (LV) function is affected by RV dilation, bowing of septum, mitral valve prolapse
    - Indexed volumes & function of right heart correlate with overall prognosis
      - RV end-diastolic volume index > 200 & RV EF < 40% are helpful factors to identify ↑ perioperative risk

Echocardiographic Findings

- Echocardiogram
  - Right chamber enlargement with "atrialized" portion of RV
  - Enlarged tricuspid anulus (expressed in Z score)
  - Apical displacement of septal tricuspid leaflet (> 15 mm in children < 14 years; > 20 mm in adults)
- Color Doppler
  - Tricuspid regurgitation
  - PFO with right-to-left shunting

Angiographic Findings

- Characteristic notch at inferior RV border at insertion of displaced anterior tricuspid leaflet
- Seldom required for primary diagnosis

Imaging Recommendations

- Protocol advice
  - Anatomic & functional assessment with echocardiography in infants
  - Cardiac MR in (young) adults

DIFFERENTIAL DIAGNOSIS

Large Atrial Septal Defect

- Acyanotic
- ↑ pulmonary vascularity
- Left-to-right flow through large atrial septal defect (ASD)

Pericardial Effusion

- Acyanotic
- Easy differentiation with echocardiography

Tricuspid Insufficiency

- Primary, due to dysplastic valve
- Often secondary to pulmonary atresia with intact ventricular septum

Uhl Anomaly

- Congenital absence of RV myocardium

Arrhythmogenic Right Ventricular Dysplasia

- Fatty infiltration of RV, though fat is often not visible by imaging

Right-Sided Obstructive Cyanotic Heart Lesions With ↓ Pulmonary Vascularity

- Tetralogy of Fallot
- Pulmonary atresia
  - With ventricular septal defect & aortopulmonary collaterals
  - With intact ventricular septum
    - Causes severe cardiomegaly
- Tricuspid atresia
- Transposition of great arteries (TGA) with pulmonary stenosis
- Double-outlet RV with pulmonary stenosis

PATHOLOGY

General Features

- Genetics
  - Most often sporadic
- Associated abnormalities
  - PFO, secundum ASD in 90%
  - Ebstein anomaly frequently involves left-sided tricuspid valve in congenitally corrected (L) TGA
- Embryology

- Insufficient separation of tricuspid valve leaflets & chordae tendineae from RV endocardium
- Pathophysiology
  - 3 compartments: Right atrium, "atrialized" or noncontracting inlet portion of RV, & functional outlet portion of RV
  - Massive tricuspid regurgitation
  - Volume overload to right side of heart
  - Right-to-left shunt through PFO → cyanosis
  - LV diastolic dysfunction may result from massive right-sided cardiac enlargement
  - Arrhythmias due to conduction abnormalities

Gross Pathologic & Surgical Features

- Thickened valve leaflets, adherent to underlying myocardium
- Downward/apical displacement of septal & posterior tricuspid leaflets
- Normally placed, redundant, sail-like anterior tricuspid leaflet
- May occur on left side of heart with congenitally corrected (L) TGA

CLINICAL ISSUES

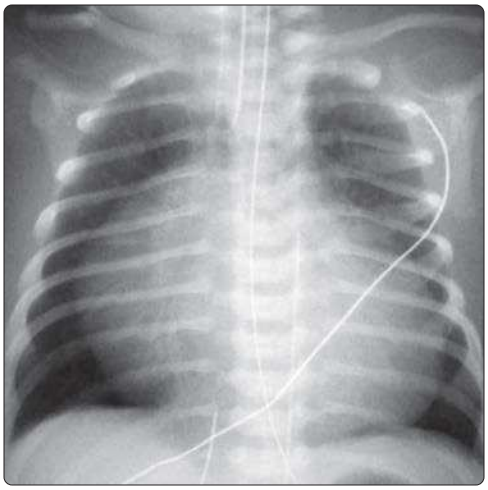
Presentation

- Most common signs/symptoms
  - Wide spectrum of findings & ages at 1st presentation; some patients are asymptomatic
  - Chronic right heart failure
    - ↓ exercise tolerance [classified as New York Heart Association (NYHA) classes I-IV]
  - Presence of cyanosis depends on balance between right & left atrial pressures
    - Physiologic ↓ in pulmonary vascular resistance in neonatal period → ↓ in right-to-left shunting through PFO → gradual improvement in cyanosis in 1st weeks of life
- Other signs/symptoms
  - Hydrops fetalis in neonatal cases
  - Severe cardiomegaly in fetal life → pulmonary hypoplasia
  - Thrombosis, paradoxic embolus
  - Arrhythmias
    - Atrial fibrillation, atrial flutter → irregular heartbeat
    - Accessory atrioventricular conduction pathways (preexcitation) → tachyarrhythmias, which can be unexpected & fatal

Demographics

- Age
  - 1st presentation can range from newborn period through old age (average: 14 years)
- Epidemiology
  - < 1% of congenital cardiac anomalies; incidence of 1/210,000 live births
  - Sex: M:F = 1:1

Natural History & Prognosis



- Sudden death due to fatal atrial arrhythmias
- Uncomplicated pregnancies are possible in women with hemodynamically well-balanced lesions
- Prognosis is highly variable, dependent on hemodynamic significance of tricuspid regurgitation, presence of cyanosis

Treatment

- Supportive treatment in cyanotic neonate: Oxygen, nitric oxide ventilation to lower pulmonary vascular resistance
- Systemic to pulmonary (Blalock-Taussig & central) shunts are ineffective
- Some patients benefit from total right-sided heart bypass procedures (Glenn → Fontan surgical treatment pathway)
- Tricuspid valve replacement &/or reconstruction (valvuloplasty): Definitive repair procedure
  - Valvuloplasty & bioprosthesis placement are preferable to mechanical valve (allow growth with no need for lifelong anticoagulation)
  - Valvuloplasty uses tissues from existing valve (redundant anterior tricuspid leaflet)
  - Bioprosthesis: Homograft or xenograft (porcine valve)
- Indications for valve repair
  - NYHA classes III & IV
  - NYHA classes I & II with cardiothoracic ratio > 0.65
  - Significant cyanosis (arterial saturation < 80%) &/or polycythemia (Hb > 16 g/dL)
  - History of paradoxic embolus
  - Arrhythmia due to accessory atrioventricular pathway
- Conal reconstruction may improve long-term RV performance & prognosis
- Arrhythmia treatments
  - Antiarrhythmic drugs
  - Permanent pacemaker implantation
  - Radiofrequency ablation

(Left) *AP radiograph of the chest demonstrates cardiomegaly with ↓ pulmonary vascularity in this patient with Ebstein anomaly. The classic differential considerations in patients with cardiomegaly & ↓ pulmonary vascularity are Ebstein anomaly, pulmonic atresia, & tricuspid atresia.* **(Right)** *Four-chamber SSFP cine of the heart shows massive dilation of the RA & RV from volume overload & "atrialization" of the RV.*

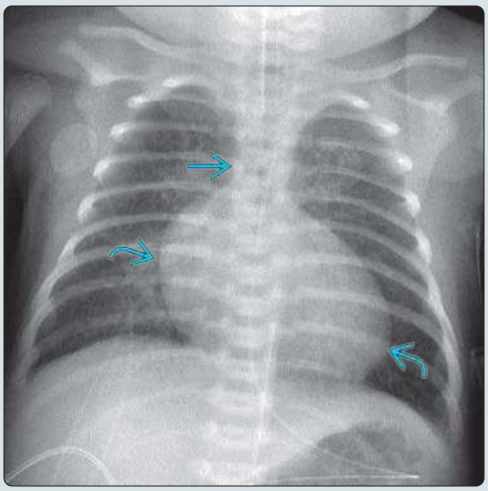
(Left) *Coronal MIP cardiac CTA shows massive dilation of the RA with enlargement of the RV in a patient with Ebstein anomaly. Note the narrowed pulmonary outflow tract.* **(Right)** *Oblique 3D reformatted cardiac CTA in an infant with Ebstein anomaly shows valvular pulmonic stenosis. Note the massively dilated RA (light blue) & the moderately dilated RV (purple).*

(Left) *Frontal view of the chest in a 3-year-old patient with Ebstein anomaly status post tricuspid valve replacement shows an abnormal orientation of the prosthetic valve between the RV & RA due to the underlying anomaly. Note the normal heart size & normal pulmonary vascularity.* **(Right)** *Axial CTA of the chest in patient with a history of Ebstein anomaly status post tricuspid valve replacement shows only mild RV enlargement.*

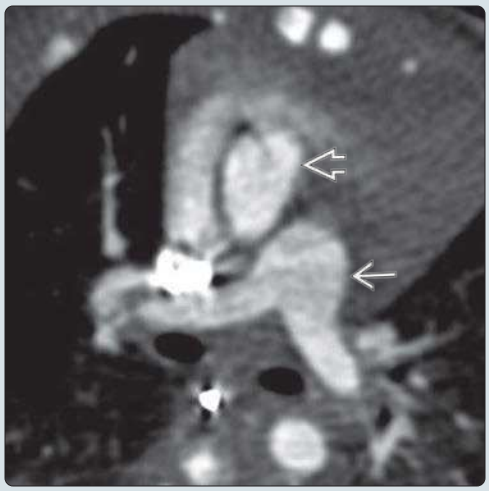
D-Transposition of Great Arteries

KEY FACTS

TERMINOLOGY

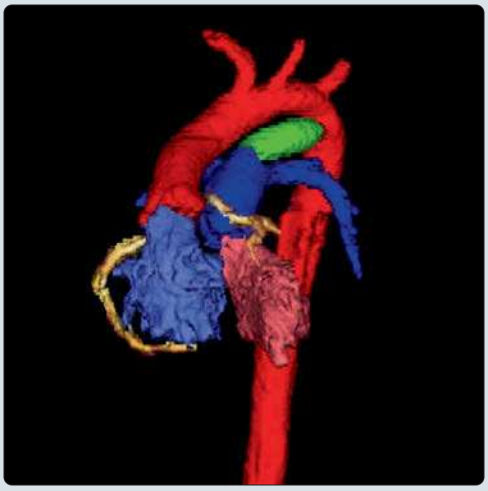


- Ventriculoarterial discordance with atrioventricular concordance: Aorta arises from right ventricle (RV) & pulmonary artery (PA) arises from left ventricle (LV)
- Complete separation of pulmonary & systemic circulations, lethal without flow admixture: Patent foramen ovale (PFO), ventricular septal defect (VSD), patent ductus arteriosus (PDA)

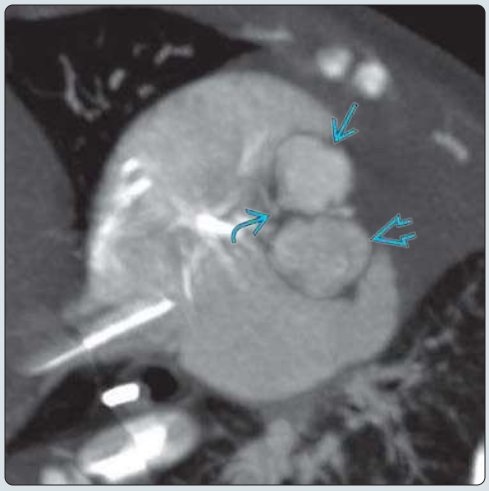


IMAGING

- Preoperative
  - Great vessels lie parallel & almost in same sagittal plane with aortic valve in anterior position & slightly to right (D-loop) of pulmonary valve; frequent coronary anomalies
  - Classic radiographic appearance: Narrow mediastinum with cardiomegaly ("egg on string/egg on its side" heart) + ↑ pulmonary vascularity
- Postoperative (after arterial switch/Jatene procedure)
  - Classic alterations of great vessel anatomy
    - PA is now anteriorly positioned with posterior aorta in same sagittal plane; right & left PAs now drape over ascending aorta
  - Transposed coronary arteries
  - Traction on both branch PAs may lead to stenosis



CLINICAL ISSUES



- Simple transposition: Good prognosis with early switch
- Large VSD: Congestive heart failure as neonate
- Patients with large VSD & (sub-) pulmonic stenosis have mild symptoms & may survive for years without treatment
- Long-term prognosis is determined by potential coronary abnormalities
- Potential treatments: Prostaglandin E1 to maintain PDA preoperatively; emergency balloon atrial septostomy (Rashkind); early surgery (preferred): Arterial switch with transposition of coronaries (Jatene); late surgery: Rerouting of venous flow in atria with pericardial baffle (Mustard) or reorientation of atrial septum (Senning)

(Left) *Frontal radiograph of the chest in an infant shows cardiomegaly & ↑ pulmonary vascularity in a patient with D-transposition of the great arteries (D-TGA). The superior mediastinum is narrow, & the heart is globular in shape. This combination is referred to as the egg-on-a-string appearance.* **(Right)** *Axial cardiac CTA in an infant shows the pulmonary artery (PA) posterior & slightly to the left of the ascending aorta. This is the classic relationship of the great vessels seen with D-TGA.*

(Left) *Oblique color-coded 3D CTA in an infant with D-TGA shows that the aorta (red) arises from the right ventricle (RV) (purple) & the PA (blue) arises from left ventricle (LV) (pink). A large patent ductus arteriosus (PDA) (green) connects aortic arch to the PA (blue). Note coronary arteries (tan).* **(Right)** *Axial oblique cardiac CTA in an infant with D-TGA shows the aorta arising anterior & to the right of the base of the PA. Note that the right coronary artery arises from the noncoronary sinus, which is typical for D-TGA.*

TERMINOLOGY

Definitions

- Aorta arises from right ventricle (RV) & pulmonary artery (PA) arises from left ventricle (LV)
- Ventriculoarterial (VA) discordance with atrioventricular (AV) concordance
- Category: Cyanotic, cardiomegaly, ↑ pulmonary vascularity
- Hemodynamics
  - RV connected with systemic circulation: Pressure overload
  - LV connected with pulmonary circulation: Volume overload
  - Lethal without flow admixture: Patent foramen ovale (PFO), ventricular septal defect (VSD), patent ductus arteriosus (PDA)

IMAGING

General Features

- Best diagnostic clue
  - Great vessels lie parallel in almost same sagittal plane: Aortic valve in anterior position & slightly to right (D-loop) of pulmonary valve

Radiographic Findings

- Radiography
  - May be normal in neonates
  - Classic appearance: Narrow mediastinum with cardiomegaly ("egg on a string" or "egg on its side" heart) + ↑ pulmonary vascularity

CT Findings

- CTA
  - Shows classic alterations of great vessel anatomy status post arterial switch procedure: PA is now anteriorly positioned with posterior aorta in same sagittal plane; right & left PAs now drape over ascending aorta
    - Traction on both branch PAs may lead to stenosis
    - Anterior tracheal or left main bronchus compression may be seen
    - Variable coronary anomalies in D-TGA; transposition is performed during surgery

MR Findings

- T1WI
  - Cardiac gated axial images for segmental cardiac analysis: AV concordance & VA discordance
    - Presence of PFO, VSD, (sub-) pulmonary stenosis
    - Postoperative assessment of PA stenosis
- T2* GRE
  - Multiplanar bright blood SSFP cine is gold standard for cardiac function evaluation & ventricular volume measurements
    - RV dysfunction following atrial switch procedures (as RV is not able to sustain systemic circulation)
- T1WI C+
  - Delayed-enhancement myocardial MR to detect ischemia complicating coronary transposition
- MRA
  - Gadolinium-enhanced MRA for postoperative PA stenosis
- Phase-contrast MR
  - Flow velocity measurements to calculate gradients across stenoses: Mustard/Senning or PA stenoses

CLINICAL ISSUES

Presentation

- Severe cyanosis not improving with oxygen with little respiratory distress

Demographics

- Epidemiology
  - Incidence: 1 in 3,000 live births
  - 5% of congenital heart disease

Natural History & Prognosis

- Early death without communicating shunt
- Large VSD: Congestive heart failure in neonatal period
- Patients with large VSD & (sub-) pulmonic stenosis have mild symptoms & may survive for years without treatment
- Simple transposition: Good prognosis with early switch
  - Long-term prognosis is determined by potential coronary abnormalities
- Complication of arterial switch: Traction on branch PAs by anteriorly transposed main PA → branch origin stenosis

Treatment

- Prostaglandin E1 to keep ductus arteriosus open preoperatively
- Emergency balloon atrial septostomy (Rashkind)
- Early surgery: Arterial switch with transposition of coronaries (Jatene)
- Late surgery (if Jatene is not performed): Rerouting of venous flow in atria with pericardial baffle (Mustard) or reorientation of atrial septum (Senning)

L-Transposition of Great Arteries

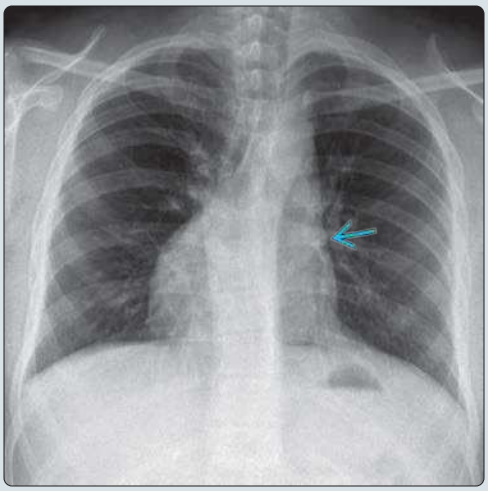
KEY FACTS

TERMINOLOGY

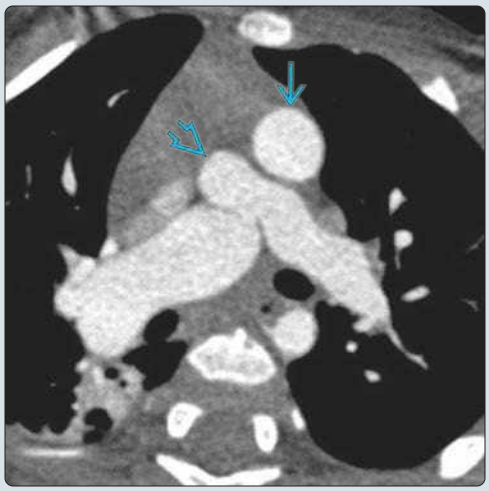
- Congenitally corrected transposition (misnomer)
- Inversion of ventricles & great arteries: Atrioventricular (AV) discordance & ventriculoarterial (VA) discordance
  - Right atrium connects via mitral valve to right-sided morphologic left ventricle (LV), which connects to pulmonary circulation
  - Left atrium connects via tricuspid valve to left-sided morphologic right ventricle (RV), which connects to systemic circulation
- Category: Dependent on associated anomalies
  - Ventricular septal defect (VSD) (60-70%): Acyanotic, ↑ pulmonary vascularity
  - Left ventricular (LV) outflow tract (subpulmonary) obstruction (30-50%): Cyanotic
  - Only 1% have no associated anomalies: True congenitally corrected transposition

IMAGING

- Classic radiograph: Straight upper left heart border
- CT & MR demonstrate complex anatomy

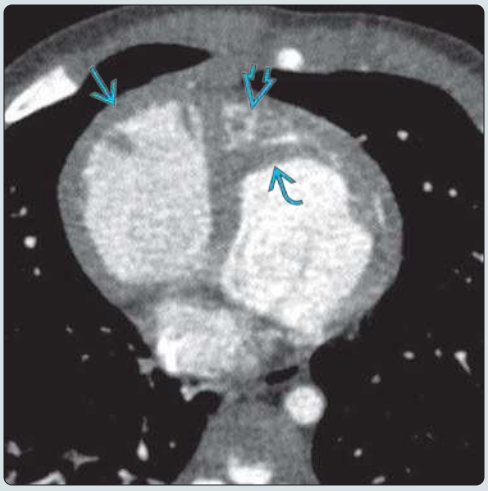


PATHOLOGY

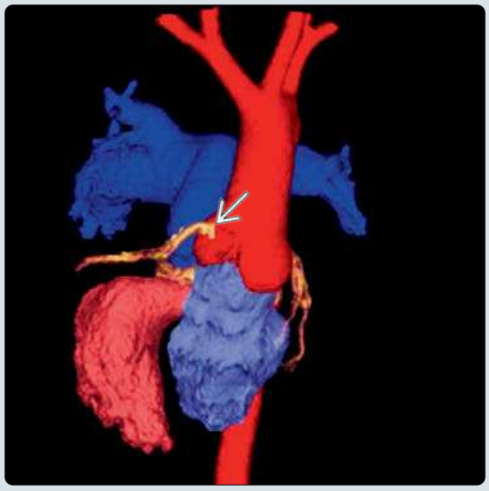


- VSD: 80%
- LV outflow tract (subpulmonary) obstruction: 30-50%
- Left-sided tricuspid valve dysplasia, Ebstein anomaly, regurgitation: 30%

CLINICAL ISSUES



- Guarded prognosis due to progressive systemic AV valve & RV dysfunction after corrective surgery: 50% mortality after 15 years
- Patients with true congenitally corrected transposition may have normal life expectancy



(Left) *Frontal radiograph of the chest in an adolescent patient shows a straightened left upper heart border due to levo-transposition of the great arteries (L-TGA).* **(Right)** *Axial cardiac CTA shows the typical position of the great vessels in L-TGA. The aorta (Ao) is anterior & to the left of the pulmonary artery (PA).*

(Left) *Axial cardiac CTA in a patient with L-TGA shows a smooth-walled, morphologic left ventricle (LV) on the right. The morphologic right ventricle (RV) is on the left, demonstrating a characteristic moderator band.* **(Right)** *Frontal 3D color-coded cardiac CTA shows the morphologic LV (pink) on the right giving rise to the PAs (blue) & the morphologic RV (purple) on the left giving rise to the Ao (red). The right coronary artery arises from the right coronary sinus & branches into the LAD & circumflex.*

TERMINOLOGY

Synonyms

- Congenitally corrected transposition (misnomer)
- Discordant transposition

Definitions

- Inversion of ventricles & great arteries: Atrioventricular (AV) discordance & ventriculoarterial (VA) discordance
- Category: Dependent on associated anomalies
  - Ventricular septal defect (VSD) (60-80%): Acyanotic, ↑ pulmonary vascularity
  - Left ventricular outflow tract (subpulmonary) obstruction (30-50%): Cyanotic
  - Only 1% have no associated anomalies: True congenitally corrected transposition

IMAGING

General Features

- Best diagnostic clue
  - Great vessels lie parallel & almost in same coronal plane with aortic valve in anterior position & slightly to left (L-loop) of pulmonary valve
- Morphology
  - S, L, L heart: Atrial situs solitus, L-loop, L-transposed great arteries
    - Right-sided morphologic left ventricle (LV) is characterized by associated mitral valve, smooth wall, & absent outflow chamber to pulmonary valve
    - Left-sided morphologic right ventricle (RV) is characterized by associated tricuspid valve, trabeculated wall with moderator band, & infundibulum below aortic valve

Radiographic Findings

- Classic plain film appearance: Straight upper left heart border

CT Findings

- 3D CT angiography can depict abnormal AV & VA relationships
- Cardiac CTA to establish coronary artery anatomy

MR Findings

- Multiplanar cardiac gated T1 & 3D gadolinium MRA for segmental cardiac analysis & anatomic evaluation
- SSFP cine & phase contrast to evaluate function & outflow tract obstruction
  - Phase-contrast imaging is used to calculate shunt fraction (Qp:Qs)

DIFFERENTIAL DIAGNOSIS

Congestive Heart Failure, Increased Pulmonary Blood Flow

- Isolated VSD
- Double-inlet ventricle
- Tricuspid atresia with ↑ pulmonary blood flow
- Double-outlet RV + subaortic VSD

Cyanosis, Decreased Pulmonary Blood Flow

- Tetralogy of Fallot

PATHOLOGY

General Features

- Associated abnormalities
  - VSD: 60-80%
  - LV outflow tract (subpulmonary) obstruction: 30-50%
  - Left-sided tricuspid valve dysplasia, Ebstein anomaly, regurgitation: 30%
  - Coronary distribution is mirror image of normal (right-sided coronary bifurcates into circumflex & anterior descending arteries)
- Embryology: Primitive cardiac tube loops to left (L-loop) → ventricular inversion & left-sided position of ascending aorta

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Congestive heart failure (VSD, systemic AV valve dysfunction)
  - Cyanosis (subpulmonary stenosis)
  - Rarely completely asymptomatic, presenting as incidental finding on chest radiograph (straight upper left heart border)

Natural History & Prognosis

- Determined by presence of AV valve dysfunction
- Guarded prognosis due to progressive systemic AV valve & RV dysfunction after corrective surgery: 50% mortality after 15 years

Treatment

- Surgical treatment is focused on associated abnormalities
  - Congestive heart failure from VSD shunt: PA banding or VSD closure
  - Cyanosis from subpulmonary stenosis: Systemic to PA shunt (Blalock-Taussig) or LV to PA conduit (Rastelli)
- Double switch operation to prevent late systemic ventricular (RV) failure
  - Venous switch (Senning) reroutes atrial blood into appropriate ventricles
  - Ventricular (Rastelli) or arterial switch: Morphologic LV becomes systemic ventricle

Tricuspid Atresia

KEY FACTS

TERMINOLOGY

- Congenital absence or agenesis of tricuspid valve & inlet portion of right ventricle (RV)

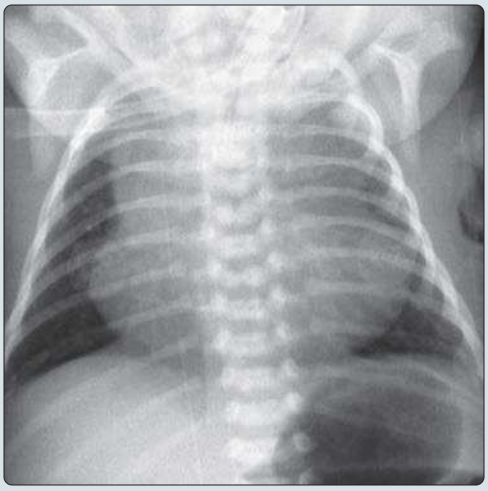
IMAGING

- Type I: Normally related great arteries (70-80%)
- Type II: D-transposition of great arteries (12-25%)
- Type III: L-transposition of great arteries/malposition (3-6%)
- Small ventricular septal defect (VSD) → heart is usually normal in size, RV is hypoplastic, pulmonary flow is diminished
- Large VSD → heart is usually large with ↑ flow or transposition of great arteries
- MR: Excellent for postoperative left ventricular functional assessment & anatomy of caval-pulmonary artery anastomosis
- CTA: Useful to assess for pulmonary artery embolus & collateral vessels in children who have ↑ cyanosis
  - Knowledge of previous surgical procedure is critical to correctly prescribing protocol & interpreting imaging, particularly in Glenn anastomosis & Fontan procedures (as unopacified blood can mimic thrombus)

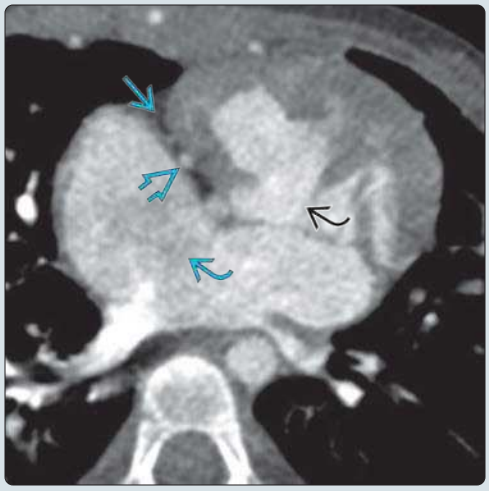
TOP DIFFERENTIAL DIAGNOSES

- Ebstein anomaly
- Tetralogy of Fallot

CLINICAL ISSUES



- 50% of neonates present with cyanosis in first 24 hours
- 30% present with signs of congestive heart failure
- Left axis deviation on newborn ECG is usually diagnostic
- Staged surgical approach, similar to single ventricle
  - Modified Blalock-Taussig shunt with systemic artery to pulmonary flow
  - Bidirectional Glenn anastomosis with superior vena cava to pulmonary artery
  - Modified Fontan procedure with inferior vena cava conduit to pulmonary artery



(Left) *Anterior 3D volume-rendered cardiac CTA in an infant with tricuspid atresia shows wide separation of right atrium (RA) (light blue) & right ventricle (RV) (purple). Right coronary artery ➡ lies deep in the atrioventricular (AV) groove. A Glenn shunt is seen with the superior vena cava (SVC) ➡ directly connected to pulmonary arteries (PAs) (dark blue).* **(Right)** *Axial cardiac CTA in an adolescent shows the right coronary artery ➡ & fat ➡ between the RA & RV in a patient with tricuspid atresia. Note unopacified blood in the RA from the Fontan shunt.*

(Left) *AP radiograph of the chest shows cardiomegaly with ↓ pulmonary vascularity in an infant with tricuspid atresia.* **(Right)** *Axial cardiac CTA in an infant shows fat & soft tissue ➡ in the right AV groove where the tricuspid valve is normally located. Note the right coronary artery ➡ deep within the groove. With absence of the tricuspid valve, the coronary often sits between the RV & RA. A large atrial septal defect (ASD) ➡ & ventricular septal defect (VSD) ➡ are also seen.*

TERMINOLOGY

Definitions

- Congenital absence or agenesis of tricuspid valve & inlet portion of right ventricle (RV)

IMAGING

General Features

- Best diagnostic clue
  - Absence of inflow portion of RV with atretic tricuspid valve
  - Outlet portion of RV depends on size of ventricular septal defect (VSD)
- Location
  - Tricuspid valve absent, fused, or stenotic; size of VSD & RV is variable
  - Right coronary artery & fat are seen within atrioventricular groove where tricuspid valve should be normally positioned
- Morphology
  - Type I: Normally related great arteries (70-80%)
  - Type II: D-transposition of great arteries (12-25%)
  - Type III: L-transposition of great arteries or malposition (3-6%)
  - VSD can occur with atresia, stenosis, or normal pulmonary valve

Radiographic Findings

- Neonatal chest radiograph is variable depending on size of VSD

CT Findings

- CECT
  - Demonstrates postoperative anastomosis, relative size of pulmonary arteries & systemic veins, & presence of collateral venous anatomy
  - Can be useful to assess for pulmonary artery embolus & collateral vessels in children with ↑ cyanosis
    - Must know underlying anatomy & type of surgical repair to interpret contrast studies as unopacified blood can mimic thrombus

MR Findings

- MR cine
  - Excellent for postoperative left ventricular (LV) functional assessment & anatomy of caval-pulmonary artery anastomosis
  - 3D contrast-enhanced MRA or spin-echo imaging can be used to assess connections & relations as well as size of proximal pulmonary arteries

Echocardiographic Findings

- Defines size & position of VSD, RV, & associated abnormalities

Angiographic Findings

- Cardiac catheterization prior to staged cardiac surgery repairs or for complications
  - Coiling of collateral arteries & veins to reduce workload of LV

Other Modality Findings

- Newborn pattern of left axis deviation on electrocardiography (ECG) is usually diagnostic

DIFFERENTIAL DIAGNOSIS

Tetralogy of Fallot

- Large aorta (right sided in 25%), concave left hilum, & ↓ peripheral flow

Ebstein Anomaly

- Newborn radiograph may show massive cardiomegaly
- Spectrum of disease, which involves downward displacement of septal & posterior leaflets of tricuspid valve

PATHOLOGY

General Features

- Etiology
  - Early embryologic insult with fusion of valve leaflet → stenosis (partial fusion) or atresia (complete fusion) of valves
- Genetics
  - Associated with asplenia syndromes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 50% of neonates present with cyanosis in first 24 hours
  - 30% present with signs of congestive heart failure
- Other signs/symptoms
  - Extracardiac anomalies may occur in 20% of patients

Demographics

- Epidemiology
  - 3% of congenital heart lesions

DIAGNOSTIC CHECKLIST

Consider

- Knowledge of previous surgical procedure is critical to correctly prescribing protocol & interpreting imaging, particularly in Glenn anastomosis & Fontan procedures

Image Interpretation Pearls

- Hallmark is lack of direct anatomic continuity between right atrium & ventricle
- Right coronary artery & fat are seen within atrioventricular groove where tricuspid valve should be normally positioned
- Ventricular anatomy, type & size of VSD & relationship of great vessels, ventriculoarterial connections, & sources of pulmonary artery flow all need to be assessed

Truncus Arteriosus

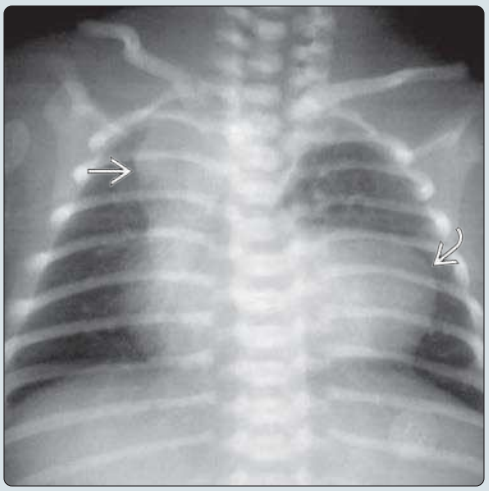
KEY FACTS

TERMINOLOGY

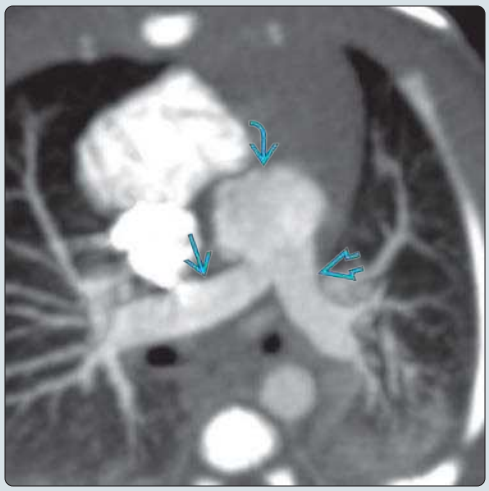
- Common arterial vessel (trunk) arising from heart; gives rise to aorta, pulmonary arteries (PAs), & coronaries
- Congenital heart lesion most commonly associated with right aortic arch (30-40%)

IMAGING

- High (outlet) ventricular septal defect (VSD) immediately below truncal valve
- Classic radiograph: Cardiomegaly, ↑ pulmonary vascularity, narrow mediastinum, right aortic arch

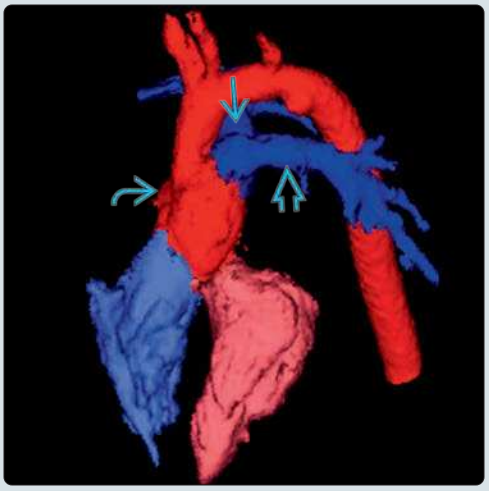


PATHOLOGY

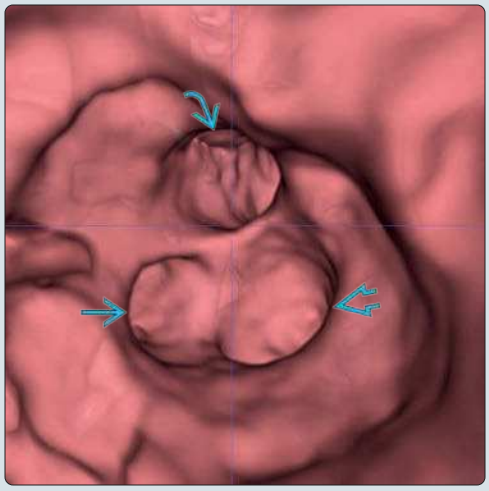


- Classification of Van Praagh
- Type A1: Same as Collett & Edwards type 1
- Type A2: Separate origins of branch PAs from common arterial trunk (CAT)
- Type A3: Origin of one branch of PA (usually right) from common trunk with other branch arising from aortic arch (collateral or patent ductus arteriosus)
- Type A4: Truncus with interrupted aortic arch

CLINICAL ISSUES



- Untreated: 65% 6-month & 75% 1-year mortality
- Intractable congestive heart failure → pulmonary hypertension → shunt reversal → ↑ cyanosis
- Associated thymic agenesis in DiGeorge syndrome → T-cell immunodeficiency
- Early complete repair (at 2-6 weeks of life) is favored by most surgeons: Placement of conduit between right ventricle & PA with closure of VSD
- Truncal valve dysfunction (regurgitation) is common → need for valvuloplasty, prosthesis



(Left) *AP radiograph shows cardiomegaly with a right aortic arch & ↑ pulmonary vascularity in an infant with truncus arteriosus. The apex of the heart is upturned. This appearance is often mistaken for tetralogy of Fallot.* **(Right)** *Axial MIP cardiac CTA in an infant shows both the right pulmonary artery (PA) & left PA arising from a common trunk with the aorta. The findings are consistent with a type A2 truncus arteriosus.*

(Left) *Lateral 3D surface-rendered cardiac CTA in an infant shows both the right PA & left PA arising from a common trunk with the aorta. The findings are consistent with a type A2 truncus arteriosus.* **(Right)** *3D surface-rendered virtual angioscopy looking superiorly from inside the common trunk in an infant with truncus arteriosus shows both the right PA & left PA arising from a common trunk with the aorta seen anteriorly. The findings are consistent with a type A2 truncus arteriosus.*

TERMINOLOGY

Definitions

- Common arterial vessel arising from heart, giving rise to aorta, pulmonary arteries (PAs), & coronaries
- Classic radiographic appearance: Cardiomegaly, ↑ pulmonary vascularity, narrow mediastinum, right aortic arch
  - Truncus arteriosus is heart lesion most commonly associated with right aortic arch (30-40%)
- Category: Cyanotic, cardiomegaly, ↑ pulmonary vascularity
- Hemodynamics
  - Both ventricles are connected to pulmonary & systemic circulation
  - Flow admixture across ventricular septal defect (VSD) & within truncus → cyanosis
  - Postnatal drop in pulmonary vascular resistance → relative ↑ in pulmonary blood flow → volume overload of pulmonary circulation
- Frequently associated with absent thymus & parathyroid glands: DiGeorge syndrome

IMAGING

General Features

- Best diagnostic clue
  - Common arterial trunk (CAT) arising from both ventricles
  - Large common valve with 2-5 leaflets

Radiographic Findings

- Radiography
  - Cardiomegaly
  - Active pulmonary vascular congestion (shunt vascularity)
  - Right aortic arch is common
  - Narrow mediastinum due to thymic agenesis
  - Dilated PAs may compress neighboring bronchi → atelectasis

CT Findings

- CTA
  - Shows relationship of branch PAs with truncus
  - Coronary anatomy is well demonstrated
  - Postoperative: Patency & size of conduit, Ca^{2+}, & stenosis
  - CTA is best technique to evaluate stent placement & airway compression

MR Findings

- T1WI
  - Cardiac gated axial images for preoperative definition of PA anatomy
  - Postoperative: Conduit stenosis, anastomotic pseudoaneurysm
- T2* GRE
  - Steady-state free precession cine MR: Truncal valve regurgitation, ventricular function & volumes
- MRA
  - Gadolinium-enhanced MRA for global anatomy, patency of PA conduit
- Phase contrast
  - Velocity-encoded phase-contrast imaging to evaluate regurgitant fraction of common truncal valve or postoperative regurgitation/stenosis
  - Qp:Qs calculated with phase-contrast imaging

Echocardiographic Findings

- Echocardiogram
  - CAT originating from both ventricles
  - High (outlet) VSD immediately below truncal valve
  - Common truncal valve with 2 (5%), 3 (60%), or 4 (25%) cusps, rarely 5
- Color Doppler
  - Bidirectional flow across VSD
  - Truncal valve regurgitation

Angiographic Findings

- Cardiac catheterization with angiography
  - To define exact type of truncal anatomy
  - Visualizes truncal valve insufficiency
  - Hemodynamic study is gold standard for calculation of pulmonary vascular resistance

Imaging Recommendations

- Protocol advice
  - Primary diagnosis is made with echocardiography
  - MR/CTA for preoperative delineation of PA anatomy
  - MR/CTA for postoperative assessment of conduit regurgitation/stenosis, stent placement

DIFFERENTIAL DIAGNOSIS

Transposition of Great Arteries

- Presents earlier in life with more severe cyanosis; ductus dependent

Aortopulmonary Window

- Congenital fenestration between separate ascending aorta & PA with separate aortic & pulmonary valves

Common Atrioventricular Canal

- When unbalanced (right or left dominant), cyanosis frequently occurs due to admixture

PATHOLOGY

General Features

- Genetics
  - Strong association with deletion on long arm of chromosome 22 (22q11 syndrome)
  - Associated findings: Cardiac anomalies (truncus arteriosus), abnormal facies, thymic hypoplasia, cleft palate, & hypocalcemia with deletion of chromosome 22 (CATCH-22)
    - Includes DiGeorge syndrome, velocardiofacial syndrome, & conotruncal anomaly face syndrome
  - Theory: Abnormal migration of neural crest tissue that interferes with development of cardiac tube
- Associated abnormalities
  - Right-sided aortic arch with mirror-image branching (30-40%)
  - Persistence of primitive aortic arches
  - Absent thymus & parathyroid glands
- Embryology
  - Lack of separation of primitive bulbus cordis into aorta & main PA
  - Associated persistence of primitive aortic arches

- Pathophysiology: Congestive heart failure vs. cyanosis (degree of cyanosis is determined by balance between pulmonary & systemic vascular resistances)
  - Marked ↑ in pulmonary blood flow in early neonatal period due to drop in pulmonary vascular resistance → slight improvement in cyanosis but worsening congestive heart failure
  - Development of pulmonary vascular obstructive disease → improvement in congestive heart failure but worsening cyanosis

Staging, Grading, & Classification

- Classification of Collett & Edwards
  - Type 1: Separation of common trunk into ascending aorta & main PA
  - Type 2: Common take-off of branch PAs from trunk with no main PA
  - Type 3: Both branch PAs originate separately from posterolateral aspect of ascending aorta
  - Type 4: Pseudotruncus: Pulmonary arterial supply from major aortopulmonary collateral arteries (MAPCAs) arising from descending aorta; controversial entity (misnomer for pulmonary atresia with VSD & MAPCAs)
- Classification of Van Praagh
  - Type A1: Same as Collett & Edwards type 1
  - Type A2: Separate origins of branch PAs from CAT
  - Type A3: Origin of 1 branch of PA (usually right) from common trunk with other branch arising from aortic arch [collateral or patent ductus arteriosus (PDA)]
  - Type A4: Truncus with interrupted aortic arch

Gross Pathologic & Surgical Features

- Common outflow tract of both ventricles over nonrestrictive VSD
- Position of common trunk with respect to VSD
  - Predominantly positioned over right ventricle (42%)
  - Predominantly positioned over left ventricle (16%)
  - Equally shared (42%)
- No separate outflow portion (infundibulum) of right ventricle
- Many variations exist involving interruption of aortic arch (11-14%), absence of branch PA (hemitruncus), & PDA

CLINICAL ISSUES

Presentation

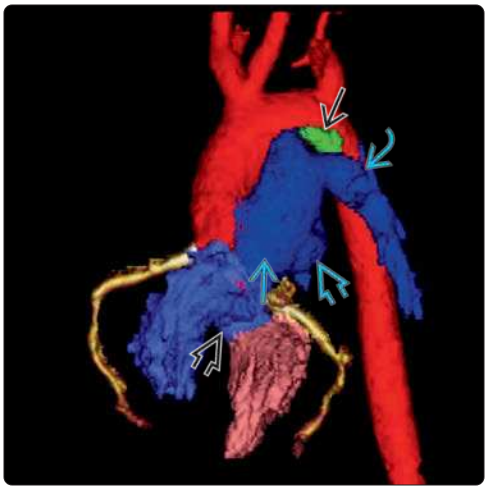
- Most common signs/symptoms
  - Progressive congestive heart failure with drop in pulmonary vascular resistance in young infant
  - ↑ cyanosis due to shunt reversal with development of pulmonary hypertension
- Other signs/symptoms
  - T-cell immunodeficiency (thymic agenesis in DiGeorge syndrome)
  - Neonatal tetany (absent parathyroid glands)

Demographics

- Epidemiology
  - 2% of congenital cardiac anomalies

Natural History & Prognosis

- Untreated: 65% 6-month & 75% 1-year mortality
- Intractable congestive heart failure
  - Marked ↑ in pulmonary flow after drop in pulmonary vascular resistance
  - Aggravated by presence of truncal valve regurgitation (in 50% of cases)
- Eventual shunt reversal with progressive cyanosis & sudden death
  - Pulmonary vascular obstructive disease with Eisenmenger physiology can develop as early as 6 months of age
- Postoperative course is determined by function of PA conduit & morbidity of conduit replacement



Treatment

- Palliative: Banding of main PA
  - Initial palliation with PA banding is often unsatisfactory with early development of pulmonary vascular disease → pulmonary hypertension
  - Early complete repair (at 2-6 weeks of life) is favored by most surgeons
- Surgical repair with placement of conduit between right ventricle & PA or creation of connection with atrial appendage & monoleaflet valve with closure of VSD
  - Conduit revisions are frequently necessary throughout patient's lifetime
    - Patient outgrows fixed conduit size
    - Ca^{2+}, stenosis, neointimal hyperplasia
    - Anastomotic pseudoaneurysm
    - Conduit valve dysfunction (regurgitation)
  - Truncal valve dysfunction (regurgitation) is common → need for valvuloplasty, prosthesis

(Left) *Sagittal MIP cardiac CTA in an infant shows a truncus arteriosus with a common pulmonary trunk ⇨ arising posteriorly before dividing into the right ⇨ & left ⇨ PAs. The findings are consistent with a type A1 truncus arteriosus.* **(Right)** *Lateral 3D surface-rendered image cardiac CTA in an infant shows a type A1 truncus arteriosus with a common pulmonary trunk ⇨ arising posteriorly before dividing into right ⇨ & left ⇨ PAs. Note the ventricular septal defect ⇨ & patent ductus arteriosus ⇨.*

(Left) *Sagittal MIP cardiac CTA in an infant shows the origin of the right PA ⇨ from the posterior aspect of a common trunk ⇨ with the left PA ⇨ arising from the undersurface of the aorta, consistent with a type A3 truncus arteriosus. Note the stenosis of the proximal left PA.* **(Right)** *Lateral 3D surface-rendered CTA shows the origin of the right PA ⇨ from the posterior aspect of a common trunk ⇨ with the left PA ⇨ arising from the undersurface of the aorta, consistent with a type A3 truncus arteriosus.*

(Left) *Oblique axial MIP cardiac CTA shows the right PA ⇨ arising from the ascending aortic trunk ⇨. The left PA ⇨ arises normally from the main PA ⇨.* **(Right)** *Lateral 3D surface-rendered cardiac CTA shows a hemitruncus variation with the origin of the right PA ⇨ from the common aortic trunk ⇨ & the left PA ⇨ arising normally from the main PA ⇨. Note the large patent ductus arteriosus (green) & the hypoplastic aortic arch ⇨.*

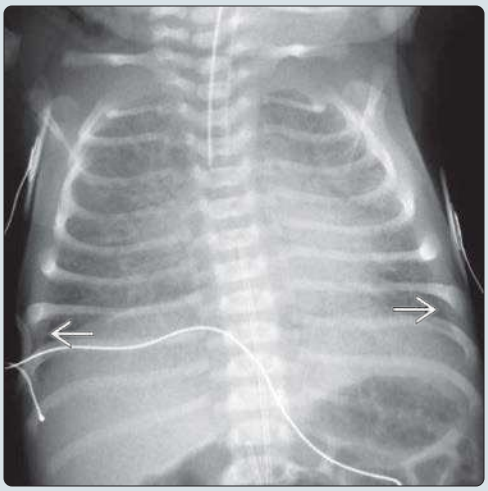
Total Anomalous Pulmonary Venous Return

KEY FACTS

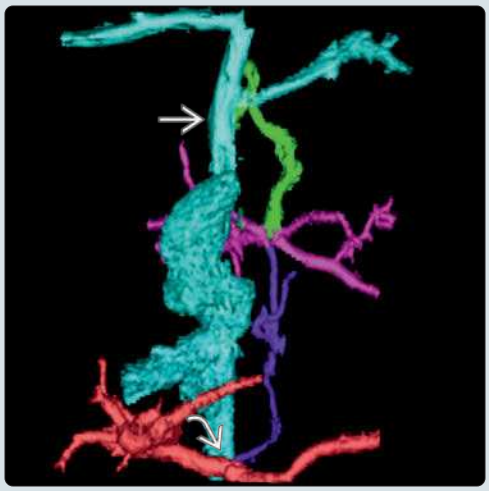
TERMINOLOGY

- Total anomalous pulmonary venous return (TAPVR) or "drainage": Failure of connection between pulmonary veins (PVs) & left atrium
- Category: Cyanotic; heart size & pulmonary vascularity depend on type
- All pulmonary venous return goes to right heart (extracardiac left-to-right shunt)
- All types are admixture lesions
- Supracardiac TAPVR (type I, 40-50%): "Vertical" common PV joins left innominate vein
- Cardiac TAPVR (type II, 20-30%): Common PV joins coronary sinus or right atrium
- Infracardiac TAPVR (type III, 10-30%): Common PV joins portal vein, ductus venosus, or inferior vena cava

IMAGING

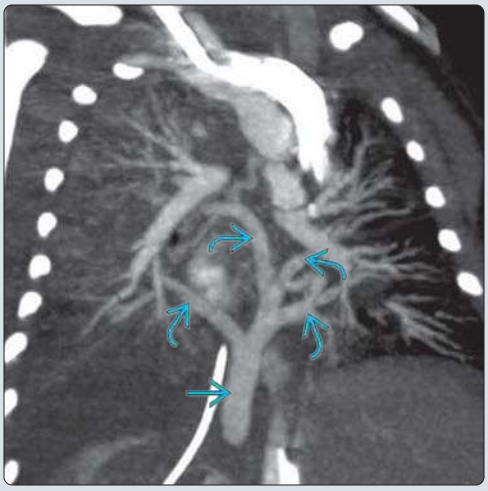


- Cardiomegaly (types I, II); small heart (type III)
- Shunt vascularity (types I, II); pulmonary edema (type III)
- Type I: "Snowman heart"
- Type II: Indistinguishable from atrial septal defect (ASD)
- Type III: Small heart, reticular pattern in lungs (edema)

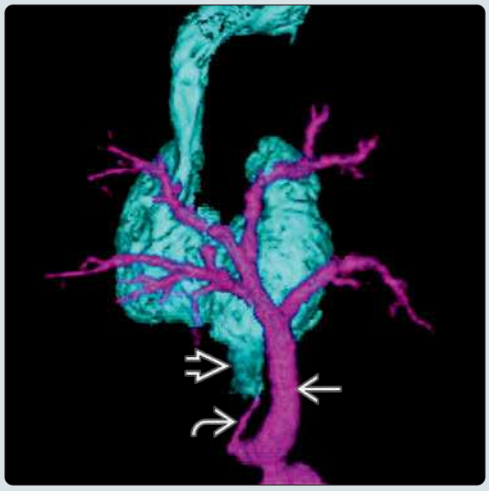


PATHOLOGY

- All types have patent foramen ovale (PFO) to allow for obligatory right-to-left flow → varying degrees of cyanosis
- TAPVR (type III): Common PV is obstructed by diaphragmatic hiatus → pulmonary venous congestion & edema
- Left-sided cardiac chambers may be underdeveloped, especially in TAPVR type III (due to ↓ in systemic flow)



CLINICAL ISSUES



- Treatment: Early surgical anastomosis of pulmonary venous confluence to left atrium
- Anastomotic PV stenosis in up to 18% of TAPVR repairs
- Longstanding PV stenosis → irreversible pulmonary hypertension (arterial pulmonary vascular disease)
- Angioplasty of distal PVs is often required after surgery

(Left) *Frontal radiograph in a newborn shows diffuse pulmonary edema with small, bilateral pleural effusions. Note that the heart size is normal in this patient with a mixed type of total anomalous pulmonary venous return (TAPVR).* **(Right)** *Frontal color-coded 3D CTA in a complex TAPVR patient shows pulmonary veins (pink) draining into superior (green) & inferior (purple) vertical veins. Superior vertical vein drains to superior vena cava, & the inferior vertical vein drains to the portal vein.*

(Left) *Coronal MIP CTA of an infant with an obstructed type III TAPVR shows that the pulmonary veins connect to a large vertical vein that then drains below the diaphragm.* **(Right)** *Posterior color-coded 3D CTA shows the pulmonary veins (purple) emptying into a large inferior vertical vein in a patient with obstructed infracardiac TAPVR. Only a small venous connection was seen to the inferior vena cava. Note the symmetric atria (light blue) in this patient with heterotaxy.*

TERMINOLOGY

Synonyms

- Total anomalous pulmonary venous connection
  - Refers to anatomy: Where pulmonary veins (PVs) connect

Definitions

- Total anomalous pulmonary venous return (TAPVR) or "drainage"
  - Refers to hemodynamics: Where pulmonary venous flow returns (drain)
- Failure of connection between PVs & left atrium
- Category: Cyanotic; heart size & pulmonary vascularity depend on type
- Hemodynamics
  - All pulmonary venous return goes to right heart (extracardiac left-to-right shunt)
  - Intracardiac right-to-left shunt through patent foramen ovale (PFO)
  - All types are admixture lesions
- 3 types
  - Supracardiac TAPVR (type I, 50%): "Vertical" common PV joins left innominate vein
  - Cardiac TAPVR (type II, 20%): Common PV joins coronary sinus or right atrium
  - Infracardiac TAPVR (type III, 20%): Common PV joins portal vein, ductus venosus, hepatic veins, or inferior vena cava
  - Mixed or complex TAPVR (type IV) when there is mixture of aforementioned types (10%)

IMAGING

General Features

- Best diagnostic clue
  - No PVs connecting to left atrium
  - Supra- or infracardiac vertical vein

Radiographic Findings

- Radiography
  - Cardiomegaly (types I, II); small or normal heart size (type III)
  - Shunt vascularity (types I, II); pulmonary edema (type III)
    - Types I & II rarely may be obstructive with pulmonary edema & effusions
  - Wide mediastinum (type I → "snowman heart"), narrow mediastinum (types II & III → thymic atrophy)
  - Classic plain film appearance
    - Type I: "Snowman heart" (due to left vertical vein)
    - Type II: Indistinguishable from atrial septal defect (ASD)
    - Type III: Small heart, reticular pattern in lungs → edema

CT Findings

- CTA is useful to define anatomy in complex types of TAPVR & to define additional congenital heart lesions
  - Thickened interlobular septa, peribronchial cuffing, & ground-glass opacities suggest anastomotic PV stenosis
  - Airway compression is well visualized by CT
- Can be used postoperatively for evaluation of PV caliber & anastomoses

MR Findings

- T1WI
  - Cardiac gated black blood imaging: Anomalous connections are best seen in coronal plane
- MRA
  - Velocity-encoded phase-contrast MRA: For detection of PV anastomotic stenosis (flow velocities > 100 cm/sec are diagnostic)
    - Phase contrast
      - Qp:Qs calculation
      - Elevated velocities in distal vertical vein
      - Quantitative evaluation of cardiac valves for regurgitation
  - Dynamic time-resolved gadolinium-enhanced 3D MRA: For detailed depiction of PV anatomy
- MR cine
  - Steady-state free precession cine MR for functional assessment, flow jets, regurgitation

Echocardiographic Findings

- Echocardiogram
  - Lack of connection of PVs to normal-sized left atrium
  - Right-sided chamber enlargement in types I, II
  - PFO
  - Associated cardiac & abdominal situs abnormalities
  - Evaluation of complex types is limited by ultrasound
  - Limited assessment for postoperative anastomotic PV obstruction

Angiographic Findings

- Conventional
  - Seldom required for primary diagnosis
  - Balloon atrial septostomy when flow across ASD is restricted
  - After repair: For diagnosis & treatment of anastomotic PV stenosis

Imaging Recommendations

- Protocol advice
  - Primary diagnosis with echocardiography
  - CT, MR for postoperative PV anastomotic stenosis
  - Conventional angiography to treat postoperative PV stenosis

DIFFERENTIAL DIAGNOSIS

Cor Triatriatum

- Pulmonary venous connection is present but remains stenotic with lack of incorporation of common PV into left atrial wall

Hypoplastic Left Heart Syndrome

- PVs insert normally into left atrium with left-to-right shunting through PFO

Persistent Fetal Circulation Syndrome/Primary Pulmonary Hypertension

- Associated with
  - Severe surfactant deficiency disease
  - Meconium aspiration

Hypogenetic Lung Syndrome (Scimitar Syndrome)

- Partial anomalous pulmonary venous return to right lower lobe
- Systemic arterial supply to right lower lobe
- Hypoplastic right lung

Partial Anomalous Pulmonary Venous Return

- Majority of PVs drain normally to left atrium
- May present with volume overload to right heart

PATHOLOGY

General Features

- Genetics
  - No specific genetic defect has been found
  - Associated with heterotaxy syndromes
- Associated abnormalities
  - Single ventricle, atrioventricular septal defect, truncus arteriosus, tetralogy of Fallot, anomalous systemic venous connection
  - Asplenia syndrome with symmetric, bilateral, morphologic right atria
  - Polysplenia syndrome is less common
  - Biliary atresia
  - Thoracic lymphangiectasia & pulmonary edema are associated with infracardiac-type TAPVR
- All anomalous pulmonary venous drainage eventually flows into right atrium
- Embryology
  - Lack of normal incorporation of primitive common PV into posterior wall of left atrium
  - Persistence & enlargement of embryologic pathways for pulmonary venous return via umbilicovitteline & cardinal veins
- Pathophysiology
  - All types have PFO to allow for obligatory right-to-left flow → varying degrees of cyanosis (less severe in types I, II → pulmonary hypercirculation)
  - Nonobstructive TAPVR (types I, II): ASD physiology, pulmonary plethora, congestive heart failure
  - Obstructive TAPVR (type III): Common PV is obstructed by diaphragmatic hiatus → pulmonary venous congestion & edema
  - Left-sided cardiac chambers may be underdeveloped, especially in TAPVR type III, due to prenatal ↓ in systemic blood flow

CLINICAL ISSUES

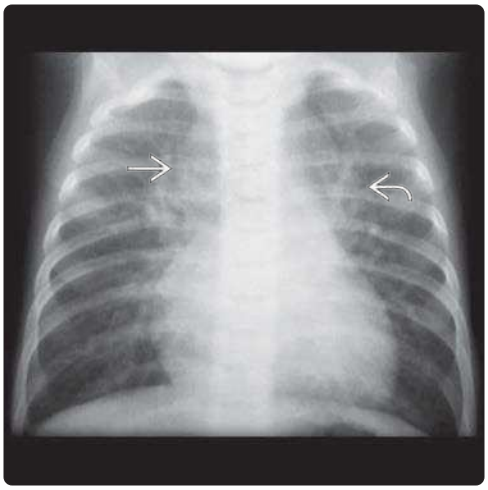
Presentation

- Most common signs/symptoms
  - Types I, II: Congestive heart failure
  - Type III: Severe cyanosis at birth
  - Patent ductus arteriosus: Persistent fetal circulation

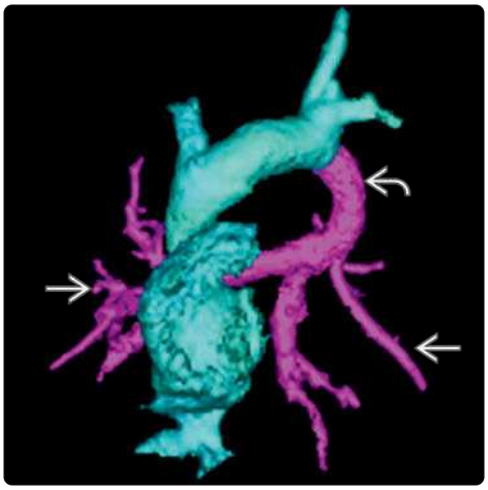
Demographics

- Epidemiology
  - 1-3% of congenital heart disease
  - More frequent in neonatal period

Natural History & Prognosis



- No patients survive without surgical treatment
- Natural history is highly variable
  - Types I, II: Initially asymptomatic with gradual development of congestive heart failure when pulmonary vascular resistance drops (ASD physiology)
  - Type III, obstructive forms: Death within month
- After surgical repair: Prognosis is determined by associated cardiac anomalies & development of PV anastomotic stenosis
  - Progressive distal PV stenosis is often seen → significant morbidity & mortality



Treatment

- Prostaglandin E1 to improve systemic perfusion in pulmonary hypertension (HTN)
- Preoperative extracorporeal membrane oxygenation is occasionally necessary to improve oxygenation & systemic perfusion
- Early surgical anastomosis of pulmonary venous confluence to left atrium
  - Anastomotic PV stenosis may occur in up to 18% of TAPVR repairs
  - Longstanding PV stenosis → irreversible pulmonary HTN (arterial pulmonary vascular disease)
  - Reoperation performed using sutureless technique with pericardial patch augmentation of anastomotic stenoses
- Angioplasty of distal PVs is often required after surgery due to stenosis

(Left) *Frontal radiograph shows a snowman appearance of the superior mediastinum in a patient with a supracardiac TAPVR. The left-sided vertical vein forms the border of the superior left mediastinum. The dilated innominate vein & superior vena cava form the superior & right borders of the superior mediastinum, respectively.* **(Right)** *Frontal projection color-coded 3D CTA shows the pulmonary veins emptying into a large left-sided vertical vein in this patient with a supracardiac TAPVR.*

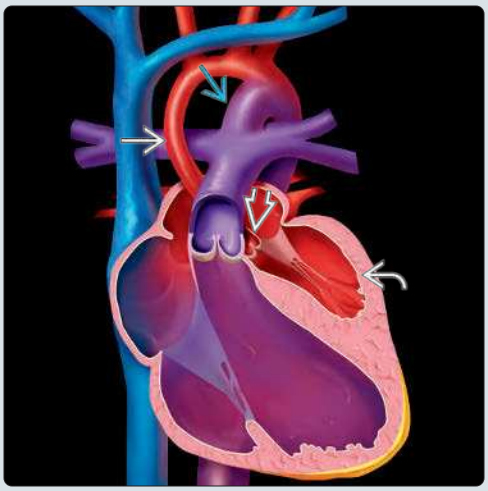
(Left) *Axial MIP cardiac CTA in an infant shows the pulmonary veins emptying directly into the right atrium. Note the isolated left atrium.* **(Right)** *Superior color-coded 3D CTA in an infant shows the pulmonary veins emptying directly into the right atrium. Note the isolated left atrium. The left atrial appendage is well demonstrated. The left ventricle (salmon) is also shown.*

(Left) *Coronal MIP cardiac CTA in an infant shows the pulmonary veins draining into a large vertical vein, which goes below the diaphragm & empties into the portal vein.* **(Right)** *Frontal color-coded 3D CTA in an infant shows the pulmonary veins draining into a large vertical vein, which goes below the diaphragm & empties into the portal vein, consistent with an infracardiac type of TAPVR. The superior vena cava, right atrium (blue), & umbilical artery catheter (green) are also shown.*

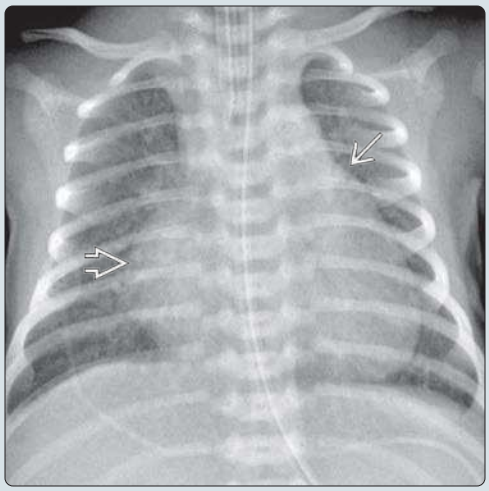
Hypoplastic Left Heart Syndrome

KEY FACTS

TERMINOLOGY

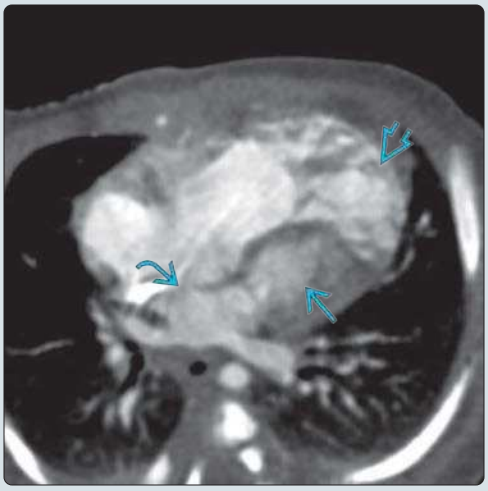


- Most severe congenital heart lesion
  - Presents in neonatal period with congestive heart failure, cardiogenic shock, & cyanosis
- Category: Cyanotic, cardiomegaly, ↑ pulmonary vascularity
- Hypoplasia/atresia of ascending aorta, aortic valve, left ventricle (LV), & mitral valve (MV)
- Secondary findings: Patent ductus arteriosus, juxtaductal coarctation



IMAGING

- Chest radiograph shows cardiomegaly, large right atrium, pulmonary venous congestion with interstitial fluid
- Postnatal echocardiogram is sufficient for treatment planning
  - Diminutive ascending aorta < 5 mm
  - Small, thick-walled LV; presence of endocardial fibroelastosis (EFE)
  - MV size is important to decide whether biventricular repair is possible in marginally hypoplastic LVs
  - Dilation of right cardiac chambers & pulmonary artery
  - Size & location of ductus arteriosus
  - Unrestricted atrial level shunt (patent foramen ovale vs. atrial septal defect) is critical for immediate postnatal care; may require emergent balloon atrial septostomy; saturations are dependent on degree of atrial level shunting
  - Abnormal ventricular wall motion (ischemic damage, EFE)
- CT can evaluate patency of aortopulmonary (Blalock-Taussig) & cavopulmonary (Glenn) shunts
- MR for functional assessment of univentricular heart to determine suitability for Fontan operation



CLINICAL ISSUES

- Mortality is high if not treated in neonatal period
- Prognosis improves substantially with surgical intervention

(Left) *Graphic shows hypoplasia of the left atrium (LA), mitral valve (MV), left ventricle (LV), aortic valve, & ascending aorta. Systemic blood flow depends on the patency of the ductus arteriosus.* **(Right)** *AP radiograph in a 3-day-old shows the typically large main pulmonary artery (MPA) along the left border of the heart + an enlarged right atrium due to left-to-right shunting of blood across the atrial septal defect (ASD). Mild pulmonary edema & ↑ pulmonary blood flow characterize the vasculature.*

(Left) *Four-chamber cardiac CTA in an infant with hypoplastic left heart syndrome (HLHS) shows a markedly hypoplastic LV. The right ventricle (RV) wraps around the smaller LV, giving the typical non-apex-forming LV seen with HLHS. Note the ASD, which, if too small, may have to undergo septostomy to ↑ mixing of blood.* **(Right)** *Four-chamber echocardiogram shows a small, muscle-bound LV & small LV outflow tract (LVOT). The RV is large relative to the hypoplastic LV & wraps around the apex of the LV.*

TERMINOLOGY

Abbreviations

- Hypoplastic left heart syndrome (HLHS)

Synonyms

- 4 classic types: Mitral atresia/aortic atresia, mitral atresia/aortic stenosis, mitral stenosis/aortic atresia, mitral stenosis/aortic stenosis

Definitions

- Hypoplasia/atresia of ascending aorta, aortic valve, left ventricle (LV), & mitral valve (MV)
  - Secondary findings: Patent ductus arteriosus (PDA), juxtaductal coarctation
- Most severe congenital heart lesion
  - Presents in neonatal period with congestive heart failure, cardiogenic shock, & cyanosis
- Category: Cyanotic, cardiomegaly, ↑ pulmonary vascularity
- Hemodynamics
  - Severe obstruction of flow to systemic circulation (ductal dependent)
  - Retrograde flow in hypoplastic aortic arch & ascending aorta for cranial & coronary perfusion
  - Volume overload in pulmonary circulation
  - Obligate left-to-right shunt at atrial level via patent foramen ovale (PFO) or secundum atrial septal defect (ASD)
    - Restrictive atrial septum in neonate is highly lethal & requires emergent catheter-based balloon atrial septostomy
  - Flow admixture in right atrium → severe cyanosis

IMAGING

General Features

- Best diagnostic clue
  - Hypoplasia of ascending aorta, LV

Radiographic Findings

- Cardiomegaly, pulmonary venous congestion with interstitial fluid, hyperinflation, narrow mediastinum due to thymic atrophy

Echocardiographic Findings

- Echocardiogram
  - HLHS is often diagnosed prenatally
    - Retrograde flow in diminutive ascending aorta
    - LV growth arrest only manifests between 18-22 weeks of gestation
  - Postnatal diagnosis with echo is sufficient for treatment planning
    - Diminutive ascending aorta < 5 mm
    - Small, thick-walled LV
    - MV anulus Z score: Important parameter to decide whether biventricular repair is possible in marginally hypoplastic LVs
    - Dilation of right-sided cardiac chambers & main pulmonary artery (MPA)
    - Size & location of ductus arteriosus
    - Atrial level shunt: PFO or secundum ASD (often superior secundum defect); any degree of atrial level restriction can play significant role in decision making, pre- & post natal
    - Abnormal ventricular wall motion (ischemic damage); endocardial fibroelastosis of diminutive LV
    - Tricuspid valve regurgitation: Best marker of clinical outcomes
- Color Doppler
  - Diagnosis of HLHS subtype (mitral stenosis or atresia; aortic stenosis or atresia)
  - Left-to-right shunting through PFO/ASD: Mean diastolic gradient estimates degree of atrial-level restriction
  - Tricuspid valve regurgitation: Clinically important indicator

CT Findings

- CTA
  - Presurgical
    - Small left atrium with atretic/stenotic MV, hypoplastic LV with ascending & transverse aortic arch hypoplasia, single dilated right ventricle & MPA with large PDA continuation to descending aorta
    - Unusual anatomic variants or borderline LV volumes (mitral stenosis/aortic stenosis variants); severe single ventricle dysfunction
  - Postsurgical
    - Patency of aortopulmonary (Blalock-Taussig) & cavopulmonary (bidirectional Glenn) shunts
    - Seroma associated with Blalock-Taussig shunt
    - Airway compression (left bronchus) &/or left pulmonary artery (PA) compression by dilated neoaortic arch following Norwood repair
    - Residual stenosis of neoaortic arch, coarctation

MR Findings

- T2* GRE
  - SSFP cine MR for ventricular volume measurements in marginally hypoplastic left heart (to determine feasibility of biventricular repair)
  - Short-axis SSFP cine MR for functional assessment of univentricular heart (to determine suitability for Fontan operation)
- MRA
  - Velocity-encoded phase-contrast MRA for measurements of flow through aortic isthmus, PDA, & PFO
    - Can predict response to intraoperative test closure of ASD & PDA to determine feasibility of biventricular repair

Angiographic Findings

- Cardiac catheterization with angiography
  - Primarily interventional (as opposed to diagnostic): Obtained in case of atrial level restriction & need for early balloon atrial septostomy (BAS)
    - Delivery at pediatric care center where immediate BAS can be performed
    - Catheter & BAS can be performed via umbilical venous & arterial catheters
    - Retrograde flow in hypoplastic ascending aorta

  - Catheter can be placed across ductus arteriosus to image PAs retrograde

Imaging Recommendations

- Protocol advice
  - Primary diagnosis made with pre- & postnatal transthoracic echocardiography in majority of cases
  - Postsurgical: Functional MR & interventional catheterizations for residua/sequelae of Fontan operation

DIFFERENTIAL DIAGNOSIS

Interrupted Aortic Arch

- Pressure overload of normally developed LV

Hepatic Congenital Hemangioma

- Structurally normal heart with volume overload of all chambers

Endocardial Fibroelastosis

- Globally enlarged, structurally normal heart with myocardial dysfunction

Anomalous Left Coronary Artery From Pulmonary Artery

- Left coronary originates from PA → myocardial infarction

Severe Arrhythmias: Paroxysmal Supraventricular Tachycardia

- Characteristic electrocardiogram

CLINICAL ISSUES

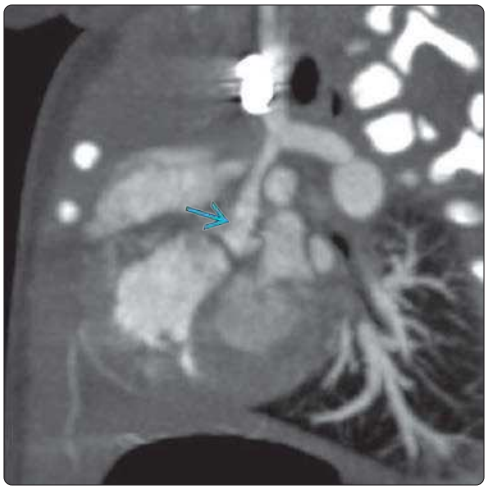
Presentation

- Most common signs/symptoms
  - No circulatory symptoms immediately at birth but rapid deterioration
    - Congestive heart failure (volume overload of pulmonary circulation)
    - Cardiogenic shock after closure of PDA
    - Cyanosis (flow admixture in right heart)
    - Hypoxia → pulmonary hypertension, persistent fetal circulation
- Other signs/symptoms
  - Poor systemic perfusion, metabolic acidosis
    - Acute tubular necrosis, renal failure
    - Necrotizing enterocolitis

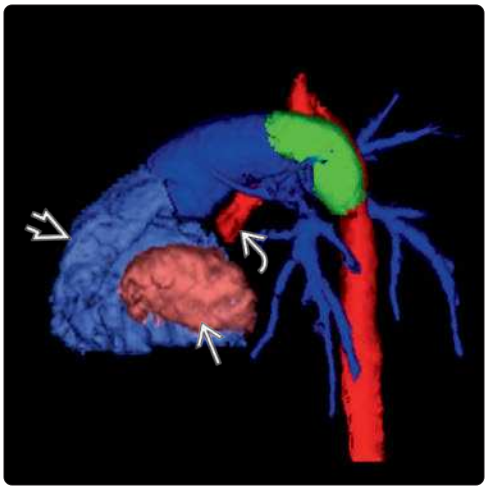
Demographics

- Epidemiology
  - 1-3 per 10,000 live births, M:F = 2:1
  - 4th most common congenital heart lesion presenting under 1 year (7-9%)

Natural History & Prognosis



- Death within days/weeks when untreated
- Prognosis improves substantially with treatment
- Prognosis is determined by complications, residua, & sequelae of staged Norwood repair & Fontan operation (right ventricular dysfunction, venous hypertension)
- Significant tricuspid regurgitation after surgical palliation correlates with poor outcome



Treatment

- Medical: Prostaglandins initiated at birth/time of diagnosis to keep PDA open (provides right-to-left flow to descending aorta)
- Prenatal: US-guided balloon dilation of aortic valve in mid-/late fetal period is being studied
  - Change in fetal hemodynamics may enhance prenatal growth of left-sided cardiac structures
- Rashkind BAS (in case of flow restriction across PFO)
- Palliative repair: 3-stage approach
  - Norwood: Neoaorta creation from PA (with incorporation of native hypoplastic ascending aorta), atrial septectomy, & Blalock-Taussig shunt (Gore-Tex shunt from base of innominate artery to right PA) **or** Sano shunt (Gore-Tex shunt from RV to mid-PA) for controlled pulmonary blood flow (1-3 weeks of age)
  - Damus-Kaye-Stansel anastomosis: Essentially occurs with every Norwood as hypoplastic ascending aorta is filleted & incorporated into neoaorta/PA (classic description is side-to-side anastomosis between PA & aorta)
  - Conversion to hemi-Fontan: Glenn shunt between superior vena cava & right PA (4-6 months)
  - Bidirectional Glenn anastomosis: Offloads ventricle, not shunt dependent (more stable), prepares lungs for passive lung perfusion via cavopulmonary anastomosis
  - Fontan: Fenestrated venous conduit through right atrium for inferior cava flow to right PA (1.5-2 years)
- Marginally hypoplastic LV: Biventricular repair may be feasible
  - LV volume is commonly underestimated with echocardiography
  - Functional MR (SSFP cine): Ventricular volumes & mass determination are more reliable
- In some centers: Cardiac transplantation

(Left) *Sagittal cardiac CTA in an infant with HLHS shows marked hypoplasia of the ascending aorta due to aortic atresia.* **(Right)** *Left lateral 3D surface-rendere cardiac CTA shows a markedly hypoplastic LV with hypoplasia of the ascending aorta due to aortic atresia. Note the enlarged RV & the large patent ductus arteriosus (PDA) (green) connecting the aorta (red) to the main PA (blue).*

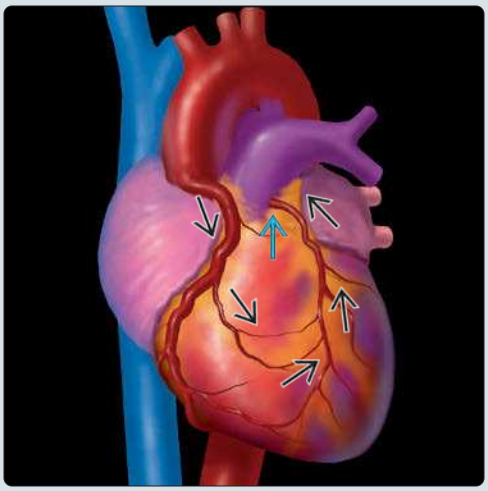
(Left) *Frontal radiograph of the chest in a patient with HLHS shows mild perihilar pulmonary edema with small, bilateral pleural effusions. The findings are consistent with heart failure, which occurs when the PDA closes. Note that the tip of the PICC is abnormally deep in the right atrium.* **(Right)** *Axial T1 MR at the level of the ventricles in the same patient shows the large RV & the diminutive LV. Note the large RA.*

(Left) *Four-chamber cardiac CTA in an infant shows a markedly hypoplastic LV with marked enlargement of the RA. Note the bilateral pulmonary edema as the PDA was closing.* **(Right)** *Anterior 3D surface-rendered cardiac CTA in an infant shows a markedly enlarged RA & hypoplastic ascending aorta in a patient with HLHS. Note the enlarged PA, which is critical as this is a ductal-dependent type of congenital heart disease.*

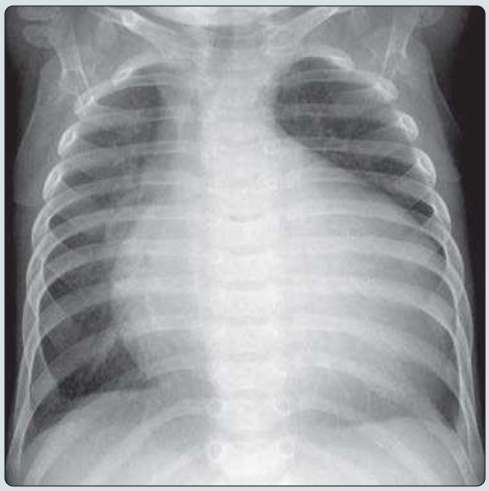
Left Coronary Artery Anomalous Origin

KEY FACTS

TERMINOLOGY

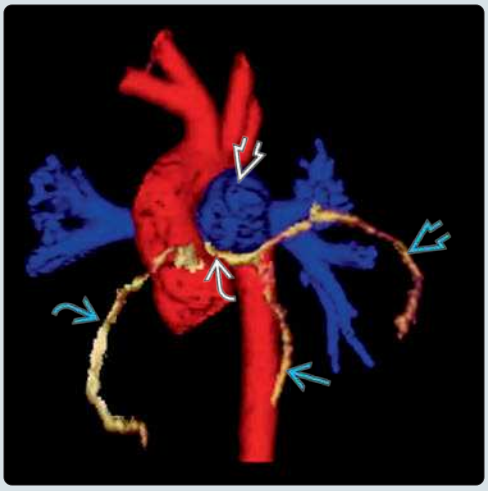


- Anomalous origin of left coronary artery (LCA) from pulmonary artery: Most common congenital coronary artery anomaly presenting in children
- Causes cardiac ischemia & infarction, poor left ventricular (LV) systolic function, & significant mitral regurgitation



IMAGING

- Chest radiograph demonstrates cardiomegaly
- Echocardiogram (~ 90% diagnostic accuracy) demonstrates
  - Abnormal LCA ostium arising from pulmonary trunk
  - Retrograde flow in LCA toward pulmonary artery
  - Right coronary artery dilation & abundant intercoronary septal collaterals
  - Depressed LV systolic function & dilated LV chamber
  - Significant mitral regurgitation from ischemic papillary muscle dysfunction & mitral annular dilation
- CTA/MRA to identify coronary origins when echo is limited (~ 100% diagnostic accuracy)



CLINICAL ISSUES

- Rare congenital anomaly
  - Up to 90% mortality if not identified & surgically corrected
- Up to 90% present in infancy with nonspecific symptoms of irritability, failure to thrive, & wheezing (from mitral regurgitation)
  - ECG shows anterior lateral wall infarct pattern
- Older children are often asymptomatic until sudden event with syncope, dysrhythmia, & occasional sudden cardiac death
  - Surgical options include coronary reimplantation to aorta, bypass grafting with anomalous origin ligation, Takeuchi baffle
  - Simultaneous repair of mitral valve is controversial as severe regurgitation may improve with revascularization

(Left) *Graphic shows an anomalous left coronary artery (LCA) origin from the main pulmonary artery (PA). Collateral flow from the normal right coronary artery (RCA) to the LCA allows retrograde flow through the LCA to the low-resistance PA (with flow direction denoted). This flow bypasses the high-resistance myocardial bed of the left ventricle (LV).* **(Right)** *AP radiograph from an 8-month-old with wheezing shows a markedly enlarged cardiac silhouette. Echocardiography showed the LCA arising from the PA.*

(Left) *Frontal view surface-rendered cardiac CTA shows the LCA arising from the right aspect of the main PA before bifurcating into the left anterior descending (LAD) & left circumflex (LCX). Note the normal origin of the RCA from the right coronary sinus of the ascending aorta.* **(Right)** *Coronal CTA demonstrates an anomalous LCA originating from the right inferior aspect of the main PA, consistent with ALCAPA. The LV is markedly dilated due to ischemia from coronary steal.*

TERMINOLOGY

Synonyms

- Anomalous origin of left coronary artery from pulmonary artery (ALCAPA) = Bland-White-Garland (BWG) syndrome

Definitions

- ALCAPA: Most common congenital coronary artery anomaly presenting in children
  - Causes cardiac ischemia & infarction, depressed left ventricular (LV) systolic function, & significant mitral valve regurgitation

IMAGING

General Features

- Best diagnostic clue
  - Chest radiograph: Cardiomegaly in infant
  - Electrocardiogram (ECG): Deep Q waves in leads I & aVL, consistent with anterior lateral wall infarct
  - Echocardiogram: Abnormal left coronary artery (LCA) ostium arising from pulmonary trunk, retrograde LCA flow, right coronary artery (RCA) dilation, abundant intercoronary septal collaterals, significant mitral regurgitation, & depressed LV systolic function
    - ~ 90% diagnostic accuracy
  - CTA/MRA: Anomalous origin of LCA ostium; large tortuous coronary vessels with dilated RCA & significant collaterals
    - ~ 100% diagnostic accuracy

Radiographic Findings

- Radiography
  - Cardiomegaly, left atrial & LV enlargement, ↑ pulmonary vascularity or pulmonary edema (from depressed LV function & mitral regurgitation)

CT Findings

- Multidetector CTA demonstrates coronary artery anatomy & LV enlargement
  - Volume or surface 3D rendering from contrast-enhanced imaging assists with visualization

MR Findings

- T2WI
  - Myocardial edema in LV
- MRA
  - Anomalous LCA from pulmonary trunk, dilated RCA, significant intercoronary septal collaterals
- MR cine
  - Ventricular function is quantified by summation of short-axis stack
  - Wall motion abnormalities are assessed on 4-chamber & short-axis stacks, particularly LCA distribution
  - Ventricular chamber size is quantified by end-diastolic volume
- Double IR FSE
  - Thin-slice (4 mm) demonstrates excellent vessel anatomy: ALCAPA & dilated RCA
- Delayed enhancement
  - Myocardial late gadolinium enhancement (LGE) in LCA distribution is consistent with infarcted or fibrotic segments: Focal with transmural or near-transmural LGE

Echocardiographic Findings

- Abnormal origin of coronary artery recognized by retrograde flow from LCA into pulmonary artery, dilated RCA, & multiple collateral vessels
- Echocardiography demonstrates ↓ LV systolic function, segmental wall abnormalities in LCA distribution (typically representing anterolateral infarct), & significant mitral regurgitation

Angiographic Findings

- Invasive coronary angiography by cardiac catheterization: 100% diagnostic accuracy
  - Performed only when echo & cross-sectional imaging are not diagnostic
  - Pulmonary arteriogram demonstrates anomalous origin of LCA
  - Selective injection of RCA demonstrates dilated vessel & tortuous collateral vessels

Imaging Recommendations

- Best imaging tool
  - ECG in infancy: Infarct pattern with abnormal deep Q waves (particularly in leads I & aVL), ST segment depression, & T-wave inversion
  - Chest radiograph: Cardiomegaly
  - Echocardiogram: ↓ LV systolic function, anomalous origin of coronary artery, collateral vessels, significant mitral regurgitation
  - CTA/MRA when echocardiogram is not definitive
- Protocol advice
  - CTA performance is best with ECG-synchronized gating (prospective), suspended respiration (if possible), high contrast injection rate (4-5 mL/s), & contrast bolus timed or tracked to fill entire PA & aorta

DIFFERENTIAL DIAGNOSIS

Dilated Cardiomyopathy

- Most common cause of depressed LV function in infancy
  - Genetic/metabolic vs. viral origin
- Similar clinical presentation with irritability, failure to thrive, wheezing

Kawasaki Disease

- Vasculitis of medium-sized vessels leading to coronary artery ectasia or aneurysms; etiology unknown
- Myocarditis is common; aneurysms occur in < 2%
- May develop stenosis associated with aneurysm → clot → infarction

Coronary Artery Fistula

- May produce cardiac ischemia if coronary steal leads to reduced blood flow to coronary circulation

Single Coronary Artery Origin

- 40% are associated with other anomalies, including tetralogy of Fallot, transposition of great arteries, etc.
- Usually asymptomatic but occasional sudden cardiac death

PATHOLOGY

General Features

- Associated abnormalities

- Coronary artery anomalies can be isolated or associated with other defects; important to identify for surgical planning
  - Tetralogy of Fallot: Coronary anomalies include small conal branch (88%), large conal branch (6%), left anterior descending (LAD) from RCA (3%), dual LAD (2%), single RCA (0.3%), & single LCA (0.2%)
  - Transposition of great arteries: Coronary anomalies from aortic valve malposition include left circumflex from RCA (14%), single RCA (9%), LAD from RCA (6%), interarterial course of LCA or RCA (4%)
- Embryology
  - Abnormalities in signaling pathways or alterations in local factors that direct coronary development

Microscopic Features

- Signs of LV ischemia & varying degrees of reparative changes are evident on autopsy or transplant
  - Anterolateral papillary muscle is atrophic & scarred
  - Thinning & scarring of anterolateral LV wall & apex due to infarction

CLINICAL ISSUES

Presentation

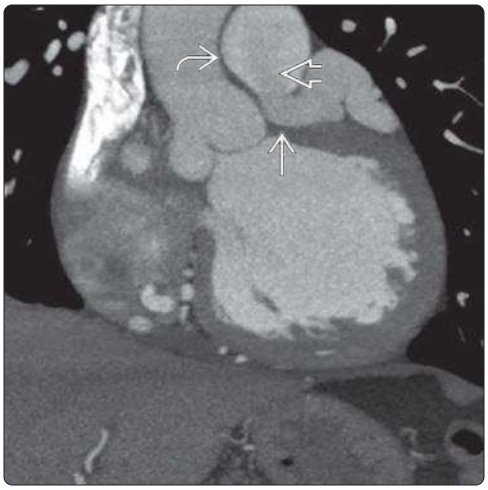
- Most common signs/symptoms
  - ~ 90% present in infancy with nonspecific symptoms of irritability, fussiness, wheezing, &/or failure to thrive
- Other signs/symptoms
  - Diaphoresis or ↓ oxygenation & perfusion (severe cyanosis or grayish appearance)
- Older child or adolescent
  - Usually asymptomatic until sudden catastrophic event occurs with syncope, dysrhythmic event, occasional death
    - May occur with exercise (suggesting coronary artery or other heart disease)

Natural History & Prognosis

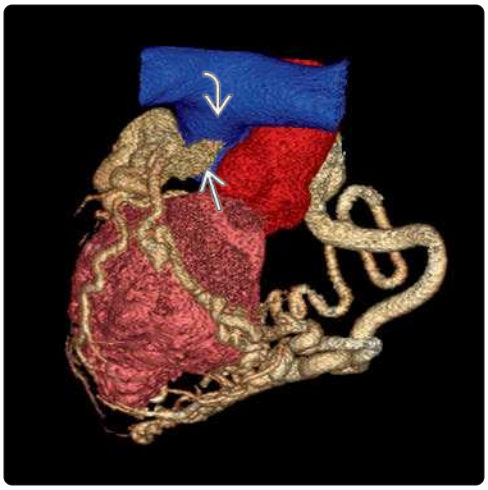
- Fetal life: Lungs are collapsed; normal myocardial perfusion
- Stage 1: Newborn with high pulmonary vascular resistance (PVR)
  - Preferential flow into anomalous LCA (antegrade) from pulmonary artery → normal myocardial perfusion without symptoms or ischemia
- Stage 2: PVR ↓ ~ 2-4 months of life
  - ↓ PA diastolic pressure is inadequate to provide forward flow to anomalous LCA to keep LV myocardium perfused
  - Collateral vessels develop from RCA → RCA dilation
  - Flow from RCA & collaterals meets high resistance of LV myocardial bed → preferential retrograde LCA flow into low-resistance PA
    - Retrograde flow of fully oxygenated blood into PA creates left-to-right shunt
- Later stages: Cardiac ischemia & infarct
  - Myocardial steal occurs with ↑ in collateral vessels
  - Ischemia & infarct develop in anterolateral distribution → global ventricular dilation & dysfunction + significant mitral regurgitation (secondary to papillary muscle infarction)

Treatment

- Medical therapy to stabilize patient initially
  - Mechanical ventilation with oxygen to prevent hypoxia & treat cardiogenic shock
  - Sedation to ↓ myocardial oxygen demand
    - Cardiac anesthesia team is involved due to ↑ potential for cardiac arrest or arrhythmia
- Surgical therapy: Up to 90% mortality if left unrepaired; prognosis is related to degree of preoperative LV systolic dysfunction
  - LV assist device may be utilized preoperatively
  - Surgical techniques include
    - Direct transfer of LCA to aortic root: Button of tissue around LCA ostium is transferred posteriorly to aorta
    - Bypass grafting: Proximal anomalous LCA is ligated + bypass graft to reestablish normal flow direction & tissue perfusion
    - Takeuchi repair: Intrapulmonary baffle from aorta to anomalous LCA origin
    - Simultaneous repair of mitral valve is controversial as severe regurgitation may improve with revascularization
  - Surgical mortality ~ 5-10%, usually related to poor LV function
    - Complications include bleeding, cardiac arrest, heart failure, & stroke
    - Heart transplant is warranted in cases where LV function does not improve after coronary artery surgical intervention



DIAGNOSTIC CHECKLIST



Consider

- ALCAPA in infant with abnormal ECG & unknown cause of LV systolic dysfunction
  - Readily diagnosed by imaging

(Left) *Coronal oblique cardiac CTA in an older patient with longstanding ALCAPA shows the LCA arising from the undersurface of the main PA. Note the blush of unopacified blood extending into the main PA due to the retrograde flow in the LCA toward the PA.* **(Right)** *Posterior 3D surface-rendered cardiac CTA in an older patient with longstanding ALCAPA shows the LCA arising from the undersurface of the main PA. Note the enlarged, tortuous coronaries from chronic coronary steal.*

(Left) *Anterior oblique conventional angiogram shows antegrade flow through a large RCA during an injection of the ascending aorta. Retrograde flow in the LCA (which is filled by multiple collateral vessels) opacifies the PA.* **(Right)** *Echocardiogram demonstrates an ALCAPA with retrograde blood flow into the PA. While the LCA appears to arise from the aorta on grayscale imaging, the color Doppler ultrasound shows flow reversal of the LCA into the PA (demonstrated by a red jet toward the transducer).*

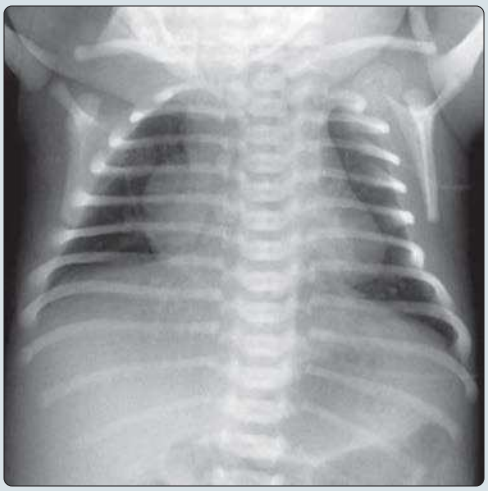
(Left) *ECG of a neonate shows pathologic deep Q waves in leads I & aVL, consistent with a diagnosis of ALCAPA & myocardial ischemia.* **(Right)** *Anterior oblique 3D-rendered CTA performed for 3D printing demonstrates a normal origin of the RCA (with acute marginal branch) from the aorta (red). An ALCAPA arises from the underside of the pulmonary trunk (blue).*

Double-Outlet Right Ventricle

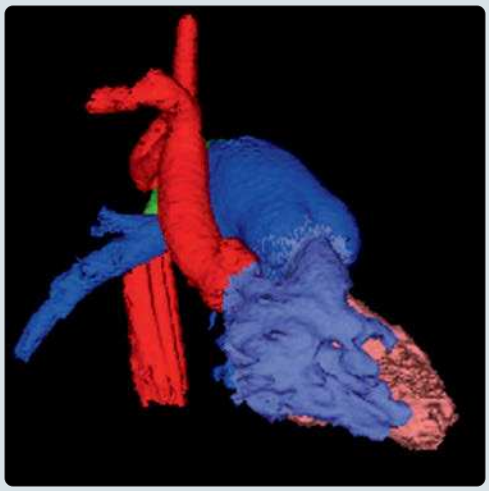
KEY FACTS

TERMINOLOGY

- Double-outlet right ventricle (DORV): Form of abnormal ventriculoarterial connection in which both great arteries arise completely or predominately from morphologic right ventricle (RV)
  - 16 variants based on relationship of great arteries & position/location of ventricular septal defect (VSD)
- May be part of complex congenital heart disease coexisting with ventricular anomalies, valve stenosis or atresia, abnormal atrioventricular valve, aortic valve anomalies, coarctation, coronary anomalies, & anomalies of systemic or pulmonary venous return



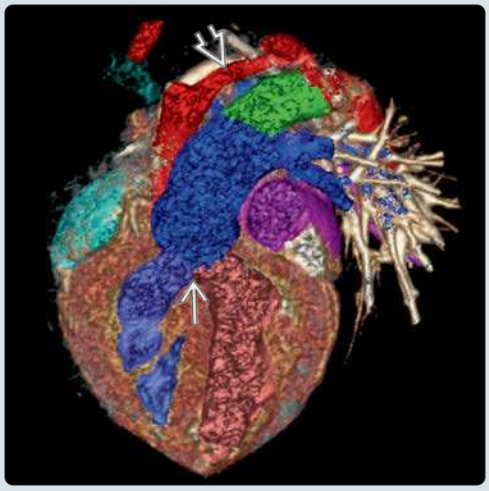
IMAGING



- Opacification of both great arteries during RV injection
- Pulmonary flow is dependent on site of VSD & degree of outflow or pulmonary valve stenosis
- Side-by-side relationship of aorta & pulmonary artery with aorta on right in 50-64%
- 3D imaging can help with complex intracardiac relationships for presurgical planning

CLINICAL ISSUES

- May be diagnosed in utero; usually has clinical symptoms at birth or in 1st month
  - DORV with pulmonic stenosis: Cyanosis, failure to thrive, tachypnea
  - DORV with subaortic VSD without pulmonic stenosis: Symptoms of large left-to-right shunt & early evidence of pulmonary hypertension
- Surgery depends on anatomy
  - Closure of VSD & placement of RV to pulmonary artery conduit if 2 developed ventricles exist
  - Norwood/Fontan procedure if hypoplasia of ventricle
- 15-year survival rate for noncomplex lesions: 85-90%
  - Mortality rate is higher after operation for complex lesions



(Left) *AP chest radiograph in a patient with double-outlet right ventricle (DORV) shows ↓ pulmonary vascularity & mild cardiomegaly. Pulmonic stenosis in this patient makes the radiographic appearance similar to that of a patient with tetralogy of Fallot.* **(Right)** *Frontal 3D cardiac CTA shows both the aorta (red) & pulmonary artery (PA, blue) arising from the right ventricle (RV, purple) in a patient with DORV. Note the ↑ size of the PA (blue), reflecting ↑ left-to-right shunting.*

(Left) *Coronal MIP cardiac CTA in a newborn with DORV shows both the PA ➡ & aorta ➡ arising from the RV ➰. Note the enlarged PA, reflecting left-to-right shunting.* **(Right)** *Four-chamber sectioned volume-rendered cardiac CTA in an infant with DORV shows the subpulmonic position of the ventricular septal defect ➡ between the RV (light blue) & the left ventricle (salmon). Also note the patent ductus arteriosus (green) & hypoplastic aortic arch ➡.*

TERMINOLOGY

Abbreviations

- Double-outlet right ventricle (DORV)

Definitions

- Form of abnormal ventriculoarterial connection in which both great arteries arise completely or predominately from morphologic right ventricle (RV)
- 16 variants based on relationship of great arteries & position/location of ventricular septal defect (VSD)

IMAGING

General Features

- Best diagnostic clue
  - Radiologic appearance, regardless of modality, depends on physiology of lesion, which reflects variable anatomy of DORV
    - Pulmonary flow is dependent on site of VSD & degree of outflow or pulmonary valve stenosis
      - Most common VSD type is subaortic with normally related great vessels
- Morphology
  - Hallmarks of anatomy: Both great arteries originate from morphologic RV
  - Possible relationships of great vessels
    - Side-by-side relationship of aorta & pulmonary artery with aorta on right in 50-64%
  - Possible positions of VSD
    - Subaortic VSD is located anatomically closer to aortic valve than to pulmonary valve
    - Subpulmonary type of DORV: VSD is located closer to pulmonary valve; when supracristal in location, it is called Taussig-Bing anomaly
    - Doubly committed VSD is subaortic, subpulmonary type: Usually large & related to both semilunar valves
    - Remote type or noncommitted VSD is distant from both semilunar valves & may be of atrioventricular canal type or muscular VSD

Radiographic Findings

- Chest radiographs cannot reliably differentiate DORV from other forms of congenital heart disease
- DORV with subaortic VSD + severe pulmonic stenosis + normally related great vessels
  - ↓ pulmonary flow
  - Similar appearance to tetralogy of Fallot (TOF)
- DORV without pulmonic stenosis but with normally related great vessels
  - ↑ pulmonary flow
  - Appears similar to large VSD

CTA or MRA

- Shows relationships of great vessels, position of VSD, relative size of ventricles, & associated anomalies
  - Altered ventricular-great vessel relationship
  - Aortic valve & pulmonic valve may be at same level
- 3D imaging can help with complex intracardiac relationships for presurgical planning
- Postoperative assessment in older patients is useful for anatomy & functional assessment

Angiographic Findings

- Opacification of both great arteries during RV injection
- Filling defect dividing 2 outflow tracts or double conus

DIFFERENTIAL DIAGNOSIS

Ventricular Septal Defect

- Clinically presents with tachypnea, feeding problems, & failure to thrive
- DORV without pulmonic stenosis radiographically simulates large left-to-right shunt
- Distinguishing feature for VSD is normal fibrous continuity between posterior leaflet of aortic valve & anterior leaflet of mitral valve

Tetralogy of Fallot

- With severe outflow tract obstruction & VSD, aorta overrides ventricular septum & simulates DORV with pulmonic stenosis
- Physiology may be similar to DORV, but TOF has aortic-mitral continuity despite anterior position of aorta & overriding of RV

D-Transposition of Great Arteries

- Shows atrioventricular concordance & ventriculoarterial discordance (i.e., aorta arises from RV & pulmonary artery arises from left ventricle)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - May be diagnosed in utero; patients usually have clinical symptoms at birth or in 1st month
    - DORV with pulmonic stenosis: Cyanosis, failure to thrive, tachypnea
    - DORV with subaortic VSD without pulmonic stenosis: Symptoms of large left-to-right shunt & early evidence of pulmonary hypertension

Demographics

- DORV accounts for 1.0-1.5% of all congenital heart disease with incidence of 1 per 10,000 live births

Treatment

- Surgery depends on anatomy
  - Closure of VSD & placement of RV to pulmonary artery conduit if 2 developed ventricles exist
  - Norwood/Fontan procedure if hypoplasia of ventricle
- Survival statistics depend on specific type of DORV
  - 15-year survival rate for noncomplex lesions: 85-90%
  - Reoperation may be required for RV outflow obstruction

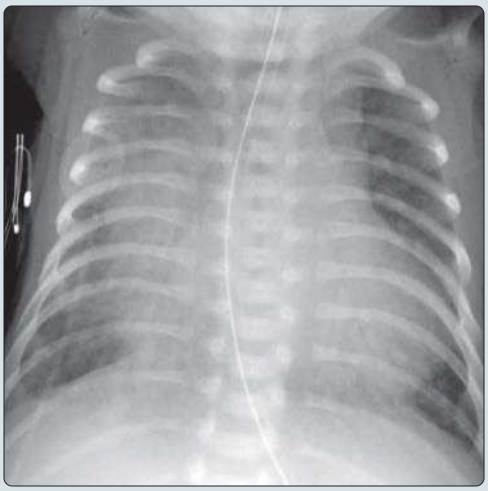
Aortic Coarctation

KEY FACTS

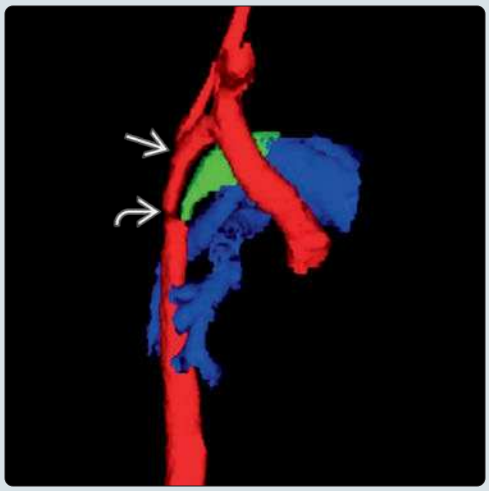
TERMINOLOGY

- Narrowing of aortic lumen with obstruction to blood flow

IMAGING

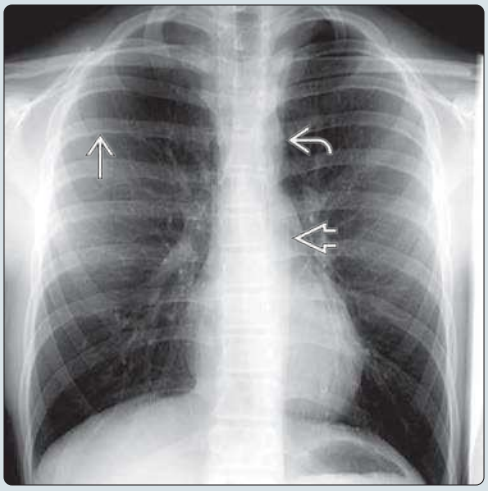


- Locations: Preductal, typically hypoplastic (infantile); juxtaductal or post ductal, typically focal (adult); abdominal, middle aortic syndrome (rare)
  - May have diffuse hypoplasia of aortic isthmus + focal coarctation (important for surgical planning)
- Can be simple (isolated coarctation in adult) or complex (additional cardiac anomalies, presenting in infancy)
- Classic radiographic findings
  - Poststenotic dilation of proximal descending aorta (figure 3 sign)
  - Rib notching (age > 5 years)
  - Left ventricular hypertrophy: Rounded cardiac apex
- Echocardiography for primary diagnosis in infancy
- CTA depicts coarctation site, percentage of stenosis, & presence/location of collaterals
- MR in older children for preoperative work-up & postoperative surveillance

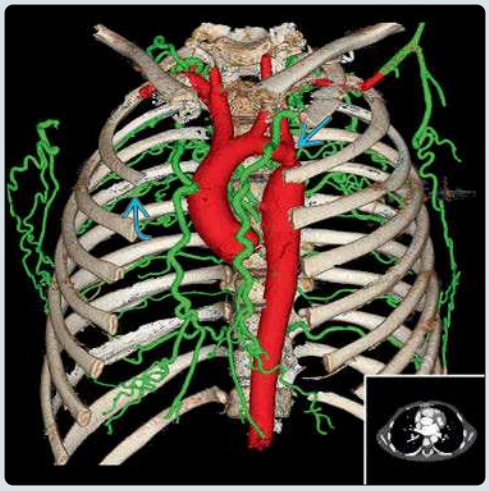


PATHOLOGY

- Most common additional cardiac anomalies: Ventricular septal defect (33%), PDA (66%), bicuspid aortic valve (50%)
- Turner syndrome: 20-36% have coarctation



CLINICAL ISSUES



- Presentations include
  - Infancy: Congestive heart failure (due to aortic arch interruption, associated anomalies)
  - Older child, adult: Hypertension (HTN), diminished femoral pulses, differential blood pressure between upper & lower extremities (arm-leg gradient)
- Treatment: Resection + end-to-end anastomosis, interposition graft, patch + aortoplasty, balloon angioplasty
- Complications: Recoarctation (< 3%; ↑ if operation in infancy), postoperative aneurysms (24% after patch)
- ↓ long-term survival (HTN, coronary disease)

(Left) *Frontal radiograph in a 2-week-old infant with congestive heart failure & severe coarctation of the aorta shows cardiomegaly with bilateral pulmonary edema.* **(Right)** *Lateral oblique view of a 3D color-coded cardiac CTA shows a preductal hypoplastic-type coarctation of the aorta with a periductal focal coarctation. Note that the patent ductus arteriosus (PDA) (green) is beginning to close with severe narrowing near the aortic connection.*

(Left) *Frontal radiograph in a teenage patient with coarctation of the aorta shows prominence of the aortic knob & descending aorta with intervening indentation, creating a figure 3 sign. Note the notching, sclerosis, & undulation of the undersurface of the ribs from collateral vessels.* **(Right)** *Frontal oblique view from a 3D color-coded CTA shows a focal coarctation of the aorta with prominent arterial collaterals (green) circumventing the obstruction. Note the dilated intercostal collaterals.*

TERMINOLOGY

Definitions

- Narrowing of aortic lumen with obstruction to blood flow
- Category of congenital heart disease: Acyanotic, normal heart size (most commonly), normal pulmonary vascularity
- Hemodynamics: Left ventricular (LV) pressure overload

IMAGING

General Features

- Best diagnostic clue
  - Focal or diffuse aortic narrowing with presence of collaterals in older patients
- Location
  - Preductal: Typically hypoplastic (infantile)
  - Juxtaductal or post ductal: Typically focal (adult)
  - Abdominal: Middle aortic syndrome (rare)
    - Should be specifically looked for in patients with differential blood pressures + normal thoracic aorta
- Morphology
  - Simple (isolated coarctation in adults) or complex (associated with other cardiac anomalies, presenting in infancy)

Radiographic Findings

- Poststenotic dilation of proximal descending aorta (figure 3 sign)
- Rib notching (age > 5 years) or undulation & sclerosis of undersurface of ribs due to collaterals (Roesler sign)
  - If rib notching is unilateral & right-sided, then coarctation is likely distal to brachiocephalic artery but proximal to left subclavian artery
  - If rib notching is bilateral, then coarctation is distal to both subclavian arteries
  - If rib notching is unilateral & left-sided, then there is likely aberrant left subclavian artery
- LV hypertrophy: Rounded cardiac apex

Fluoroscopic Findings

- Esophagram: Impression by dilated descending aorta (reverse figure 3 sign)

CT Findings

- CTA
  - Cardiac CTA with prospective ECG gating is increasingly used in diagnosis
    - Advantages
      - Speed of exam
      - Highest resolution of all cross-sectional imaging modalities, provides best 3D reconstructions
      - Functional data can be obtained to evaluate ejection fraction & volumes
    - Disadvantages: Radiation dose
  - Depicts coarctation site, percentage of stenosis, & presence/location of collaterals

MR Findings

- T1WI
  - Black blood imaging (cardiac gated spin-echo or double inversion recovery)
    - Sagittal oblique ("candy cane") plane through aortic arch shows location of coarctation
    - Perpendicular views for cross-sectional diameter measurements
- T2* GRE
  - Bright blood imaging (cardiac gated steady-state free precession cine MR)
    - More reliable for diameters than black blood imaging
    - Sagittal oblique plane for anatomy
    - Length of systolic (dark) flow jet correlates with hemodynamic significance
    - ± aortic regurgitation (bicuspid aortic valve)
- MRA
  - Velocity-encoded phase-contrast MRA: For estimate of gradient, collateral flow, & aortic valve regurgitation fraction
  - 3D gadolinium-enhanced MRA: For anatomy & depiction of collaterals
- Multiple MR techniques are now available to calculate pressure gradients

Ultrasonographic Findings

- Pulsed Doppler
  - Aortic & visceral arterial waveforms distal to coarctation may show parvus et tardus morphology
    - Slowly rising & diminished systolic upstroke

Echocardiographic Findings

- Echocardiogram
  - Imaging of aortic arch & branches in suprasternal long-axis view
  - Relationship of coarctation with patent ductus arteriosus (PDA)
  - Notch in descending aorta at level of coarctation (shelf sign)
- Pulsed Doppler
  - Estimate of gradient across coarctation

Angiographic Findings

- Cardiac catheterization: Direct measurement of gradient
- Intervention: Balloon angioplasty

Imaging Recommendations

- Protocol advice
  - Echocardiography for primary diagnosis in infancy
  - Cardiac CTA with prospective ECG gating in infancy for complex anatomy
  - MR in older children for preoperative work-up & postoperative surveillance for recoarctation & aneurysms
  - Cardiac catheterization is reserved for gradient measurement & intervention

DIFFERENTIAL DIAGNOSIS

Hypoplastic Left Heart Syndrome

- Congestive heart failure in newborn
- Hypoplastic LV
- Ductus-dependent systemic perfusion
- Retrograde flow in hypoplastic ascending aorta

Interrupted Aortic Arch

- Flow reaches descending aorta via PDA

Pseudocoarctation

- Elongation & kinking of aorta without obstruction/gradient

Takayasu Arteritis

- Acquired inflammatory condition
- Acute phase: Aortic wall enhancement
- Chronic phase: Narrowing/occlusion of aorta & branch vessels

PATHOLOGY

General Features

- Etiology
  - 2 developmental theories
    - Abnormal fetal hemodynamics [when associated with cardiac lesions ↓ LV output & flow through aortic isthmus, such as hypoplastic left heart syndrome (HLHS) or large ventricular septal defect (VSD)] can lead to preductal coarctation & diffuse hypoplasia of isthmus
    - Postnatal contraction of fibrous ductal tissue in aortic wall at time of PDA closure
- Genetics
  - Usually sporadic
- Associated abnormalities
  - Cardiac: VSD (33%), PDA (66%), bicuspid aortic valve (50%), transposition, subaortic & mitral stenosis (parachute deformity: Shone syndrome), Taussig-Bing anomaly, endocardial fibroelastosis
  - Associated with Turner syndrome (20-36% have coarctation)
  - Berry aneurysms of circle of Willis
  - Scoliosis (in boys)
  - Abdominal coarctation is associated with neurofibromatosis, Williams syndrome, Alagille syndrome, fibromuscular dysplasia, mucopolysaccharidosis, fetal alcohol syndrome, & arteritis
- Pathophysiology
  - ↑ in systemic vascular resistance → ↑ in LV afterload → LV hypertrophy
  - Hypertension (HTN) due to renal hypoperfusion
  - Congestive heart failure
    - May be due to PDA closure in severe coarctation
    - May be due to associated complex heart disease
  - Arterial collaterals develop to bypass stenosis when not detected at birth
    - Internal mammary, intercostal, paravertebral, epigastric

Gross Pathologic & Surgical Features

- Focal shelf or waist lesion
- Diffuse narrowing of aortic isthmus
- Poststenotic dilation of descending aorta

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Frequently asymptomatic & incidentally found
  - Infancy: Congestive heart failure (due to aortic arch interruption, associated anomalies)
  - Older child, adult: HTN, ↓ femoral pulses, differential blood pressure between upper & lower extremities (arm-leg gradient)
- Other signs/symptoms
  - Bacterial endocarditis

Demographics

- Epidemiology
  - Incidence: 2-6 per 10,000 live births
  - More common in male patients (2:1), White patients

Natural History & Prognosis

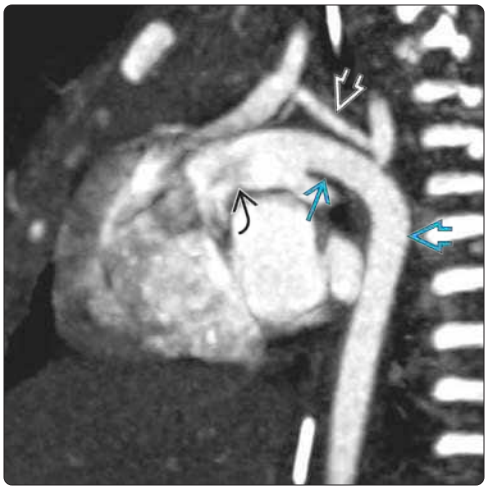
- ↓ long-term survival (late HTN, coronary artery disease)

Treatment

- Resection & end-to-end anastomosis
- Interposition graft
- Prosthetic patch, subclavian flap aortoplasty
- Balloon angioplasty
- Complications
  - Recoarctation (< 3% but higher when operation occurs in infancy)
  - Postoperative aneurysms (24% after patch aortoplasty)

DIAGNOSTIC CHECKLIST

Consider



- Diffuse hypoplasia of aortic isthmus in addition to focal coarctation (important for surgical planning)

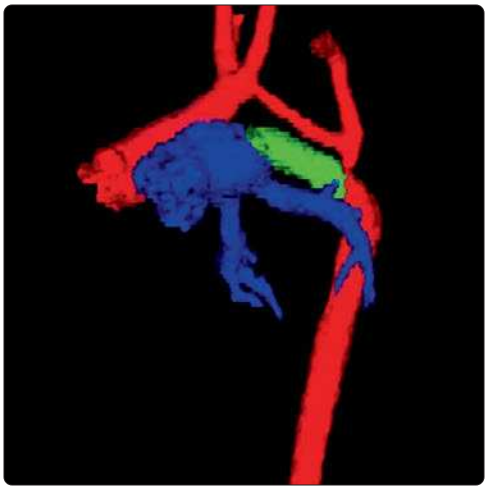


Image Interpretation Pearls

- Rib notching in asymptomatic individuals can be 1st clue to hemodynamically significant coarctation

(Left) *Sagittal oblique cardiac CTA in a newborn shows a hypoplastic-type coarctation of the aorta with a large PDA connecting the main pulmonary artery to the descending aorta.* **(Right)** *Lateral oblique 3D color-coded cardiac CTA shows a hypoplastic-type coarctation of the aorta (red) with a large PDA (green) connecting the pulmonary arteries (blue) to the descending aorta.*

(Left) *Sagittal MIP cardiac CTA in an adolescent shows a focal coarctation of the aorta with dilation of the left subclavian artery. Also note the tortuous collaterals along the descending aorta as flow circumvents the stenotic aorta.* **(Right)** *Endoluminal view of the descending thoracic aorta looking up at the focal coarctation is shown. Note the collaterals along the aorta as the flow circumvents the obstruction.*

(Left) *Oblique sagittal MRA shows focal obstruction of the midabdominal aorta with a dilated superior mesenteric artery & a large collateral circumventing the obstruction.* **(Right)** *Lateral oblique 3D CTA shows a tortuous but normal-caliber portion of the descending aortic arch. No collaterals were seen, & no significant gradient was detected in this patient with pseudocoarctation of the aorta.*

Aortic Stenosis

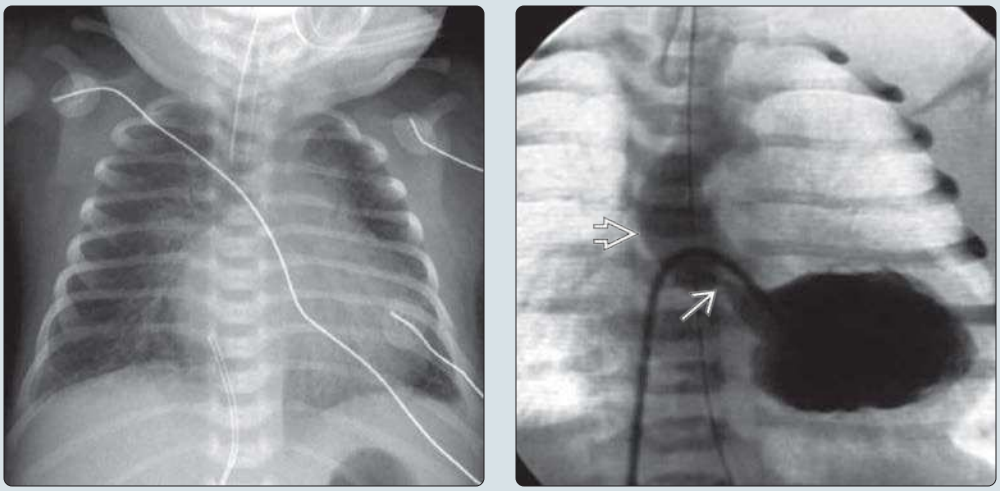
KEY FACTS

TERMINOLOGY

- Spectrum of aortic valve abnormalities that ranges from asymptomatic bicuspid aortic valve to thickened & obstructed aortic valve stenosis to severe neonatal aortic atresia & hypoplastic left heart syndrome (HLHS)
- Aortic stenosis (AS) may be valvar, supravalvar, or subvalvar
  - Valvar stenosis is most common at 80%

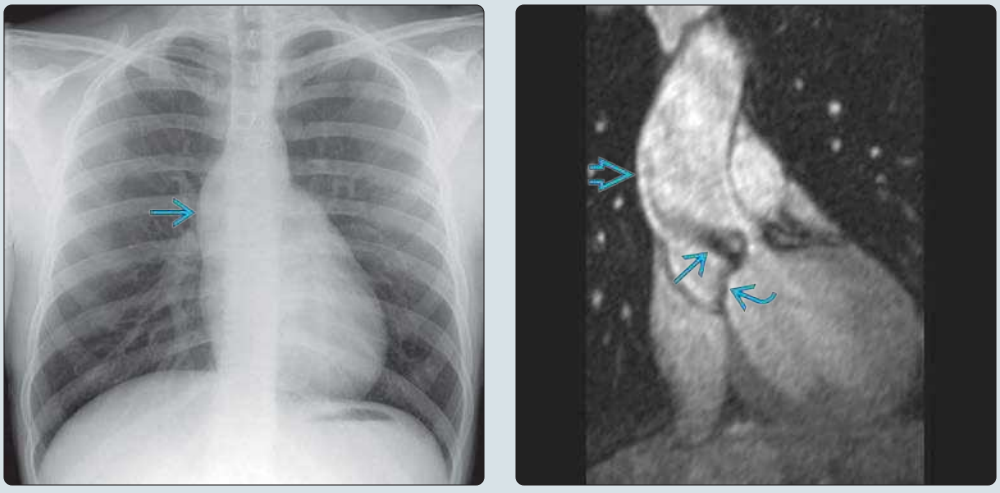
IMAGING

- Varies by location, etiology, & severity of stenosis
- Chest radiographs range from cardiomegaly & edema in severely affected infants to normal in adolescents
- Poststenotic dilation of ascending aorta in valvar stenosis
  - Due to flow jet through stenotic valve
- Supravalvar shows hourglass shape of ascending aorta
- Subaortic stenosis may have hypertrophic cardiomyopathy
- Cardiac enlargement may not be seen in childhood
- MR & echo allow quantitative assessments
- Cardiac catheterization for interventional treatment with balloon valvotomy, leading to aortic regurgitation



PATHOLOGY

- Grading of AS: Jet velocity, gradient across valve, valve area
  - Mild has gradient < 20 mm Hg
  - Moderate has gradient from 20-40 mm Hg
  - Severe has gradient > 40 mm Hg
- Associations include Williams syndrome, HLHS, bicuspid aortic valve, hypertrophic cardiomyopathy, endocarditis



CLINICAL ISSUES

- 10-20% of AS presents in 1st year of life
- Neonatal: Signs of poor or low cardiac output with tachypnea & feeding problems
- Childhood: Usually asymptomatic but may have systolic murmur or suprasternal thrill
- 1% of sudden deaths may be related to undetected AS

(Left) *Frontal chest radiograph shows a 2-week-old infant in heart failure with perihilar pulmonary edema & cardiomegaly. This patient had critical aortic stenosis.* **(Right)** *Single frontal left ventricular angiogram shows a jet across the aortic valve ⇨ from severe aortic stenosis in a 2-week-old infant. Note the dilation of the ascending aorta ⇨.*

(Left) *Single frontal radiograph of the chest in an adolescent demonstrates a border-forming ascending aorta ⇨ along the right mediastinum. This patient had aortic stenosis & typical poststenotic dilation of the ascending aorta.* **(Right)** *Coronal FIESTA cine MR in an adolescent with a bicuspid aortic valve shows a dephasing effect with signal void ⇨ from the flow jet through the stenotic valve. Note the thickened aortic valve ⇨ & dilation of the ascending aorta ⇨.*

TERMINOLOGY

Abbreviations

- Aortic stenosis (AS)

Synonyms

- Aortic valvar stenosis, aortic valvular stenosis

Definitions

- Spectrum of aortic valve abnormalities that ranges from asymptomatic bicuspid aortic valve to thickened, obstructing aortic valve stenosis to severe neonatal aortic atresia & hypoplastic left heart syndrome (HLHS)
- AS may be valvar, supravalvar, or subvalvar (subaortic)
  - Valvar stenosis most common at 80%

IMAGING

General Features

- Best diagnostic clue
  - Thickened valve leaflets with fusion
    - Bicuspid aortic valve in 80% of valvar AS
    - Unicuspid aortic valve is seen in HLHS with endocardial fibroelastosis
  - High-velocity jet of blood is ejected from left ventricle during systole
  - Poststenotic dilation of ascending aorta
  - Concentric left ventricular hypertrophy
- Location
  - Stenosis may be subvalvar, valvar (most common), or supravalvar
- Size
  - Valve anulus may be small for age; valve leaflets are usually thickened; commissures may be fused
- Morphology
  - Normal valve is tricuspid & mobile; stenotic valve is usually thickened with restricted systolic motion

Radiographic Findings

- Neonates & infants may have normal chest radiograph vs. mild cardiomegaly & edema
- Children & adolescents may have normal heart size even in severe AS
  - Dilation of ascending aorta
  - Left ventricle may enlarge secondary to aortic regurgitation (AR) following balloon valvotomy for treatment
  - Ca^{2+} of valve is rare in childhood

CT Findings

- CTA
  - Used to evaluate complex anatomy
  - Can provide volumetric functional data in HLHS with AS
  - Supravalvar stenosis (as seen in Williams syndrome) shows concentric narrowing of ascending aorta (hourglass shape)
    - ± coarctation or pulmonary artery stenoses

MR Findings

- MR cine
  - Ventricular function can be qualitatively assessed on 4-chamber view & quantitatively assessed on stack of short-axis views
  - Stenosis & regurgitation evaluation
    - Flow jet: Signal loss caused by high-velocity flow & turbulence
    - Valve motion: Abnormal motion of stenotic valve is evaluated in plane parallel to anulus
    - Secondary changes in chamber size & degree of wall thickening can be measured
- Velocity-encoded (VENC) or phase-contrast MR
  - Allows quantification of transvalvular pressure gradient & valve area
  - Can quantify regurgitant fraction
  - Flow velocity maps across valve can be generated
- Delayed enhancement
  - Look for infarction or fibrosis both pre- & postablation in subaortic stenosis obstructive cardiomyopathy patients

Echocardiographic Findings

- Gold standard for making diagnosis in infants; used to assess
  - Aortic jet velocity, gradient across valve, valve area
  - Left ventricular function, aortic valve thickness & motion, & associated anomalies, such as mitral insufficiency
- Doppler echocardiography
  - Systolic high-velocity flow jet in left ventricle outflow tract

Angiographic Findings

- Cardiac catheterization for interventional treatment with balloon valvotomy
- Findings include thickened aortic valve, doming of aortic valve, systolic flow jet into ascending aorta, enlarged ascending aorta, & thickened left ventricle

DIFFERENTIAL DIAGNOSIS

Rheumatic Heart Disease

- Multisystem disease with fever, rash, carditis, & valvular disease

Marfan Disease

- Connective tissue disorder associated with aneurysmal dilation of ascending aorta

Coarctation of Aorta

- May have dilation of aorta proximal to narrowing
- 75% may have associated bicuspid valve

Systemic Hypertension

- Left ventricular hypertrophy & prominent ascending aorta, typically in older individuals

PATHOLOGY

General Features

- Genetics
  - Bicuspid aortic valve: One of most common congenital malformations
  - Williams syndrome: Due to chromosomal abnormality of 7q11.2; autosomal dominant
- Associated abnormalities
  - Endocarditis occurs in 4%
  - Williams syndrome: Associated with supravalvar AS & pulmonary artery stenosis

- Coarctation of aorta: Associated with bicuspid aortic valve & AS
- HLHS

Staging, Grading, & Classification

- Grading of AS incorporates aortic jet velocity, valve gradient, valve area
  - Mild has gradient ≤ 20 mm Hg
  - Moderate has gradient 20-40 mm Hg
  - Severe has gradient > 40 mm Hg
- Classification of AS
  - Subvalvar (left ventricular outflow tract) AS (or subaortic stenosis) due to
    - Membrane that partially obstructs left ventricular outflow
    - Thickening of interventricular septum in patients with obstructive cardiomyopathy
  - Valvar in 80% of cases, most frequently in association with bicuspid aortic valve
  - Supravalvar shows concentric narrowing in ascending aorta
    - May be isolated or associated with Williams syndrome

CLINICAL ISSUES

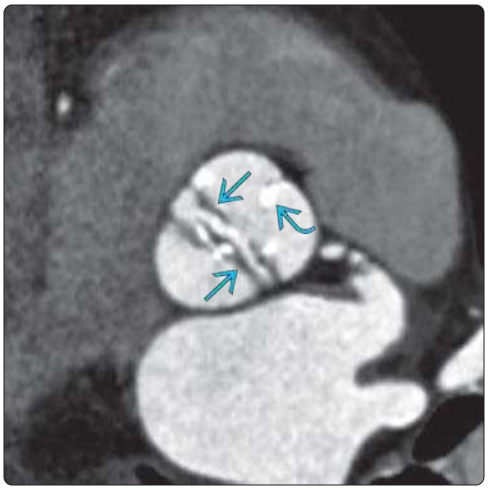
Presentation

- Most common signs/symptoms
  - Neonatal: Signs of poor or low cardiac output with tachypnea & feeding problems
  - Childhood: Usually asymptomatic but may have systolic murmur or suprasternal thrill
    - If prior valvotomy, there will be dilation of ascending aorta & large left ventricle secondary to AR
    - Sudden death, which usually occurs during exercise
    - Children with Williams syndrome are recognized due to multiple manifestations of disease

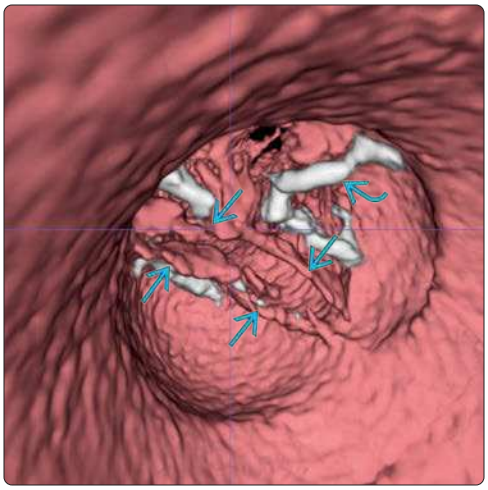
Demographics

- Age
  - 10-20% in 1st year of life
- Sex
  - M:F = 4:1
- Epidemiology
  - Occurs in 3-5% of children with congenital cardiac defects

Natural History & Prognosis



- Infants with critical AS may be diagnosed in utero
  - Mortality relates to degree of stenosis, presence of neonatal symptoms, & lower birth weights
    - HLHS has highest mortality
    - Endocardial fibroelastosis with ↓ left ventricular outflow
    - Coronary blood flow to subendocardium is reduced, ischemia may occur
- Children with AS constitute 3-5% of all congenital heart defects
  - Usually stenosis progresses; 20% have associated lesions
  - 1% of sudden deaths are thought to be related to undetected AS
  - Once balloon valvotomy occurs, children will have both residual AS & AR



Treatment

- In infants, AS may be part of spectrum of HLHS
  - Treated with prostaglandin to maintain ductal patency
  - May need balloon atrial septostomy or Rashkind procedure with staged Norwood procedure
  - Occasionally treated with heart transplant
- In infants with "critical" AS
  - Percutaneous balloon valvotomy urgently (but may result in AR)
  - Ross surgical procedure is performed when valvotomy is inadequate or regurgitation is moderate
    - Native pulmonary valve is placed in aortic position; homograph is placed for pulmonary valve
- In children, depends on degree of obstruction & progression
  - Mild stenosis: Monitored with echocardiogram & ECG
  - Moderate stenosis: May require valvotomy
  - Severe stenosis: Valvotomy is required
- Surgical aortic valvotomy
  - Performed for supravalvar AS, resection of subaortic membrane, & enlargement of aortic anulus
  - Mechanical valves usually need anticoagulation (undesirable for normal children)
- Replacement of aortic valve with pulmonary valve (Ross procedure)
  - Pulmonary valve is replaced with homograft or reconstruction with conduit
  - Indicated in peak-to-peak gradients > 70 mm & where valvotomy has failed
- All children need prophylaxis to prevent bacterial endocarditis

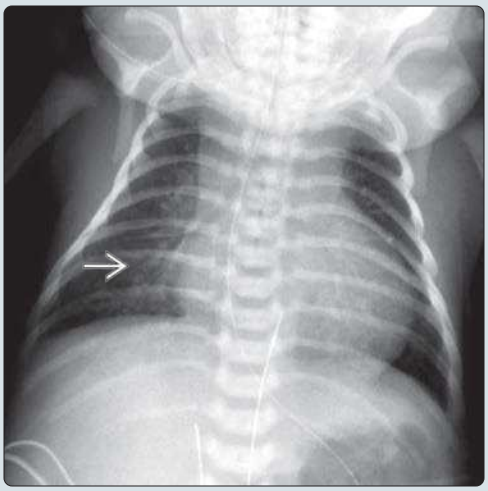
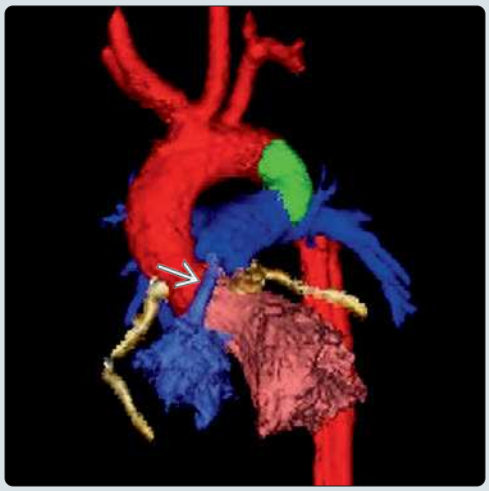
Pulmonary Artery Stenosis

KEY FACTS

TERMINOLOGY

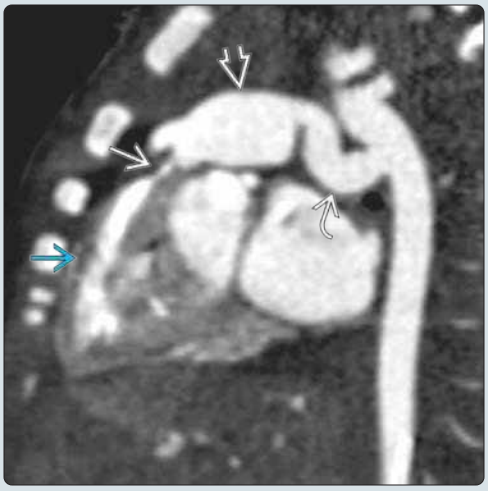


- Stenosis at level of infundibulum, pulmonary valve, supravalvar main pulmonary artery, or branches of pulmonary artery
- Pulmonary valvar stenosis is most common (> 90%)

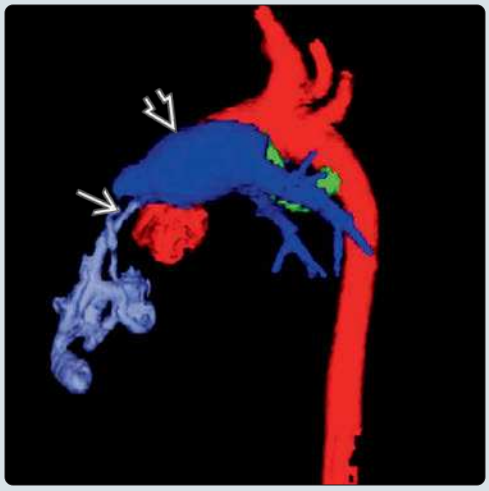


IMAGING

- Valvar stenosis: Normal heart size with dilated main pulmonary artery segment in ~ 80%
  - Thickened valve leaflets, doming of valve, systolic high-velocity flow jet in pulmonary outflow tract
- Supravalvar pulmonary artery stenosis in Williams syndrome
- Alagille syndrome has valvar pulmonary stenosis & peripheral pulmonary artery stenosis
- Infundibular narrowing in tetralogy of Fallot & complex malformations
- Right ventricle hypertrophy occurs secondary to ↑ work



CLINICAL ISSUES



- Pulmonary stenosis is often diagnosed between 2-6 years of age during routine physical exam
- Mild stenosis: Usually asymptomatic with systolic ejection murmur
- Moderate stenosis: Exertional dyspnea, easy fatigability
- Severe stenosis: Infants may present with severe cyanosis
- Balloon valvuloplasty is treatment of choice for moderate to severe gradients > 50 mm Hg
  - Newborns with critical PS may need immediate valvotomy
    - Prostaglandin to maintain ductus arteriosus flow
    - May need surgical valvotomy or palliative Blalock-Taussig shunt
  - Not as effective in dysplastic valves (e.g., Noonan syndrome), which may require surgery

(Left) *Frontal radiograph shows mild cardiomegaly & perihilar pulmonary edema in a patient with severe pulmonary stenosis. Note how the interstitial edema makes the pulmonary vessels indistinct. (Right) Anterior oblique color-coded 3D cardiac CTA in an infant shows focal pulmonary stenosis with marked narrowing of the pulmonary outflow tract. A large patent ductus arteriosus (PDA) (green) is seen connecting the main pulmonary artery (blue) to the descending aortic arch (red).*

(Left) *Sagittal MIP cardiac CTA shows severe pulmonic stenosis with poststenotic dilation of the main pulmonary artery & right ventricular (RV) hypertrophy. Note the tortuous PDA extending from the descending aorta to the main pulmonary artery.* **(Right)** *Lateral 3D color-coded cardiac CTA shows severe pulmonary stenosis with poststenotic dilation of the main pulmonary artery. Note the large PDA (green) extending from the aorta (red) to the pulmonary artery (blue).*

TERMINOLOGY

Abbreviations

- Pulmonary stenosis (PS)

Definitions

- Stenosis at level of infundibulum, pulmonary valve, supravalvar main pulmonary artery, or branches of pulmonary artery
- Pulmonary valvar stenosis is most common (> 90%)

IMAGING

General Features

- Best diagnostic clue
  - Normal heart size & prominent main pulmonary artery segment
  - Left pulmonary artery is occasionally larger than right
  - Normal pulmonary flow
- Location
  - Infundibulum, pulmonary valve, supravalvar main pulmonary artery, &/or pulmonary artery branches
- Size
  - Orifice of valve is reduced, which creates turbulence & ↑ work of right ventricle
- Morphology
  - Thickened & stenotic pulmonary valve is most common
    - Valvar stenosis in > 90%
    - Poststenotic dilation of pulmonary artery is frequently seen
  - Dysplastic pulmonary valve in Noonan syndrome
  - Supravalvar PS in Williams syndrome
    - Also has supravalvar aortic stenosis
  - Infundibular narrowing in tetralogy of Fallot & complex malformations
  - Pulmonary artery branch stenosis in tetralogy of Fallot
  - Alagille syndrome has PS & peripheral pulmonary artery stenosis
  - Congenital rubella may have pulmonary branch stenosis
  - Right ventricle hypertrophy occurs secondary to ↑ work

Radiographic Findings

- Normal heart size with dilated main pulmonary artery segment in ~ 80%

CT Findings

- CTA
  - Most useful for supravalvar PS or peripheral PS

MR Findings

- Assessment of right ventricle function
- Can quantitate degree of pulmonary insufficiency
- MRA is useful for supravalvar & peripheral PS

Echocardiographic Findings

- Echocardiogram
  - Pulmonary valvar stenosis
    - Fusion of valve commissures
    - Thickened valve with systolic restricted motion & doming
    - Poststenotic dilation of pulmonary artery
    - Right ventricle hypertrophy
  - Dysplastic pulmonary valve
    - Thickened, irregular, redundant tissue
- Pulsed Doppler
  - Systolic high-velocity flow jet in pulmonary outflow tract
  - Can accurately determine velocity of flow, which can help predict pressure gradients

Angiographic Findings

- Conventional
  - Key features: Thickened valve, dysplastic valve, poststenotic dilation
  - Used to evaluate for coexisting abnormalities, which occur in 10-20%
  - Cardiac catheterization is utilized to measure pressures
    - Demonstrates degree of outflow tract obstruction
    - Degree of trabeculation of right ventricle relates to degree of obstruction
  - Cardiac catheterization is utilized for treatment with balloon valvotomy

Imaging Recommendations

- Best imaging tool
  - Diagnosis in infancy by echocardiography
  - Cardiac catheterization is done as part of therapeutic intervention
    - Shows thickened valve leaflets, doming of valve, & poststenotic dilation

DIFFERENTIAL DIAGNOSIS

Normal Chest Radiograph in Adolescent

- Main pulmonary artery is prominent normally
- Occasionally confused with dilation of pulmonary artery
- Patients have no murmur or symptoms

Pulmonary Hypertension

- Heart may have normal size with right ventricle enlargement
- Central pulmonary arteries are large

Congenital Heart Disease With Large Left-to-Right Shunt

- Main pulmonary artery is large with ↑ pulmonary flow

PATHOLOGY

General Features

- Etiology
  - Pulmonary valvar stenosis is congenital anomaly
    - Maldevelopment of pulmonary valve tissue & distal portion of bulbus cordis
- Genetics
  - No genetic predisposition in valvar stenosis
  - Williams syndrome is related to contiguous gene deletion of locus 7q4
    - Distinct facial features & personality, mild cognitive impairment, cardiovascular abnormalities, elastin arteriopathy
  - Noonan syndrome is autosomal dominant
    - > 50% of individuals have changes in *PTPN11* gene
    - Multiple anomalies with dysplastic pulmonary valve, growth failure, mild cognitive impairment

- Alagille syndrome is autosomal dominant, related to mutations on chromosome 20p12
  - Pulmonic valve & peripheral stenoses + cholestatic jaundice in infancy
    - Jaundice due to bile duct hypoplasia/paucity
  - Butterfly vertebrae, abnormal facies, cognitive impairment, eye & renal anomalies
- Associated abnormalities
  - Most children are normal without any other lesions
  - Can be associated with other common congenital lesions in 10%
    - Infundibular stenosis & ventricular septal defect in tetralogy of Fallot
    - Atrial septal defect, patent ductus arteriosus
    - Complex cardiac lesions
  - Williams syndrome
    - Supravalvar aortic stenosis, coarctation, supravalvar PS, peripheral pulmonary stenoses
  - Noonan syndrome
    - Dysplastic pulmonary valve
  - Alagille syndrome
    - PS with multiple peripheral artery stenoses

Staging, Grading, & Classification

- Pulmonary valvar stenosis: Mild, moderate, severe

Gross Pathologic & Surgical Features

- Valve thickened with fused commissure
- Dysplastic valves have redundant tissue & thickened leaflets

Microscopic Features

- Valve is thickened with fibrous, myxomatous, & collagenous tissue

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Mild stenosis: Usually asymptomatic with systolic ejection murmur
  - Moderate stenosis: Exertional dyspnea, easy fatigability
  - Severe stenosis: Infants may present with severe cyanosis
    - ↓ pulmonary flow, ↑ right ventricle pressure, tricuspid regurgitation, & shunting from right atrium to left atrium
    - Severe stenosis may appear similar to pulmonic atresia, right ventricle hypoplasia, or coronary artery fistulas
- Other signs/symptoms
  - Loud systolic ejection murmur & click at left upper heart border

Demographics

- Age
  - Critical pulmonic stenosis occurs in newborns
  - PS is often otherwise diagnosed between 2-6 years of age during routine physical exam
- Sex
  - M = F

Natural History & Prognosis

- Critical pulmonic stenosis in infancy will progress; can be fatal if not treated
- Pulmonary valvar stenosis with mild gradient does not usually progress
  - Children have normal life expectancy
- Pulmonary valvar stenosis of moderate degree will progress
  - Clinically well tolerated
  - After valvotomy, may have pulmonary insufficiency, which is usually tolerated
- Mortality depends on severity of lesions but mild to moderate degree have normal life expectancy

Treatment

- Observation, medical management for mild valvar stenosis gradients < 25 mm Hg
- Balloon valvuloplasty is treatment of choice for moderate to severe valvar gradients > 50 mm Hg
  - Balloon catheter is placed over wire
  - Balloon is dilated > estimated pulmonary valve anulus while straddling valve
  - Long-term ↓ in right ventricle pressure & estimated gradient
  - Hemodynamically insignificant pulmonary insufficiency may occur in 80%
  - Recurrence of PS occurs in 15% at 10 years
  - Excellent outcome with survival being similar to general population
  - Balloon valvotomy is not as effective in dysplastic valves, which may need surgery
- Angioplasty is done for branch stenosis
- Newborns with severe or critical pulmonic stenosis
  - Prostaglandin to maintain ductus arteriosus flow
  - May need immediate valvotomy or palliative Blalock-Taussig shunt
  - Lesion may be associated with hypoplasia of right ventricle requiring univentricular repair

DIAGNOSTIC CHECKLIST

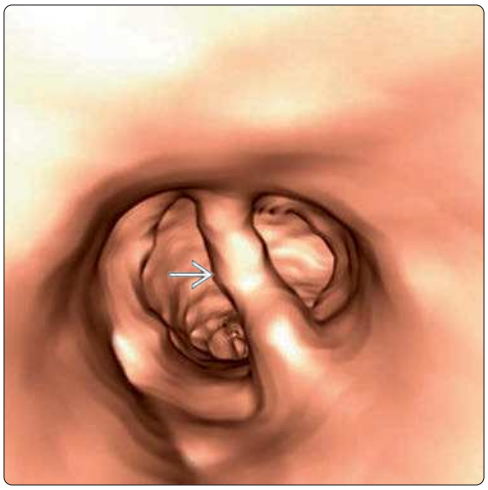


Image Interpretation Pearls

- Normal adolescent can have mildly prominent pulmonary artery

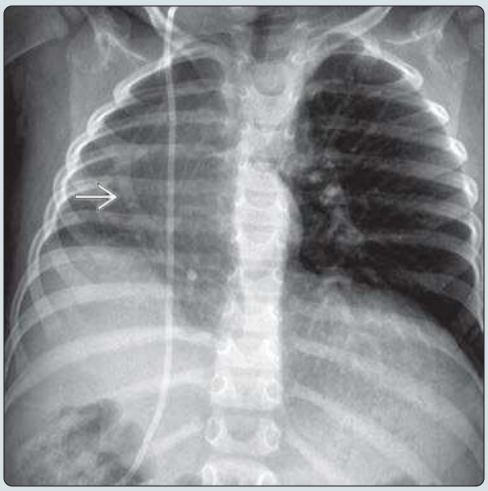
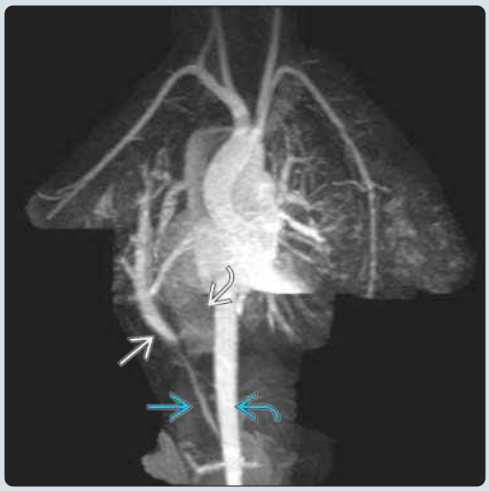
Scimitar Syndrome

KEY FACTS

TERMINOLOGY

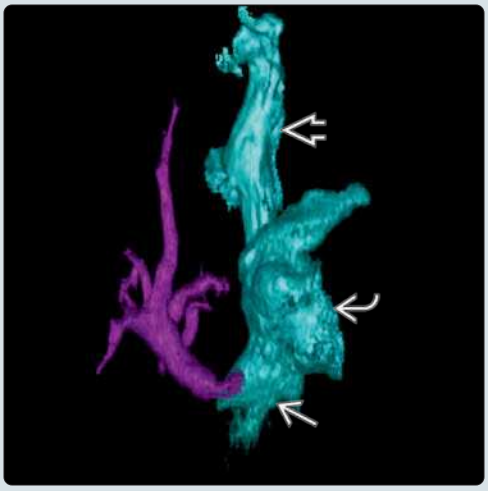


- Synonyms: Hypogenetic lung syndrome, congenital pulmonary venolobar syndrome
- Scimitar syndrome triad: Right lung hypoplasia, anomalous right pulmonary venous connection to inferior vena cava (IVC), & anomalous systemic arterial supply to right lower lobe
  - Extracardiac left-to-right shunt
  - Form of partial anomalous pulmonary venous return (PAPVR)
- Category: Acyanotic, right-sided cardiac chamber enlargement, ↑ pulmonary vascularity

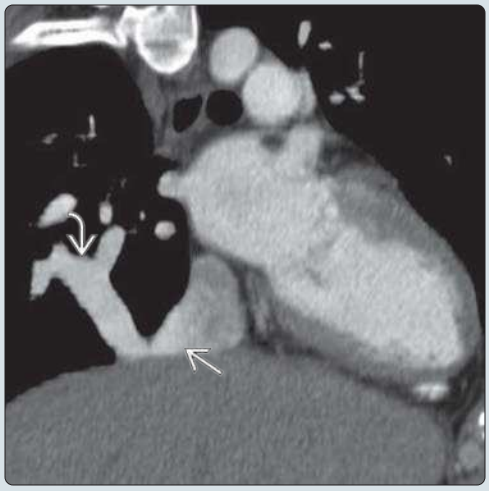


IMAGING

- Scimitar sign: Curved anomalous venous trunk, resembling Turkish sword, in right medial costophrenic sulcus near right heart border; typically ↑ in caliber in caudad direction
- Right lung hypoplasia with mediastinal shift
- Dextroversion of heart (not dextrocardia as apex is still directed toward left)
- Prominent right atrium, active pulmonary vascular congestion → shunt vascularity



CLINICAL ISSUES



- Newborn: Congestive heart failure, right heart volume overload, pulmonary hypertension
- Young child: Recurrent infections in right lung base
- Older child & adult: Often asymptomatic (incidental finding on chest radiograph)
- Treatment
  - Embolization of systemic arterial supply
  - Baffling of common right pulmonary vein onto left atrium
    - Surgical repair when left-to-right shunt > 2:1

(Left) *Frontal radiograph shows mediastinal shift to the right from a hypoplastic right lung. There is an enlarged curvilinear vein in the right lower lobe from partial anomalous pulmonary venous return (PAPVR) in this patient with scimitar syndrome.* **(Right)** *Anterior MRA shows a large scimitar (pulmonary) vein draining to the inferior vena cava (IVC) with systemic arterial supply to the right lower lobe (RLL) arising from the proximal abdominal aorta.*

(Left) *Posterior 3D color-coded CTA shows PAPVR of the RLL with the anomalous vein (pink) draining to the IVC. The superior vena cava (SVC) & right atrium are also shown.* **(Right)** *Coronal oblique MIP CTA of the chest shows PAPVR of the RLL pulmonary vein draining into the IVC.*

TERMINOLOGY

Synonyms

- Hypogenetic lung syndrome, congenital pulmonary venolobar syndrome

Definitions

- Scimitar syndrome triad: Right lung hypoplasia, anomalous right pulmonary venous connection to inferior vena cava (IVC), & anomalous systemic arterial supply to right lower lobe
  - Scimitar vein represents form of partial anomalous pulmonary venous return (PAPVR)
- Hemodynamics: Venous flow from right lung returns to right atrium → volume overload of right heart [atrial septal defect (ASD)-type physiology]

IMAGING

General Features

- Best diagnostic clue
  - Scimitar sign: Curved anomalous pulmonary vein, resembling Turkish sword, typically draining right lower & middle lobes
    - ↑ in caliber in caudad direction

Radiographic Findings

- Right lung hypoplasia with mediastinal shift
- Prominent right atrium & shunt vascularity when multiple lobes drain to IVC
- Scimitar vein may be seen in right medial costophrenic sulcus

CT Findings

- CTA with 3D reconstruction is most helpful to demonstrate venous drainage, anomalous systemic arterial supply, & right pulmonary artery & main bronchus hypoplasia

MR Findings

- Phase-contrast MRA for shunt flow calculation (Qp:Qs)
- Gadolinium-enhanced MRA coronal acquisition with 3D reconstruction for anomalous right pulmonary venous & arterial development

Echocardiographic Findings

- Echocardiogram
  - Scimitar vein connecting to IVC
  - Enlarged right atrium & ventricle with significant shunt

Angiographic Findings

- Conventional
  - Scimitar vein opacifies during venous phase of pulmonary artery injection
  - Injection of abdominal aorta: Anomalous systemic arterial supply to right lung base originating from abdominal or thoracic aorta

Imaging Recommendations

- CTA or MRA is better than echocardiography for complete assessment & can replace diagnostic angiocardiography
- Angiography is reserved for coil embolization

DIFFERENTIAL DIAGNOSIS

Other Forms of PAPVR

- Right pulmonary vein(s) to azygous vein, superior vena cava (SVC), or right atrium (with sinus venosus ASD)

True Dextrocardia With Abdominal Situs Solitus

- Other complex cardiac anomalies

Isolated Right Pulmonary Hypoplasia

- Normal right pulmonary venous connection to left atrium

Bronchopulmonary Sequestration

- Mass in lung base not connected to bronchial tree, receives systemic arterial supply

PATHOLOGY

General Features

- Embryology
  - Primary abnormality in development of right lung with secondary anomalous pulmonary venous connection
- Pathophysiology
  - Extracardiac left-to-right shunt: ASD physiology

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Depends on age at presentation & size of left-to-right shunt
    - Newborn: Congestive heart failure, right heart volume overload, pulmonary hypertension
    - Young child: Recurrent infections in right lung base
    - Older child & adult: Often asymptomatic (incidental finding on chest radiograph)

Natural History & Prognosis

- Large shunt → irreversible pulmonary hypertension
- Moderate to poor prognosis with neonatal presentation
- May be asymptomatic for many years with small shunt

Treatment

- Surgical repair is indicated when left-to-right shunt > 2:1
- Baffling of common right pulmonary vein into left atrium
- Embolization of systemic arterial supply

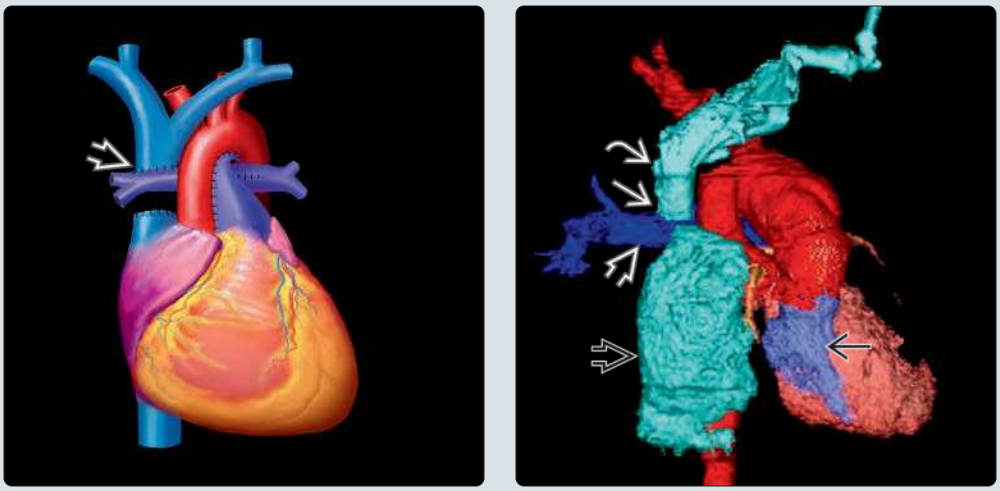
Glenn Shunt

KEY FACTS

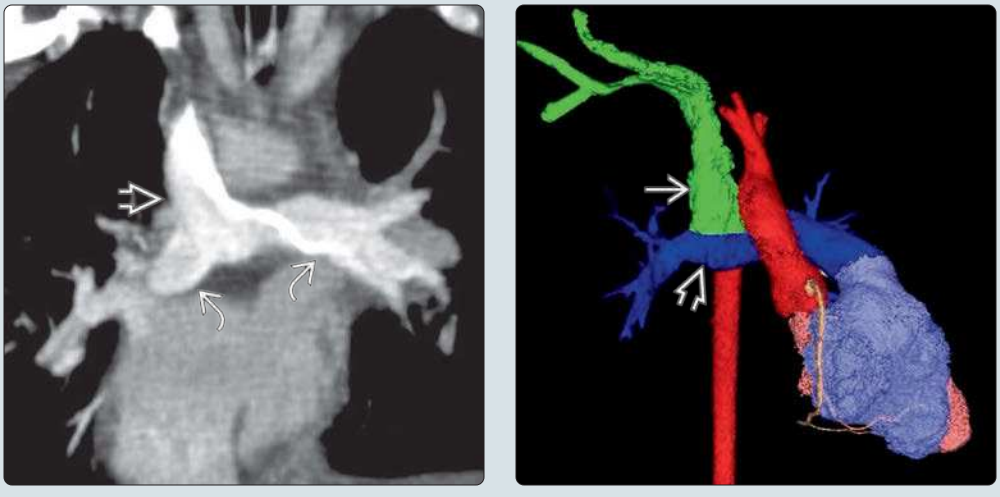
TERMINOLOGY

- Superior cavopulmonary shunt
- Goal is to direct systemic venous return from upper 1/2 of body to pulmonary circulation, directly bypassing right heart
  - Superior vena cava (SVC) is divided from right atrium at superior cavoatrial junction
  - End-to-side anastomosis between divided SVC & right pulmonary artery (PA)
  - SVC flow is directed to confluent branch PAs
- Used in patients with single ventricle physiology as staged palliative procedure prior to Fontan, ultimately resulting in total cavopulmonary connection
- Comprises stage 2 of Norwood procedure for hypoplastic left heart syndrome
- Typically performed between 3-9 months of age when pulmonary vascular resistance has ↓ sufficiently
- If 2 SVCs are present, each can be anastomosed to its respective PA, creating bilateral Glenn shunts



IMAGING

- CECT can be used to assess for shunt patency, collaterals, & branch PA stenoses
  - Delayed equilibrium-phase CTA should be performed to avoid contrast mixing artifact within branch PAs
- MR can be used in pre-Glenn & post-Glenn evaluation
  - Evaluate cardiac anatomy with ventricular & atrioventricular valve function
  - Evaluate branch PAs for stenoses along with flow differential calculation by phase-contrast imaging (PCI)
    - Velocities are picked for PCI across branch PAs typically < 100 cm/s, since venous flow occurs via Glenn shunt
  - Evaluate neoaorta
  - Quantify pulmonary-to-systemic blood flow & collaterals



TOP DIFFERENTIAL DIAGNOSES

- Hemi-Fontan operation

(Left) *Graphic shows a Glenn shunt as part of a stage 2 Norwood procedure. A direct connection between the superior vena cava (SVC) & the right pulmonary artery (PA) is created with deoxygenated systemic venous flow directed to both lungs.* **(Right)** *Frontal color-coded surface-rendered 3D cardiac CTA shows a bidirectional Glenn shunt connecting the SVC to the PA. Note the gap between the right atrium & right ventricle, consistent with known tricuspid atresia.*

(Left) *Coronal CTA reconstruction with contrast injected via the right upper extremity demonstrates direct communication between the SVC & PAs, consistent with a right-sided bidirectional Glenn shunt with opacification of both PAs.* **(Right)** *Frontal color-coded surface-rendered 3D cardiac CTA demonstrates direct communication between the SVC & PAs, consistent with a right-sided bidirectional Glenn shunt.*

TERMINOLOGY

Synonyms

- Superior cavopulmonary shunt

Definitions

- Goal is to direct systemic venous return from upper 1/2 of body to pulmonary circulation, directly bypassing right heart
- Originally described by Dr. William Glenn in 1958
  - End-to-end anastomosis of divided superior vena cava (SVC) to divided right pulmonary artery (PA)
  - SVC flow is directed to right lung only
- Bidirectional Glenn shunt is more commonly used now
  - SVC is divided from right atrium at superior cavoatrial junction followed by end-to-side anastomosis between divided SVC & right PA
  - SVC flow is directed to both right & left PAs
- Performed in patients with single ventricle physiology as staged palliative procedure prior to Fontan; final result is called total cavopulmonary connection
- Glenn shunt forms stage 2 of Norwood procedure for hypoplastic left heart syndrome
- By reducing volume load, bidirectional Glenn shunt reduces single ventricle wall stress & atrioventricular valve insufficiency
- Since no synthetic graft material is used, shunt grows with child
- Typically performed between 3-9 months of age
  - By this age, pulmonary vascular resistance has ↓ to level where systemic venous return enters pulmonary circulation without assistance of right heart pump
- If 2 SVCs are present, each can be anastomosed to its respective PA, creating bilateral Glenn shunts
- Azygous & hemiazygos veins are ligated as part of procedure

IMAGING

General Features

- Complications
  - Superior-to-inferior systemic venous collaterals
    - Can be coil embolized
  - Progressive cyanosis
  - Formation of pulmonary arteriovenous malformations (AVMs)
    - Hypothesized to be secondary to exclusion of hepatic venous flow through lungs
    - Resultant lack of hepatic factor delivery to pulmonary circulation
    - Subsequent lack of inhibition of endothelial proliferation in lungs
  - Branch PA stenosis
  - Arrhythmias

CT Findings

- Can be used postoperatively to assess for shunt patency
- Useful in evaluating thoracic vasculature, including neoaorta, branch PAs, pulmonary veins, & collaterals
- Can be used for detection of pulmonary AVM
- Pre-Glenn evaluation of cardiac anatomy, including branch PAs, instead of cardiac MR
- 3D reconstructions are helpful

MR Findings

- Traditionally used in pre-Glenn evaluation instead of conventional angiography
  - Evaluate cardiac anatomy & function
  - Evaluate valvular function
  - Evaluate central PAs & veins
  - Evaluate neoaorta
  - Quantify pulmonary-to-systemic blood flow
- Useful in post-Glenn evaluation
  - Evaluate ventricular function
  - Evaluate shunt patency & flow
  - Evaluate PA narrowing
  - Evaluate collaterals & pulmonary AVMs

Ultrasonographic Findings

- Echocardiography is used for pre- & postoperative anatomic & hemodynamic assessment
- Limited evaluation of branch PAs & pulmonary veins

Angiographic Findings

- Considered gold standard in preoperative assessment of anatomic & hemodynamic suitability for Glenn shunt
- Catheter-based interventions, such as collateral embolization & aortic balloon dilation, can be performed if required

DIFFERENTIAL DIAGNOSIS

Hemi-Fontan Operation

- Similar to Glenn, except continuity of SVC & right atrium are maintained
- SVC is anastomosed to right PA
- Patch of homograft tissue is sewn across superior cavoatrial junction, preventing systemic venous return from upper body into right atrium
- Simplifies subsequent lateral tunnel Fontan completion as continuity of right atrium & SVC are maintained

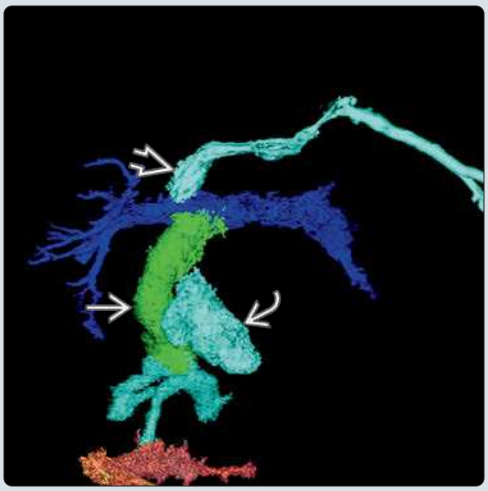
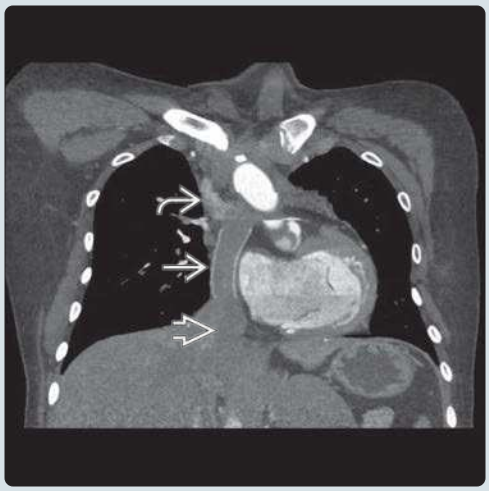
Fontan Operation

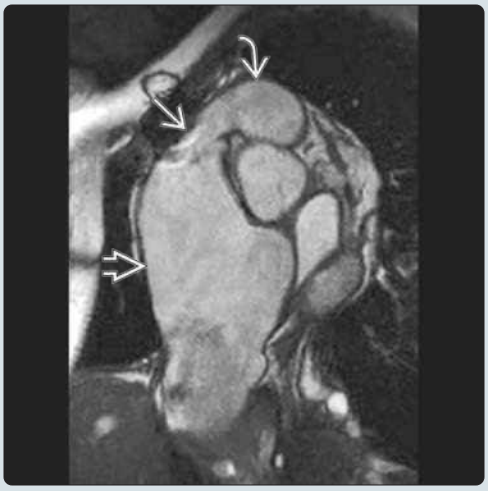


KEY FACTS



TERMINOLOGY

- Total cavopulmonary connection
- Used in single ventricle physiology as stage 3 of Norwood procedure
  - Tricuspid atresia
  - Hypoplastic left heart syndrome
  - Double inlet ventricle
  - Some heterotaxies
- Typically performed between 18-36 months of age
- Lateral tunnel Fontan
  - Intraatrial tunnel created in right atrium connecting inferior vena cava (IVC) to pulmonary artery
- Extracardiac conduit Fontan (typically favored)
  - Synthetic graft tube connected to IVC & right pulmonary artery
- Excellent early-, mid-, & late-term outcomes with mortality rates < 5-10%



IMAGING

- CECT can be used for detection of Fontan complications, such as thrombus, hepatomegaly, effusions, & pulmonary arteriovenous malformation
  - Delayed-phase of image acquisition during CTA eliminates contrast mixing artifacts within branch pulmonary arteries & Fontan conduit
- MR can be used in pre-Fontan & post-Fontan assessment
  - Evaluation of branch pulmonary arteries, including determination of flow differential using phase-contrast sequences
  - Evaluation of superior cavopulmonary connection (Glenn shunt)
  - Identification of collaterals
  - Evaluation of ventricular function
  - Determine patency of Fontan conduit & exclude thrombus
  - Assessment of hepatic fibrosis & lesions

(Left) *Frontal surface-rendered chest CTA shows postoperative changes from a Fontan ➡ & Glenn ➡ shunt connecting the systemic venous return directly to the right & left pulmonary arteries (PAs) (dark blue), bypassing the right atrium (RA) ➡. Note the extracardiac course of the Fontan that bypasses the right atrium.* **(Right)** *Coronal chest CTA in a patient with a Fontan shunt shows a stent along the Fontan shunt ➡, which connects the inferior vena cava ➡ to the PAs ➡.*

(Left) *Oblique coronal SSFP cine cardiac MR demonstrates a Fontan shunt where the RA ➡ is connected to the PAs ➡ via the atrial appendage ➡. Note the enlarged RA.* **(Right)** *Frontal surface-rendered cardiac CTA shows a Fontan shunt where the RA ➡ is connected to the PA ➡ via the atrial appendage ➡. Over time, ↑ pressure may lead to systemic venous collaterals (green) that communicate ➡ directly with the pulmonary veins (pink), leading to cyanosis.*

TERMINOLOGY

Synonyms

- Total cavopulmonary connection

Definitions

- Goal is to direct systemic venous return to pulmonary circulation directly, bypassing right heart
- Initially described by Dr. Francis Fontan in 1968
- Used in single ventricle physiology
  - Tricuspid atresia
  - Hypoplastic left heart syndrome
  - Double inlet ventricle
  - Some heterotaxies
- Stage 3 of Norwood procedure
- Typically performed between 18-36 months of age
- Originally described as extracardiac valved conduit between right atrium & left pulmonary artery
  - In combination with Glenn shunt, creates physiologic correction of blood flow
  - Superior vena cava (SVC) blood is directed to right pulmonary artery & inferior vena cava (IVC) blood is directed to left pulmonary artery
  - Complications of classic Fontan
    - Right atrial enlargement & hypertension
    - Impaired ventricular function
    - ↓ pulmonary vascular blood flow
    - Tricuspid valve insufficiency
- In order to preserve ventricular & pulmonary vascular function, modified Fontan is now favored
  - Lateral tunnel Fontan
    - Intraatrial tunnel created in right atrium using prosthetic material
    - IVC is anastomosed to caudal aspect of tunnel
    - Pulmonary artery is anastomosed to cephalad aspect of tunnel
  - Extracardiac conduit Fontan (typically favored)
    - IVC is divided from right atrium
    - Synthetic graft tube is connected to IVC inferiorly & right pulmonary artery superiorly; travels along side of right atrium
  - In either form, IVC blood directed to pulmonary circulation, bypassing right heart structures
- Small fenestration is often created between Fontan circuit & right atrium
  - Prevents volume overload to lungs
  - Buffers any ↑ in systemic venous pressure
- Excellent early-, mid-, & late-term outcomes with mortality rates < 5-10%

IMAGING

General Features

- Complications
  - Arrhythmias
  - Liver dysfunction due to fibrosis; liver lesions
  - Protein-losing enteropathy
  - Heart failure
  - Thrombus & emboli
  - Formation of pulmonary arteriovenous malformations (AVMs)
    - Hypothesized to be secondary to exclusion of hepatic veins from Fontan pathway with lack of protective hepatic factor delivery to lungs
    - Potentially reversible if hepatic venous flow can be redirected to lungs
  - Chylous pleural effusions
  - Plastic bronchitis

CT Findings

- Can be used for detection of Fontan complications, such as thrombus, hepatomegaly, effusions, & pulmonary AVM
- 3D reconstructions are very helpful

MR Findings

- Pre-Fontan evaluation
  - Can potentially obviate need for preoperative catheter angiography
  - Evaluation of superior cavopulmonary connection formed by Glenn procedure
  - Evaluation of branch pulmonary arteries
  - Identification of collaterals
  - Evaluation of ventricular function
- Post-Fontan evaluation
  - Evaluate patency of Fontan pathway
  - Evaluate ventricular function
  - Evaluate pulmonary artery stenosis
  - Identify collaterals
  - MR elastography for evaluation of hepatic fibrosis
    - ± hepatobiliary contrast agent for liver lesions
  - MR lymphangiography for chylous effusion, plastic bronchitis

DIFFERENTIAL DIAGNOSIS

Kawashima Procedure

- Used in patients with single ventricle physiology & interrupted IVC
  - Fontan not feasible
- SVC, including azygous continuation, connected to right pulmonary artery
  - All systemic venous return is directed to pulmonary artery
    - Except hepatic veins & coronary sinus

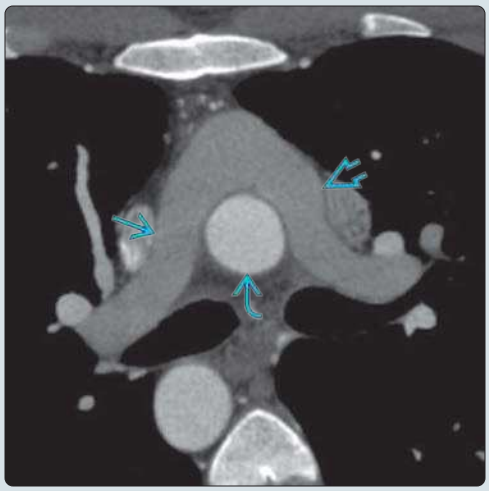
Arterial Switch Procedure

KEY FACTS

TERMINOLOGY

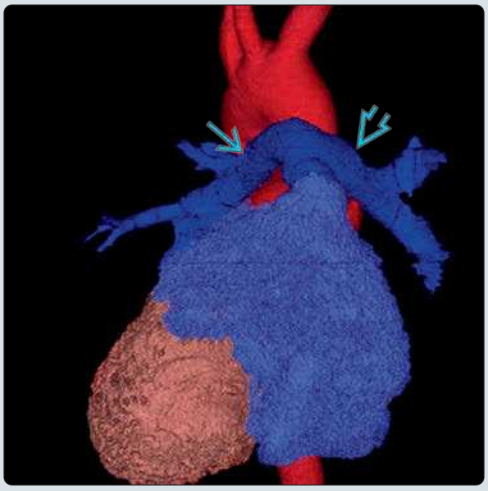
- Surgical procedure to correct D-transposition of great arteries (D-TGA)
  - Coronary arteries are translocated to base of neoaorta
  - Ascending aorta & main pulmonary artery are transected & transposed
    - Ascending aorta is connected to left ventricular outflow tract
    - Main pulmonary artery is relocated anterior to aorta & connected to right ventricular outflow tract as part of Lecompte maneuver
- Typically performed in first 2 weeks of life
- Survival rate & freedom of reoperation at 5 years: 90% & 97%, respectively

IMAGING

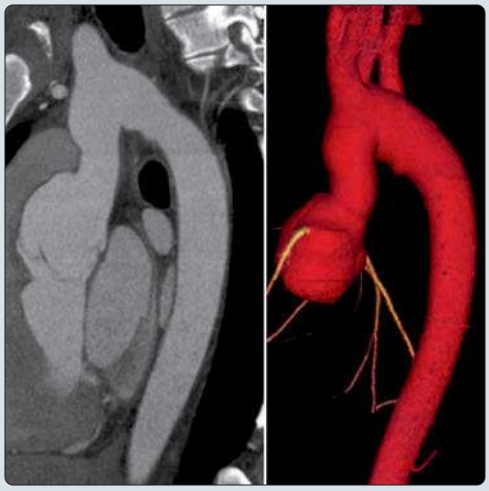


- Typical postoperative appearance: Pulmonary artery arises directly anterior to ascending aorta; branch pulmonary arteries drape over either side of ascending aorta
- Complications
  - Supravalvular pulmonic stenosis & branch pulmonary artery stenoses
  - Aortic root dilation & regurgitation
  - Ischemia secondary to coronary artery stenosis/occlusion
- CTA is useful in immediate postoperative period to assess for complications & to follow status of coronary arteries & branch pulmonary arteries
- MR provides comprehensive evaluation of postoperative anatomy & function without ionizing radiation

TOP DIFFERENTIAL DIAGNOSES



- Mustard/Senning: Late atrial level repair of D-TGA with baffle
- Rastelli: Performed on subset of patients with D-TGA, ventricular septal defect, & left ventricular outflow tract stenosis/obstruction



(Left) *Preoperative axial CTA in a patient with D-transposition of great arteries (D-TGA) shows abnormal positions of the great vessel origins with the ascending aorta ⇨ very anterior & mildly right of the pulmonary artery ⇨.* **(Right)** *Oblique axial cardiac CTA in a patient status post arterial switch procedure shows the right ⇨ & left ⇨ pulmonary arteries draped around the ascending aorta ⇨. This is the classic postoperative appearance in a patient status post arterial switch procedure.*

(Left) *Frontal volume-rendered cardiac CTA in a patient status post arterial switch procedure shows the right ⇨ & left ⇨ pulmonary arteries draped around the ascending aorta. This is the classic postoperative appearance in a patient post arterial switch procedure.* **(Right)** *Sagittal & lateral surface-rendered CTA images of the aorta status post arterial switch procedure show a posterior position of the ascending aorta & acute angle of the arch due to mass effect from the pulmonary arteries.*

TERMINOLOGY

Synonyms

- Jatene arterial switch

Definitions

- Surgical procedure to correct D-transposition of great arteries (D-TGA)
  - D-TGA involves ventriculoarterial discordance & atrioventricular concordance
    - Pulmonary trunk arises from left ventricle (LV)
    - Aorta arises from right ventricle (RV)
    - Frequently associated with ventricular septal defect (VSD) & outflow tract obstruction
- Arterial switch was 1st successfully used in 1975 by Dr. Adib Jatene
  - Coronary arteries are transposed to base of neoaorta
  - Aorta & pulmonary trunks are then sectioned, transposed, & anastomosed
    - Ascending aorta ends up being connected to LV outflow tract
    - Main pulmonary artery (PA) is relocated anterior to aorta & connected to RV outflow tract
      - This relocation of pulmonary trunk is referred to as Lecompte maneuver
      - Reduces risk of coronary artery kinking
- VSD is corrected if present
  - If no VSD is present, patient typically undergoes PA banding prior to correction to prepare LV for systemic pressures
- Arterial switch is performed in first 2 weeks of life
- If not performed early in neonatal period, PA banding ± Blalock-Taussig shunt is used to acclimate LV to systemic pressures in preparation for connection to aorta
- Arterial switch is contraindicated in presence of coronary anomalies, such as intramural course
- Arterial switch may not be feasible in presence of significant LV outflow obstruction
  - Rastelli procedure is often used instead in this situation
- Benefits of arterial switch
  - LV is used as systemic pump & mitral valve as systemic atrioventricular valve
  - Lower incidence of arrhythmias compared to atrial switch (Senning/Mustard)
  - No baffle obstructions/leaks as with atrial switch (Senning/Mustard)
  - Can be performed earlier in neonatal period than atrial switch (Senning/Mustard)
  - Survival rate & freedom of reoperation at 5 years of 90% & 97%, respectively

IMAGING

General Features

- Complications
  - Supravalvular pulmonic stenosis
    - May require angioplasty or surgical correction in small percentage of patients
  - Branch PA stenoses
  - Supravalvular aortic stenosis
  - Aortic root dilation & regurgitation
  - LV dysfunction
  - Persistent pulmonary hypertension
  - Ischemia secondary to coronary artery stenosis/occlusion, typically at ostium

CT Findings

- Useful in immediate postoperative period to assess for airway compression, branch PA stenosis, & mediastinitis
- Can be utilized to evaluate coronary artery lesions, such as ostial stenosis/kink

MR Findings

- Comprehensive evaluation of postoperative anatomy & function; excellent follow-up tool
  - Quantify RV & LV chamber sizes & function
  - Evaluate valvular function by flow quantification across vessels using phase-contrast imaging
  - Measure aortic root dilation & degree of aortic regurgitation
  - Delayed enhancement techniques are useful for evaluation of myocardial ischemia or infarction
  - 3D SSFP sequence for coronary anatomy

DIFFERENTIAL DIAGNOSIS

Mustard/Senning

- Atrial level repair of D-TGA
- Intraatrial baffle is created
  - Superior & inferior vena cava form superior & inferior limbs of systemic venous baffle, routed to morphologic LV & hence PA
  - Pulmonary veins are routed to morphologic RV & hence aorta
- Mustard procedure uses autologous or synthetic pericardium to form baffle
- Senning uses native atrial tissue to form baffle
- Complications include arrhythmias, RV dysfunction, tricuspid regurgitation, pulmonary & systemic pathway stenoses, & baffle leaks/stenoses

Rastelli

- Performed on subset of patients with D-TGA, VSD, & LV outflow tract stenosis/obstruction
- PA is divided just above valve plane, & cardiac end closed, followed by placement of extracardiac RV to PA conduit
- Intraventricular tunnel is created directing blood flow from LV through VSD into aorta

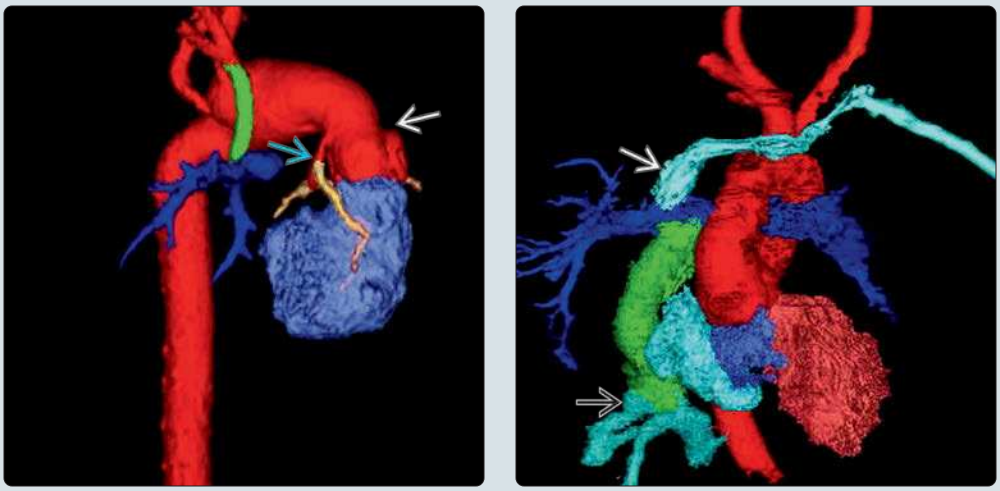
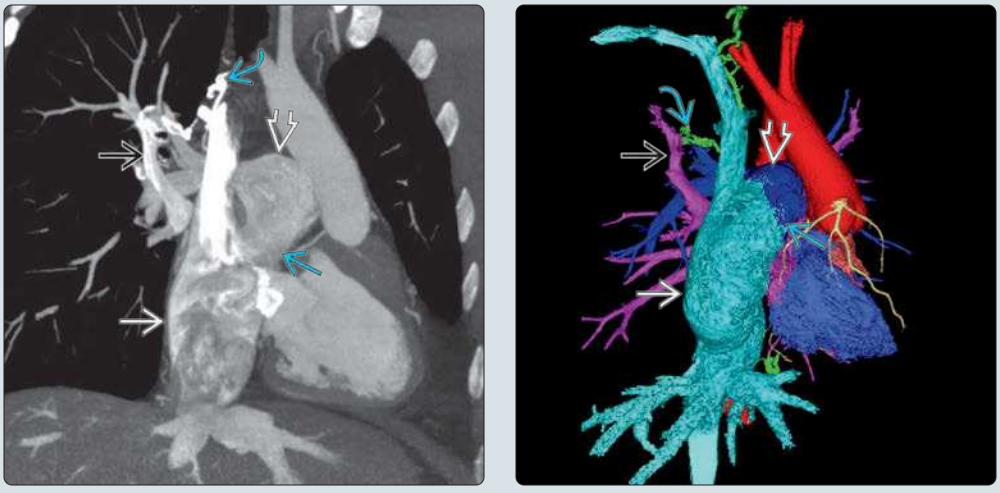
Norwood Procedure



KEY FACTS

TERMINOLOGY



- 3-stage procedure to palliate single ventricle physiology (most commonly hypoplastic left heart syndrome)
- Goals of Norwood procedure
  - Utilize single right ventricle as systemic pump & reconstruct systemic arterial outflow
  - Ensure pulmonary venous return to right heart
  - Reroute systemic venous return directly to lungs
- Stage 1 Norwood
  - Neoaorta is constructed using divided main pulmonary artery (PA) anastomosed to aortic root
  - Blalock-Taussig (BT) or Sano shunt is created to provide blood flow to high-resistance pulmonary arterial circulation
  - Ductus arteriosus is ligated
  - Atrial septum is resected
- Stage 2 Norwood
  - BT or Sano shunt is excised
  - Bidirectional Glenn shunt is created
- Stage 3 Norwood
  - Lateral tunnel or extracardiac Fontan procedure is performed
- ~ 70% 5-year survival of Norwood procedure
- Norwood procedure alternatives for hypoplastic left heart syndrome
  - Hybrid procedure (ductus arteriosus stenting, PA banding, & atrial septal defect ballooning in lieu of stage 1 Norwood)
  - Primary cardiac transplantation

IMAGING

- CECT can be used pre- & postoperatively to evaluate complex anatomy
- CECT is useful in evaluation of complications, such as mediastinitis, shunt thrombus, collaterals, & effusions
- MR is most commonly used between stages or after completion

(Left) *Lateral color-coded 3D CTA shows a Norwood stage 1 with a hypoplastic native ascending aorta ⇨ combined with the main PA ➡ to form a neoaorta from a single ventricle (purple). A BT shunt (green) carries blood to the PAs (dark blue).* **(Right)** *Anterior color-coded 3D CTA shows a patient with a Norwood stage 3. A Fontan shunt (green) is seen carrying blood from the IVC ⇨ to the PAs (dark blue). A Glenn shunt is also present connecting the SVC ➡ to the PAs. Note the hypoplastic RV (purple).*

(Left) *Coronal MIP CTA shows an RA ➡ to PA ➡ (atriopulmonary)-type Fontan connection ⇨. Over time, there is often ↑ venous pressure that causes systemic ⇨ to pulmonary ⇨ venous collaterals to develop, resulting in ↑ cyanosis.* **(Right)** *Anterior color-coded 3D CTA shows an RA ➡ to PA ➡ (atriopulmonary)-type Fontan connection ⇨. Over time, there is often ↑ venous pressure that causes systemic ⇨ to pulmonary ⇨ venous collaterals to develop, resulting in ↑ cyanosis.*

TERMINOLOGY

Definitions

- 3-stage procedure to palliate single ventricle physiology (most commonly hypoplastic left heart syndrome)
  - Staged approach is necessary due to high pulmonary vascular resistance in neonatal period
  - Developed in early 1980s, initially as 2 stages
- Goals of Norwood procedure
  - Utilize single right ventricle (RV) [or, less frequently, single left ventricle (LV)] as systemic pump & reconstruct systemic arterial outflow
  - Ensure unobstructed pulmonary venous return to right heart
  - Reroute systemic venous return directly to lungs
- Stage 1 Norwood
  - Performed within 1st few days after birth
  - Neoaorta construction: Divide main pulmonary artery (PA) & anastomose to aortic root
    - Single, unobstructed arterial trunk from RV to systemic circulation is now in place
  - Blalock-Taussig (BT) or Sano shunt is created to provide blood flow to high-resistance PA circulation
  - Ductus arteriosus is ligated
  - Atrial septum is resected
    - Common atrium receives blood from superior & inferior vena cavae (SVC & IVC) & pulmonary veins
- Stage 2 Norwood
  - Performed between 3-6 months of age
    - Pulmonary vascular resistance has ↓ by this time to normal levels
  - BT or Sano shunt is excised
  - Bidirectional Glenn shunt is created
    - End-to-side anastomosis of SVC to PAs
- Stage 3 Norwood
  - Typically performed between 18-36 months of age
  - Lateral tunnel or extracardiac type of Fontan is now performed; atriopulmonary type is not common today
    - IVC blood flow is directed to PAs

IMAGING

General Features

- Complications
  - Heart failure, pleural & pericardial effusions, arrhythmias
  - Valvular dysfunction
  - Branch PA stenoses
  - Shunt thrombosis/stenosis/obstruction
  - Liver fibrosis, liver lesions
  - Protein-losing enteropathy
  - Pulmonary arteriovenous malformation
  - Neurologic complications
  - Unexplained sudden death

Radiographic Findings

- After stage 1: Signs of RV hypertrophy, ↓ pulmonary venous congestion, & occasional new paratracheal shadow from BT shunt
- After stage 2: Normalized pulmonary vascularity & elimination of BT shunt shadow, ↑ size of head & neck (initially) from ↑ pressure in SVC
- After stage 3: ↑ pulmonary vascularity & pleural effusions

CT Findings

- CECT
  - Can be used pre- & postoperatively to evaluate patients with complex anatomy &/or for whom long anesthesia times may be difficult
  - Useful in evaluation of complications, such as mediastinitis, shunt thrombus, venous & arterial collaterals, effusions

MR Findings

- Occasionally used preoperatively in complex cases when biventricular vs. univentricular repair is being contemplated
- Used frequently after stage 1, prior to bidirectional Glenn shunt
  - Assess anatomy & ventricular/valvular function
- Can be helpful after stage 2, prior to Fontan procedure
  - Glenn pathway can be evaluated in addition to ventricular & valvular function & other anatomy
  - PA sizes & anatomy can be ascertained, which affects surgical decision making for Fontan
- Very helpful after stage 3
  - Evaluate Fontan pathway patency & for presence of thrombus
  - Evaluate for PA stenoses
  - Evaluate for venous & arterial collateral formation
- MR elastography is helpful in evaluating liver fibrosis
  - ± hepatobiliary contrast to assess liver lesions

DIFFERENTIAL DIAGNOSIS

Norwood Procedure Alternatives for Hypoplastic Left Heart Syndrome

- Hybrid procedure
  - In lieu of Norwood stage 1
  - Ductus arteriosus stenting, PA banding, & atrial septal defect ballooning
  - No cardiopulmonary bypass or thoracotomy required
  - Comparable outcomes to full Norwood
- Primary cardiac transplantation
  - ~ 70% 7-year survival
  - Lifelong immunosuppression is needed

CLINICAL ISSUES

Natural History & Prognosis

- ~ 70% 5-year survival of Norwood procedure

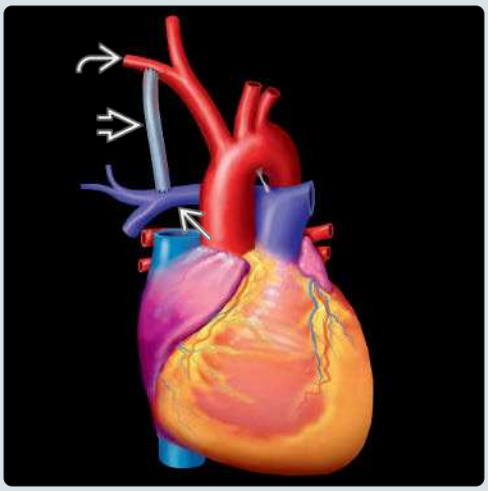
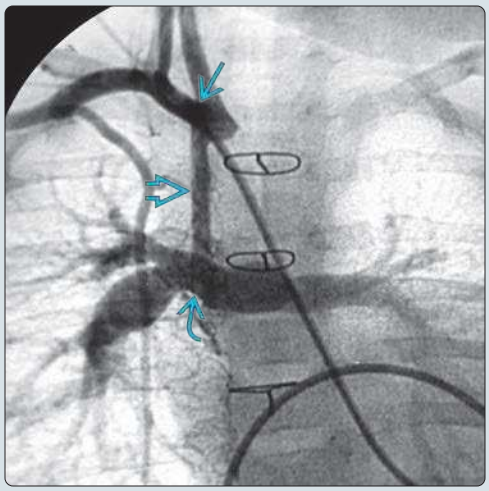
Blalock-Taussig Shunt

KEY FACTS

TERMINOLOGY

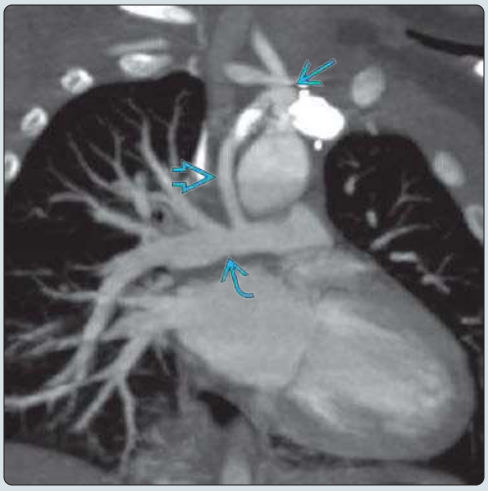


- Original/classic Blalock-Taussig (BT) shunt
  - Ligation & division of subclavian artery with end-to-side anastomosis of proximal subclavian artery to pulmonary artery
  - Rarely performed today due to complications
    - Overshunting, nerve injury, & potential growth disturbance of ipsilateral upper extremity
- Modified BT shunt
  - Synthetic prosthetic graft (Gore-Tex) between subclavian artery & ipsilateral pulmonary artery
    - Contralateral to side of aortic arch
  - Up to 90% patency rate at 2 years of age
- Used as palliative procedure to ↑ pulmonary blood flow prior to definite repair
  - Tetralogy of Fallot
  - Tricuspid atresia
  - Pulmonary atresia
  - Hypoplastic left heart syndrome (part of stage 1 Norwood procedure)

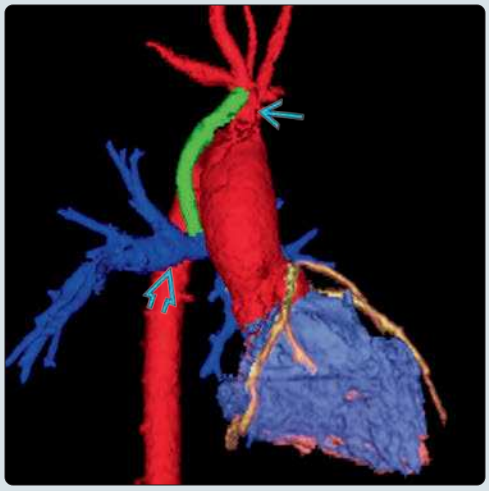


IMAGING

- CTA/MRA: Linear, tubular, contrast-opacified structure connecting subclavian artery to ipsilateral pulmonary artery (usually right sided)
  - Multiplanar & 3D reformations are helpful
- Dark signal intensity within patent shunt on black blood MR sequences
- Complications
  - Stenosis/thrombosis/occlusion
  - Perigraft seroma
  - Pseudoaneurysm



TOP DIFFERENTIAL DIAGNOSES



- Other palliative shunts (Glenn, Waterston, Potts, Sano)

(Left) *Coronal graphic shows a modified Blalock-Taussig (BT) shunt extending from the right subclavian artery to the right pulmonary artery. (Note that the superior vena cava has been excluded from the graphic in order to visualize the BT shunt.)* **(Right)** *Frontal conventional angiogram shows a patent BT shunt originating from the right subclavian artery & inserting into the confluence between the right & left pulmonary arteries in a patient with pulmonic atresia.*

(Left) *Coronal oblique CTA MIP in an infant with tetralogy of Fallot status modified BT shunt shows the shunt extending between the right brachiocephalic artery & the proximal right pulmonary artery. Flow may be ↑ to the right lung if there is any narrowing at the confluence between right & left pulmonary arteries.* **(Right)** *Frontal oblique surface-rendered CTA in an infant with tetralogy of Fallot shows a BT shunt (green) extending from the right brachiocephalic artery to the right main pulmonary artery.*

TERMINOLOGY

Abbreviations

- Blalock-Taussig (BT) shunt

Definitions

- Palliative procedure to augment pulmonary blood flow in various uni- & biventricular anatomies: Tetralogy of Fallot, tricuspid atresia, pulmonary atresia, & hypoplastic left heart syndrome (part of Norwood stage 1)
  - Original/classic BT shunt
    - Developed in 1945 by Dr. Alfred Blalock, Dr. Helen Taussig, & Vivien Theodore Thomas
    - Ligation & division of right subclavian artery with end-to-side anastomosis of proximal right subclavian artery to right pulmonary artery
    - Complications included shunt thrombosis, overshunting, nerve injury, & potential growth disturbance of ipsilateral upper extremity
    - Rarely performed today
  - Modified BT shunt
    - Synthetic graft prosthesis (Gore-Tex) between subclavian artery & ipsilateral pulmonary artery, contralateral to side of aortic arch
    - End-to-side anastomosis at each connection is performed through median sternotomy or lateral thoracotomy (with former preferred)
    - Up to 90% patency rate at 2 years of age

IMAGING

General Features

- Complications
  - Thrombosis
    - Can be early or late complication
  - Complete occlusion
    - ~ 10% of cases
    - More common in grafts < 3 mm in size
  - Stenosis, typically near proximal or distal anastomosis
  - Perigraft seroma
    - Complication secondary to leakage of fluid across Gore-Tex graft
  - Pseudoaneurysm

Radiographic Findings

- Typically ↑ pulmonary vascularity compared to pre-BT shunt radiograph
- Postthoracotomy rib changes
- Features of underlying congenital heart disease

CT Findings

- Tubular, contrast-opacified structure (synthetic graft) connecting subclavian artery to ipsilateral pulmonary artery, usually right sided
- Abrupt cut-off is consistent with occlusion or prior takedown in older child
- Filling defect within shunt compatible with thrombosis
- Evaluate for proximal or distal anastomotic stenosis
- Look for associated perigraft seroma or, rarely, pseudoaneurysm (especially if recently stented)
- In patients who have undergone classic BT shunt in past, ipsilateral subclavian artery may be absent

MR Findings

- Tubular structure connecting subclavian artery to ipsilateral pulmonary artery is seen as dark signal intensity structure on black blood sequences
- Contrast-enhanced MRA is best to confirm & characterize thrombus, occlusion, stenosis, pseudoaneurysm, or associated perigraft seroma
- Can quantify flow on phase-contrast sequences

Echocardiographic Findings

- Can evaluate BT shunt for patency & measure gradient across stenosis
- Can evaluate perigraft seroma

Angiographic Findings

- Typically performed for angioplasty with stenting of shunt stenosis or occlusion
- Pseudoaneurysm can develop around stent

Imaging Recommendations

- Best imaging tool
  - CTA/MRA with multiplanar & 3D reformations

DIFFERENTIAL DIAGNOSIS

Other Palliative Shunts

- Glenn shunt
  - Superior vena cava to pulmonary artery
  - Requires low pulmonary vascular resistance
    - Not performed under 3-6 months of age due to high pulmonary vascular resistance
- Waterston shunt
  - Ascending aorta to pulmonary artery
  - No longer performed
    - Congestive heart failure & pulmonary hypertension occur due to excessive pulmonary blood flow
- Potts shunt
  - Descending aorta to left pulmonary artery
  - No longer performed
    - Pulmonary hypertension & pulmonary artery kinking
- Sano shunt
  - Direct shunt between right ventricle & pulmonary artery
  - Performed as part of Norwood stage 1 in lieu of BT shunt in some cases of hypoplastic left heart syndrome
- PDA stent
  - PDA stent may be better tolerated than BT shunt

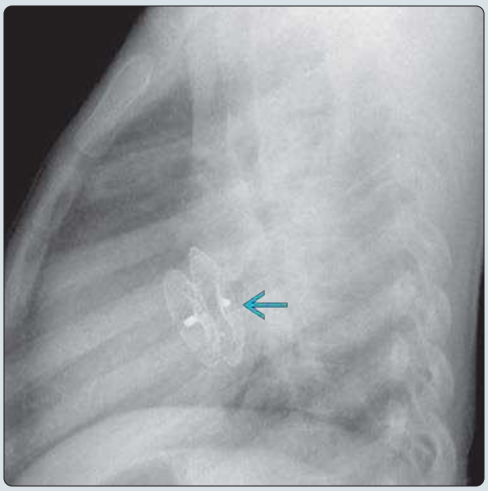
Amplatzer Occluder Device

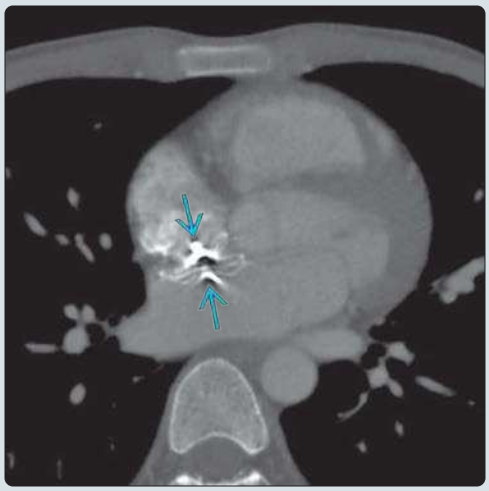
KEY FACTS

TERMINOLOGY

- Percutaneous transcatheter occlusion of septal defect or vessel
- 4 varieties
  - Septal occluder (for secundum atrial septal defect)
  - Muscular ventricular septal defect occluder
  - Duct occluder (for patent ductus arteriosus)
  - Vascular plug (for embolization of peripheral arteries & veins)
- Device is made from nitinol mesh & polyester fabric, which provide rapid occlusion & substrate for tissue ingrowth
- Can be repositioned & recaptured during placement

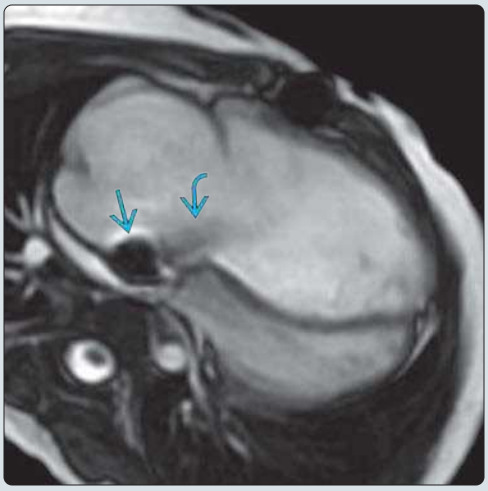


IMAGING

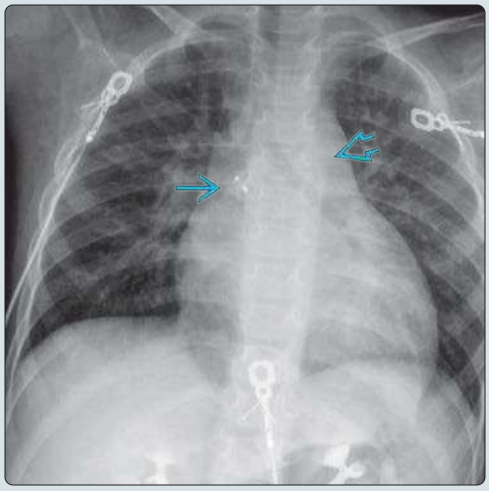


- Requires transesophageal or intracardiac echocardiography as well as fluoroscopic imaging during implantation
- Septal occluder device: 2 radiodense dots define ends of 3- to 4-mm long waist with 2 radiodense discs on either side of waist
- Ductal occluder device: 2 radiodense dots define ends of 5- to 8-mm long waist of device with single radiodense disc on aortic side of waist
- Best visualized with bone windows on CT
- Subsequent MR scanning is safe up to 3.0 Tesla with maximum spatial gradient magnetic field of up to 720 Gauss/cm & maximum specific absorption rate of 3 W/kg for up to 15 minutes

CLINICAL ISSUES



- Very high closure rates (> 95%)
- Requires endocarditis prophylaxis & antiplatelet/anticoagulation therapy for 6 months post implantation
- Early complications: Perforation of vessel or myocardium, thrombus formation, dislodgement/embolization, & percutaneous access site complications
- Late complications: Arrhythmia (most common), thrombosis, cardiac erosion, & infection or endocarditis



(Left) *Lateral radiograph of the chest shows an atrial septal closure device in an expected location & configuration in a 4-year-old patient with a septum secundum type of atrial septal defect (ASD).* **(Right)** *Axial CECT shows a septal closure device across a secundum-type ASD. Note the 2 central metallic dots (indicating the ends of the device waist) & the discs on either side of the atrial septum.*

(Left) *Four-chamber cardiac GRE MR shows an atrial septal closure device in place. Note the signal void in the right atrium from a small peridevice leak. Also note the enlarged right atrium & ventricle from a longstanding left-to-right shunt in this teenage patient.* **(Right)** *AP radiograph in a 3-year-old immediately after placement of a patent ductus arteriosus (PDA) closure device shows an abnormal location of the device at the right pulmonary artery after migration (embolization) from the expected left PDA site.*

TERMINOLOGY

Synonyms

- Septal occluder device
- Duct occluder device

Definitions

- Percutaneous, transcatheter occlusion of atrial or ventricular septal defect or vessel
- Invented by Dr. Kurt Amplatz, radiologist
- 4 varieties
  - Septal [atrial septal defect (ASD)] occluder
    - FDA approved in 2001
    - Designed to close atrial septal wall on each side of secundum defect
    - Available in 4- to 38-mm sizes in USA
    - Multifenestrated ASD requires cribriform occluder subtype
  - Muscular [ventricular septal defect (VSD)] occluder
    - Designed to close VSD on each side of defect
    - 2 discs are connected together by waist that corresponds to size of VSD
    - Available in 4- to 18-mm waist sizes
  - Duct occluder
    - Designed to seal patent ductus arteriosus (PDA)
    - Conical shape to conform to PDA
    - Available in 5- to 16-mm diameters
  - Vascular plug
    - Used for embolization of peripheral arteries & veins
    - Alternative to coils
- Device is made from nitinol mesh & polyester fabric, which provide rapid occlusion & substrate for tissue ingrowth
- Sizing balloon is used to determine correct size device
- Requires transesophageal or intracardiac echocardiography as well as fluoroscopic imaging during procedure
- Can be repositioned & recaptured during placement
- Very high closure rates (> 95%)
- Indications for ASD closure device
  - Ostium secundum ASD
  - Clinical evidence of right ventricular (RV) volume overload
    - Left-to-right shunt 1.5:1 ≥, or RV chamber enlargement
- Contraindications
  - Sepsis within 1 month prior to implantation
  - Bleeding disorder or other contraindication to aspirin therapy after device placement
  - Intracardiac thrombi
  - Septal defect location < 5 mm from coronary sinus, atrioventricular valves, or pulmonary vein orifice
  - Nickel allergy (as nitinol contains nickel)
- Follow-up
  - Requires endocarditis prophylaxis & antiplatelet/anticoagulation therapy for 6 months post implantation
  - Devices are "conditional 6" to 3.0 Tesla magnet

IMAGING

General Features

- Complications
  - Early complications include: Perforation of vessel or myocardium, thrombus formation, dislodgement/embolization, & percutaneous access site complications
  - Late complications include: Arrhythmia (most common), thrombosis, cardiac erosion, & infection or endocarditis

Radiographic Findings

- Septal occluder device
  - 2 radiodense dots define ends of 3- to 4-mm long waist of device
  - 2 radiodense flat discs on either side of waist
  - 2 dots & 2 discs may not be visualized on each view depending on projection & overlapping structures
- Ductal occluder device
  - 2 radiodense dots define ends of 5- to 8-mm long waist of device
  - 1 radiodense flat disc on aortic side of waist

CT Findings

- Best visualized on bone windows
- Radiodense dots (at either end of waist) & radiodense flat discs are easily identified

MR Findings

- Device is not evaluated/followed by MR but can be scanned immediately after placement
  - Scanned safely up to 3.0 Tesla with maximum spatial gradient magnetic field of up to 720 Gauss/cm & with maximum specific absorption rate of 3 W/kg for up to 15 minutes
- Will cause susceptibility artifact

Ultrasonographic Findings

- Transesophageal or intracardiac echocardiography is used to monitor implantation & to assess success of ASD closure

Angiographic Findings

- Catheter angiography & fluoroscopy are used to define anatomy & monitor implantation

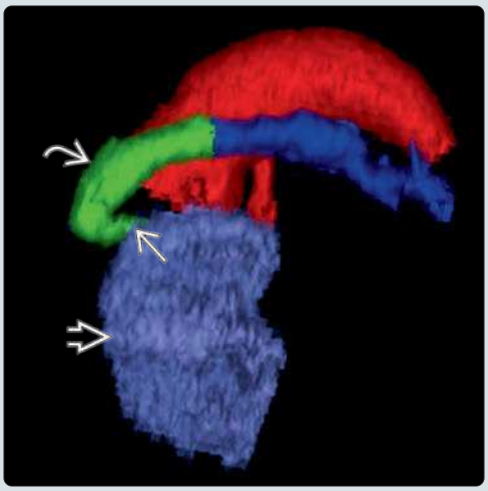
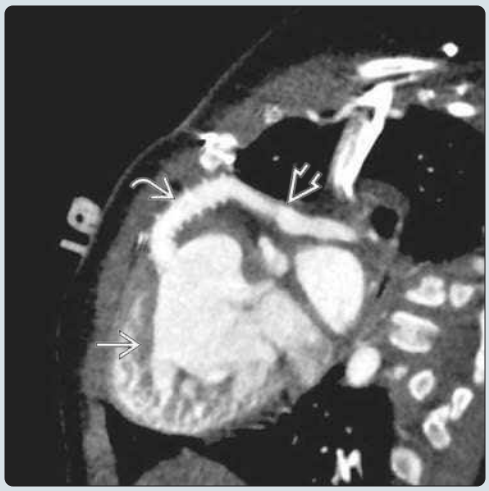
Sano Shunt

KEY FACTS

TERMINOLOGY

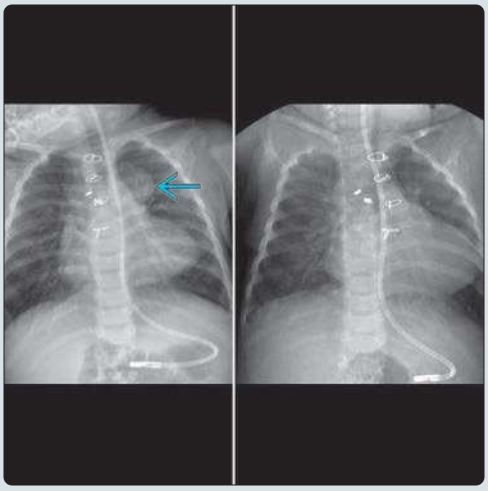


- Sano shunt provides alternate source of pulmonary blood flow to modified Blalock-Taussig (BT) shunt in hypoplastic left heart patients undergoing stage 1 Norwood procedure
- Extracardiac conduit between right ventricle & pulmonary artery
  - Small ventriculotomy made in right ventricular outflow tract
  - Conduit is nonvalved, thus allowing free regurgitation
- Typically performed during 1st few days of life
- Benefits
  - Elimination of coronary steal phenomenon secondary to reversal of diastolic flow with modified BT shunt
  - Forward flow through shunt only occurs during systole
  - Improved hemodynamic stability postoperatively compared to modified BT shunt
  - Higher rate of transplantation-free survival at 12 months compared with modified BT shunt

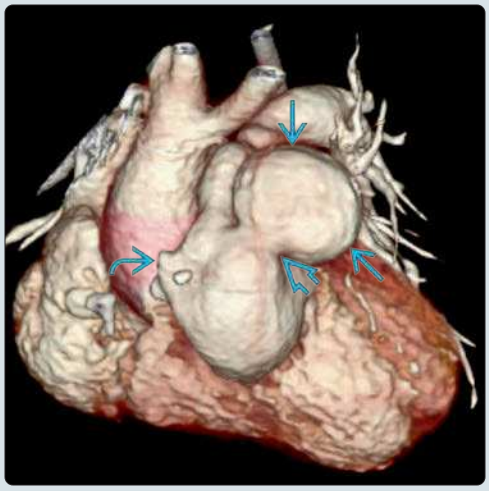


IMAGING

- CECT is useful in immediate postoperative period to assess for complications
- CT can also be used to evaluate status of Sano shunt itself & branch pulmonary arteries
  - Evaluate shunt thrombosis or occlusion
  - Branch pulmonary artery stenoses
  - Aneurysm/pseudoaneurysm at ventriculotomy site
- MR provides comprehensive, ionizing radiation-free evaluation of postoperative anatomy & function
- 3D reconstructions of CTA/MRA are extremely helpful



TOP DIFFERENTIAL DIAGNOSES



- Modified BT shunt

(Left) *Lateral color-coded 3D surface-rendered CTA in an infant shows a Sano shunt arising from the right ventricle (RV) in an infant status post stage 1 Norwood procedure. Note the focal narrowing at the origin of the shunt from the RV. This is designed to control flow.* **(Right)** *Lateral oblique cardiac CTA shows a Sano shunt extending between the RV chamber & the pulmonary artery in a 4-month-old with a history of a Norwood operation for hypoplastic left heart syndrome.*

(Left) *Frontal radiographs obtained at 6 (left) & 3 (right) months of age show postoperative changes from a Sano procedure. The more recent radiograph shows a new rounded opacity along the left mediastinum, which could represent thymic rebound, round pneumonia, or pseudoaneurysm.* **(Right)** *Anterior 3D surface-rendered CTA in the same patient shows a 19-mm pseudoaneurysm arising from the left aspect of the RV outflow tract. A smaller pseudoaneurysm is also noted on the right.*

TERMINOLOGY

Synonyms

- Right ventricle-pulmonary artery (RV-PA) conduit

Definitions

- Norwood stage 1 involves using main PA to augment ascending aorta in patients with hypoplastic left heart syndrome (HLHS)
  - New source of pulmonary blood flow is required
    - Blalock-Taussig (BT) shunt provides source of pulmonary blood flow from systemic arterial system
    - BT flow is continuous in both systole & diastole
    - Because ~ 75% of coronary blood flow occurs during diastole, coronary steal phenomenon develops
      - Diastolic retrograde flow occurs in coronaries & descending thoracic aorta
      - Resultant coronary insufficiency is theorized to play major role in operative & postoperative morbidity/mortality of stage 1 Norwood with BT shunt
  - Sano conduit (extracardiac conduit between RV & PA) is alternative to modified BT shunt
    - Small ventriculotomy is made in RV outflow tract
    - 4- to 6-mm synthetic graft is anastomosed to RV & PA to left of neoaorta
    - Conduit is nonvalved, thus allowing free regurgitation
- Typically performed during 1st few days of life
- Stage 2 Norwood (Glenn anastomosis) typically needs to be performed slightly earlier after Sano shunt than with modified BT shunt in 3- to 6-month timeframe
- Benefits
  - Elimination of coronary steal phenomenon secondary to reversal of diastolic flow with modified BT shunt
    - Forward flow through shunt only occurs during systole
  - Improved hemodynamic stability postoperatively compared to modified BT shunt
  - Higher rate of transplantation-free survival at 12 months compared with modified BT shunt
  - Nonrandomized & retrospective studies have shown potential benefit in outcomes associated with RV-PA conduit when compared to modified BT shunt
- One limitation cited in available literature is poor ventricular performance in view of ventriculotomy
  - Current available evidence, although weak, does not show any adverse effects of ventriculotomy on ventricular performance in patients with Sano shunt in short & medium terms

IMAGING

General Features

- Complications
  - Arrhythmias
  - Shunt stenosis/obstruction
  - Shunt thrombosis
  - Branch PA stenoses
  - RV dysfunction
  - Aneurysm/pseudoaneurysm formation at ventriculotomy site
  - Shunt infection & pulmonary embolism
  - May require more extensive PA reconstruction at time of Glenn anastomosis (stage 2 Norwood)

CT Findings

- Useful in immediate postoperative period to assess for complications
  - Mediastinitis
  - Hemorrhage
  - Aneurysm
- Can also be used to evaluate status of Sano shunt itself & branch PAs
- Radiation exposure is concern; however, newer generation scanners can provide requisite information in sub-mSv radiation doses
- 3D reconstructions are extremely helpful

MR Findings

- Comprehensive evaluation of postoperative anatomy & function, without ionizing radiation
- Functional analysis for systemic ventricle
- Phase-contrast imaging can be used to quantify flow in
  - Sano shunt
  - Branch PAs
  - Neoaorta
- Pulmonary:systemic arterial flow ratio (Qp:Qs) can be calculated
- 3D reconstructions are extremely helpful

Echocardiographic Findings

- Duplex Doppler imaging of mid- to distal portion of Sano shunt can provide flow information & evaluation for stenosis
- Proximal anastomosis of shunt & branch PAs may not be adequately visualized in view of poor acoustic windows

DIFFERENTIAL DIAGNOSIS

Modified Blalock-Taussig Shunt

- Synthetic graft connection between subclavian artery & ipsilateral PA as part of stage 1 of Norwood

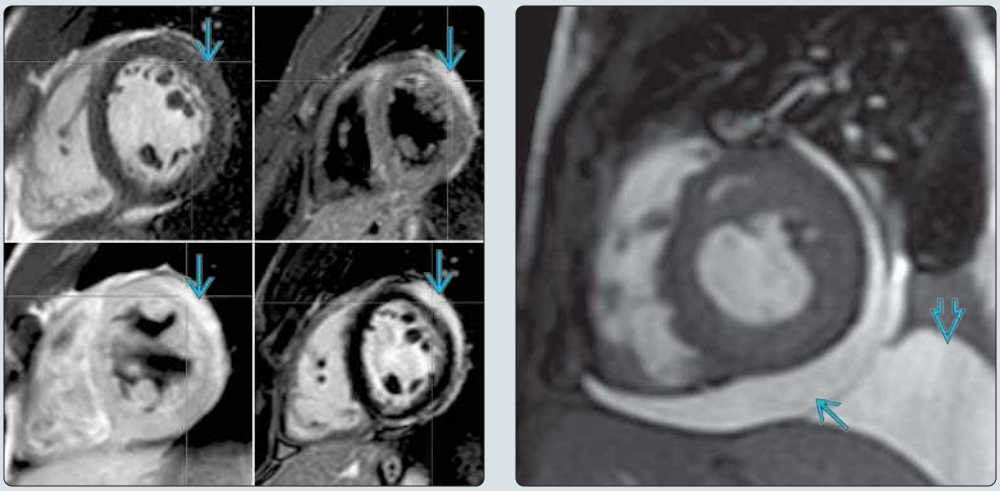
Myocarditis

KEY FACTS

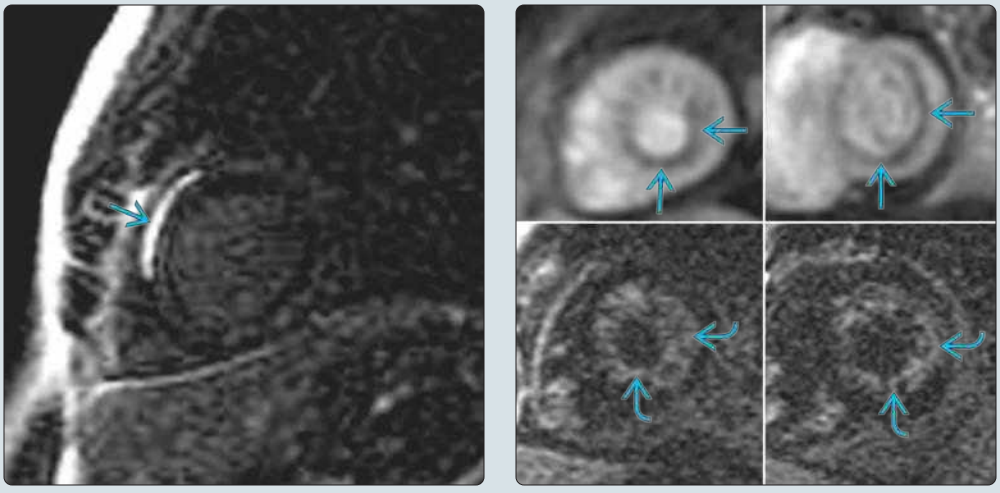
IMAGING

- Chest radiograph: Many cases are normal
  - Cardiomegaly &/or pericardial effusion in setting of cardiac dysfunction
  - Pulmonary edema in more severe cases
- Echocardiography: Often 1st imaging, identifies cardiac dysfunction &/or pericardial effusion
- Cardiac MR: Increasingly utilized for diagnostic capabilities
  - Cardiac volumes & functional assessment: ↓ ejection fraction with wall motion abnormality, ± pericardial effusion
  - Myocardial tissue characterization (edema, hyperemia, & fibrosis): ↑ T2 signal, early & late gadolinium enhancement, native T1 values > 990 ms
  - ≥ 2 positive criteria in acute phase: 80% sensitivity, 90% specificity
- Cardiac catheterization & endomyocardial biopsy: Historic gold standard (but invasive & can miss patchy inflammation)



PATHOLOGY

- Infectious etiology (typically viral) most common in otherwise healthy individuals
  - Postinfectious immune mediated: MIS-C from SARS-CoV-2, Kawasaki
- Toxins/drug reactions: Antibiotics, antiepileptics, carbon monoxide, illegal drugs (cocaine)
- Autoimmune: Lupus, sarcoidosis, Takayasu arteritis
- Ischemic: Acute coronary syndrome/myocardial infarction



CLINICAL ISSUES

- Nonspecific symptoms: Fever, fatigue, malaise, dyspnea, muscle aches, & unexplained sinus tachycardia
- May imitate acute myocardial infarction
- Rarely, fulminant with cardiovascular collapse & shock
- May account for 10% of sudden death in young
- Most cases: Mild symptoms, need only supportive care

(Left) *Short-axis MR tissue characterization in myocarditis: A region of interest with ↑ signal is seen in the anterolateral segment ⇨ on SSFP (upper left), T2 (upper right), early gadolinium (lower left), & late gadolinium (lower right) enhancement images.* **(Right)** *Short-axis SSFP cine MR in a patient with known myocarditis shows a moderate-sized pericardial effusion ⇨. Also note the pleural effusion ⇨.*

(Left) *Delayed short-axis image from a cardiac MR perfusion shows delayed enhancement ⇨ in the midmyocardium of the interventricular septum of the left ventricle.* **(Right)** *Short-axis cardiac perfusion MR from an adolescent patient show changes of myocarditis. Immediate dynamic postcontrast images (top) show ↓ uptake ⇨ circumferentially in the endocardium extending into the myocardium. Delayed enhancement ⇨ is shown on delayed images (bottom) in the same distribution.*

TERMINOLOGY

Definitions

- Inflammation of myocardium with edema, hyperemia, & fibrosis, often leading to cardiac dysfunction & pericardial effusion
  - Clinical symptoms are often nonspecific

IMAGING

Radiographic Findings

- Chest radiograph findings vary based on severity
  - Many cases are normal
  - Cardiomegaly &/or pericardial effusion in setting of cardiac dysfunction
  - Severe cases show interstitial &/or alveolar pulmonary edema

MR Findings

- T2WI
  - Triple inversion recovery (with inversion pulses for fat & blood) show ↑ T2 signal
    - Quantitative analysis of signal intensity is more sensitive
      - Identification of edema throughout myocardium
    - Limited sensitivity in mild cases
- T1WI C+
  - Early gadolinium enhancement (EGE)
    - Hyperemia & capillary leak show enhancement 1 minute post gadolinium
  - Late gadolinium enhancement (LGE)
    - Fibrosis & necrosis
      - May be irreversible
    - Differentiates ischemic injury (always subendocardial) from nonischemic injury
- Native T1 mapping demonstrates location, extent, & pattern of myocarditis
  - Threshold of T1 > 990 ms (sensitivity & specificity ~ 90%) detects significantly larger areas of involvement than T2 & LGE

Echocardiographic Findings

- Often 1st imaging performed; neither sensitive nor specific
  - Mild cases: ↓ function ± wall motion abnormalities, ± pericardial effusion
  - Moderate to severe cases: ↓ function with associated wall motion abnormalities, left ventricular chamber dilation, ↑ wall thickness, ± pericardial effusion

Imaging Recommendations

- Best imaging tool
  - Cardiac MR: Functional assessment with myocardial tissue characterization
- Protocol advice
  - SSFP 2-chamber, 3-chamber, 4-chamber, & short-axis stack
  - Tissue characterization with precontrast T2 3-slice short-axis (edema) & postcontrast 3-slice short-axis EGE (hyperemia) & LGE (fibrosis)
  - Native T1 values: Most accurate detection of myocarditis

PATHOLOGY

General Features

- Etiology
  - Infectious etiology is most common if otherwise healthy
    - Direct viral infection of myocardium: Coxsackie B virus, adenovirus, parvovirus B19, echoviruses, EBV
      - May see dystrophic Ca^{2+} in neonates with enteroviral myocarditis
    - Immune-mediated postinfectious reaction
      - Kawasaki disease
      - MIS-C from SARS-CoV-2
    - Chagas disease: *Trypanosoma cruzi* (Central & South America)
  - Other causes
    - Toxins/drug reactions: Antibiotics, antiepileptics, carbon monoxide, illegal drugs (cocaine)
    - Autoimmune: Lupus, Takayasu arteritis, granulomatosis with polyangiitis, giant cell arteritis

Microscopic Features

- Endomyocardial biopsy in severe cases when definitive diagnosis is required, otherwise not recommended
  - Histopathology shows infiltration of inflammatory cells
  - Immunohistochemistry: Best sensitivity but less available
  - Viral genome analysis: PCR for most common viruses

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Often nonspecific with fatigue, dyspnea, muscle aches, unexplained tachycardia, or ventricular ectopy
- Other signs/symptoms
  - Many cases are asymptomatic; no medical care sought
  - May imitate acute myocardial infarction
  - Rarely fulminant with cardiovascular collapse & shock
  - Infants & small children: Dyspnea, poor feeding, & fever
    - Mistaken for reactive airway disease or pneumonia
  - ~ 10% of sudden cardiac deaths in young

Treatment

- Most cases have mild symptoms, need only supportive care
- With cardiac dysfunction, treatment is similar to other causes of heart failure
  - Drugs that stimulate heart should be avoided
  - Complete heart block requires temporary pacing
- Intravenous immunoglobulin: Variable results

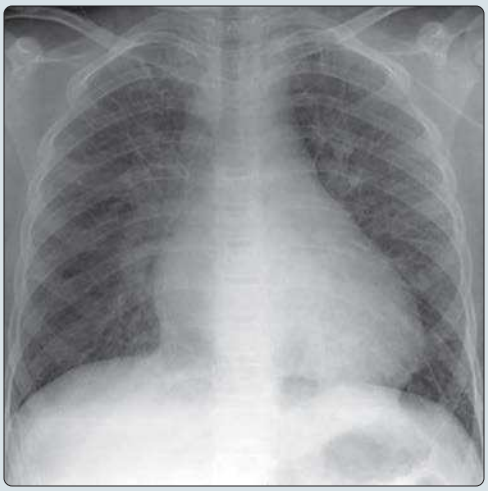
Left Ventricular Noncompaction

KEY FACTS

TERMINOLOGY

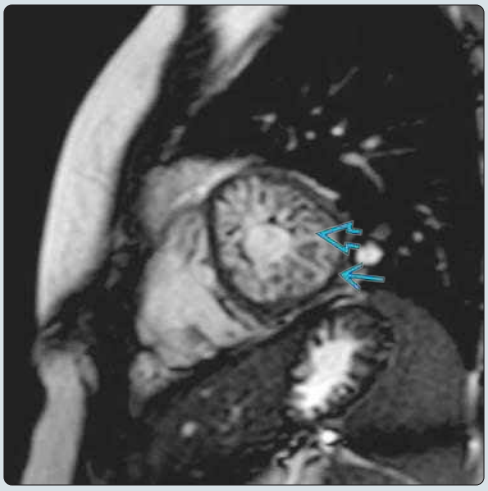
- Left ventricular noncompaction cardiomyopathy (LVNC): Cardiomyopathy characterized by sponge-like appearance of left ventricular (LV) myocardium
  - 2-layer appearance: Heavily trabeculated, noncompacted (NC) layer & thin, dense compacted (C) layer
  - NC:C ratio > 2.3:1 is strongly suggestive
- Controversial diagnosis due to lack of definitive criteria & variable prognostic data
  - ↑ in diagnosis has occurred with improved echocardiogram & MR imaging quality
- Primitive appearance of myocardium suggests potential arrest in fetal LV myocardial development
  - LVNC is also seen in association with other cardiomyopathies & congenital heart disease



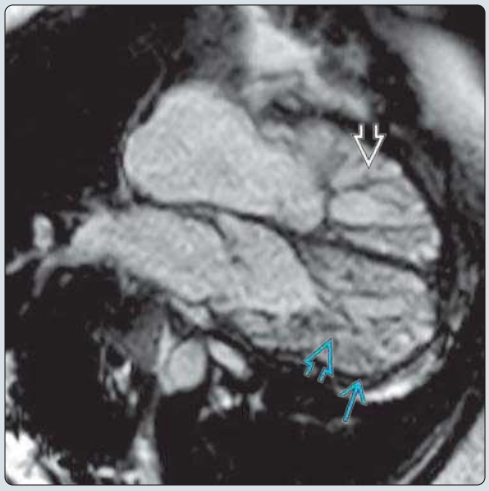
IMAGING

- Echocardiography is widely used
- CMR defines location & extent of trabeculations, ventricular volumes & ejection fraction, fibrosis (with late gadolinium enhancement), & apical thrombus
- Multitude of imaging "criteria" have been proposed; however, varying results of imaging findings compared to prognostic data

CLINICAL ISSUES



- Highly variable clinical presentations are described, ranging from completely asymptomatic to symptomatic with heart failure, cardioembolic events, & ventricular arrhythmias
  - Mural thrombus develops within deep trabeculations of LV → significant risk factor for cardioembolic events
- Predictors of prognosis may include number of affected segments, heart failure at presentation, & ventricular arrhythmias
- Treat/prevent: Heart failure, ventricular arrhythmias, & embolic stroke



(Left) *Frontal view of the chest in a child presenting with shortness of breath shows bilateral interstitial pulmonary edema with cardiomegaly. The patient was ultimately diagnosed with left ventricular noncompaction cardiomyopathy (LVNC).* **(Right)** *Short-axis SSFP cine from a cardiac MR shows hypertrabeculated left ventricular myocardium ⇨ in a patient presenting in heart failure. A thin, peripheral, compacted layer ⇨ is noted.*

(Left) *Short-axis SSFP MR in end-diastole demonstrates marked left ventricular hypertrabeculation of the noncompacted layer ⇨ & a thin, dense appearance of the compacted layer ⇨ in a patient with LVNC.* **(Right)** *Four-chamber SSFP MR shows marked left ventricular hypertrabeculation of the noncompacted layer ⇨ & a thin, dense, compacted layer ⇨ in a patient with LVNC. Also note the hypertrabeculated right ventricle (RV) ⇨, suggesting biventricular NC.*

TERMINOLOGY

Abbreviations

- Left ventricular noncompaction cardiomyopathy (LVNC)

Synonyms

- Noncompacted left ventricle (NCLV), left ventricular hypertrabeculation, spongy myocardium

Definitions

- Inherited cardiomyopathy characterized by extensive hypertrabeculation of left ventricular (LV) myocardium
- 2-layer appearance of LV with sponge-like noncompacted (NC) inner layer & thinner, dense compacted (C) outer layer
- Primitive appearance of myocardium suggests potential arrest in fetal LV myocardial development

IMAGING

General Features

- Best diagnostic clue
  - LV myocardium in 2 layers: Thick, hypertrabeculated inner layer (NC) & thin, dense outer layer (C)
  - NC:C thickness ratio > 2.3:1 in patients with LVNC
- Location
  - Typically, LV has coalescent pattern in inferior & lateral segments of apical & midregions; rare in basal region
  - Normally RV is somewhat trabeculated; can be heavily trabeculated in severe LVNC

Radiographic Findings

- Cardiomegaly in patients with heart failure

MR Findings

- SSFP cine
  - 2-, 3-, & 4-chamber views & short-axis stacks are best sequences to locate segment distribution & extent of trabeculations
  - NC:C thickness ratio > 2.3:1 is strongly suggestive; measured in end-systole or end-diastole
  - ↑ LV end-diastolic volume (EDV): Contours performed on compacted layer in end-diastole
  - ↓ LV ejection fraction: Challenging to contour in end-systole due to heavy trabeculations coalescing
  - Can determine trabecular mass vs. total mass ratio
- Delayed enhancement
  - Myocardial fibrosis assessment by late gadolinium enhancement (LGE)
    - Difficult to accurately depict given deep trabeculations
      - Requires multiple slice planes
    - ± wall motion abnormalities if LGE is positive

Echocardiographic Findings

- Primary diagnostic modality; 3 descriptions
  - Minor trabeculation: Prominent trabeculation in posteroapical LV in noncoalescent pattern; NC:C ratio < 2.3
  - Major trabeculation: Prominent trabeculation in posteroapical LV in coalescent pattern; NC:C ratio < 2.3
  - Noncompaction: Prominent trabeculation in posteroapical LV in coalescent pattern; NC:C ratio > 2.3
- Color Doppler demonstrates flow within trabeculations & communication with ventricular cavity
- Evaluate for septal defects, apical thrombus, LV systolic &/or diastolic dysfunction

Imaging Recommendations

- Best imaging tool
  - Cardiac MR with SSFP 2-, 3-, & 4-chamber views & short-axis stack; LGE for fibrosis
- Protocol advice
  - Artifact from parallel imaging may obscure trabeculations; best images are without parallel imaging

DIFFERENTIAL DIAGNOSIS

Normal With Prominent Trabeculations

- Likely normal if NC:C ratio is < 2.3, noncoalescent trabecular pattern, normal ejection fraction & LV EDV, absence of symptoms

Dilated Cardiomyopathy

- Hypertrophy of cardiac trabeculations can imitate noncompaction; cardiac apex is not involved in dilated cardiomyopathy

Hypertrophic Cardiomyopathy

- Most commonly seen in apical hypertrophic cardiomyopathy (HCM); ↑ myocardial mass in HCM compared to LVNC

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Tachypnea due to low cardiac output or heart failure
    - Infants & small children with tachypnea, cyanosis, acute life-threatening event, or failure to thrive
    - Older patients with exertional dyspnea
  - Tachyarrhythmias; most have ECG abnormalities
  - Cardioembolic event

Demographics

- Familial in ~ 50%
- Sex: M > F, 3:2 ratio

Natural History & Prognosis

- Variable natural history & prognostic data → controversy in diagnosis
- Predictors of prognosis may include heart failure at presentation, systolic/diastolic dysfunction, thromboembolic events, & ventricular arrhythmias

Treatment

- Aimed at preventing/treating heart failure, ventricular arrhythmias, & stroke; new therapies target LV remodeling

Hypertrophic Cardiomyopathy

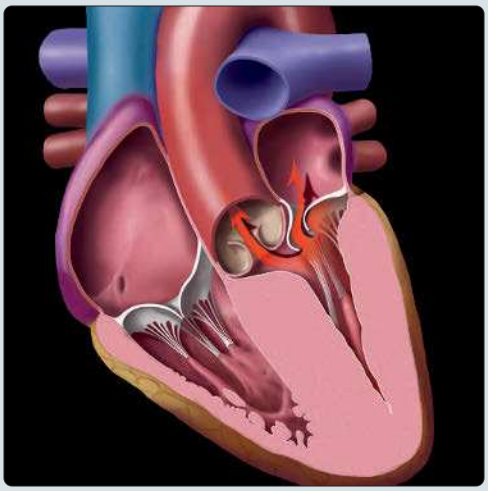
KEY FACTS

TERMINOLOGY

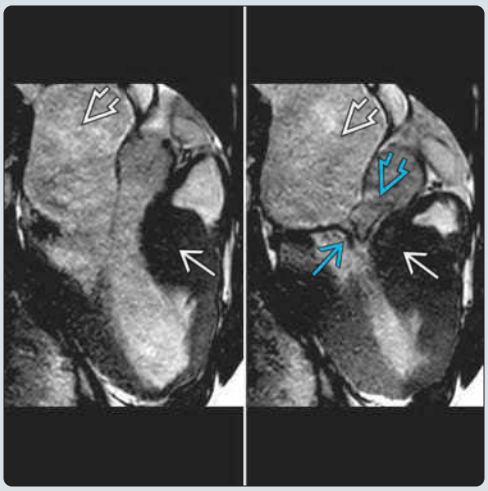
- Familial cardiomyopathy is characterized by thickened but nondilated LV & no identifiable systemic or cardiac cause
- Most common genetic cardiomyopathy (1 in 500)

IMAGING

- Echocardiography is primary diagnostic/screening tool
- Cardiac MR is utilized for ventricular dimensions, LVOT obstruction, & late gadolinium enhancement (LGE)
  - Asymmetric septal hypertrophy, typically of basal septum
    - Septal wall thickness > 15 mm (or > 13 mm with positive family history)
    - > 30 mm is risk factor for sudden cardiac death (SCD)
  - Dynamic LVOT obstruction
    - Severe thickening of septum during systole causes midcavitary obstruction
    - Systolic anterior motion of mitral valve
  - Systolic & diastolic dysfunction are variable
  - Patchy or focal LGE (from fibrosis) of basal & midventricle septal segments
    - Risk factor for ventricular arrhythmia & SCD

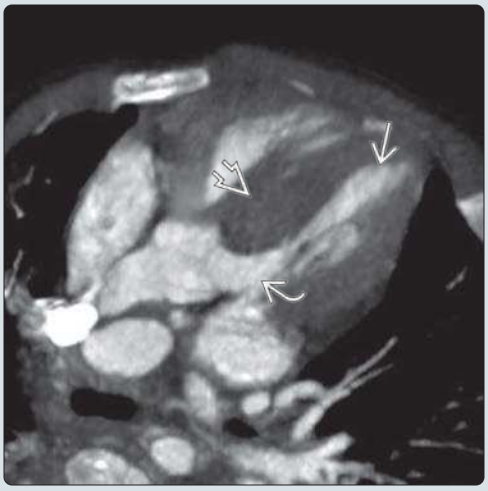


PATHOLOGY

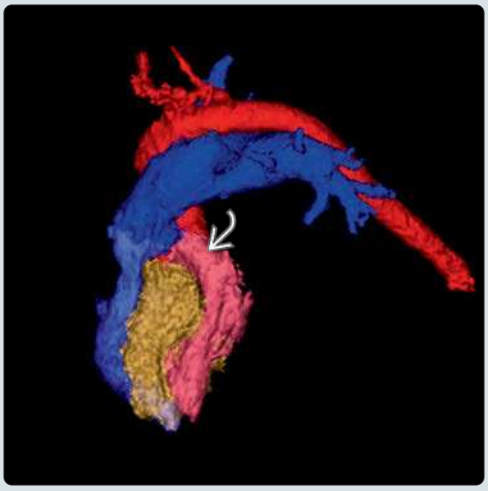


- Primary: Typically autosomal dominant inheritance
- Secondary: Associated with syndromic, neuromuscular, & metabolic disorders
- Idiopathic: ~ 50% of affected children < 1 year old

CLINICAL ISSUES



- Typical symptoms include dyspnea, chest pain, or syncope, typically with exertion
  - Ventricular arrhythmias are common
  - Increasing intensity in systolic heart murmur with Valsalva, positional change (standing/squatting), or exercise
  - Leading cause of SCD in youth
- Treatments include β-blockers, antiarrhythmics, pacemaker, septal ablation, myomectomy



(Left) *Five-chamber graphic demonstrates concentric hypertrophic obstructive cardiomyopathy. Septal hypertrophy & systolic anterior motion (SAM) of the mitral valve leaflet combine to cause left ventricular outflow tract (LVOT) obstruction & mitral regurgitation.* **(Right)** *Three-chamber SSFP MRs during diastole (left) & systole (right) demonstrate LVOT obstruction from severe septal hypertrophy & SAM of the mitral valve apparatus. Also note the left atrial enlargement.*

(Left) *Four-chamber view of the heart from a cardiac CTA shows a small left ventricular cavity with asymmetric septal hypertrophy & narrowing of the LVOT.* **(Right)** *Lateral oblique surface-rendered color-coded image from a cardiac CTA shows a small left ventricular cavity (pink) with septal hypertrophy (gold) & mild narrowing of the LVOT.*

TERMINOLOGY

Abbreviations

- Hypertrophic cardiomyopathy (HCM)

Synonyms

- Idiopathic hypertrophic subaortic stenosis, hypertrophic obstructive cardiomyopathy

Definitions

- Familial cardiomyopathy with thickening of left ventricular (LV) myocardium without other cardiac or systemic disease; typically involves ventricular septum

IMAGING

General Features

- Best diagnostic clue
  - Significant thickening of LV myocardium, typically septal
    - Diastolic wall thickness ratio: Thickest/thinnest > 2.0
- Location
  - Most common: Anteroseptal portion of basal LV
  - Less common: Concentric/symmetric or apical
- Morphology
  - 3 types: Asymmetric septal, concentric, or apical

Radiographic Findings

- Typically normal chest radiograph
- Left atrial dilation with mitral regurgitation, diastolic issues
- Cardiomegaly is evident in later stages with chamber dilation

MR Findings

- SSFP cine
  - 3-chamber, 4-chamber, & short-axis stack are best sequences for ventricular dimensions & ejection fraction
  - Asymmetric septal hypertrophy, typically basal septum
    - Septal wall thickness > 15 mm (or > 13 mm with positive family history)
    - LV thickness > 30 mm: Risk factor for sudden cardiac death (SCD)
  - Mechanism of LV outflow tract (LVOT) obstruction
    - Severe septal thickening → midcavitary obstruction
    - Systolic anterior motion of mitral valve apparatus → anterior leaflet & chordae are pulled into LVOT via Venturi effect
- Myocardial late gadolinium enhancement (LGE)
  - Patchy LGE (from fibrosis) with occasional focal areas (anteroseptal > inferoseptal)
    - Positive LGE = poor prognostic indicator

Imaging Recommendations

- Best imaging tool
  - Echocardiography: Primary diagnostic/screening tool
    - Better for diastolic dysfunction & LVOT gradient
  - Cardiac MR: Secondary diagnostic/prognostic tool
    - Better for ventricular wall dimensions & fibrosis

DIFFERENTIAL DIAGNOSIS

Secondary Left Ventricular Hypertrophy

- Typically concentric
- Due to hypertension, aortic stenosis, coarctation

Athlete's Heart (Physiologic Hypertrophy)

- LV cavity size is near normal or mildly ↑ (> 55 mm)

Left Ventricular Noncompaction

- Inner thick trabecular (noncompacted) myocardial layer + thin outer compacted layer
- Similar genetic abnormalities to HCM

PATHOLOGY

General Features

- Genetics
  - Familial form is typically autosomal dominant (AD) with de novo mutations making up small percentage of cases
  - 70% of genes involved in HCM encode β-myosin heavy chain & myosin-binding protein C; remaining in troponin T or I, α-actin, or multiple other genes

Staging, Grading, & Classification

- Primary: Familial HCM (AD inheritance)
- Secondary: Syndromic, neuromuscular, & metabolic
- Idiopathic: ~ 50% of affected children < 1 year of age

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic (often discovered via family history)
  - Physical exam: Systolic heart murmur that ↑ in intensity with position changes (squatting), Valsalva, or exercise; prominent LV apical impulse
  - Red flags: Exertional symptoms, including dyspnea, chest pain, or syncope; arrhythmias (typically ventricular)
  - SCD: Most common cause in children is HCM

Demographics

- Ethnicity
  - Black > White or Latino
- Epidemiology
  - Most common genetic heart disease (1:500)
  - Most common childhood cardiomyopathy (42%)

Natural History & Prognosis

- Variable clinical course with 1% annual mortality

Treatment

- Medical management
  - β-adrenergic blocking agents limit heart rate at baseline & with exertion
  - Antiarrhythmics reduce potential for arrhythmic events
- Invasive: Pacemaker, septal ablation, myomectomy

Duchenne Muscular Dystrophy-Related Cardiomyopathy

KEY FACTS

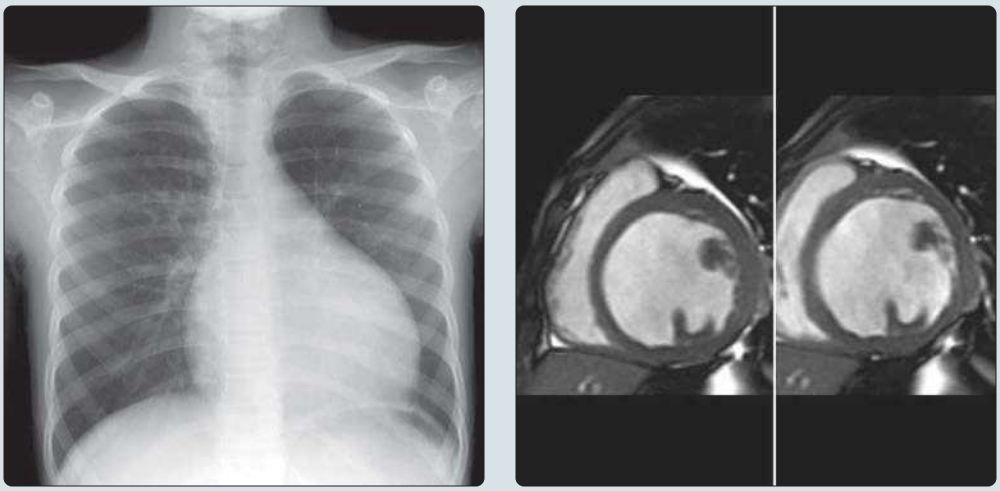
TERMINOLOGY

- Dystrophin-associated inherited disorders with progressive muscle wasting & weakness

IMAGING

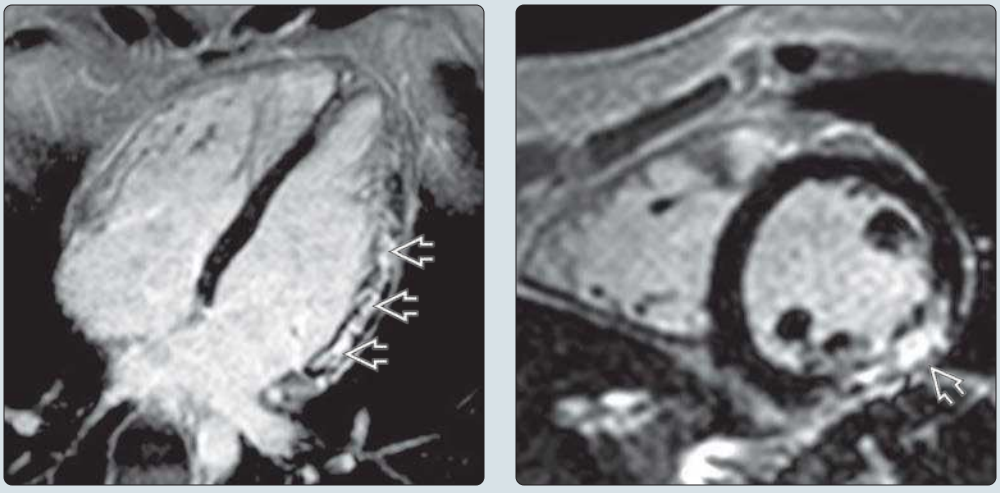
- Cardiac MR (CMR) is important for early detection of Duchenne muscular dystrophy (DMD)-associated cardiomyopathy
  - Initially, normal function with normal ejection fraction (EF)
  - Late gadolinium enhancement (LGE) from fibrosis in left ventricle (LV), typically in inferolateral segments
  - ↓ EF over time with progressive LV dilation
  - CMR allows much earlier detection of cardiac involvement than echocardiography

PATHOLOGY



- Dystrophinopathies
  - DMD: Absent dystrophin
  - Becker MD: Abnormal/reduced dystrophin
- X-linked disorders occurring in males
- Dystrophin is large, sarcolemmal glycoprotein connecting actin filaments & extracellular matrix
- Dystrophin plays role in stabilizing plasma membranes
  - Absence, reduction, or dysfunction → sarcolemmal fragility → myocyte degeneration & death
  - End result is fibrosis & myocardial dysfunction

CLINICAL ISSUES



- In past, DMD patients often died of respiratory complications; improved respiratory therapy → more cardiac complications
- Patients are often asymptomatic until late in heart failure (as immobility from skeletal muscle weakness obscures typical symptoms of heart failure)

DIAGNOSTIC CHECKLIST

- LGE is usually subepicardial in inferolateral segments
- Myocardial dysfunction is progressive

(Left) *Frontal radiograph of the chest in a patient with known Duchenne muscular dystrophy (DMD) shows moderate cardiomegaly. Patients with DMD may develop a severe dilated cardiomyopathy.* **(Right)** *Short-axis SSFP cine bright blood MR images at end-systole (left) & end-diastole (right) show a dilated left ventricle in this patient with end-stage dilated cardiomyopathy due to DMD. Findings are consistent with very poor function, as shown by the depressed ejection fraction (EF).*

(Left) *Four-chamber late gadolinium enhancement (LGE) MR in the myocardium of a 19-year-old man with DMD shows intense, well-defined enhancement of fibrosis ⇨ in the inferolateral wall. The enhancement is usually less intense & patchy.* **(Right)** *Short-axis midventricle LGE MR performed using 3D phase-sensitive inversion recovery, shows LGE ⇨ of fibrosis located in the inferolateral wall, which is a typical pattern seen in DMD.*

TERMINOLOGY

Abbreviations

- Duchenne muscular dystrophy (DMD)

Definitions

- Dystrophin-associated inherited disorders with progressive muscle wasting & weakness

IMAGING

General Features

- Best diagnostic clue
  - Muscle biopsy or genetics to confirm DMD prior to presenting for cardiac imaging
  - Subepicardial late gadolinium enhancement (LGE) in left ventricle (LV) inferolateral wall
  - ↓ ejection fraction (EF)

Echocardiographic Findings

- Used to follow ventricular size & function
  - Limited due to lung artifact, pectus deformity, scoliosis, ↑ fat due to steroids

MR Findings

- Progressive LV dysfunction develops over time
  - Initially, normal function with normal EF
  - LGE in LV, typically in inferolateral segments
    - Can occur with normal EF or ↓ EF
  - ↓ EF over time with progressive LV dilation

Imaging Recommendations

- Best imaging tool
  - Cardiac MR (CMR) with LGE assessment
    - Much more reproducible than echocardiography
    - Typical short-axis cine bright blood stack for LV function & volume
    - LGE can detect areas of damaged myocardium
      - Often precursor to more rapid decline in function
    - Specialized strain analysis utilizing tracking or tagging techniques can detect LV dysfunction before EF ↓
    - CMR provides prognostic information
- Protocol advice
  - Perform standard functional analysis, which provides left ventricular end-diastolic volume, end-systolic volume, EF, & myocardial mass
  - LGE is performed in short-axis plane at minimum
    - 2-chamber, 3-chamber, & 4-chamber LGE images are very helpful

DIFFERENTIAL DIAGNOSIS

Cardiomyopathy of Other Causes

- Acute viral myocarditis
- Hypertrophic cardiomyopathy
- Noncompaction cardiomyopathy

PATHOLOGY

General Features

- Etiology
  - Dystrophinopathies: DMD with absent dystrophin; Becker MD (BMD) with abnormal/reduced dystrophin
    - X-linked disorders occurring in males
    - Dystrophin: Large, sarcolemmal glycoprotein connecting actin filaments & extracellular matrix
    - Dystrophin plays role in stabilizing plasma membranes
      - Anecdotally described as shock absorber
      - Dystrophin absence or dysfunction → sarcolemmal fragility → myocyte degeneration & death
      - End result is fibrosis & myocardial dysfunction

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - In past, DMD patients often died of respiratory complications; improved respiratory therapy → more cardiac complications
  - Often no heart failure symptoms until later due to immobility from skeletal muscle weakness
  - Nearly all dystrophinopathy patients develop cardiomyopathy by 3rd decade
  - Death is typically related to cardiopulmonary complications in 3rd decade
  - CMR is important for early detection of DMD-associated cardiomyopathy
    - Provides prognostic information
    - CMR allows much earlier detection of cardiac involvement than echocardiography
    - Cardioprotective medical therapies slow progression

Demographics

- Age
  - Progressive muscle weakness manifests in childhood with ambulation (Gower sign)
  - Loss of ambulation by teenage years
    - 50% by 8-10 years of age
  - By 20 years of age, nearly all have dilated cardiomyopathy
- Sex
  - X-linked disorder afflicting males
- Epidemiology
  - Incidence of 1 in 3,500 males

Natural History & Prognosis

- DMD has more rapid skeletal myopathy than BMD
- BMD experience worse cardiomyopathy than DMD
- Cardiomyopathy is progressive but can be modified by medical therapies that improve quality of life & survival

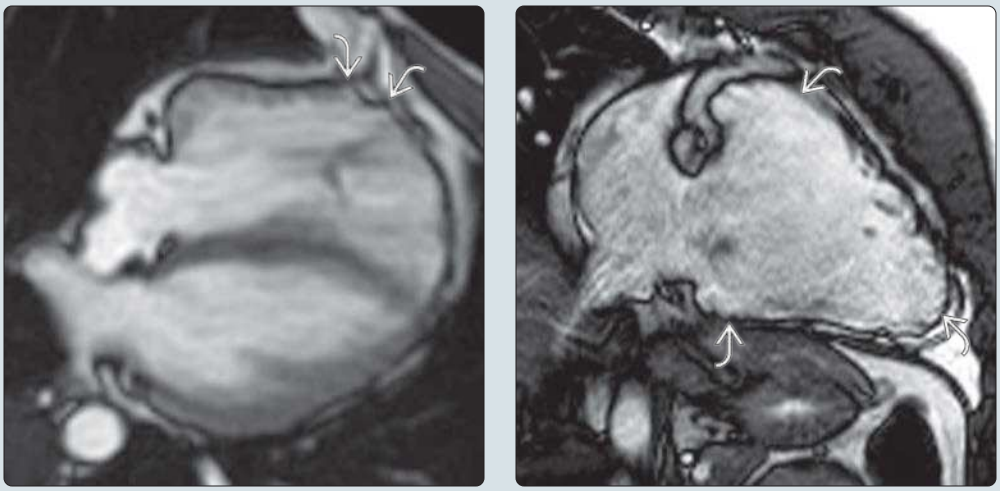
Arrhythmogenic Right Ventricular Dysplasia

KEY FACTS

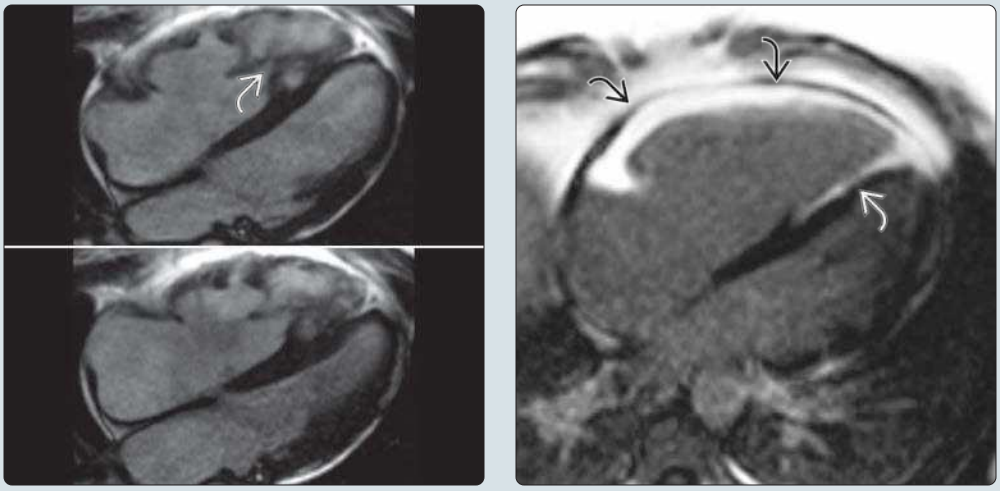
TERMINOLOGY

- Distinct cardiomyopathy thought to be caused by mutations in genes coding for desmosomal proteins
  - Results in apoptosis & early cell death with fibrofatty replacement
  - Predominantly affects right ventricle (RV) with variable left ventricular (LV) involvement
  - Frequently associated with arrhythmias, including sudden cardiac death



IMAGING

- Diagnosis is made using set of major & minor criteria in 6 categories (task force criteria, 2010)
- Imaging can supply only 1 major or 1 minor criterion for diagnosis
- Epicardial subtricuspid region & basal RV free wall are most commonly involved
- RV is usually dilated & shows impaired systolic function
- RV microaneurysms & thickened trabeculae are often evident
- Right ventricular outflow tract (RVOT) is commonly dilated & poorly contractile
- LV is involved in ≥ 50% of cases & may predominate in small percentage of cases
- Attempts to visualize intramyocardial fat are no longer advised since they frequently result in misdiagnosis
- May demonstrate delayed hyperenhancement of RV wall, representing fibrosis in up to 88% of cases



TOP DIFFERENTIAL DIAGNOSES

- Myocarditis
- RV volume overload
- RV infarction
- Idiopathic RVOT tachycardia

(Left) *Four-chamber SSFP bright blood cine MR in an adolescent shows a globally dilated right ventricle (RV) with severely thinned & scalloped anterior free wall in a patient who met criteria for arrhythmogenic right ventricular cardiomyopathy (ARVC).* **(Right)** *RV long-axis SSFP cine MR in a patient with ARVC shows the triangle of dysplasia extending from the subtricuspid region to the RV apex & superiorly to the infundibulum. Note the irregular outpouchings along the superior margin of the RV.*

(Left) *Four-chamber cine SSFP MR images in diastole (top) & systole (bottom) in a patient with documented ARVC show dilation of the RV & prominent trabeculations. Also note the poor systolic function evidenced by the lack of change in the volume of the RV from diastole to systole.* **(Right)** *Four-chamber LGE MR in the same patient demonstrates extensive enhancement of the RV free wall & the septum.*

TERMINOLOGY

Abbreviations

- Arrhythmogenic right ventricular cardiomyopathy (ARVC)

Synonyms

- Formerly known as arrhythmogenic right ventricular dysplasia (ARVD)
- Term arrhythmogenic cardiomyopathy (AC) has recently been proposed to include both left ventricular (LV) & right ventricular (RV) disease

Definitions

- Distinct entity caused by mutations in genes encoding desmosomal proteins (plakoglobin, plakophilin, desmophilin, & desmocollin)
  - Result is apoptosis & early cell death with replacement by fibrofatty tissue
  - Predominantly affects RV with variable LV involvement; is associated with arrhythmias, including sudden cardiac death (SCD)

IMAGING

General Features

- Best diagnostic clue
  - Task force criteria (TFC) representing combination of clinical, pathologic, electrophysiologic, & imaging information
  - Diagnosis is considered definite when 2 major, 1 major & 2 minor, or 4 minor criteria from different categories are present; imaging can only contribute either 1 major or 1 minor or no criterion
- Location
  - Change in perception of regional structural involvement in ARVC in last decade
    - Recent studies suggest displacement of RV apex from previously accepted triangle of dysplasia (RV outflow tract, RV inflow tract, & apex)
  - Structural abnormalities are preferentially located to epicardial subtricuspid region & basal RV free wall
- Size
  - RV is commonly dilated in proven cases with wall thinning & hypertrabeculations
- Morphology
  - Often, entire RV free wall is involved, but extent of RV involvement is variable & may progress over time
    - RV free wall microaneurysms & dyskinetic segments are noted on cine imaging
    - Minimal involvement of subtricuspid RV free wall may result in accordion sign, wherein focal area of dyssynchrony results in crinkling of myocardium, resembling accordion

CT Findings

- CTA
  - Dilated RV with reduced systolic function (requires multiphase gated image acquisition)

MR Findings

- Cine steady-state free precession (SSFP) imaging
  - RV is usually dilated with impaired function & regional wall motion abnormalities (RWMA), including akinesia, dyskinesia, & contractile dyssynchrony
  - RV aneurysms, microaneurysms, & thickened trabeculae
  - Single MR diagnostic TFC includes RWMA (dyssynchronous RV contraction, dyskinesia, or akinesia) with either RV dilation or ↓ RV ejection fraction (RVEF)
    - Minor: iEDV ≥ 100 to < 110 mL/m² (male); ≥ 90 to < 100 mL/m² (female); RVEF > 40% to ≤ 45%
    - Major: iEDV ≥ 110 mL/m² (male); ≥ 100 mL/m² (female); RVEF ≤ 40%
- Black blood SE
  - May detect intramyocardial fat (not part of TFC due to high retest & interobserver variability & potential to result in misdiagnosis)
- Late gadolinium enhancement (LGE)
  - May demonstrate LGE of RV wall, representing fibrosis in 2/3 of cases, but is not TFC
  - LV involvement in ARVC may manifest as LGE, often involving inferior & lateral walls without concomitant wall motion abnormalities
    - Septal LGE is unusual in right dominant pattern

Echocardiographic Findings

- Echocardiogram
  - Hypokinetic & dilated RV with ↓ RVEF
  - Echo can supply 1 diagnostic TFC with severe (major) or moderate (minor) RV dysfunction

Imaging Recommendations

- Best imaging tool
  - MR is excellent for RV volumes & morphology
  - LGE of RV is seen in up to 88% of cases & correlates with inducibility of arrhythmias
- Protocol advice
  - Cine MR of entire RV is essential, with views of right ventricular outflow tract (RVOT) in long axis & short axis in addition to stack of 4-chamber views

DIFFERENTIAL DIAGNOSIS

Myocarditis

- Selective RV involvement is uncommon; usually LV involvement predominates
- Often patchy without predilection for "subtricuspid region"
- At follow-up, asymptomatic & free from arrhythmia (vs. 50% recurrent arrhythmia in ARVC)

Right Ventricular Dilatation in Endurance Athletes

- Marathon runners & other endurance athletes often develop RV dilation; RV function is usually preserved

Right Ventricular Volume Overload

- Pretricuspid left-to-right shunts
  - Has normal or hyperdynamic RV function
  - Shunt seen: Atrial septal defect (ASD), partial anomalous pulmonary venous return (PAPVR), unroofed coronary sinus
- Repaired tetralogy of Fallot
  - Often has significant pulmonic regurgitation with RV volume overload & failure

Right Ventricular Infarction

- Usually associated with inferior wall LV infarct (right coronary artery territory)
- Not commonly associated with localized aneurysm formation

Idiopathic Right Ventricular Outflow Tachycardia

- Benign, nonfamilial condition that may clinically mimic ARVC; usually no imaging abnormality is seen

Pitfalls

- RV free wall tether: Pericardial connective tissue joining anterior RV free wall to posterior sternum, mistaken as dyskinesia
- Apicolateral bulge: Seen in 79% as wall motion abnormality in RV at site of insertion of moderator band
- Butterfly apex: Prominent RV apex confused for aneurysm, but isolated apical aneurysm is unusual; normal systolic & diastolic motion
- Pectus excavatum: Distortion of RV; enlargement of RV apex & RVOT; restricted motion of basolateral & inferolateral walls
- Pulmonary valve sinuses: Systolic bulge due to filling with blood mimics dyskinesia; located above pulmonary valve anulus

PATHOLOGY

General Features

- Etiology
  - Mutations in genes coding for desmosomal proteins lead to early apoptosis, likely hastened by "wear & tear," which is particularly induced by repetitive exercise
- Genetics
  - Multiple mutations are now recognized, with predominantly autosomal dominant heritability with variable penetrance
    - Mutations of genes encoding plakophilin (most common), desmoglein, desmoplakin, & desmocollin
    - Cardiac ryanodine receptor defect: Calcium released from sarcoplasmic reticulum; may be responsible for adrenergically mediated arrhythmias
  - Family history may provide task force criterion if 1st-degree relative with proven (major) or suspected (minor) ARVC

Gross Pathologic & Surgical Features

- Apparent RV dilation & wall thinning
- Involves LV in 40-76% of autopsy cases

Microscopic Features

- Biopsy findings demonstrating myocyte depletion with fibrous replacement may provide TFC
- Fibrofatty infiltration of myocardium on biopsy is no longer major TFC

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Early ("concealed") phase: Patients are often asymptomatic but may be at risk of SCD due to arrhythmia
  - Overt ("electric") phase: Patients present with symptomatic arrhythmias & RV morphologic abnormalities, detectable with imaging
    - Characteristic arrhythmia is that of ventricular tachycardia (VT) with left bundle branch block morphology
- Other signs/symptoms
  - Palpitations are very common once symptoms develop
- Clinical profile
  - Should be considered in athletes of any age as cause of syncope or cardiovascular collapse
  - Can lead to isolated RV or biventricular heart failure
- Diagnosis
  - Made on basis of TFC representing combination of clinical, pathologic, electrophysiologic, & imaging information

Demographics

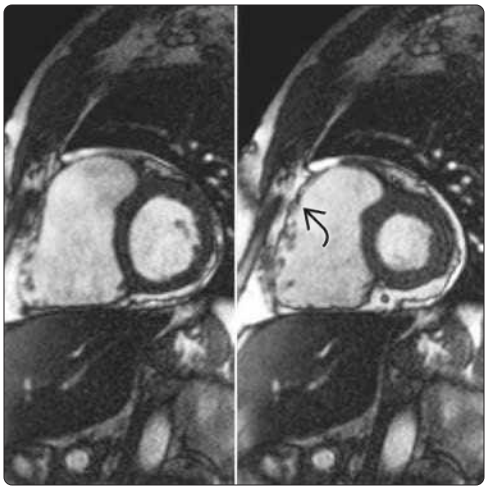
- Age
  - More clinically apparent in 2nd-4th decades of life
- Sex
  - M:F = 3:1 in younger age groups; M = F in later-onset cases
- Epidemiology
  - Estimated incidence: 1 in 2,000-5,000
  - ~ 50% of affected patients have positive family history

Natural History & Prognosis

- Annual mortality rate: ~ 0.08-3.6%

Treatment

- Avoid vigorous athletics
- Pharmacotherapy: Antiarrhythmic agents, β-blockers, & heart failure drug therapy
- Implantable cardioverter defibrillator in patients with history of VT, cardiac arrest, syncope or RV/LV dysfunction
- Catheter ablation of VT
- Heart transplant, predominantly for heart failure or untreatable arrhythmias



DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Cine MR & volumetric analysis are often very helpful in providing diagnostic imaging

(Left) *Short-axis bright blood cine SSFP MR images in diastole (left) & systole (right) show RV dilation & ↓ function in a patient with ARVC. Note the tiny, focal outpouchings, often termed microaneurysms, along the RV free wall in the systolic image.* **(Right)** *Short-axis LGE MR in the same patient shows enhancement of the RV wall, consistent with fibrosis. This finding is seen in ~ 2/3 of patients with ARVC.*

(Left) *Four-chamber cine SSFP (top) & LGE (bottom) MR images in a patient with ARVC show tiny foci of fat along the RV side of the septum, denoted by the "etching" artifact seen in this SSFP image. Note the enhancement of the same area of the septum & the RV free wall on the LGE image.* **(Right)** *Sagittal cine SSFP bright blood MR in an adolescent boy through the right ventricular outflow tract (RVOT) in diastole (left) & systole (right) in a patient with ARVC shows ↑ dilation of the RVOT during systole.*

(Left) *Four-chamber cine SSFP MR (left) in a patient with minimal involvement by ARVC shows a focal systolic outpouching, termed the accordion sign, along the RV free wall in the subtricuspid region. Note also that this is the only region with abnormal enhancement on the LGE image (right).* **(Right)** *Short-axis (top) & 4-chamber (bottom) LGE MR images in a patient with cardiac sarcoidosis show abnormal RV enhancement, similar to findings seen in ARVC.*

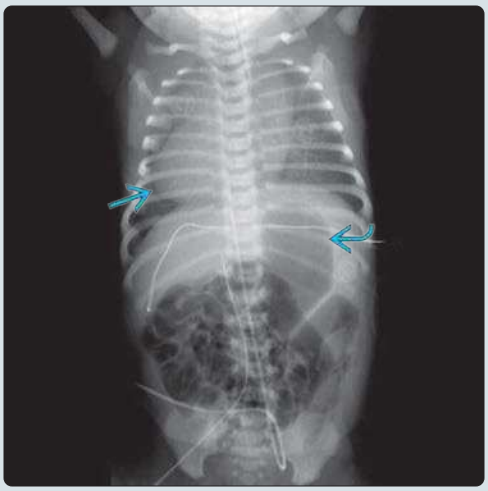
Heterotaxy Syndromes

KEY FACTS

TERMINOLOGY

- Disturbance of normal left-right asymmetry in position of thoracic & abdominal organs
  - Typically described in terms of right atrial isomerism vs. left atrial isomerism

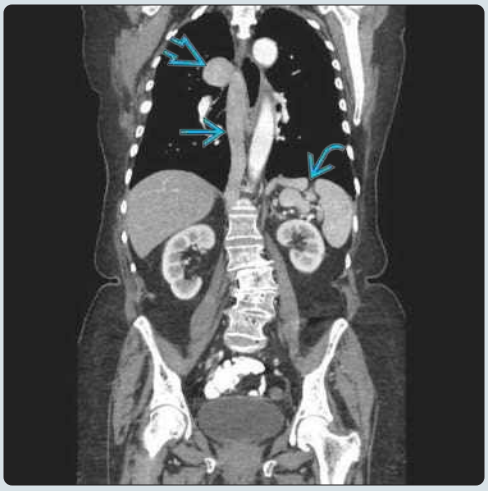
IMAGING



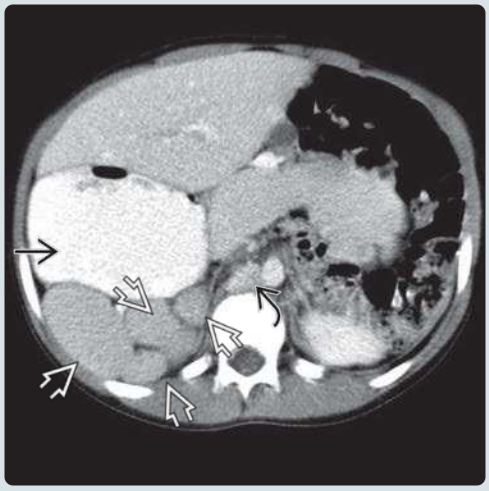
- Best diagnostic clue
  - Abnormal symmetry in chest & abdomen
- Classic radiographic appearance
  - Transverse midline liver, discrepancy between position of cardiac apex & stomach, bilateral left- or right-sidedness in chest, cardiomegaly or other findings of congenital heart disease
- Ultrasound: Easy screening of abdominal viscera
- CTA: Rapid examination of chest & abdomen for abnormalities of situs, systemic & pulmonary venous connections, tracheobronchial anatomy
- Multiplanar MR for segmental analysis of intracardiac connections & defects
  - Gadolinium-enhanced 3D MRA: Comparable to CTA
- Upper GI study: Malrotation is common

PATHOLOGY

- Any arrangement other than situs solitus or inversus is termed situs ambiguous
- Heterotaxy syndrome represents spectrum with overlap between classic asplenia & polysplenia manifestations & other anomalies



CLINICAL ISSUES



- Asplenia: Male neonate with severe cyanosis, susceptibility for infections, severe congenital heart disease
- Polysplenia: Less severe cardiac disease (i.e., systemic venous malformations, atrial septal defect), often presents later

(Left) *Frontal radiograph of the chest & abdomen in a newborn demonstrates dextrocardia with a right-sided cardiac apex & a left-sided stomach in a patient with known complex congenital heart disease. The findings are consistent with heterotaxy syndrome.* **(Right)** *Axial CECT shows a midline liver with no splenic tissue seen in a patient with known heterotaxy syndrome.*

(Left) *Coronal CECT shows azygous continuation of the inferior vena cava (IVC) with polysplenia in a patient with heterotaxy syndrome. Note the enlarged distal azygous vein.* **(Right)** *Axial CECT through the upper abdomen in a child with heterotaxy shows a right-sided stomach & multiple spleens. An enlarged azygous vein is noted, but no intrahepatic IVC is visualized, consistent with azygous continuation of the IVC.*

TERMINOLOGY

Synonyms

- Situs ambiguous, right/left isomerism, cardiosplenic syndromes, Ivemark syndrome

Definitions

- Disturbance of normal left-right asymmetry in position of thoracic & abdominal organs

IMAGING

General Features

- Best diagnostic clue
  - Abnormal symmetry in chest & abdomen

Radiographic Findings

- Radiography
  - Classic appearance: Transverse midline liver, discrepancy between position of cardiac apex & stomach, bilateral left- or right-sidedness in chest, cardiomegaly or other findings of congenital heart disease (CHD)
  - Asplenia syndrome or right atrial isomerism
    - Bilateral minor fissures
    - Symmetrical, short main bronchi with right-sided morphology (narrow carinal angle, early take-off of upper lobe bronchus)
    - Bilateral eparterial bronchi: Main bronchus is superior to branch pulmonary artery (eparterial bronchus)
    - Cardiomegaly, pulmonary edema
  - Polysplenia syndrome or left atrial isomerism
    - No minor fissure on either side
    - Symmetrical long main bronchi with left-sided morphology (wide carinal angle)
    - Bilateral hyparterial bronchi: Main bronchus is inferior to branch pulmonary artery (hyparterial bronchus)
    - Absent inferior vena cava (IVC) shadow on lateral film, prominent azygous shadow on AP
  - Both syndromes
    - Cardiac malposition (40%: Mesocardia, dextrocardia)
    - Transverse liver
    - Right-sided stomach bubble with levocardia, left-sided stomach bubble with dextrocardia, or midline stomach

Echocardiographic Findings

- Initial diagnostic test for characterization of intracardiac anomalies, abnormal systemic &/or pulmonary venous connections

Ultrasonographic Findings

- Easiest assessment of abdominal viscera
  - Look for spleen adjacent to stomach

CT Findings

- CTA
  - Rapid examination of chest & abdomen: Situs abnormalities, systemic & pulmonary venous connections, tracheobronchial anatomy
  - Best for postoperative patients with metallic coils, stents, & clips
  - Preferred modality over conventional angiography due to more detailed anatomic information

MR Findings

- T1WI
  - Multiplanar imaging for segmental analysis of intracardiac connections & defects
- T2* GRE
  - Cine MR for ventricular volumes & function to determine suitability for biventricular vs. univentricular repair
- MRA
  - Ultrafast time-resolved MRA C+ with repeated acquisitions allows for dynamic circulation study
  - Velocity-encoded phase-contrast MRA for flow quantification

Other Modality Findings

- Upper GI study: Malrotation is common

Imaging Recommendations

- Protocol advice
  - Echocardiography, followed by MR
  - CTA for anatomic study in postoperative patients

DIFFERENTIAL DIAGNOSIS

Situs Inversus Totalis (I, L, L)

- Mirror image of normal
- Low association with CHD (3-5%)
- May be associated with immotile cilia syndrome (Kartagener): Sinusitis, bronchiectasis, infertility

True Dextrocardia + Abdominal Situs Solitus or Levocardia + Abdominal Situs Inversus

- Both have high association with CHD (95-100%)

Dextroversion of Heart

- Heart positioned in right chest with apex & stomach still directed toward left
  - Right lung hypoplasia (scimitar syndrome)
  - Left-sided mass lesions
    - Diaphragmatic hernia
    - Congenital pulmonary airway malformation

PATHOLOGY

General Features

- Heterotaxy syndrome represents spectrum with overlap between classic asplenia & polysplenia manifestations & other anomalies
- Embryology: Early embryologic disturbance (5th week of gestation) leading to complex anomalies
- Pathophysiology: Determined by complexity of associated CHD
- Genetics: No specific genetic defect in majority (usually sporadic)

Staging, Grading, & Classification

- Segmental approach to analysis of complex cardiac anomalies with cardiac malposition (reported by Anderson or Van Praagh systematic descriptions)
  - Visceroatrial situs designated by S (solitus = normal) or I (inversus = mirror image of normal)
  - Always associated on same side
    - Major lobe of liver, IVC, anatomic right atrium, trilobed lung, eparterial bronchus

  - Spleen, stomach, descending aorta, anatomic left atrium, bilobed lung, hyparterial bronchus
- Any arrangement other than situs solitus or inversus is termed situs ambiguous (heterotaxia)
- Ventricular loop: D loop (normal) or L loop (inverted)
- Orientation of great arteries (presence of transposition) is also designated by D or L
- Van Praagh segmental analysis is summarized by 3-letter code describing relationships of atria, ventricles, & great arteries: S,D,D; I,L,L; S,D,L
- Anderson connections described as concordant or discordant between atria, ventricles, & great arteries
- Associated abnormalities: Transposition of great arteries (TGA), double-outlet right ventricle (DORV), total anomalous pulmonary venous return (TAPVR), unbalanced atrioventricular septal defects

- 2 major subtypes
  - Asplenia syndrome = right atrial isomerism or double right-sidedness
    - Absence of spleen
    - IVC & aorta are on same side
    - Bilateral superior vena cavae (~ 36%); absent coronary sinus
    - Right isomerism of atrial appendages
    - Common atrium with band-like remnant of septum crossing atria in anteroposterior direction
    - Bilateral trilobed lungs
    - Bilateral eparterial bronchi
    - Associated with severe cyanotic CHD (atrioventricular septal defect, common atrioventricular valve, DORV, TGA, pulmonary stenosis/atresia)
    - Abnormalities of pulmonary venous connections
      - TAPVR, > 80%; often obstructed, below diaphragm (type III)
      - Findings of pulmonary venous outflow obstruction may be masked when there is restriction to pulmonary arterial inflow at same time (pulmonary atresia)
  - Polysplenia syndrome = left atrial isomerism or double left-sidedness
    - Multiple spleens, anisosplenia, multilobed spleen (functional asplenia)
    - Abnormalities of systemic venous connections: Interrupted IVC with azygous continuation (> 70%), hepatic veins drain separately into common atrium
    - Bilateral superior vena cavae (~ 41%); 1 or both may connect to coronary sinus
    - Left isomerism of atrial appendages
    - Common atrium or large ostium primum atrial septal defect
    - Bilateral bilobed lungs
    - Bilateral hyparterial bronchi
    - Associated with less severe CHD (common atrium, ventricular septal defect)

CLINICAL ISSUES

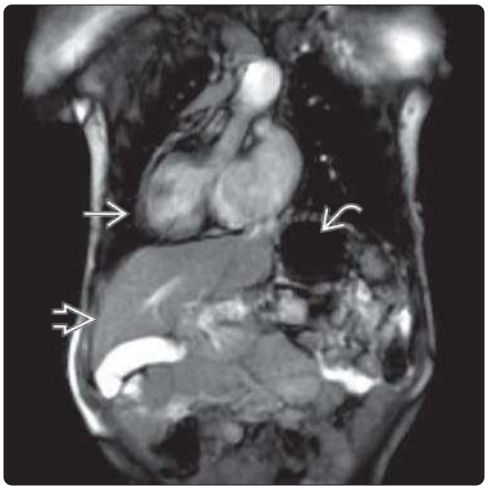
Presentation

- Most common signs/symptoms
  - Asplenia: Male neonate with severe cyanosis, susceptibility for infections
  - Polysplenia: More variable, often presents later
- Other signs/symptoms
  - Malrotation, volvulus, preduodenal portal vein, absent gallbladder, extrahepatic biliary atresia, short pancreas (dorsal head agenesis)

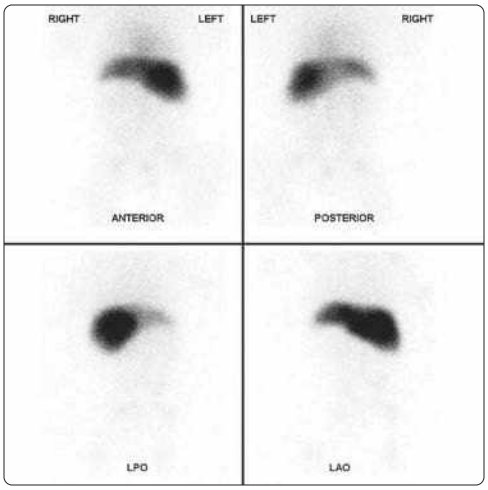
Demographics

- Epidemiology
  - Prevalence: 1 per 22,000 to 24,000; 1-3% of CHD
  - Asplenia: M > F; polysplenia: M = F

Natural History & Prognosis



- 1st-year mortality: 85% asplenia, 65% polysplenia



Treatment

- Supportive, prostaglandins (if CHD lesion has inadequate pulmonary blood flow or if aortic arch has interruption/obstruction), antibiotic prophylaxis (functional asplenia)
- Asplenia/polysplenia with pulmonary overcirculation: Pulmonary artery banding
- Asplenia with obstructed pulmonary flow & TAPVR: Delicate balance between pulmonary arterial inflow & venous outflow
  - Placement of palliative systemic to pulmonary artery (Blalock-Taussig or central) shunt ↑ inflow
  - TAPVR repair needs to be done at same time to reduce outflow obstruction
- Early biventricular repair, if possible
- Univentricular repair, step 1: Bidirectional Glenn (superior cavopulmonary anastomosis) or hemi-Fontan
- Polysplenia: Incorporation of azygous vein to cavopulmonary anastomosis (Kawashima operation) to reduce occurrence of microscopic pulmonary arteriovenous malformation
  - Postsurgical: Development of pulmonary to systemic venous collaterals, arteriovenous malformations, pulmonary vein stenosis
- Completion of total cavopulmonary anastomosis (i.e., Fontan procedure), if possible
  - 1 or more hepatic veins may have to be excluded from Fontan shunt → venovenous collaterals
  - CTA or MRA prior to catheterization as road map for coil embolization of collaterals

(Left) *Coronal SSFP MR in a patient with asplenia demonstrates a right-sided cardiac apex, right-sided liver, left-sided stomach, & no splenic tissue.* **(Right)** *Multiple images from a Tc-99m sulfur colloid scan in a patient with heterotaxy demonstrate normal liver uptake but no splenic tissue, confirming asplenia.*

(Left) *3D surface-rendered CTA (left) & coronal CECT (right) through the airway in a patient with heterotaxy show bilateral right-sided tracheobronchial branching with eparterial bronchi [bronchi above pulmonary arteries (PAs)] & early right upper lobe branching.* **(Right)** *3D surface-rendered CTA (right) & coronal CECT (left) through the airway in a patient with heterotaxy syndrome show bilateral left-sided tracheobronchial branching with elongated hyparterial bronchi (PAs go above the bronchi).*

(Left) *3D-printed model of a heterotaxy patient shows bilateral SVCs (blue), interrupted IVC with azygous continuation, hepatic veins draining directly to right atrium, & complex pulmonary venous return (red). 3D model was created for surgical planning.* **(Right)** *Posterior 3D surface-rendered cardiac CTA in an infant with heterotaxy syndrome shows type 3 TAPVR with all pulmonary veins draining to a large vertical vein that courses below the diaphragm. Note the symmetric atrial appendages with 2 right-sided atria.*

Rhabdomyoma

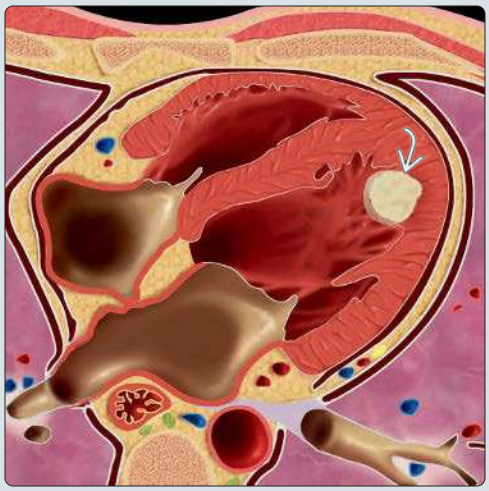
KEY FACTS

TERMINOLOGY

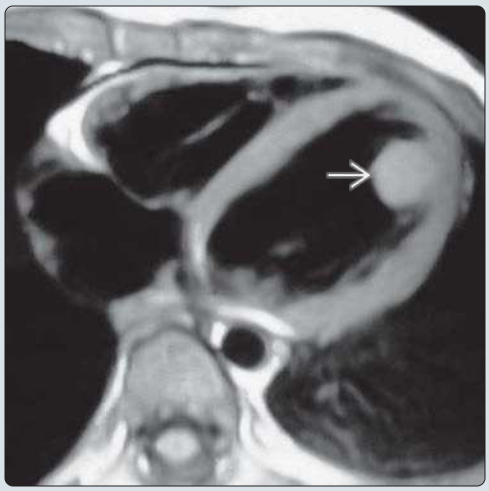
- Congenital cardiac hamartoma composed of abnormal myocytes

IMAGING

- Initial diagnosis is often by fetal &/or postnatal echocardiogram
  - Homogeneous, hyperechoic mass(es) of myocardium
    - Intramyocardial: May appear as wall thickening
    - Intracavitary: Mass attached to myocardium protrudes into lumen
- MR is leading diagnostic test to delineate location, extent, & tissue characteristics of cardiac masses in children
  - T1: Iso- or mildly hyperintense to myocardium
  - T2: Hyperintense to myocardium
  - 1st-pass perfusion: Hypointense to myocardium
  - Late gadolinium enhancement: Isointense to myocardium
  - Homogeneous appearance on all sequences
- Normal chest radiograph in small masses
  - Cardiomegaly & signs of congestive heart failure in large masses
- Image brain (MR) & kidneys (US) for findings of tuberous sclerosis complex (TSC)
  - ~ 100% of patients with multiple rhabdomyomas & 50% with single rhabdomyoma have TSC



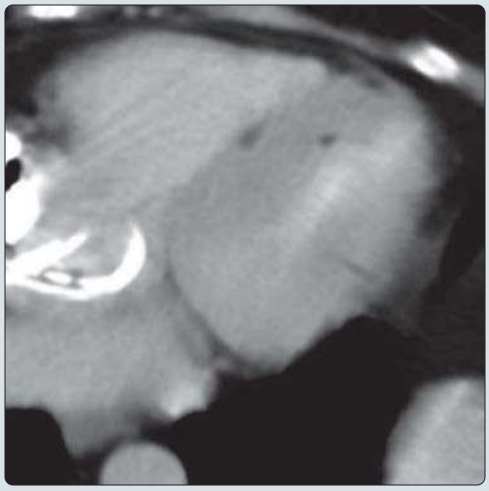
TOP DIFFERENTIAL DIAGNOSES



- Fibroma; pericardial teratoma

CLINICAL ISSUES

- Cardiac tumors are rare in children
- Rhabdomyoma is most common pediatric cardiac tumor
- 75% are diagnosed before 1 year of age
- Natural history: Up to 93% show spontaneous regression; 70% regress by 4 years of age
- Surgical excision for minority of cases with refractory arrhythmias or hemodynamic compromise



(Left) *Axial graphic shows a partially exophytic rhabdomyoma in the apex of the left ventricle (LV).* **(Right)** *Axial T1 MR was performed in an asymptomatic 8-year-old girl with tuberous sclerosis complex (TSC) after a routine screening echocardiogram showed an intracardiac mass. MR shows a round, well-demarcated, intraluminal mass originating from the free wall of the LV. It is slightly hyperintense to myocardium, a characteristic finding of rhabdomyomas.*

(Left) *Axial US through the fetal chest shows multiple echogenic, intracardiac masses involving both ventricles & the interventricular septum. Multiple rhabdomyomas are virtually diagnostic of TSC.* **(Right)** *Axial CECT of the heart in a 15-year-old patient with a history of multiple rhabdomyomas shows complete involution of masses with only small fatty deposits now seen along the interventricular septum, consistent with known TSC.*

TERMINOLOGY

Definitions

- Congenital cardiac hamartoma composed of abnormal myocytes

IMAGING

General Features

- Best diagnostic clue
  - Cardiac mass within or contiguous with myocardium
- Location
  - Interventricular septum > left or right ventricular free wall > > atrium
  - Multiple in up to 90% of cases
- Size
  - < 1 mm to 10 cm; most are 3-4 cm
- Morphology
  - Well-circumscribed, nonencapsulated mass(es)
  - Intramural or exophytic
    - May involve entire wall & appear as wall thickening

Radiographic Findings

- Normal chest radiograph in small masses
- Cardiomegaly & signs of heart failure in large masses

Echocardiographic Findings

- Often superior to MR for detection of small masses
- Homogeneous, hyperechoic mass involving myocardium
- No blood flow within mass
- Most often in interventricular septum but can be anywhere
- May appear as simple wall thickening
- Intraluminal portion of mass may move across adjacent valve during cardiac cycle

CT Findings

- NECT
  - Often hypodense compared with myocardium
- CECT
  - Intraluminal component may be assessed with contrast-enhanced studies

MR Findings

- T1WI
  - Iso- or mildly hyperintense to myocardium
- T2WI
  - Hyperintense to myocardium
  - No change with fat saturation (rules out lipoma)
- T1WI C+
  - Minimal initial enhancement (1st-pass perfusion)
  - Isointense to myocardium with late gadolinium enhancement (LGE)
- SSFP cine
  - Help to differentiate tumor from contractile myocardium, evaluate hemodynamic effect of mass, & look for valvular leak

Imaging Recommendations

- Best imaging tool
  - Dedicated transthoracic echo in all cases
  - MR is helpful for diagnostic uncertainty, large masses, & surgical planning
- Protocol advice
  - If cardiac mass is identified
    - Look for additional masses
    - Assess location & quality of mass
  - Look for rhythm abnormalities
    - Premature atrial or ventricular contractions are common
    - Supraventricular tachycardia
    - Sinus bradycardia
  - Look for signs of obstruction
    - Ventricular inflow or outflow obstruction
    - May manifest as valve regurgitation or stenosis
    - ↑ cardiac work to overcome obstruction → wall hypertrophy
  - Evaluate for other findings of tuberous sclerosis complex (TSC)
  - In fetus, monitor for signs of hydrops (poor function, effusions)

DIFFERENTIAL DIAGNOSIS

Fibroma

- Benign congenital cardiac neoplasm composed of fibroblasts & collagen
- 2nd most common cardiac neoplasm in pediatric population after rhabdomyoma
- Often arises from interventricular septum or left ventricular free wall
- MR: Isointense on T1, hypointense on T2

Teratoma

- Pericardial (not myocardial) tumor
- Exophytic growth (will not be in cardiac chamber)
- Pericardial effusion is often present
- Contains all 3 germ cell layers → may be very heterogeneous on imaging with cystic, fatty, & calcified components

Lipoma

- Most arise from endocardial surface & protrude into chamber lumen
- Fat density/intensity on imaging studies allows for specific diagnosis

Myxoma

- Majority manifest in adulthood (4th-7th decades)
- 90% are solitary & atrial in location
  - 75% in left atrium, 10-20% in right atrium
  - Predilection for interatrial septum adjacent to fossa ovalis

Papillary Fibroelastoma

- > 90% involve valves
- Typically small (< 15 mm)

Cardiac Malignancies

- Extremely uncommon in children
- Sarcomas account for most (with angiosarcoma being most common)
- Usually large masses with invasive features
- Pericardial & pleural effusion are often present

PATHOLOGY

General Features

- Etiology
  - Unknown, but data suggests maternal hormones may play role in growth & development of fetal rhabdomyomas
    - Helps explain regression after delivery
- Genetics
  - Nearly 100% of patients with multiple & 50% with single rhabdomyomas have TSC
  - TSC: Autosomal dominant with variable expressivity
    - ~ 30% of cases are inherited
    - Other cases are due to new mutation
  - Caused by mutations in *TSC1* or *TSC2* genes
    - *TSC1* is located on chromosome 9q
      - Encodes for hamartin protein
      - Complexes with tuberin to regulate cell cycle
    - *TSC2* located on chromosome 16p
      - Encodes for tuberin protein
      - Participates in normal brain development & cardiomyocyte differentiation
- Associated abnormalities
  - Other findings of TSC
    - Brain: Subependymal nodules, cortical/subcortical tubers, subependymal giant cell astrocytoma
    - Lung: Lymphangioleiomyomatosis
    - Kidney: Angiomyolipomas & cysts
    - Eye: Retinal hamartomas
    - Nails: Ungual fibromas
- Pathophysiology
  - Mass may interfere with myocardial contraction
  - Exophytic masses frequently obstruct blood flow or cause valvular insufficiency

Gross Pathologic & Surgical Features

- Well-circumscribed, intramyocardial or exophytic mass(es)

Microscopic Features

- Large, vacuolated myocytes
- Glycogen-rich vacuoles stretch perinuclear cytoplasm (spider cells)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Obstruction to blood flow → heart failure
  - Arrhythmias
  - Large intracavitary tumors causing turbulent flow → hemolytic anemia & thrombocytopenia
- May be seen prenatally
  - Generally incidental finding
  - Rarely presents with arrhythmia or hydrops
  - Can detect as early as 22-weeks gestation
    - May discover more masses as pregnancy progresses
    - Tend to ↑ in size prenatally & then regress after birth

Demographics

- Age
  - 75% are diagnosed before 1 year of age
- Epidemiology
  - Cardiac tumors rare (1:30,000-1:100,000)
  - Rhabdomyoma is most common pediatric cardiac tumor

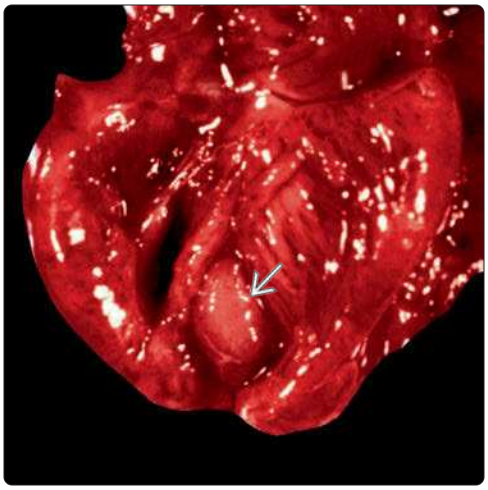
Natural History & Prognosis

- Generally excellent with spontaneous regression in 70% of children by 4 years of age
- Poor prognosis for untreated large masses interfering with cardiac hemodynamics
  - Most respond well to surgical excision
  - Case reports of response to mTOR (mammalian target of rapamycin) inhibitor sirolimus
    - mTOR: Protein kinase that regulates cellular proliferation; used to treat subependymal giant cell tumors & angiomyolipomas

Treatment

- Surgical excision should be considered only for those with refractory arrhythmias or hemodynamic compromise
  - Partial resection of intraluminal component of large exophytic masses may be necessary
  - 3D printing from CT/MR data can build heart model with tumor location & extent for easy visualization; can assist with procedural planning
  - Attempts at electrophysiology testing & ablation around tumor focus have variable success rates
    - 3D printed models have been helpful
- Small, intramural masses with no hemodynamic effect typically need no treatment or surgical excision

DIAGNOSTIC CHECKLIST



Consider

- Overall prognosis is excellent
- However, rhabdomyomas may cause significant morbidity from obstruction to inflow or outflow, ventricular dysfunction, or arrhythmias

(Left) *Four-chamber view from a fetal echocardiogram shows an echogenic mass in the apex of the right ventricle (RV), most consistent with a rhabdomyoma. The patient was later diagnosed with TSC. A mass this size will likely have no physiologic effect on the cardiac function.* **(Right)** *Gross pathology of the heart shows a well-defined mass ➡ arising from the wall of the ventricle. Histology confirmed a rhabdomyoma.*

(Left) *SSFP bright blood cine short-axis MR in a neonate demonstrates a large, hypointense rhabdomyoma ⇨ within the RV wall ⇨.* **(Right)** *SSFP cine short-axis MR in same patient at 13 years of age demonstrates near-complete resolution of the rhabdomyoma with minimal residual tumor ⇨. The RV ⇨ appears borderline dilated, & the LV ➡ appears normal.*

(Left) *Postnatal axial US in a patient with tuberous sclerosis shows a large echogenic mass ➡ filling the LV. Rhabdomyomas are often large at birth but usually spontaneously regress postnatally.* **(Right)** *Four-chamber view double IR image from a cardiac MR demonstrates an echogenic mass ➡ filling the LV, consistent with a rhabdomyoma. Masses of this size may have cardiac obstruction & heart failure. Note the marked enlargement of the heart ⇨ in this neonate.*

Kawasaki Disease

KEY FACTS

TERMINOLOGY

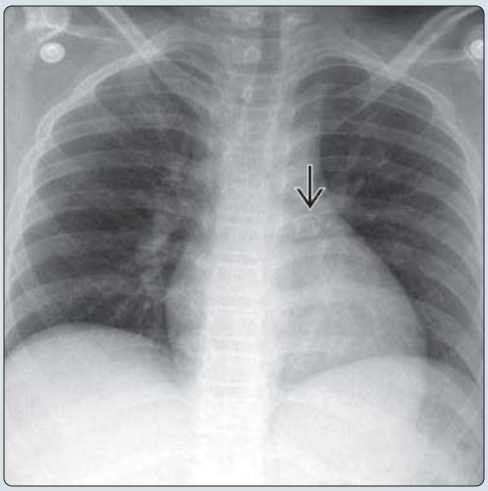
- Inflammatory disease of small- & medium-sized blood vessels of unknown etiology, mainly in young children
  - Widespread but characteristic manifestations
  - Coronary artery aneurysms are most feared complication

IMAGING

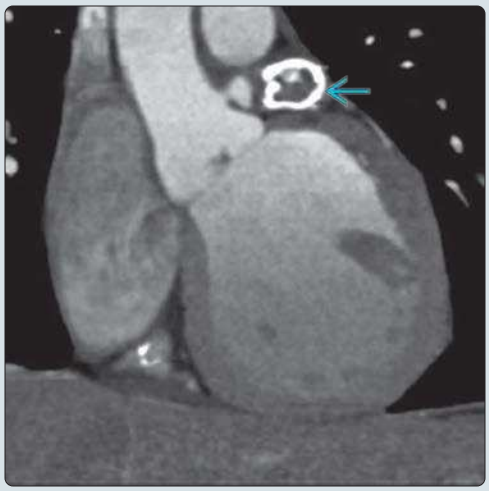
- Chest radiography is usually normal
- Echocardiography has sufficient sensitivity & specificity in detecting proximal coronary artery aneurysms
  - Remains 1st-line modality
- CTA can demonstrate aneurysms, stenoses, & Ca^{2+} of coronary or other arteries
- Cardiac MR protocol includes function, coronary artery imaging, 1st-pass perfusion, & late gadolinium enhancement for myocardial viability
- MRA with large field of view can show aneurysms of peripheral arteries

TOP DIFFERENTIAL DIAGNOSES

- MIS-C from SARS-CoV-2 (COVID-19); exanthematous infections; allergic/hypersensitivity reactions; vasculitides

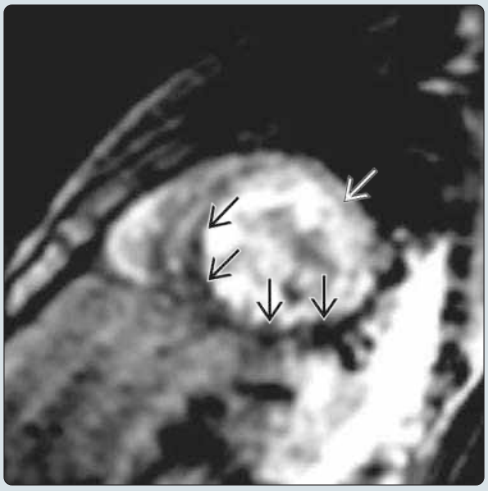


PATHOLOGY

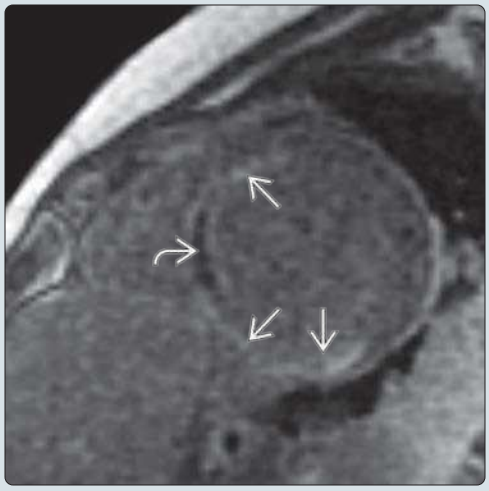


- Etiology is unclear, but clinical & epidemiologic features suggest abnormal immune response to toxin or infection

CLINICAL ISSUES



- Acute febrile phase (days 1-11): Fever for 5 days > 104°F, bilateral, nonpurulent conjunctivitis & rash, hands, & feet develop erythema/edema, tongue & oral mucosa become red & cracked, myocarditis (36-50%) & pericarditis (16%)
- Subacute phase (days 11-21): Thrombocytosis, desquamation of digits, aneurysms develop
- Convalescent phase (days 21-60): Symptoms have resolved
- Chronic phase (> 60 days): Cardiac complications
- Favorable outcome with early recognition & treatment with intravenous γ globulin, aspirin



(Left) *Frontal view of the chest in an adolescent presenting with chest pain shows a left perihilar Ca^{2+} ⇨, later shown to be a calcified left coronary artery aneurysm in a patient with undiagnosed prior Kawasaki disease.* **(Right)** *Coronal coronary CTA in the same patient shows a large calcified left proximal coronary artery aneurysm ⇨.*

(Left) *Short-axis T2* GRE MR 1st-pass perfusion shows a large area of nonenhancing myocardium ⇨. Note the normally enhancing myocardium ➡ for comparison.* **(Right)** *Short-axis late gadolinium enhanced (LGE) MR shows enhancement ➡ in the same distribution of myocardium that showed no 1st-pass perfusion, confirming the distribution of ischemic myocardium. The septum ➡ also demonstrated a no-reflow phenomenon due to continued microvascular occlusion.*

TERMINOLOGY

Synonyms

- Mucocutaneous lymph node syndrome; acute febrile mucocutaneous syndrome

Definitions

- Inflammatory disease of small- & medium-sized blood vessels of unknown etiology, occurring mainly in children
  - Manifests mainly with prolonged fever, nonsuppurative conjunctivitis, inflamed mucosal membranes of mouth & lips, cervical lymphadenopathy, maculoerythematous rash, & desquamation of hands & feet

IMAGING

General Features

- Best diagnostic clue
  - Multiple fusiform & saccular coronary aneurysms in severe cases; coronary artery ectasia in minor cases
- Location
  - Multisystem disease affecting skin, lymph nodes, mucous membranes, conjunctiva, myocardium, pericardium, coronary arteries, joints, bowel, gallbladder, kidney, urethra, & other sites

Radiographic Findings

- Chest radiography is usually normal
- Occasionally, may have large cardiac silhouette due to pericardial effusion or cardiomegaly

CT Findings

- CTA
  - Can demonstrate aneurysms, stenoses, & Ca^{2+} of coronary or other arteries

MR Findings

- T2WI
  - Can show edema secondary to myocarditis in acute phase
    - Myocarditis in up to 50%
- T2* GRE
  - MR stress imaging with quantification of regional perfusion
- MRA
  - Accurately images coronary artery aneurysms, occlusions, & stenoses
  - Used to depict & follow other aneurysms of thorax & abdomen or peripheral involvement
- MR cine
  - SSFP cine MR shows regional wall motion abnormalities
  - Can measure cardiac function with end-diastolic volumes, systolic ejection, & ejection fraction
- Delayed enhancement
  - Late gadolinium enhancement can show infarcted myocardium

Echocardiographic Findings

- Sufficient sensitivity & specificity for proximal coronary artery ectasia & aneurysms → 1st-line modality
  - Sensitivity: 80-85%
  - Evaluates ventricular function, valvar function, & pericardial effusion

Ultrasonographic Findings

- Grayscale ultrasound
  - Lymphadenopathy is usually nonsuppurative, unilateral, & in anterior triangle of neck
  - Gallbladder may be hydropic
  - ± nephromegaly
  - Aneurysms may be identified outside of chest

Angiographic Findings

- Conventional coronary angiography demonstrates aneurysm size & extent of stenosis
  - Aneurysms occur at bifurcating sites
  - Acute thrombotic occlusion of coronary artery may occur; thrombolytic therapy may be indicated

Nuclear Medicine Findings

- Thallium (Tl-201) or technetium (Tc-99m) sestamibi myocardial perfusion imaging (SPECT)
  - Pharmacologic stress testing with dipyridamole or adenosine can demonstrate myocardial ischemia

Imaging Recommendations

- Best imaging tool
  - Echocardiography for initial & sequential studies
  - Cardiac MR in older children & adults for assessing function, myocardial ischemia, myocardial viability, & aneurysms
- Protocol advice
  - Comprehensive cardiac MR protocol includes function, coronary artery imaging, 1st-pass perfusion, & late gadolinium enhancement for myocardial viability
  - MRA with large field of view can show aneurysms of peripheral arteries

DIFFERENTIAL DIAGNOSIS

MIS-C From SARS-CoV-2/COVID-19

- Occurs 2-6 weeks after COVID-19 infection
- Fever, rash, coagulopathy, gastrointestinal symptoms, hypotension
- Elevated inflammatory markers
- Higher incidence of coronary artery aneurysms than Kawasaki disease
- Mean age: 7-11 years

Exanthematous Infections: Viral or Bacterial

- Toxic shock syndrome has high fever, desquamation of hands & feet
- Rheumatic fever has skin rash, fever, arthritis, myocarditis, & pericarditis
- Mononucleosis has fever, lymphadenopathy, splenomegaly, & liver disease

Allergic or Hypersensitivity Reactions

- Drug reactions, Stevens-Johnson syndrome, & erythema multiforme have systemic signs, rash, & fever but usually do not have cardiac involvement

Vasculitides

- SLE, polyarteritis nodosa
- Takayasu may have medium- to large-vessel disease

PATHOLOGY

General Features

- Etiology
  - Remains elusive, but clinical & epidemiologic features suggest abnormal immune response to toxin or infection
- Laboratory evidence
  - C-reactive protein (CRP) is elevated
  - WBC count is elevated
  - Thrombocytosis with marked elevation of platelet counts appearing in 2nd & 3rd weeks

Gross Pathologic & Surgical Features

- Generalized systemic vasculitis involving small- & medium-sized arteries
- Late-phase fibroblastic proliferation & active inflammation replaced by progressive fibrosis & scar

Microscopic Features

- Perivasculitis involving small vessels
- Larger vessels become secondarily inflamed with aneurysm & thrombus formation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute febrile phase (days 1-11)
    - Temperature elevated > 104°F for 5 days
    - Bilateral, nonpurulent conjunctivitis & rash
    - Hands & feet develop erythema & edema
    - Tongue & oral mucosa become red & cracked
    - Cervical lymphadenopathy, usually unilateral
    - Cardiac complications of myocarditis (36-50%) & pericarditis (16%)
  - Subacute phase (days 11-21): Fever has resolved
    - Persistent irritability, anorexia, conjunctivitis
    - Thrombocytosis develops
    - Desquamation of fingers & toes
    - Aneurysms may develop; greatest risk for sudden death
  - Convalescent phase (days 21-60): Symptoms of illness have disappeared
  - Chronic phase (> 60 days): Cardiac complications
- Other signs/symptoms
  - Dilation of gallbladder (hydrops) early in disease (15%)
  - Hepatic enlargement & jaundice can occur
  - Gastrointestinal complaints include diarrhea, vomiting, abdominal pain

Demographics

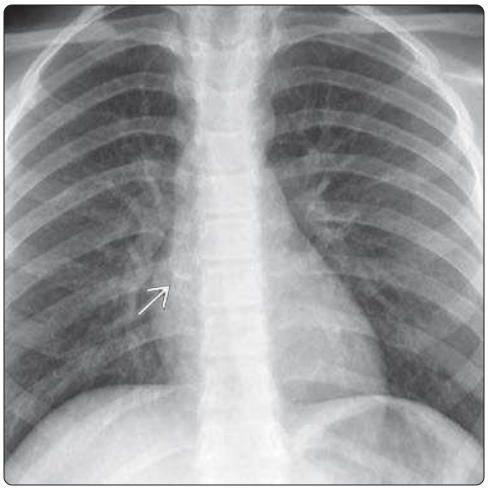
- Age
  - Peak incidence: 6 months to 2 years
  - Most are < 5 years old
- Sex
  - M:F = 5:1
- Epidemiology
  - Japan: Incidence 50/100,000 children < 4 years of age (10x incidence in USA)
  - Also prevalent in other countries, affecting mainly Asian populations
  - Minor epidemic outbursts every 3-4 years with seasonal variation

Natural History & Prognosis

- Self-limited disease in majority of cases
- Favorable outcome with early recognition, treatment with intravenous γ globulin, aspirin
- With development of coronary artery aneurysms
  - Thrombosis, arrhythmia, infarct, or delayed rupture
  - Persistent wall abnormalities after aneurysm regression
  - Chronic coronary insufficiency, premature atherosclerosis in < 4%
  - Death in > 1% due to arrhythmias

Treatment

- High-dose aspirin is used as antiinflammatory agent early in disease until fever has ↓
- Low-dose aspirin is used in children for 6-8 weeks & for prolonged period in children with confirmed aneurysms
- Intravenous γ globulin is given in acute phase to reduce coronary artery abnormalities
- Transcatheter coronary intervention if thrombosis occurs: Thrombolysis with tissue plasminogen activator (tPA)
- Long-term treatment directed by degree of coronary involvement
  - Coronary bypass surgery or cardiac transplantation may be necessary



DIAGNOSTIC CHECKLIST

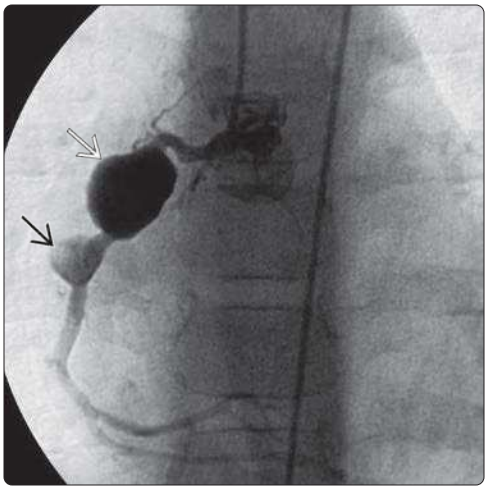


Image Interpretation Pearls

- Masquerades as many common diseases in children, but distinct pattern & progression of acute illness is striking

(Left) *PA radiograph shows a curvilinear Ca^{2+} ➡ projecting inferior to the right hilum. The patient's history revealed that the child had been diagnosed with Kawasaki disease at age 4, confirming that this abnormality is due to a calcified aneurysm.* **(Right)** *Frontal angiogram of a right coronary artery injection shows a large proximal aneurysm ➡ & a smaller, more distal aneurysm, which may contain some thrombus ⇨. This patient eventually developed stenosis requiring stenting.*

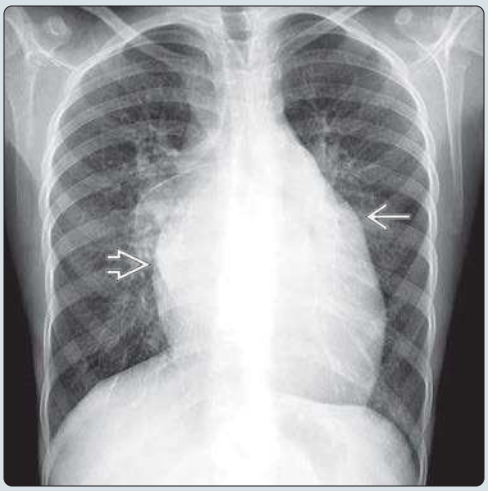
(Left) *Oblique MIP coronary CTA shows multiple bilateral calcified & noncalcified coronary artery aneurysms ⇨ in a patient with Kawasaki disease.* **(Right)** *Color-coded 3D surface-rendered coronary CTA shows multiple bilateral calcified & noncalcified coronary artery aneurysms in the same patient with Kawasaki disease.*

(Left) *Oblique ultrasound of the right upper quadrant in a 5-year-old with fever & pain shows an enlarged, hydropic gallbladder. This finding ultimately led to the diagnosis of Kawasaki disease.* **(Right)** *Coronal MRA in a child with Kawasaki disease shows multiple aneurysms ➡ of the peripheral arteries. This same MRA was also able to depict aneurysms of the coronary arteries (not shown). (Courtesy S. Yoo, MD.)*

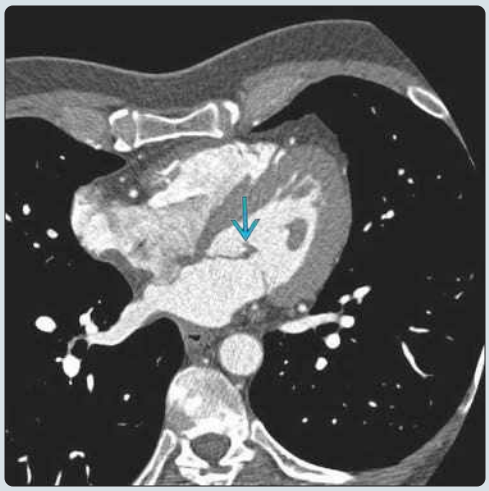
Rheumatic Heart Disease

KEY FACTS

TERMINOLOGY

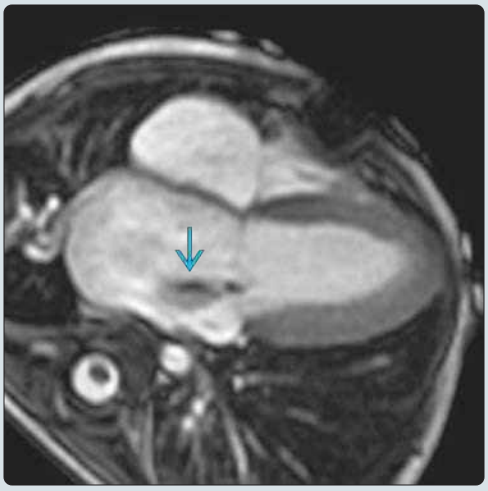


- Acute rheumatic fever: Multisystem disease affecting heart, joints, skin, & brain 1-5 weeks following infection with group A β-hemolytic *Streptococcus*
  - Due to autoimmune response
  - 40% of acute rheumatic fever patients develop cardiac involvement (RHD)

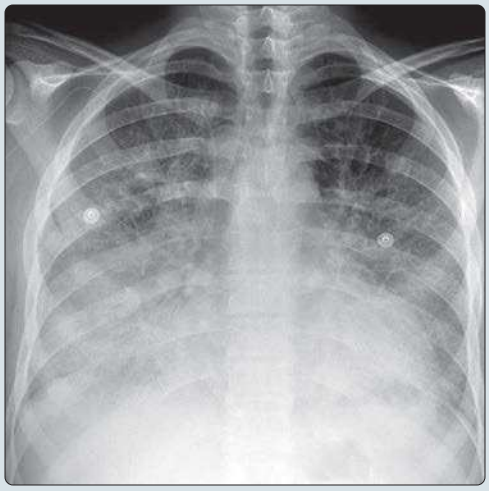


IMAGING

- Acute rheumatic fever: Large heart, left atrial enlargement, pulmonary edema (due to left ventricular dysfunction with mitral insufficiency)
  - Rheumatic pneumonia is rarely seen
  - Pericardial effusion
- Chronic RHD: Ca^{2+} of valves, especially mitral or aortic
- Echocardiogram during acute disease quantitates degree of mitral insufficiency & left ventricular function
- Echocardiogram in chronic disease shows progression of valve stenosis with thickened leaflets, which calcify



CLINICAL ISSUES



- Acute disease occurs in young children 3-15 years who present with streptococcal sore throat
  - RHD develops after 0.3% of such infections in USA
- Initial treatment: Therapy aimed at preventing acute rheumatic fever by treating group A streptococcal pharyngitis & eradicating reservoir for transmission
  - Disease has dramatically ↓ in USA where sore throat from *Streptococcus pyogenes* is treated
  - Disease is now most common in overcrowded areas of world where infection can spread in dry, hot climate
    - High mortality rate in malnourished populations
- Jones criteria for rheumatic fever
  - Major: Carditis, polyarthritis, chorea, subcutaneous nodules, & erythema marginatum
  - Minor: Fever, arthralgia, elevated acute phase reactants, ↑ sedimentation rate

(Left) *PA radiograph in an adult with rheumatic heart disease (RHD) shows cardiomegaly with dilation of the left atrial appendage, creating a broad bump on the lateral margin of the heart below the level of the pulmonary artery. The left atrium splays the carina & creates a double shadow over the right heart border.* **(Right)** *Axial CECT in a young adult shows irregular thickening of the mitral valve due to RHD.*

(Left) *Four-chamber SSFP cine cardiac MR in an adolescent demonstrates a dephasing jet in the left atrium due to mitral regurgitation from a damaged mitral valve in a patient with RHD.* **(Right)** *AP radiograph in a 17-year-old patient shows pulmonary edema due to progressive aortic insufficiency from acute bacterial endocarditis complicating rheumatic aortic valve disease.*

TERMINOLOGY

Abbreviations

- Rheumatic heart disease (RHD)

Definitions

- Acquired heart disease due to autoimmune response to prior group A β-hemolytic *Streptococcus* infection
- Part of multisystem disease affecting heart, joints, skin, & brain; occurs 1-5 weeks following infection

IMAGING

General Features

- Best diagnostic clue
  - Large heart, left atrial enlargement (LAE), pulmonary edema
    - Due to left ventricular dysfunction with mitral insufficiency
  - Pericardial inflammation & effusion
  - Multisystem involvement

Radiographic Findings

- Acute disease
  - Cardiomegaly & pulmonary congestion, pericardial effusion
  - LAE when mitral insufficiency or stenosis is present
  - Rheumatic pneumonia is rarely seen; various patterns have been described
- Chronic RHD
  - Ca^{2+} of valves, especially mitral or aortic
  - LAE with mitral regurgitation or stenosis

Echocardiographic Findings

- Acute disease
  - Quantitates degree of mitral insufficiency & left ventricular function
- Chronic
  - Progression of valve stenosis with thickened leaflets, which calcify
  - Fusion of commissures & chordae

MR Findings

- MR to assess cardiac function
  - Quantitates degree of valve insufficiency/stenosis

PATHOLOGY

General Features

- Etiology
  - Infection with group A *Streptococcus* is precipitating event
    - RHD develops after 0.3% of such infections in USA
  - May lead to acute rheumatic fever with inflammation of joints, heart, brain, connective tissue
    - Genetic susceptibility to rheumatic fever is related to human leukocyte antigens
    - Immune reactions with cross-reactive antibody or cell-mediated immunity

Gross Pathologic & Surgical Features

- Inflammatory reaction involves connective or collagen tissue
- Acute carditis affects endocardium & myocardium
- Pericardial serositis may later calcify
  - Pericardium is thickened & irregular
- Mitral valve involvement in 75% of cases
  - Verrucous lesions
- Arthritis does not affect cartilage, but synovial lining shows fibrinoid degeneration

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Cardiac symptoms
    - 39% of patients with rheumatic fever develop pancarditis with valve insufficiency
    - Pericardial friction rub: Pericardial involvement
  - Prominent noncardiac manifestations
    - Jones major criteria: Carditis, polyarthritis, chorea, subcutaneous nodules, & erythema marginatum
    - Jones minor criteria: Fever, arthralgia, elevated acute phase reactants, ↑ sedimentation rate
- Significant change in presentation over past 25 years
  - Disease has dramatically ↓ in USA where sore throat from *Streptococcus* is treated
  - Disease is now most common in overcrowded regions where *S. pyogenes* can spread in dry, hot climate

Demographics

- Age
  - Acute disease occurs in young children 3-15 years of age who present with streptococcal sore throat
  - Chronic disease can have multiple recurrences & progression
- Sex
  - Equal in numbers but prognosis is worse for females

Natural History & Prognosis

- Group A *Streptococcus* is gram-positive coccus that colonizes skin & oral pharynx
  - Acute infection may precipitate acute rheumatic fever
    - Occurs 1-5 weeks later in 0.3%
  - Chronic sequelae of acute rheumatic fever
    - 40% of patients develop cardiac involvement
    - Mitral valve is most severely affected in 65-75%, aortic valve in 25%
    - Varying degrees of arrhythmia, valve insufficiency, or ventricular dysfunction
- High mortality rate in malnourished populations
  - Mortality rate is ~ 0 in USA
  - 90,000 deaths worldwide each year

Marfan Syndrome

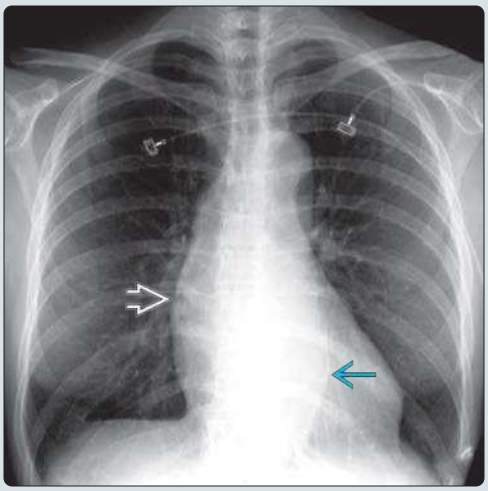
KEY FACTS

TERMINOLOGY

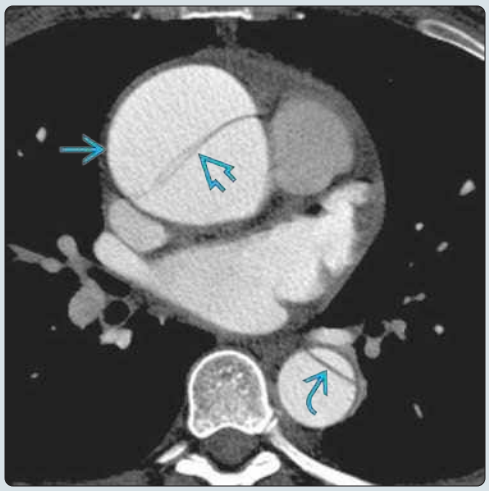
- Inherited autosomal dominant connective tissue disorder due to *FBN1* mutation → abnormal fibrillin-1

IMAGING

- Cardiovascular: Aortic root dilation at sinuses of Valsalva (75%), ascending aortic dissection, mitral valve prolapse (MVP) (50-70%), main pulmonary artery dilation, mitral anulus Ca^{2+}, dilation of abdominal aorta
- Skeletal: Pectus excavatum, pectus carinatum, long arms & legs, arachnodactyly, joint hypermobility, scoliosis, thoracic lordosis, pes planus, protrusio acetabuli
- Pulmonary: Spontaneous pneumothorax, apical blebs
- Dural: Ectasia (enlarged nerve sleeves & posterior vertebral body scalloping)
- Postoperative complications: Pseudoaneurysm, aortic dissection, rupture
- Best imaging tools
  - CTA in acute setting to exclude dissection &/or rupture
  - Echocardiography or cardiac MR for routine follow-up of aortic root dilation & valvular disease

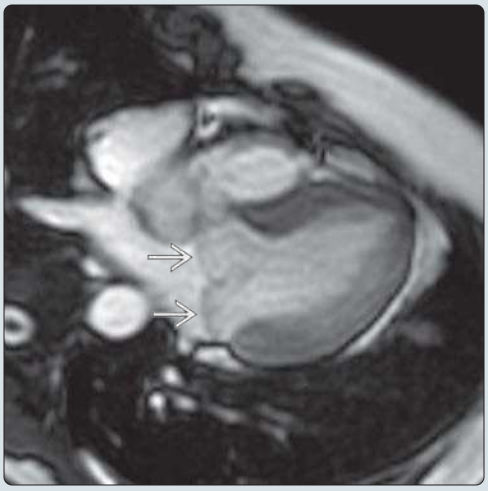


PATHOLOGY

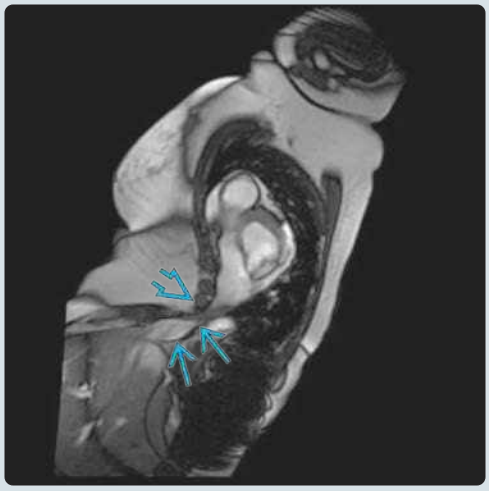


- 2010 revised Ghent nosology for diagnosis
  - Based on family history, aortic root size/dissection, ectopia lentis, *FBN1* mutation, systemic score

CLINICAL ISSUES



- 90% of deaths are from cardiovascular complications (aortic dissection, congestive heart failure, & cardiac valve disease)
  - Progressive aortic dilation → highest risk of dissection
    - Chest pain radiating down back in Marfan syndrome patient → suspect aortic dissection
- Treatment
  - Medical: β-blocker or angiotensin II receptor blocker
  - Surgery: Prophylactic aortic root surgery when diameter at sinuses of Valsalva exceeds 5 cm



(Left) *Frontal radiograph of the chest demonstrates a right border-forming ascending aorta with a tortuous, descending aorta in this 18-year-old patient with known Marfan syndrome who presented with chest pain.* **(Right)** *Axial cardiac CTA in an adolescent patient with Marfan syndrome shows marked aneurysmal dilation of the ascending aorta with a dissection noted in the ascending & descending aorta.*

(Left) *Four-chamber cine bright blood SSFP cardiac MR demonstrates mitral valve prolapse with ballooning of the leaflets of the mitral valve into the left atrium in a Marfan syndrome patient.* **(Right)** *Short-axis FIESTA cine image from a cardiac MR in a patient with Marfan syndrome shows severe pectus excavatum deformity with compression of the upper inferior vena cava.*

TERMINOLOGY

Definitions

- Inherited autosomal dominant connective tissue disorder due to *FBN1* mutation → abnormal fibrillin-1

IMAGING

General Features

- Best diagnostic clue
  - Aortic dissection in tall, thin patient with pectus deformity, scoliosis, & long fingers
- Location
  - Cardiovascular: Aortic root dilation at level of sinuses of Valsalva (75%), ascending aortic dissection, mitral valve prolapse (MVP) (50-70%), main pulmonary artery dilation, mitral anulus Ca^{2+}, dilation of abdominal aorta
  - Skeletal: Pectus excavatum, pectus carinatum, long arms & legs, arachnodactyly, joint hypermobility, scoliosis, thoracic lordosis, pes planus, protrusio acetabuli
  - Ocular: Ectopia lentis (50%), flat cornea, cataract, hypoplastic iris, nearsightedness, glaucoma (< 50 years of age), retinal detachment
  - Pulmonary: Spontaneous pneumothorax (5-10%), apical blebs
  - Skin: Stretch marks in absence of weight changes or pregnancy, recurrent hernia
  - Dural: Ectasia (widening & dilation of dural sac with enlarged nerve sleeves & posterior vertebral body scalloping)

Radiographic Findings

- Enlargement of ascending aorta creates right-sided border forming mediastinal prominence
- Enlarged main pulmonary artery
- Pectus excavatum or carinatum
- Apical bleb, spontaneous pneumothorax

CT Findings

- CTA
  - Dilation of ascending aorta (starts at sinuses of Valsalva)
  - Aortic dissection, dilated pulmonary artery, mass effect on heart or inferior vena cava from pectus excavatum
    - CTA is fast & effective way to exclude aortic dissection in acute setting
    - Coronary CTA is helpful in patients with dissection to evaluate coronary artery involvement
  - Apical blebs, pneumothorax
  - Posterior scalloping of vertebrae from dural ectasia

MR Findings

- Anatomic imaging: Ascending aortic aneurysm, dissection
- Functional cine bright blood imaging
  - Dephasing artifact from aortic & mitral regurgitation
  - MVP
  - Ventricular function is best on short-axis imaging
- Phase-contrast imaging
  - Quantify aortic & mitral regurgitant fraction
  - Pulse wave velocity measurements to evaluate aortic stiffness

Imaging Recommendations

- Best imaging tool
  - CTA in acute setting to exclude dissection &/or rupture
  - Echocardiography or cardiac MR for routine follow-up of aortic root dilation & valvular disease

PATHOLOGY

General Features

- Genetics
  - Autosomal dominant
  - Mutation in *FBN1* gene located on chromosome 15q21.1
    - Mutation causes abnormal fibrillin (major substrate for microfibrils)

Staging, Grading, & Classification

- 2010 revised Ghent nosology for diagnosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Chest pain radiating down back from aortic dissection
  - Heart murmurs from aortic & mitral regurgitation
  - Unilateral chest pain from spontaneous pneumothorax
- Other signs/symptoms
  - Visual disturbances

Demographics

- Frequency: 2-3:10,000
- Diagnosis may be made in infancy or well into adulthood

Natural History & Prognosis

- 90% of deaths are from cardiovascular complications (aortic dissection, congestive heart failure, & cardiac valve disease)
  - Progressive aortic dilation carries highest risk of aortic dissection
- Improved detection & treatment has helped prolong survival to nearly normal levels

Treatment

- Moderate restriction of physical activity
- β-blocker or angiotensin II receptor blocker
  - For prophylaxis of progressive aortic root dilation
  - Initiated at disease diagnosis
- Prophylactic aortic root surgery when diameter at sinuses of Valsalva exceeds 5 cm

Loeys-Dietz Syndrome

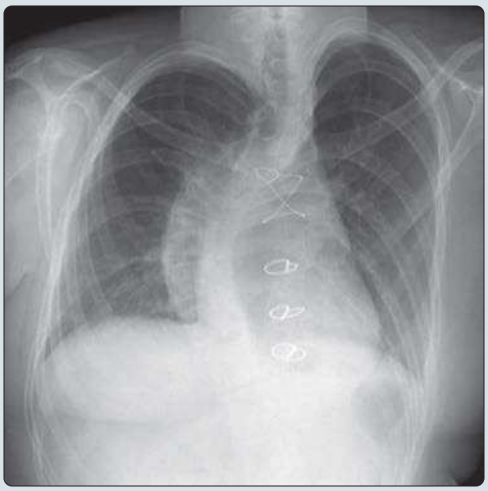
KEY FACTS

TERMINOLOGY

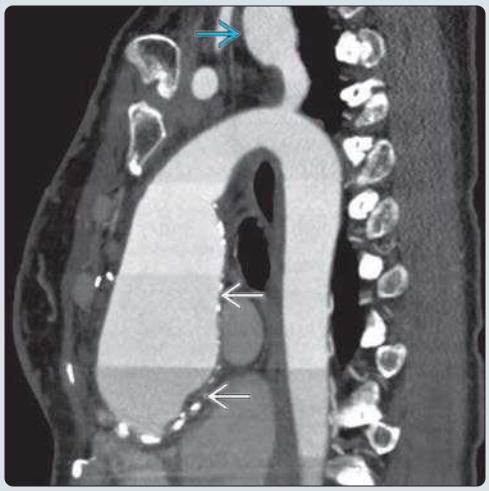
- Autosomal dominant connective tissue disorder due to 1 of 5 genetic mutations affecting transforming growth factor β

IMAGING

- 98% have aortic root aneurysms
- 20% have aneurysms in head & neck region
- Aneurysms also occur in coronary arteries, pulmonary arteries, & ductus arteriosus
- Recommendations
  - Baseline imaging
    - Echocardiography every 6-12 months
    - Screening CTA or MRA of head through pelvis every 2 years
  - For acute chest pain: Chest CTA for aortic dissection & aneurysms
  - For acute headache: Noncontrast head CT for intracranial hemorrhage; if positive, follow with head CTA

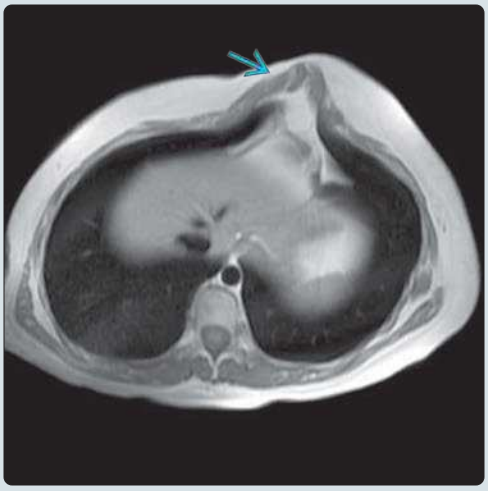


TOP DIFFERENTIAL DIAGNOSES

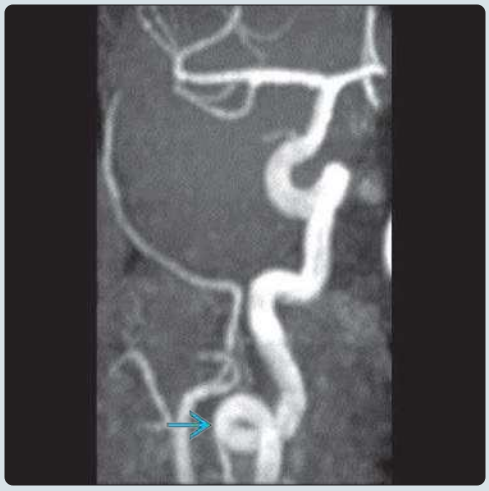


- Marfan syndrome
- Vascular Ehlers-Danlos syndrome

CLINICAL ISSUES



- Systemic involvement with craniofacial, cardiovascular, skeletal, skin, & nervous system abnormalities
- Characteristic clinical triad of hypertelorism, bifid uvula or cleft palate, & aortic aneurysms ± dissection & tortuous arteries
- Leading cause of death: Aortic dissection (67%)
  - ↑ risk for dissection or rupture at > 3.9-cm diameter
- Abdominal aortic dissection & cerebral hemorrhage from ruptured aneurysm account for 22% of deaths
- Preventative treatment with hypertension/heart rate control: β-blocker, angiotensin II receptor blocker



(Left) *Frontal radiograph of the chest in a 15-year-old patient with Loeys-Dietz syndrome shows severe dextroscoliosis of the thoracic spine. Note the postoperative changes of a prior sternotomy for repair of the aortic root.* **(Right)** *Oblique sagittal CTA in a 15-year-old patient with Loeys-Dietz syndrome shows an aneurysm of the left subclavian artery. Note the ascending aortic aneurysm & postoperative changes.*

(Left) *Axial DIR cardiac MR in a 15-year-old patient with Loeys-Dietz syndrome shows a pectus carinatum deformity. While this can be seen in patients with Marfan syndrome, it is more often associated with Loeys-Dietz.* **(Right)** *Anterior 3D TOF MRA in a 15-year-old patient with Loeys-Dietz syndrome shows tortuosity of the proximal right internal carotid artery, which is frequently seen in this syndrome.*

TERMINOLOGY

Definitions

- Autosomal dominant connective tissue disorder with aortic/arterial abnormalities

IMAGING

General Features

- Best diagnostic clue
  - Arterial tortuosity with aortic aneurysm & dissection
  - Hypertelorism
  - Bifid uvula or cleft palate
  - Instability or malformation of spine/neck
  - Club foot
  - White sclera of eye looks blue or gray
- Location
  - 98% have aortic root aneurysms
  - 20% have aneurysms in head & neck region
  - Aneurysms also occur in coronary arteries, pulmonary arteries, & ductus arteriosus

CT Findings

- CTA
  - Evaluation of aortic aneurysm & dissection; associated coronary artery, pulmonary artery, & ductus arteriosus aneurysms

MR Findings

- MRA
  - Evaluation of aortic aneurysm & dissection
    - Phase contrast to evaluate aortic valve regurgitation, which often accompanies aortic root aneurysm
  - Tortuosity of intracranial vessels

Echocardiographic Findings

- 1st-line evaluation of aortic root, myocardial function, valve morphology (including bicuspid aortic valve)

Imaging Recommendations

- Best imaging tool
  - For acute chest pain: CTA of chest for aortic dissection & aneurysms
  - For acute headache: Noncontrast head CT for acute intracranial hemorrhage; if positive, follow with head CTA
- Baseline imaging
  - Echocardiography + screening CTA or MRA of head, neck, chest, abdomen, & pelvis
- Follow-up imaging
  - Echocardiography every 6-12 months
  - CTA or MRA of head to pelvis at least every 2 years

DIFFERENTIAL DIAGNOSIS

Marfan Syndrome

- Dissection & aortic rupture tend to occur at larger diameter & later in life than patients with Loeys-Dietz syndrome
- Lacks tortuosity, aneurysms, & dissections beyond aorta
- Lens dislocation is typical

Vascular Ehlers-Danlos Syndrome

- Aortic dissection & rupture without preceding dilation
  - Usually affects descending rather than proximal aorta
- Spontaneous carotid-cavernous fistula, bowel perforations

PATHOLOGY

General Features

- Connective tissue disorder from mutations in 1 of 5 genes

Staging, Grading, & Classification

- *TGFBR1* mutation causes Loeys-Dietz type 1
- *TGFBR2* mutation causes Loeys-Dietz type 2
- *SMAD3* mutation causes Loeys-Dietz type 3
- *TGFB2* mutation causes Loeys-Dietz type 4
- *TGFB3* mutation causes Loeys-Dietz type 5

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Characteristic clinical triad of hypertelorism, bifid uvula or cleft palate, & aortic aneurysms ± dissection & tortuous arteries
- Other signs/symptoms
  - Systemic involvement with craniofacial, cardiovascular, skeletal, skin, & nervous system abnormalities
    - Congenital heart problems, such as patent ductus arteriosus, bicuspid aortic valve, or atrial septal defect
    - Scoliosis or kyphosis, pectus excavatum or carinatum deformity, camptodactyly, arachnodactyly, club foot
    - Translucent skin, joint hypermobility
    - Craniosynostosis, dural ectasia
    - Strabismus from weakened eye muscles

Natural History & Prognosis

- Leading cause of death: Aortic dissection (67%)
  - ↑ risk for dissection/rupture at aortic diameter > 3.9 cm
- Abdominal aortic dissection & cerebral hemorrhage from ruptured aneurysm account for 22% of deaths

Treatment

- Preventative treatment: Hypertension/heart rate control with β-blocker, angiotensin II receptor blocker

Imaging Techniques

Pediatric radiologists must have an understanding not only of the unique disorders that affect children but also the expected range of normal appearances that occur from infancy to early adulthood. The radiologist must also be able to tailor the imaging study to meet a child's needs, which includes explaining the procedure in an age-appropriate manner, distracting the child so that imaging can be performed, &, when needed, immobilizing the child safely during the procedure. In addition, radiologists must remember that children are more sensitive to the effects of ionizing radiation than adults. This should be considered when deciding on the most appropriate imaging study to diagnose a suspected condition. If the selected test requires ionizing radiation, pediatric-specific protocols should be employed to keep the dose as low as reasonably achievable (the ALARA principle).

Many imaging modalities are available for diagnosing abdominal pathology in children. Depending on the patient age, presentation, & specific clinical question, each modality has unique advantages & disadvantages.

Radiography

Constipation, pain, vomiting/bowel obstruction, & necrotizing enterocolitis are common indications for obtaining pediatric abdominal radiographs. Modifications for children include a single view for suspected constipation & the decubitus view or cross-table lateral view to look for free air in infants.

Fluoroscopy

Methods to reduce radiation exposure to the patient include minimizing fluoroscopy time, pulsed fluoroscopy, fluoroscopic image hold or clips rather than digital spot exposures, small image intensifier-to-patient distance, appropriate collimation, & low-dose fluoroscopy settings for pediatric patients based on size.

Upper GI

Common pediatric indications for the upper GI series include bilious & intractable nonbilious emesis & difficulty swallowing. A single-contrast upper GI is typically employed for these investigations, though a double-contrast study is sometimes performed in teenagers when looking for esophagitis or gastric ulcers (i.e., studies requiring fine mucosal detail). Note that evaluating the position of the duodenojejunal junction (DJJ) is crucial, especially in young vomiting infants.

The typical single-contrast upper GI technique should include the following images: A left-side-down lateral view of the esophagus while swallowing, a supine frontal view of the esophagus (which can include a fluoroscopic clip of peristalsis), a right-side-down lateral view of the 1st pass of contrast into the duodenum as it courses posteriorly in the retroperitoneum & ascends toward the DJJ, & a straight supine frontal view of the duodenum during the 1st pass of contrast to document the normal DJJ to the left of the spine at or nearly at the same level as the duodenal bulb.

Contrast Enema

Common indications for a contrast enema include the failure of a newborn to pass meconium, newborn bilious emesis (if the radiograph suggests a distal obstruction), & chronic constipation.

Enema modifications for children include selecting a rectal catheter that is appropriate for size & the use of a water-soluble contrast agent instead of barium.

The typical contrast enema technique includes the following images: An early left-side-down lateral view of the rectum through the sigmoid colon (to evaluate the rectosigmoid ratio) while contrast is flowing, a frontal view of the rectum through the sigmoid colon during active filling, an overhead frontal view of the abdomen when filled just barely to the cecum, & an overhead frontal view of the abdomen after spontaneous contrast evacuation. In newborns with a suspected distal bowel obstruction, reflux of contrast into the terminal ileum is helpful. Spot images (± oblique positioning) may be helpful at sites of suspected stricture or redundancy.

Enema Reduction of Intussusception

Various techniques can be used to reduce an ileocolic intussusception. However, air reduction is widely accepted as a safe, effective, & established method. In this procedure, air is insufflated into the colon under fluoroscopic monitoring until gas refluxes into the terminal ileum & the soft tissue mass of the intussusceptum disappears. Important points for performing this technique include: An adequate seal must be created by the rectal tube at the anus to build effective intraluminal pressure, the sustained colonic pressure must be kept below 120 mm Hg, & an 18-gauge IV-type cannula should be kept at the bedside to reduce a tension pneumoperitoneum if perforation occurs. Note that an enema reduction is contraindicated with peritoneal signs or pneumoperitoneum.

Abdominal US

US is a simple, cost-effective, noninvasive, & ionizing radiation-free method of imaging the pediatric abdomen.

Common indications for pediatric abdominal US include suspected hypertrophic pyloric stenosis (HPS), intussusception, appendicitis, a palpable mass or organomegaly, abdominal pain, hematuria, oliguria, & organ dysfunction suspected by laboratory values. US is also increasingly used for bowel abnormalities outside of intussusception, such as necrotizing enterocolitis & inflammatory bowel disease.

Sonographic modifications for children include the selection of an appropriate transducer & distraction of the patient during scanning.

Abdominal CT

Common indications for pediatric abdominal CT include trauma, abdominal pain, suspected appendicitis with an equivocal US, complications of pancreatitis, & abscess. It should be noted, however, that, outside of trauma, US & MR are increasingly replacing CT due to the concerns of ionizing radiation.

Modifications for children include the use of weight-/size-based protocols & automatic tube current modulation techniques.

The use of IV &/or oral contrast should be driven by the specific clinical indication.

Abdominal MR

MR imaging uses no ionizing radiation & provides excellent soft tissue contrast.

Common indications for pediatric abdominal MR include the further investigation of a mass, surveillance after the treatment of a cancer, assessment of inflammatory bowel disease & pancreatobiliary disorders, liver quantification (of iron, fat, &/or fibrosis), & utilization as an alternative modality for suspected appendicitis.

Specific indications will help drive the selection of the appropriate contrast agent & protocol. Diffusion-weighted imaging can be particularly helpful in increasing the conspicuity of inflammatory & neoplastic pathologies against collapsed normal bowel loops.

Modifications for children include the use of video goggles for distraction, pretest practice/simulation to prepare young patients for the noise & relatively small bore size, & the use of sedation or general anesthesia for most patients < 6 years of age.

Differential Diagnoses

Neonatal Bowel Obstruction
High or proximal intestinal obstruction (with radiographs showing a few dilated proximal loops with a paucity of distal bowel gas) should be evaluated with an upper GI, though the true double bubble sign (with bulbous distention of the stomach & proximal duodenum without any distal gas) strongly suggests duodenal atresia & requires no further imaging. Differential considerations for proximal neonatal bowel obstruction include malrotation with midgut volvulus, duodenal atresia/stenosis, duodenal web, annular pancreas, & jejunal atresia.

Low or distal intestinal obstruction (with radiographs showing many dilated loops) should be evaluated with a water-soluble contrast enema. Differential considerations in this setting will include Hirschsprung disease, meconium plug/small left colon syndrome, meconium ileus, ileal atresia, & anorectal malformation.

Specific Neonatal Disorders
Esophageal atresia with a tracheoesophageal fistula (TEF) may show a distended proximal esophageal pouch containing the tip of an enteric tube. A proximal atresia with a distal TEF is the most common type, & air is typically seen in the stomach & intestines.

Necrotizing enterocolitis typically occurs in premature neonates & presents as stagnant dilated, air-filled bowel loops & pneumatosis, ± portal venous gas & pneumoperitoneum.

Neonatal abdominal masses in the GI tract include a duplication cyst, obstructed bowel loop, meconium pseudocyst, hepatic hemangioma, hepatoblastoma, & mesenchymal hamartoma. Abdominal masses in the neonatal GU tract include severe hydronephrosis, mesoblastic nephroma, Wilms tumor, autosomal recessive polycystic kidneys, neuroblastoma, bladder outlet obstruction, hydrocolpos, & ovarian cyst.

Vomiting Infant
If bilious emesis is present, an emergent upper GI series is the study of choice to look for a proximal obstruction, such as malrotation with midgut volvulus (even though bilious emesis in a neonate is more commonly due to distal bowel obstruction). The diagnoses of malrotation & midgut volvulus are classically made on an upper GI, though they can potentially be made by other modalities, such as US.

If nonbilious emesis is present, US is an ideal test for the evaluation of suspected HPS. HPS is typically found in infants 2-12 weeks old with progressive nonbilious projectile vomiting.

Bowel Obstruction Beyond Neonates
The differential diagnosis for obstruction in this setting can be remembered by the mnemonic AAIIMM (appendicitis, adhesions, intussusception, inguinal hernia, Meckel diverticulum, malrotation/midgut volvulus), though other entities (such as foreign bodies & inflammatory bowel disease) may also cause obstruction in children.

Abdominal Pain
Common causes of abdominal pain in children include constipation, appendicitis, referred pain from pneumonia, trauma, intussusception, enteritis/colitis, & pancreatitis. The clinical history, signs, & symptoms help to focus the differential diagnosis & guide imaging options.

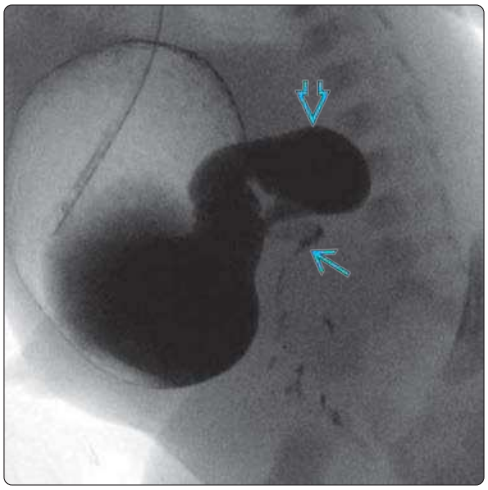
Radiographs & US are the most common 1st imaging choices in a child with abdominal pain. US is preferred to work-up suspected appendicitis, intussusception, or hepatobiliary abnormality, though CT remains the modality of choice in the rapid evaluation of trauma. MR imaging is preferred to diagnose inflammatory bowel disease & the potential underlying causes of pancreatitis. Either MR or CT can be used to diagnose appendicitis after an equivocal US.

Abdominal Tumors
Young children are afflicted with a unique set of tumors. The most common abdominal malignancies affecting children are Wilms tumor, neuroblastoma, & hepatoblastoma. The remaining malignancies are all considered rare tumors.

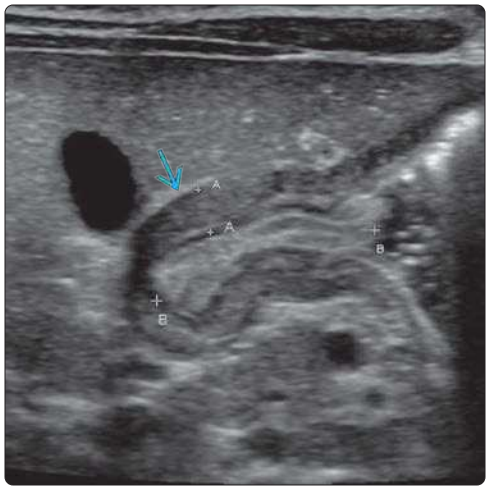
Wilms tumor is the most common pediatric malignancy of the kidney. It can invade the renal vein, uncommonly has Ca^{2+} (in ~ 15%), & rarely crosses midline.

Neuroblastoma is the most common extracranial solid tumor in children. It most commonly arises from the adrenal gland or paraspinal sympathetic ganglia. It often encases & displaces vessels, crosses the midline, & contains Ca^{2+} (~ 90%). Up to 30% of neuroblastomas arise in the neck or chest.

Hepatoblastoma is the most common pediatric hepatic malignancy. It is usually a large, heterogeneous, solid liver mass, presenting before 5 years of age. This lesion has Ca^{2+} in 50% of cases & typically causes an ↑ α-fetoprotein.

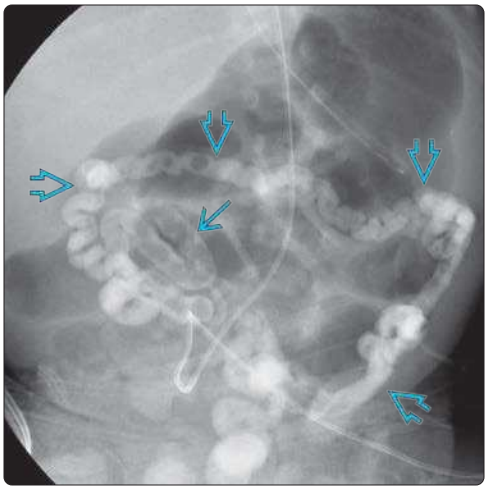


Pediatric Abdominal Trauma
Trauma is the leading cause of death in children.

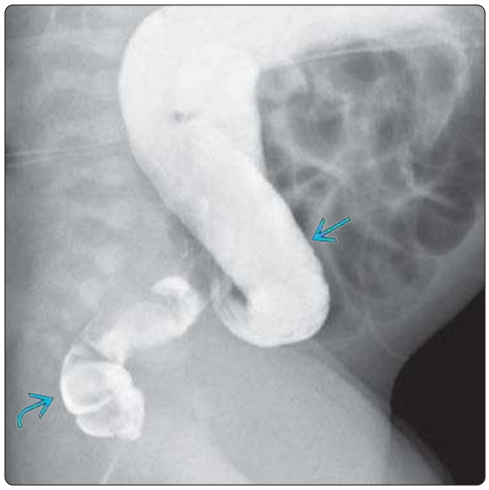


Children are at ↑ risk of abdominal traumatic injury, as their visceral organs are proportionately larger compared to adult organs (leading to greater force per body surface area). Additionally, there is little fat to cushion direct blows.

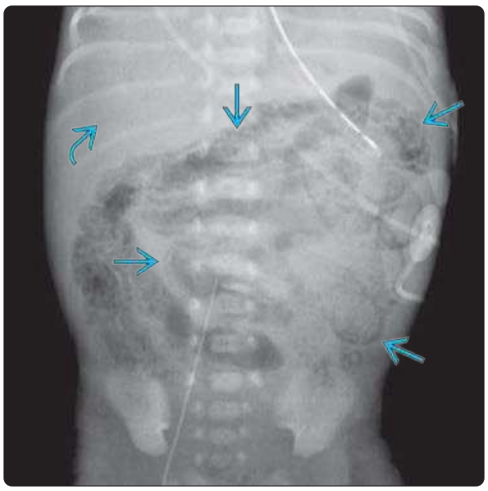
Approximately 60-80% of children with seat belt contusions have intraabdominal injuries in the plane of the seat belt. Rapid deceleration in these cases causes hyperflexion with compression of the abdominal viscera. Injuries of the small & large bowel, mesentery, liver, spleen, pancreas, kidneys, aorta, & lumbar spine may occur.

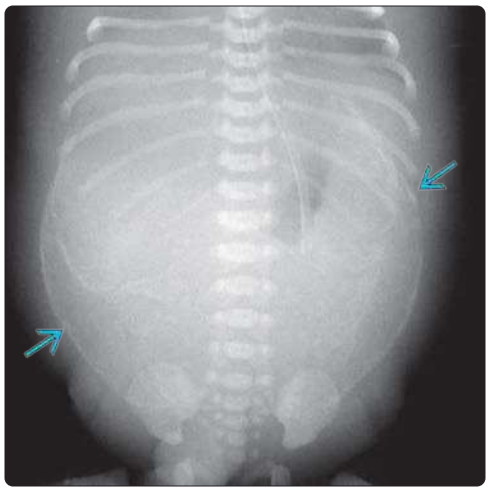


Abusive abdominal trauma is the 2nd most common form of fatal child abuse. The liver & spleen are the most commonly affected organs, but pancreatic or bowel trauma without explanation should also raise suspicion.

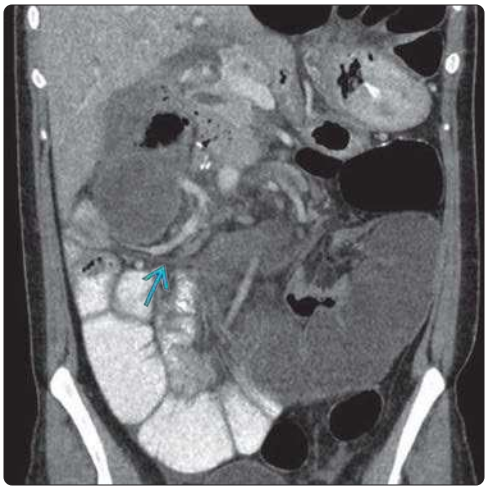


(Left) *Lateral upper GI examination in a neonate with bilious emesis shows dilation of the stomach & proximal duodenum. There is rapid tapering, twisting, & narrowing of the duodenum beyond this level. The findings are consistent with malrotation with midgut volvulus.* **(Right)** *Longitudinal US of the pylorus in a young infant with projectile vomiting shows findings of hypertrophic pyloric stenosis with a single pyloric wall thickness > 3 mm & pyloric channel length > 16 mm.*

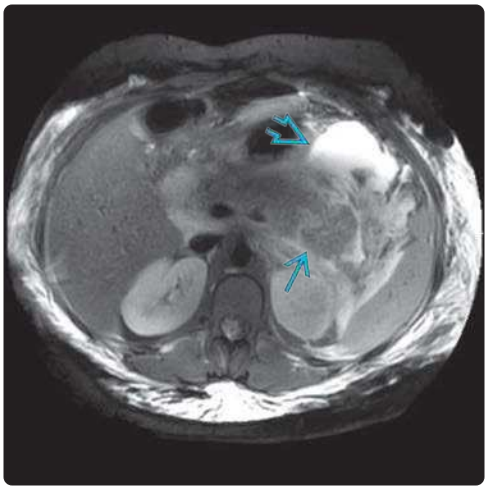


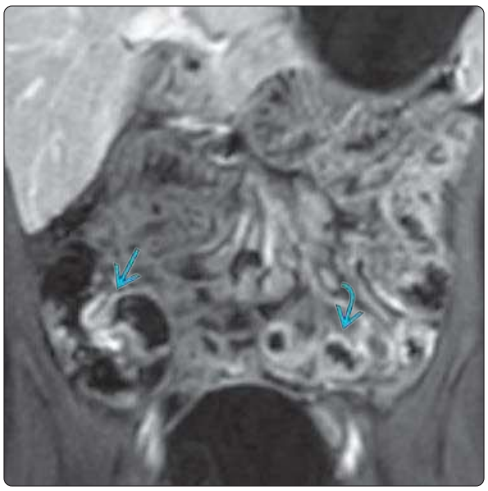


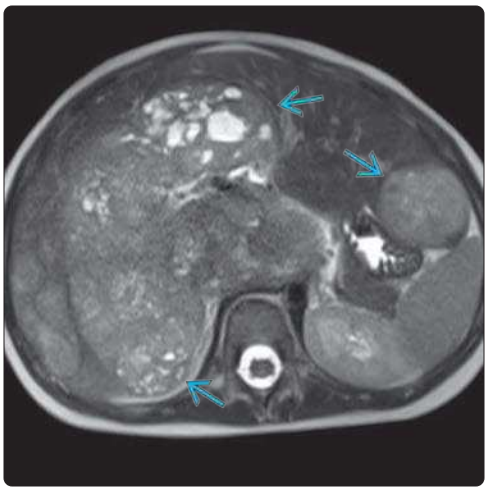
(Left) *AP water-soluble contrast enema in a newborn with a prenatal diagnosis of cystic fibrosis shows a microcolon & filling defects within the distal ileum, consistent with meconium ileus, which is the presenting manifestation of cystic fibrosis in up to 20% of patients.* **(Right)** *Lateral water-soluble contrast enema in an infant with difficulty stooling shows a smaller caliber of the rectum in relation to the sigmoid colon. A rectosigmoid ratio < 1 is a classic finding of Hirschsprung disease.*



(Left) *AP radiograph of the abdomen in a premature neonate shows extensive pneumatosis intestinalis & portal venous gas. Necrotizing enterocolitis is the most common cause of pneumatosis intestinalis in neonates.* **(Right)** *AP radiograph of the abdomen in a neonate delivered after fetal distress shows a distended abdomen with Ca^{2+} lining the peritoneal surface. This pattern of abdominal Ca^{2+} in a neonate is consistent with meconium peritonitis.*







(Left) *Longitudinal US in an adolescent with right lower quadrant pain shows a dilated appendix (> 6 mm in diameter) with echogenic periappendiceal fat. The findings are consistent with acute appendicitis.* **(Right)** *Coronal CECT in a child with prior abdominal surgery shows a thick adhesion causing a small bowel obstruction. Bowel proximal to the adhesion is dilated & fluid filled.*

(Left) *Axial T2 FS MR in a child with severe upper abdominal pain shows findings of acute pancreatitis with edema of the tail of the pancreas. This portion of the pancreas did not enhance with contrast (not shown). An acute necrotic peripancreatic collection is also present.* **(Right)** *Coronal CECT in a patient status post motor vehicle accident shows devascularization of the left kidney. Note also the adjacent splenic lacerations.*

(Left) *Coronal T1 C+ FS MR in a patient with Crohn disease shows enhancement & wall thickening of the terminal ileum. Skip lesions are also present in the more proximal ileum.* **(Right)** *Axial T2 MR in a young child shows multifocal heterogeneous but predominantly solid masses, consistent with hepatoblastoma. Hepatoblastoma is the most common primary hepatic malignancy in children.*

Normal Variations of Duodenojejunal Junction Position

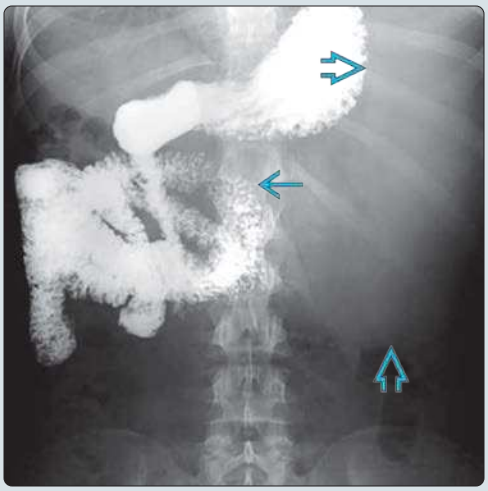
KEY FACTS

TERMINOLOGY

- Ligament of Treitz (LOT): Combination of muscle & fibrous tissue, very pliable
  - Normal LOT position implies normal bowel rotation & fixation, low risk of midgut volvulus

IMAGING

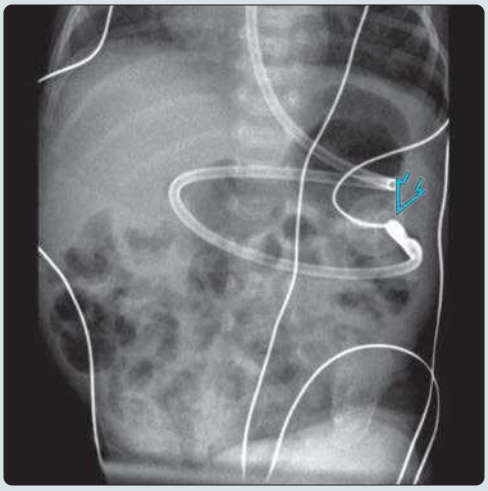
- LOT is not directly depicted on any imaging study
- LOT position is inferred by imaging depictions of duodenum, duodenojejunal junction (DJJ), & proximal jejunum
- Guidelines for normal position of duodenum & DJJ
  - Supine upper GI: DJJ at or leftward of left vertebral pedicle & nearly as craniad as duodenal bulb
  - Lateral upper GI: D2-D4 overlap posteriorly close to spine; DJJ superimposes on or adjacent to duodenal bulb
  - US/CECT/MR: D3 crosses midline to left between superior mesenteric artery (SMA) & aorta; DJJ lies near same vertical level as duodenal bulb; SMA lies left & posterior of superior mesenteric vein



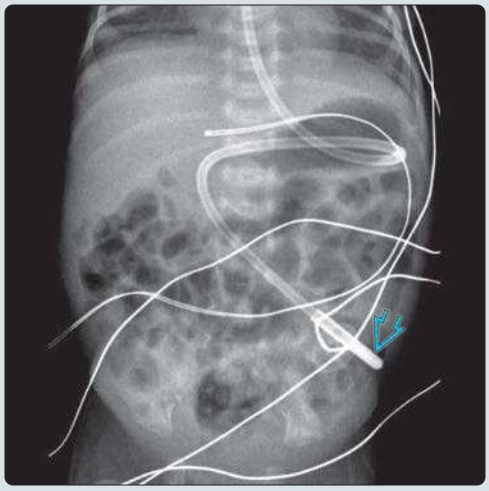
TOP DIFFERENTIAL DIAGNOSES

- True malrotation
- Artifactual displacement of normal DJJ
  - By mass or organomegaly
  - By bowel dilation
  - By enteric tube
- Redundant duodenum
- Duodenum inversum

CLINICAL ISSUES



- Treatment: None for normal variations
  - Importance lies in distinguishing normal variant from malrotation, which can predispose to life-threatening midgut volvulus



(Left) *Supine image from an upper GI shows an abnormal position of the duodenojejunal junction (DJJ) & proximal small bowel (SB) in the right upper quadrant, highly suggestive of malrotation. However, the child was not malrotated but had splenomegaly displacing the DJJ & SB.* **(Right)** *Coronal STIR MR in the same patient shows splenomegaly & a small, cirrhotic liver. The combination of the large spleen & small liver has shifted the proximal bowel into the right upper quadrant, mimicking malrotation.*

(Left) *AP radiograph in a 4-week-old infant with a nasojejunal feeding tube placed several days before this exam shows the tip of the tube at the laterally deviated DJJ.* **(Right)** *AP radiograph several hours later in the same infant shows that the tip of the tube (which denotes the position of the DJJ) has moved inferiorly, not due to malrotation but likely due to the torque of the tube & the pliability of the ligament of Treitz (LOT), which has both muscular & fibrous components.*

TERMINOLOGY

Abbreviations

- D1-D4: 1st-4th duodenal segments

Definitions

- Ligament of Treitz (LOT): Combination of muscle & fibrous tissue; normal position implies normal midgut rotation & fixation, low risk of midgut volvulus
  - Upper portion of LOT (Hilfsmuskel) is attached to diaphragmatic crus near esophageal hiatus; skeletal muscle & fibrous tissue component attaches to celiac axis
  - Lower portion of LOT (suspensory muscle of duodenum) inserts at duodenojejunal junction (DJJ) & has fibrous connection to celiac axis
  - Function
    - Involved in process of normal bowel rotation
    - With contraction, suspensory muscle of LOT widens angle of duodenojejunal flexure, allowing movement of intestinal contents

IMAGING

General Features

- Location
  - LOT is not directly depicted on any imaging study
  - LOT position is inferred by imaging depictions of duodenum, DJJ, & proximal jejunum
    - Normal DJJ is suspended by LOT: Attached craniad by diaphragmatic crus near esophageal hiatus & DJJ in left upper quadrant of abdomen
- Morphology
  - LOT is very pliable structure
    - Composed, at least partly, of muscle
    - Normal position of DJJ can be displaced by organomegaly, mass, adjacent bowel distention, or enteric tubes
  - Normal duodenum may have variant courses leading up to normal DJJ

Fluoroscopic Findings

- Upper GI
  - Supine image
    - DJJ at or leftward of left vertebral pedicle
    - DJJ nearly as craniad as duodenal bulb
  - Lateral image
    - D2-D4 course posteriorly, nearly overlap anterior to spine
      - Cannot confirm true retroperitoneal position on upper GI
    - DJJ superimposes on or adjacent to (as craniad as) duodenal bulb

Ultrasonographic Findings

- Does not visualize exact DJJ position
- Normal midgut rotation is implied if
  - D3 crosses midline to left between aorta & superior mesenteric artery (SMA)
    - Not seen with malrotation
  - Normal SMA lies to left & slightly posterior to superior mesenteric vein
    - Some false-positives & false-negatives

CT Findings

- Multiplanar CECT reconstructions can demonstrate normal retroperitoneal D3 course between aorta & SMA + appropriate height of DJJ in many cases

DIFFERENTIAL DIAGNOSIS

True Malrotation

- Abnormal DJJ position
- ± duodenal dilation/obstruction (Ladd bands or midgut volvulus)
- Cross-sectional imaging in difficult cases: Assess D3 course in relation to aorta & SMA
  - US can be reassuring, but 100% reliability is debated; requires time & expertise to demonstrate D3 relative to SMA

Artifactual Displacement of DJJ

- By gastrojejunostomy or nasojejunal tube
- By adjacent solid or cystic abdominal mass
- By organomegaly (liver, spleen, kidney)
- By adjacent dilated viscus
  - Obstructed jejunal, ileal, or colonic loops
  - Marked gastric distention can displace DJJ caudally

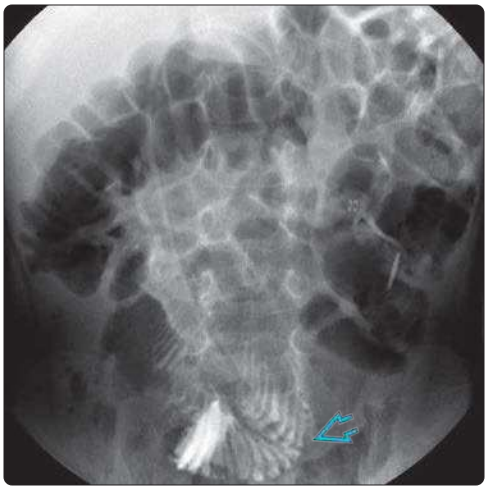
Redundant/Wandering Duodenum

- D2-D4 segments may be long & redundant, ultimately passing to left of spine to normal DJJ position

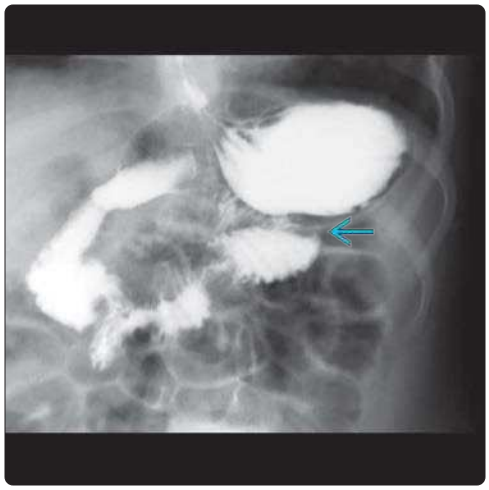
Duodenum Inversum

- Duodenum descends & ascends right of spine before coursing left to normally located DJJ
  - If D3-D4 traverses left above L1 level across gastric body, likely abnormal but not typical malrotation
    - Susceptible to duodenal obstruction & compression by adjacent structures, not volvulus
  - If D3-D4 courses to left below L1 level to normal DJJ, likely lies between aorta & SMA with normal rotation

CLINICAL ISSUES



Treatment



- None for normal variations
- Importance lies in distinguishing from malrotation, which can predispose to life-threatening midgut volvulus

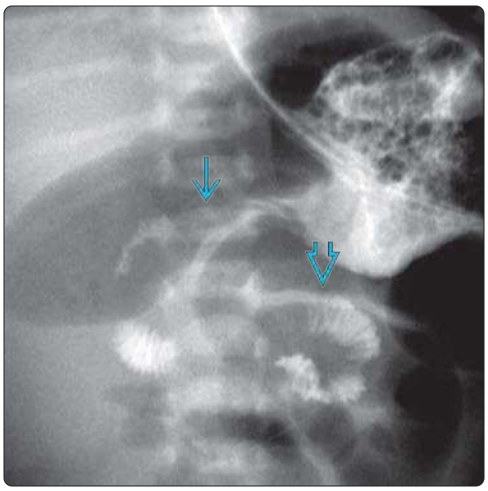
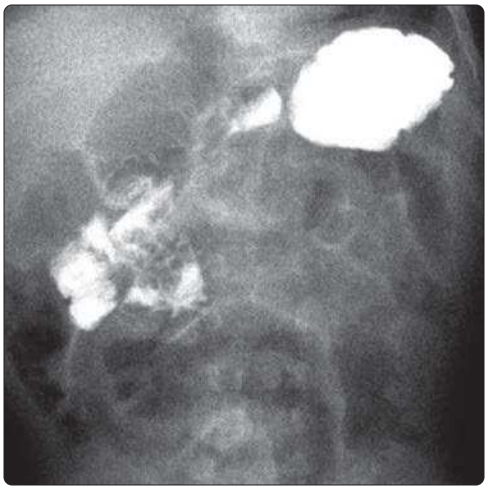
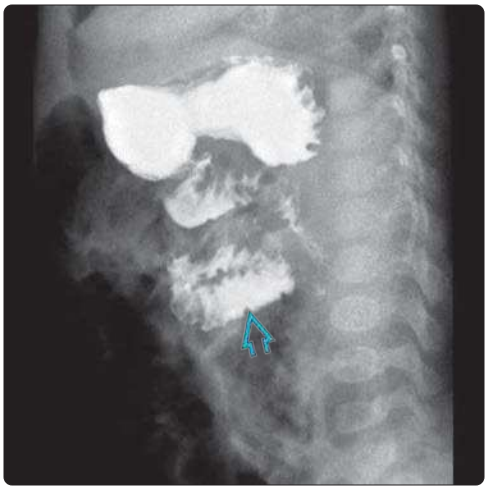
(Left) *Supine frontal radiograph during contrast injection to check the function of a gastrojejunostomy (GJ) tube shows the tip of the tube ⇨ at the DJJ, which is in the pelvis. One might conclude that the bowel must be malrotated to create this appearance.* **(Right)** *Supine upper GI image in the same patient prior to the GJ tube placement shows a normal location of the DJJ ⇨. Tubes frequently alter the DJJ position due to the pliability of the LOT, potentially displacing the DJJ anywhere in the abdomen.*

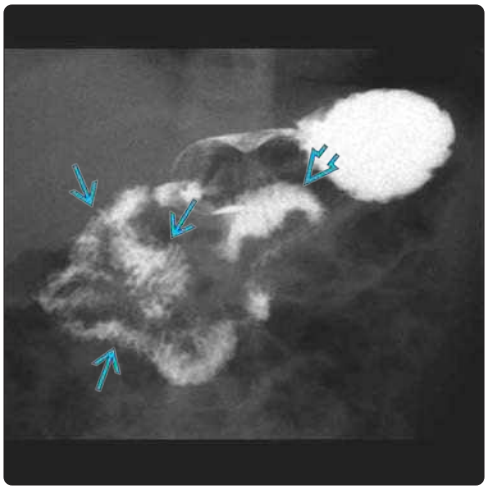


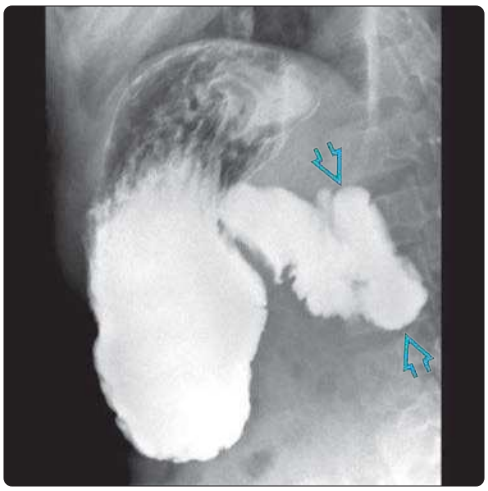
(Left) *Lateral upper GI image in a 17-year-old girl with abdominal pain & nausea shows significant redundancy of the retroperitoneal D2 & D3 segments ⇨.* **(Right)** *Supine frontal upper GI image in the same patient shows that the D2 & D3 segments ⇨ are to the right of the spine, a configuration known as duodenum inversum. Note that the remainder of the duodenum is redundant as well but courses to the left ⇨ to reach a normal DJJ ➡.*

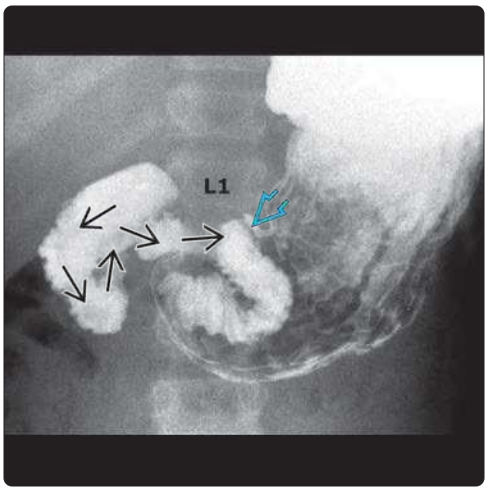


(Left) *Supine frontal upper GI image in a 2-day-old with bilious emesis shows a low position of the DJJ ⇨ compared to the duodenal bulb ⇨. This appearance is likely related to the dilated, air-filled distal bowel loops seen in the background. Such dilated loops can displace the DJJ.* **(Right)** *Supine scout fluorograph in the same patient shows the multiple, dilated, air-filled bowel loops of a congenital intestinal obstruction. Such loops can displace the DJJ & simulate malrotation.*









(Left) *Lateral upper GI image in a 2-month-old boy with failure to thrive & recurrent nonbilious vomiting shows the typical D2 retroperitoneal segment ⇨. (Right) Supine frontal upper GI image in the same patient shows that, as the contrast progresses, multiple redundant loops of the duodenum are seen to the right of the spine, suggestive of malrotation without obstruction.*

(Left) *Lateral upper GI image taken later in the same study shows the more distal loops coursing anteriorly ⇨, suggesting an intraperitoneal location of segments D3 & D4. (Right) Final supine upper GI image shows a loop of SB coursing to the expected region of the LOT ⇨. The proximal loops ⇨ appeared too long to be normal duodenum. At surgery, the duodenum was normally fixed at the LOT, consistent with a wandering duodenum.*

(Left) *Lateral upper GI image in a 9-year-old with recurrent nonbilious emesis, nausea, & abdominal pain shows a normal retroperitoneal duodenum ⇨. (Right) Supine frontal upper GI image in the same patient shows a redundant course ⇨ of the D2 & D3 segments to the right of the spine (duodenum inversum). The duodenum then courses to the left at the L2 level (likely between the aorta & SMA with the SMA takeoff usually at L1) to the DJJ ⇨ at the left pedicle, a normal variant course.*

Normal Variations of Cecal Position

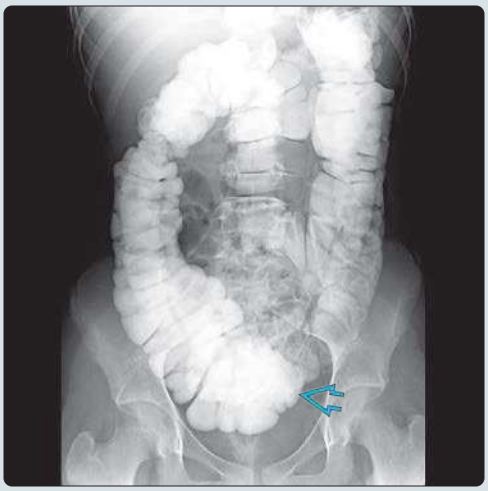
KEY FACTS

TERMINOLOGY

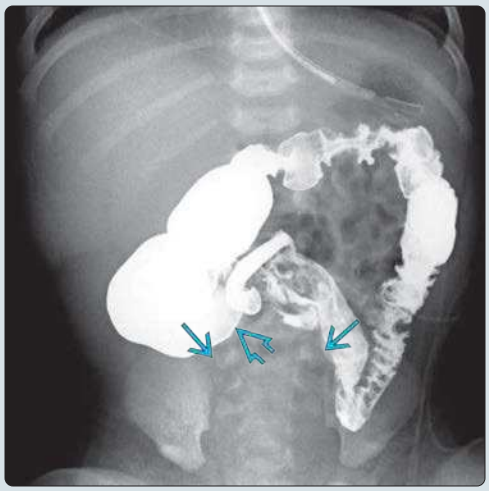
- Clinical significance of cecal position
  - Often abnormal in malrotation
    - If adjacent to duodenum, suggests short mesenteric pedicle → ↑ risk of midgut volvulus (whether or not duodenal malrotation is present)
  - If air-filled, essentially excludes ileocolic intussusception
    - Best seen with left side down decubitus position
  - In evaluation for appendicitis, appendix location follows cecum
  - Inflamed cecum (due to ruptured appendicitis) deep in pelvis can mimic abscess

IMAGING

- Fluoroscopy [contrast enema or small bowel follow-through (SBFT)]
  - Cecum can be high, low in pelvis, or medially directed
    - Often above iliac fossa in young children
    - Pelvic location is common in older children
    - High & medial position raises concern for shortened mesenteric attachment
  - If sigmoid extends into right abdomen → craniad displacement of cecum
- Protocol advice
  - If questionably abnormal duodenal rotation on upper GI, get SBFT & delayed images until sure of cecal position
  - If abnormal cecal position is suggested on SBFT, evaluate entire colon with delayed images

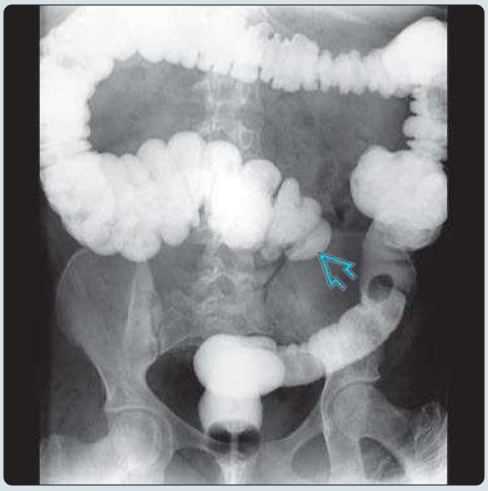


TOP DIFFERENTIAL DIAGNOSES

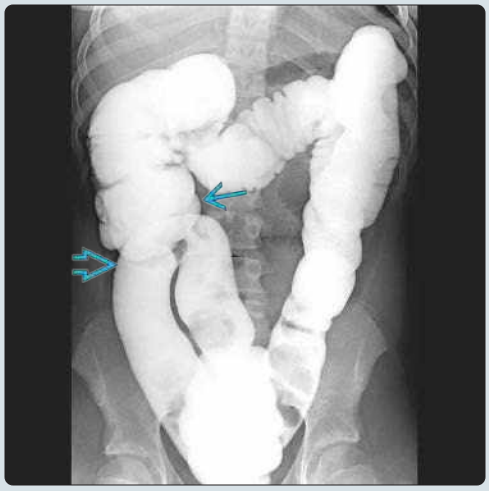


- Malrotation
- Internal hernia
- Postoperative appearance of Malone appendicostomy

DIAGNOSTIC CHECKLIST



- Likely normal variation if cecum is slightly high, low, or medially directed with normal position of remaining right colon



(Left) *Supine contrast enema in a teenager with a history of constipation shows the proximal colon in the deep pelvis with the cecal tip lying left of midline, such that the appendix could potentially lie on the left rather than the right. This is a variation of normal cecal position.* **(Right)** *Delayed supine small bowel follow-through (SBFT) colonic image in a 4- week-old shows a medially directed cecum that was noted to be mobile in comparison to a preceding contrast enema (not shown). The full bladder may also contribute.*

(Left) *Supine contrast enema in a teenager with a history of an anorectal malformation & a Malone appendicostomy for bowel management shows surgical mobilization of the cecum medially to allow the appendix to reach the umbilicus.* **(Right)** *Supine contrast enema in a 12-year-old with chronic constipation shows a long, redundant right-sided sigmoid colon with elevation of the cecum, a normal variant. On postevacuation images (not shown), the cecum was more caudally located (as expected).*

TERMINOLOGY

Definitions

- Slight mobility of fixed cecum, allowing variation in position
- Various factors can affect cecal position
- Clinical significance of cecal position
  - Often abnormal in malrotation
    - If adjacent to duodenum → short mesenteric pedicle → ↑ risk of midgut volvulus (whether or not duodenal malrotation is present)
  - If completely air-filled, excludes ileocolic intussusception
    - Best seen on left side down decubitus position
  - In imaging for appendicitis, appendix follows cecal position

IMAGING

General Features

- Best diagnostic clue
  - Mild high position of cecum on
    - Contrast enema or small bowel follow-through (SBFT)
    - US (typically when looking for appendix or terminal ileum)
- Location
  - Proximal colon, right lower quadrant (RLQ) of abdomen
  - Cecum may be high, medially directed, or deep in pelvis
    - Often mildly high (above iliac fossa) but remaining lateral in infants
- Size
  - Large in chronic illnesses
    - Myelomeningocele, cerebral palsy, other neurologic impairment; chronic constipation
    - ↑ risk of cecal volvulus
- Morphology
  - Minimally bulbous relative to ascending colon
  - Appendix emanates from inferior medial surface

Radiographic Findings

- Air- & stool-filled cecum
- RLQ extension of sigmoid colon is normal in 44%, may displace cecum craniad
  - RLQ sigmoid may mimic cecum
  - Relevant in patients with possible acute pathology
    - Misinterpreted as cecum, falsely excluding ileocolic intussusception
    - Not expecting pain from appendix in RUQ

Fluoroscopic Findings

- Cecum is located in RUQ, medially directed, or low

US/CT/MR Findings

- Find appendix or terminal ileum, trace to cecum
  - Locate relative to iliac vessels/iliac fossa
  - Stool- & air-filled proximal colon in RLQ
- Inflamed cecum deep in pelvis (due to ruptured appendicitis) can be mistaken for abscess

Imaging Recommendations

- Protocol advice
  - SBFT or contrast enema may complement evaluation for malrotation if duodenal position is unclear on upper GI: Look for abnormal cecal position (especially high & medial)
  - If cecal position is abnormal on SBFT, evaluate entire colonic position
    - With normal position of remainder of right colon, consider normal variation
    - If sigmoid extends to right, likely high normal cecum
  - If cecum lies in left abdomen or high midline → malrotation
  - Comparison with prior exams may reveal whether cecal position is fixed or mobile
    - Slight mobility can be normal variant
  - If small bowel lies along right lateral abdomen with medial right colon, consider malrotation, laxity of attachments, internal hernia, or prior surgery

DIFFERENTIAL DIAGNOSIS

Malrotation

- Look for abnormal relationships of superior mesenteric artery (SMA) to superior mesenteric vein (SMV), 3rd duodenum to SMA, duodenojejunal junction (DJJ) relative to spine & duodenal bulb

Internal Hernia

- Pericecal hernia shows small bowel loops posterior & lateral to cecum in right paracolic gutter

Postoperative Appearance of Malone Appendicostomy

- Surgical mobilization of cecum to facilitate use of appendix for catheterization for cecal irrigation

CLINICAL ISSUES

Natural History & Prognosis

- Cecal positions that are usually of no clinical significance
  - Mildly high but lateral, particularly in infant
  - Deep in pelvis
- High & medial, ± malpositioned DJJ, can predispose to volvulus
  - Short mesenteric attachment

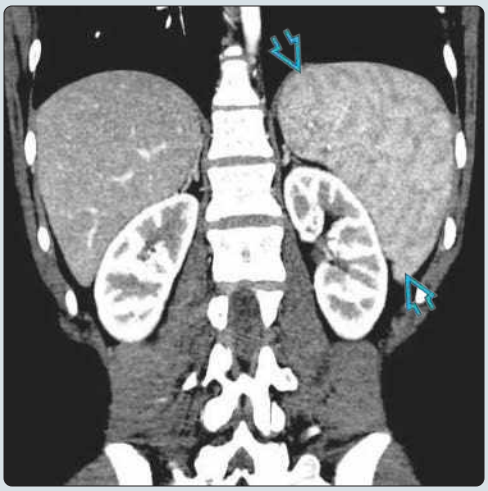
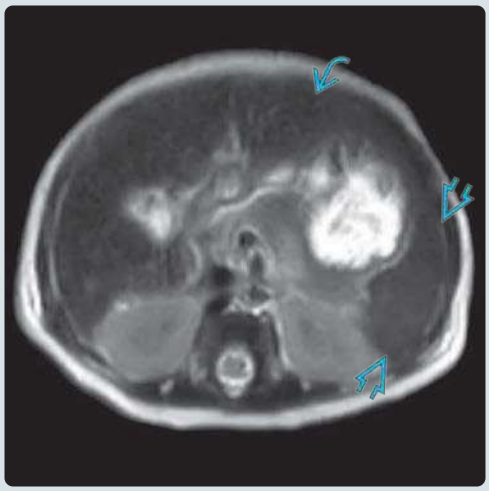
Age-Related Appearance of Spleen

KEY FACTS

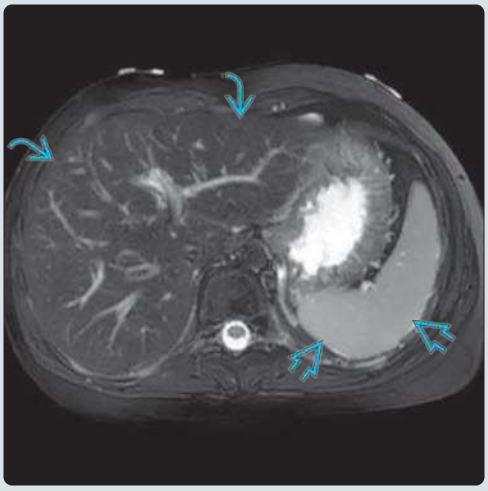


IMAGING



- Substantial changes occur in appearance of normal spleen during early childhood
  - Related to evolving white pulp:red pulp volume ratios
  - Normal spleen ↑ in size with age
- Normal MR signal
  - Older child & adult: T2 hyperintense vs. liver
  - Neonate: T2 iso- or hypointense vs. liver
  - Normal adult T2 appearance occurs by ~ 8 months of age
  - DWI: Restricts diffusion with ↑ signal relative to liver
    - Degree of diffusion restriction ↑ with age (↓ ADC values)
- CECT/MR
  - Transient patterns of heterogeneous enhancement occur when spleen is imaged in arterial phase
    - Should become homogeneous on more delayed phases of imaging
  - Seen in most children ≥ 1 year during arterial phase
    - Less common < 1 year of age due to white pulp:red pulp ratios
  - Patterns of normal splenic heterogeneity include
    - Archiform (alternating curvilinear & undulating bands)
    - Zebra stripe
    - Focal
    - Diffusely heterogeneous
- Ultrasound
  - Homogeneous, iso- to slightly hyperechoic relative to liver
  - Hypoechoic bands are rarely seen
  - High-resolution transducers may show reticulonodular pattern

PATHOLOGY



- Neonates & young infants have immature, small lymphoid follicles with relatively large red pulp volume
  - Accounts for changes in CT & MR appearances with age

(Left) *Coronal CECT in a 15-year-old boy demonstrates a normal transient pattern of heterogeneous splenic enhancement that is often seen when normal spleens (in children > 1 year of age) are imaged in the 1st minute after IV contrast injection (i.e., arterial or early phase).* **(Right)** *Axial T2 SSFSE MR in a 7-day-old girl being evaluated for an abdominal mass (not shown) demonstrates that the normal spleen is nearly isointense relative to the liver. This splenic appearance is due to a relatively high volume of red pulp at this age.*

(Left) *Axial T2 FS MR in a 9-year-old patient undergoing MR enterography shows that the normal spleen is hyperintense relative to the liver. This change in appearance as compared to the neonate/young infant is due to an adult complement of white pulp.* **(Right)** *Axial DWI MR (b=800) of the abdomen in an 18-year-old patient undergoing MR enterography shows homogeneous hyperintense signal of the normal spleen relative to the liver.*

TERMINOLOGY

Definitions

- Spleen consists of red pulp & white pulp
  - White pulp: Reticuloendothelial cells organized into lymphoid follicles (or bodies)
  - Red pulp: Vascular sinusoids

IMAGING

CT Findings

- Transient patterns of heterogeneous splenic enhancement occur when patient is imaged in arterial (early) phase after IV contrast
  - Probably due to uneven blood flow through red & white pulp
  - Less commonly encountered in children < 1 year old
- Patterns of normal heterogeneous enhancement are variable
  - Archiform (alternating curvilinear & undulating bands of low & high attenuation)
  - Zebra stripe
  - Focal
  - Diffusely heterogeneous
- Enhancement becomes homogeneous on portal venous & delayed phases

MR Findings

- T1WI
  - Neonate: Spleen is isointense to liver
  - Older child & adult: Mildly hypointense to liver
  - Normal adult appearance occurs by ~ 1 month of age
- T2WI
  - Neonate: Hypointense or isointense to liver
  - Older child & adult: Hyperintense to liver
  - Normal adult appearance occurs by ~ 8 months of age
- DWI
  - Normal spleen restricts diffusion: ↑ signal relative to liver
    - Corresponding ↓ signal on ADC
  - Degree of diffusion restriction ↑ with age (↓ ADC values)
    - Spleen remains hyperintense relative to liver on DWI through adulthood
- T1WI C+
  - Heterogeneous enhancement is normal on arterial phase (similar to CECT)
    - Becomes homogeneous on later phases

Ultrasonographic Findings

- Red pulp & white pulp differences are not typically visualized
  - Normal spleen appears homogeneous in majority
    - Hypoechoic bands are rarely seen
    - High-resolution transducers may show reticulonodular pattern
  - Iso- to slightly hyperechoic relative to liver
- Age-specific normal values for spleen length are available
  - Ranges between 3.2 cm (neonate) → 12.5 cm (17-year-old boy)

DIFFERENTIAL DIAGNOSIS

Abnormal Low T2 MR Signal Intensity of Spleen

- Iron overload
  - Primary or secondary hemochromatosis; look at liver & pancreas as well
- Postchemotherapy appearance
  - Can result in low white pulp:red pulp ratio with hypointense T2 signal of spleen
- Diffuse Ca^{2+}
  - Occasionally seen in sickle cell disease with chronically infarcted spleen

Transient Heterogeneous Splenic Enhancement

- Laceration
  - Typically more focal & linear or irregular; + perisplenic hematoma & history of trauma
- Lymphoma/lymphoproliferative disorder
  - Discrete round & mass-like lesions
  - ± splenomegaly
- Infarction
  - Peripheral, wedge-shaped hypoenhancing areas
- Fungal infection
  - Numerous tiny, hypoenhancing lesions
- Sickle cell disease
  - Preserved round islands of normal splenic tissue within infarcted spleen

PATHOLOGY

General Features

- During 1st year of life, spleen undergoes histologic changes as lymphoid system matures
- Neonates have immature, small lymphoid follicles
  - ↓ white pulp & ↑ red pulp compared to adults
  - ↑ red pulp accounts for lower T2 MR signal of spleen in neonates
- By ~ 8 months of age, white pulp:red pulp ratios have ↑, giving rise to adult appearance
- Differential blood flow through cords of white & red pulp is likely reason for heterogeneous splenic enhancement on arterial-phase imaging
  - Relative lack of white pulp in neonates may explain why heterogeneous arterial enhancement is less common < 1 year of age

Malrotation

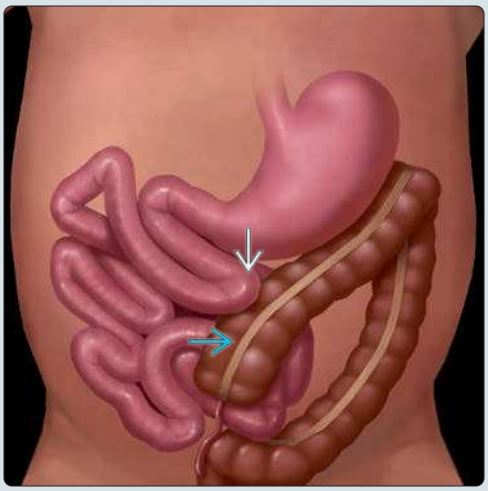
KEY FACTS

TERMINOLOGY

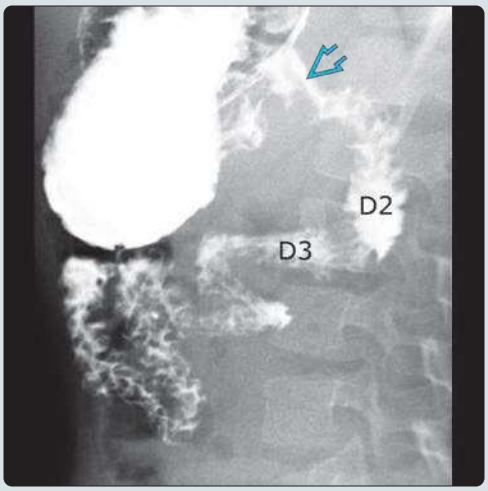
- Malrotation: Any abnormal rotation of small or large bowel, which rotate separately during development
- Rotation of duodenum/small bowel & cecum/large bowel are similar but differ in timing
  - Abnormalities of rotation may be either or both

IMAGING

- Fluoroscopic GI findings
  - D3 segment never crosses midline on frontal view, often extends anteriorly on lateral view of upper GI
    - Duodenojejunal junction (DJJ) lies to right of left pedicle & below duodenal bulb on true frontal view
  - Variable degrees of colonic malrotation with abnormal cecal position on enema or small bowel follow-through (SBFT)
- Cross-sectional (US/CT/MR) findings
  - Duodenal nonrotation: D3 segment of duodenum fails to pass between superior mesenteric artery (SMA) & aorta when crossing to left of midline
  - Reversal of normal SMA/superior mesenteric vein position (not reliable)
- Best imaging tool
  - Fluoroscopic upper GI vs. US is debated

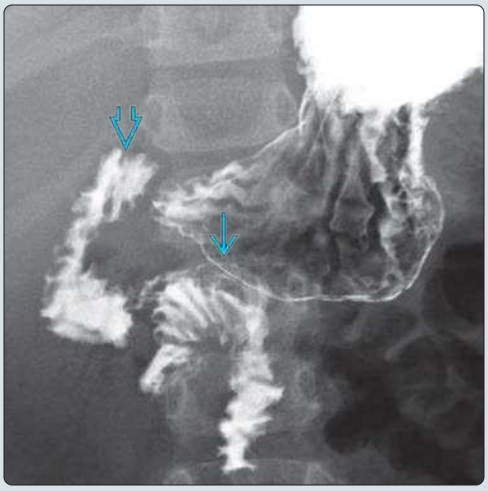


CLINICAL ISSUES

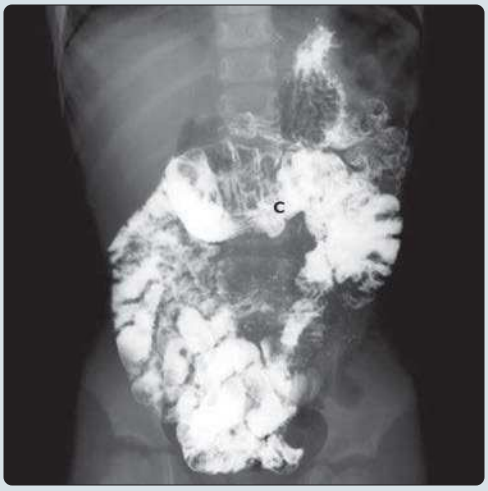


- Presentation in children: Nonbilious or bilious emesis, recurrent abdominal pain, poor weight gain, or asymptomatic

DIAGNOSTIC CHECKLIST



- If upper GI is equivocal, obtain SBFT; document cecal position & estimate length of pedicle from DJJ to cecum (which determines risk for midgut volvulus)
  - Alternatively, consider US evaluation of D3/SMA



(Left) *Anterior graphic shows abnormal positions of the small & large bowel. The duodenojejunal junction (DJJ) lies low & midline, very close to the malpositioned cecum. This results in a short mesenteric fixation that predisposes to midgut volvulus (MGV).* **(Right)** *Lateral upper GI in a 3-year-old child with a history of nonbilious vomiting shows an anterior, intraperitoneal course of the D3 segment with a low position of the DJJ below the duodenal bulb, indicating abnormal rotation.*

(Left) *Supine frontal view of the same patient shows a low DJJ (below the duodenal bulb) that fails to adequately cross the midline, consistent with malrotation. However, there is no twisting or dilation of the duodenum to suggest MGV or obstructing Ladd bands.* **(Right)** *Supine SBFT was continued in the same patient to determine the cecal position & estimate the length of the mesenteric pedicle. The cecum (C) is high & just left of the midline, suggesting a very short mesenteric pedicle that is at high risk of future MGV.*

TERMINOLOGY

Synonyms

- Malfixation

Definitions

- Malrotation: Varying degrees of abnormal positioning of small &/or large bowel due to abnormal rotation during development
  - Small & large bowel rotate separately in utero
  - Abnormalities of rotation may affect either or both
- Malfixation: Abnormal position or length of bowel fixation by mesentery, typically associated with malrotation
  - Predisposes to midgut volvulus (MGV)

IMAGING

General Features

- Best diagnostic clue
  - Upper GI: Nonretroperitoneal position of duodenum + abnormal duodenojejunal junction (DJJ) position at or to right of midline
  - Cross-sectional imaging (US/CT/MR): Failure of D3 portion of duodenum to pass leftward between aorta & superior mesenteric artery (SMA)
  - Enema or cross-sectional imaging: Abnormal configuration of colon
- Location
  - Duodenum & right colon
- Morphology
  - Abnormal rotation of duodenum, colon, or both; degree of abnormality is quite variable (i.e., partial rotational anomalies)

Radiographic Findings

- Colon may be limited to left abdomen, small bowel in right abdomen

Fluoroscopic Findings

- Upper GI
  - D3 segment never crosses midline; often extends anteriorly on lateral view
  - DJJ to right of left pedicle on true frontal view
    - True frontal view
      - Right & left ribs are equal length
      - Base of heart lies in anatomic position
      - Vertebral pedicles appear symmetric
  - Jejunum often lies in right abdomen
  - ± abnormal cecal position
  - ± bowel obstruction due to Ladd (peritoneal fibrous) bands or MGV
- Contrast enema
  - Variable degrees of colonic malrotation
    - High &/or midline cecum of partial rotation
    - Left-sided colon of nonrotation
    - Anything in between

Ultrasonographic Findings

- D3 segment of duodenum fails to pass between SMA & aorta to left of midline
- Reversal of normal SMA/superior mesenteric vein (SMV) position (not reliable)
- Dilated proximal duodenum from Ladd bands or MGV

CT Findings

- Malposition of intestine from expected location
  - Duodenal nonrotation: D3 segment fails to pass between SMA & aorta to cross left of midline
    - Duodenal partial rotation: D3 passes between SMA & aorta but abruptly turns right, coursing anterior or posterior to SMA
  - Nonrotated colon: Right colon in left lower abdomen
  - Partially nonrotated colon: Cecum in upper abdomen
- Reversal of normal SMA/SMV position (not reliable)
- ± bowel obstruction due to Ladd (peritoneal fibrous) bands or volvulus

MR Findings

- Similar to CT findings

Imaging Recommendations

- Best imaging tool
  - Fluoroscopic upper GI through DJJ
- Protocol advice
  - If upper GI is equivocal for malrotation, perform small bowel follow-through (SBFT)
    - Determine exact location of cecum; be confident, wait for adequate filling of cecum
    - Shorter distance from DJJ to cecum → shorter mesenteric attachment → ↑ risk of volvulus
  - Normal position of DJJ can be displaced due to lax ligament of Treitz in infants
    - Adjacent dilated bowel of distal bowel obstruction
    - Adjacent masses, cysts, organomegaly
    - Enteric tube may distort duodenum

DIFFERENTIAL DIAGNOSIS

Duodenum Inversum

- Duodenum descends & ascends right of spine before coursing left to normally located DJJ
  - If D3-D4 traverses left above L1 level across gastric body, likely abnormal but not typical malrotation
    - Susceptible to duodenal obstruction & compression by adjacent structures, not volvulus

Redundant (Wandering) Duodenum

- D2-D4 segments may be long & redundant, ultimately passing to left of spine to normal DJJ position

PATHOLOGY

General Features

- Etiology
  - Failure of normal embryonic 270° counterclockwise rotation of midgut & colon, resulting in malposition of bowel to varying degrees
  - Ladd (peritoneal fibrous) bands attempt to fix abnormal duodenal &/or colonic positions
    - Potentially lead to extrinsic obstruction or volvulus
- Associated abnormalities
  - Malrotation is almost always seen with left-sided Bochdalek congenital diaphragmatic hernia, gastroschisis, & omphalocele

- Malrotation is commonly associated with duodenal atresia spectrum (including stenosis & web), small bowel atresia & stenosis, heterotaxia syndromes (asplenia & polysplenia), biliary anomalies, megacystis-microcolon-intestinal hypoperistalsis syndrome
- Less common: Intestinal pseudoobstruction, Meckel diverticulum, Hirschsprung disease, anorectal malformation, absent kidney & ureter

Staging, Grading, & Classification

- Several types of malrotation
  - Complete nonrotation
  - Nonrotated duodenum & partially rotated colon
  - Isolated nonrotated duodenum
  - Partially rotated duodenum & colon
  - Isolated partially rotated duodenum
  - Isolated partially rotated colon
- Bottom line: Length of mesenteric fixation from DJJ to cecum determines risk for MGV

Gross Pathologic & Surgical Features

- Ligament of Treitz: Actually muscle that can stretch
- Ladd bands can occur anywhere, frequently across D2 or D3 to liver hilum

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Children: Nonbilious or bilious emesis, recurrent abdominal pain, poor weight gain, or may be asymptomatic
  - Adults: Nonspecific → chronic vomiting, intermittent colicky abdominal pain, diarrhea
    - ± acute abdomen

Demographics

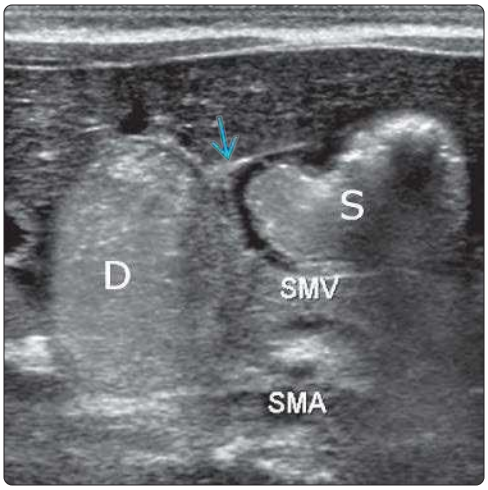
- Age
  - Majority present in 1st month of life
  - Vast majority present by 1st few years of life
  - Can present into adulthood
- 1/200 live births have asymptomatic rotational anomaly
- 1/6,000 live births have symptomatic malrotation
- M:F = 2:1
- > 33% are associated with congenital anomaly
- Patients with congenital diaphragmatic hernia, gastroschisis, & omphalocele are almost always malrotated but rarely volvulize (due to postoperative adhesions)

Natural History & Prognosis

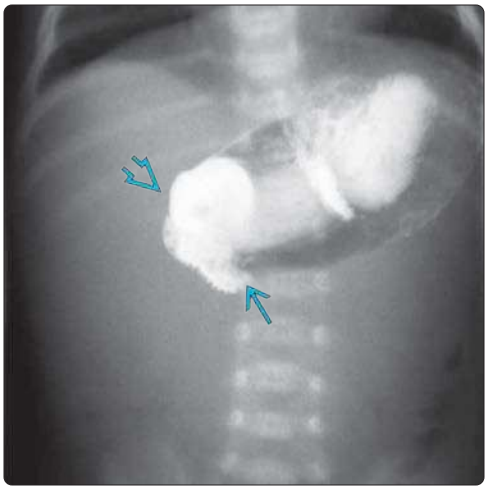
- Complications of malrotation
  - MGV: Twisting of midgut about SMA → vascular occlusion & potential bowel ischemia
  - Bowel obstruction due to Ladd bands: Obstruction can be anywhere but can mimic MGV clinically & on fluoroscopic upper GI
  - Internal hernia: Rare, usually due to duodenal malrotation with normal colonic rotation
    - Sac-like mass of malfixed bowel herniates posterior to right colic vein into right upper quadrant

Treatment

- Ladd procedure
  - Untwist volvulus if present
  - Divide Ladd bands if present
  - Reposition small & large intestine into right & left abdomen, respectively
    - Postoperative adhesions are expected to secure bowel in place
  - ± appendectomy
  - Laparoscopy vs. laparotomy
    - Laparoscopic Ladd procedure results in ↓ perioperative complications & faster recovery but may yield ↑ risk of postoperative volvulus compared to open approach (due to fewer adhesions)



DIAGNOSTIC CHECKLIST



Consider

- Normal variants of duodenal anatomy or secondary causes of displacement resulting in fluoroscopic false-positive for malrotation
- If upper GI is equivocal for malrotation, obtain SBFT & document cecal position to estimate length of mesenteric pedicle of fixation (DJJ to cecum)
  - Alternatively, consider US to evaluate D3 position relative to SMA

(Left) *Oblique pyloric ultrasound in an 18-day-old with projectile nonbilious vomiting shows a dilated stomach (S) with a normal pylorus ⇨. There is a dilated duodenum (D), & the SMV lies directly anterior to the SMA, an abnormal configuration frequently seen in patients with malrotation.* **(Right)** *Supine upper GI in the same patient shows a dilated, obstructed duodenum ⇨ up to a "beak" ⇨ at D2-D3; this appearance represents MGV until proven otherwise (though only Ladd bands were found in this case).*

(Left) *Supine water-soluble contrast enema in a 5-week-old, former 31-weeks-gestation premature infant shows a high midline cecum ⇨ with at least partial colonic malrotation. The small bowel dilation & small-caliber colon may be due to an intervening stricture from prior necrotizing enterocolitis.* **(Right)** *Supine upper GI in the same patient shows normal duodenal rotation. If a line was drawn between the DJJ ⇨ & cecum ⇨, the estimated mesenteric pedicle length would appear very short, ↑ the risk of future MGV.*

(Left) *Supine upper GI in a 2-year-old boy (who had malrotation corrected by a Ladd procedure at 6 days of age) presenting with abdominal pain & intermittent diarrhea shows malrotation without duodenal obstruction, a satisfactory postoperative appearance.* **(Right)** *Supine upper GI in a 13-year-old patient with new bilious emesis 6 days status post Ladd procedure for malrotation shows a dilated duodenum with a beak-like configuration ⇨ worrisome for MGV. In the OR, incompletely lysed bands were found.*

Midgut Volvulus

KEY FACTS

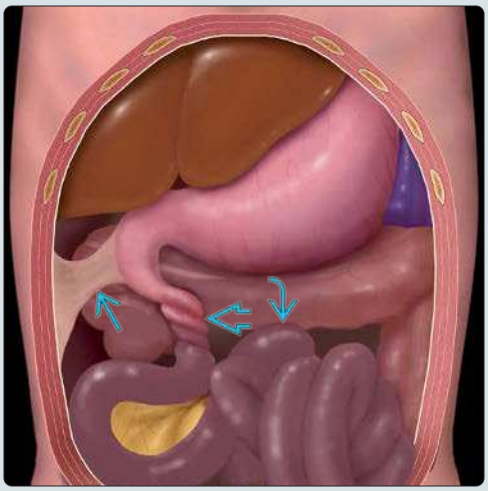
TERMINOLOGY

- Malrotation: Abnormal rotation & fixation of small bowel (SB) mesentery that can lead to complications, including
  - Midgut volvulus (MGV): Abnormal twisting of SB & veins about superior mesenteric artery (SMA) that can lead to bowel obstruction & ischemia/necrosis
  - Ladd bands: Abnormal, fibrous peritoneal bands that can also cause duodenal obstruction

IMAGING

- Radiographic appearance is often normal; may show
  - Proximal obstruction with mild/moderate distention of stomach & D1/D2 with minimal distal gas
  - Ischemic ileus in very ill children
- Upper GI: Dilated duodenum to D2-D3 segment with corkscrew/spiral sign just beyond duodenal "beak"
- US or CT: Whirlpool sign with clockwise twisting of bowel & veins around SMA
  - ± cutoff of SMV/SMA, ↓ bowel perfusion/enhancement

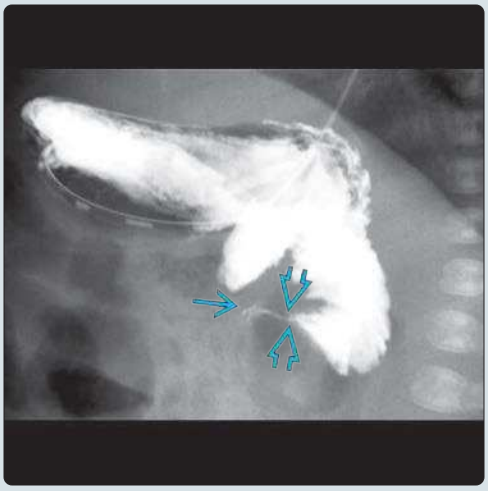
TOP DIFFERENTIAL DIAGNOSES



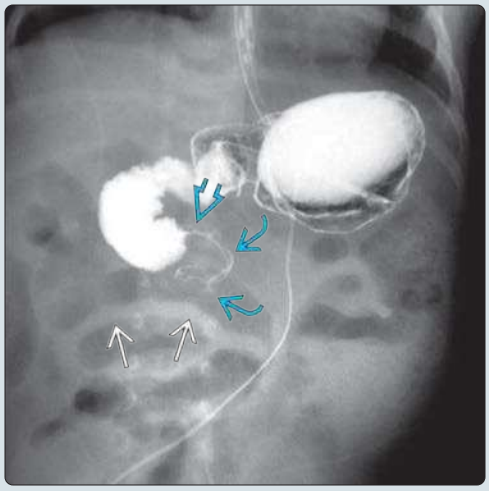
- Malrotation with obstructing Ladd band
- Various congenital duodenal obstructions
- Redundant duodenum

CLINICAL ISSUES

- Classic presentation: Infant with bilious vomiting
  - Requires emergent upper GI or US by experienced sonographer
- Treatment: Ladd procedure



DIAGNOSTIC CHECKLIST



- Complete obstruction on upper GI at D2-D3 with contrast beak is considered MGV until proven otherwise
  - Different from "double bubble" of duodenal atresia
  - US can help exclude MGV; otherwise, emergent surgery is required
    - Delayed diagnosis can lead to extensive bowel necrosis or death

(Left) *Graphic of midgut volvulus (MGV) shows a corkscrew or twisting ⇨ of the distal duodenum & proximal jejunum beyond a mildly distended proximal duodenum & stomach. Note the ischemic ileus of the small bowel ⇨ & the Ladd band ⇨ attached to the 2nd duodenum.* **(Right)** *AP radiograph shows a nonobstructive bowel gas pattern in an infant with bilious emesis who was ultimately found to have MGV by upper GI. The most frequent radiographic gas pattern in MGV is normal.*

(Left) *Lateral upper GI in a 3-day-old boy with bilious vomiting shows a dilated duodenum up to D3, which ends in a beak-like configuration ⇨ with a wisp of contrast pointing anteriorly ⇨, highly suggestive of MGV.* **(Right)** *Supine frontal upper GI in the same patient (a few seconds later) shows duodenal dilation & partial obstruction at D3 ⇨ with the corkscrew/spiral sign ⇨ of MGV. Thickened bowel wall ➡ in this context suggests bowel ischemia.*

TERMINOLOGY

Definitions

- Ligament of Treitz: Suspends duodenojejunal junction (DJJ), defines normal duodenal rotation
- Malrotation: Abnormal rotation & fixation of small bowel (SB) mesentery that can lead to complications, including
  - Midgut volvulus (MGV): Abnormal twisting of SB about superior mesenteric artery (SMA) that can lead to bowel obstruction & ischemia/necrosis
  - Ladd bands: Abnormal, fibrous peritoneal bands that can also cause duodenal obstruction
- Bilious vomiting: Green/yellow vomit, typically from obstruction of duodenum distal to ampulla of Vater

IMAGING

General Features

- Best diagnostic clue
  - MGV: Upper GI shows mildly to moderately dilated duodenum (usually through D2-D3 segment) with corkscrew or spiral sign at/distal to beak of obstruction
  - Whirlpool sign on US or CECT: Wrapping of SB, mesentery, & superior mesenteric vein (SMV) around SMA
- Morphology
  - Twisting of mesentery occurs about SMA, which can lead to venous obstruction, bowel wall ischemia, & necrosis
  - Ladd bands may cause bowel obstruction, especially of duodenum

Radiographic Findings

- Radiography
  - Most common early finding: Normal abdominal radiograph
  - Distended stomach & proximal duodenum with mild distal bowel gas is very suggestive but nonspecific
    - Usually does not show classic "double bubble" (marked bulbous proximal duodenal & stomach dilation without distal gas) as seen in longstanding in utero obstruction of duodenal atresia
  - May show diffuse bowel distention/ileus (late) from ischemia/necrosis
    - Such children are often extremely ill
  - Rarely pneumatosis, portal venous gas, free intraperitoneal air

Fluoroscopic Findings

- Upper GI
  - Dilated duodenum to D2-D3, ± to-&-fro motility due to obstruction
    - Degree of proximal duodenal dilation depends on chronicity
  - Often beaked appearance at level of twist, ± complete obstruction
  - Spiral/corkscrew appearance caudally, distal to beak
  - May see malrotation without MGV
    - In patients with bilious emesis, this may reflect intermittent volvulus
- Contrast enema
  - Not typically performed if there is high level of concern for MGV
  - Colon is often abnormally rotated with cecum in upper midline abdomen, ± obstruction of ileocecal region

Ultrasonographic Findings

- Stomach & proximal duodenum are usually dilated
- Abnormal course of D3 as it tapers anterior to SMA
  - Normally courses between SMA & aorta
- Transverse superior to inferior sweep of transducer in midline shows whirlpool sign of twisting distal duodenum/proximal jejunum, mesentery, & vessels (SMV) around SMA in clockwise fashion
  - Grayscale & Doppler are complementary
- Findings of ischemia
  - Bowel wall thickening, loss of SB perfusion, ascites
  - Pneumatosis: Foci of ↑ echogenicity within bowel wall circumferentially with "dirty" shadowing posteriorly
  - Portal venous gas: Punctate echogenic foci moving in portal vein(s) from liver hilum to periphery
    - Causes random spikes on spectral tracings

CT Findings

- CECT
  - Clockwise twisting (whirlpool sign) of SMV, bowel, & mesentery around SMA
  - Potentially ↓ or no enhancement of SB due to obstruction of SMV/SMA
    - ± frank cutoff of SMV & SMA at twist
  - May have SB distention due to ischemic ileus
  - Rare: Pneumatosis, portal venous gas, free peritoneal air

Imaging Recommendations

- Best imaging tool
  - Infant with bilious vomiting → emergent upper GI vs. US
  - SB follow-through (SBFT) or contrast enema may be helpful to confirm malrotation if no volvulus is seen
    - Shorter mesenteric base (DJJ to cecal distance) ↑ risk of volvulus
- Protocol advice
  - Upper GI in infants with bilious emesis
    - Place nasogastric tube
    - Aspirate as much fluid & air from stomach as possible prior to instilling contrast
    - Inject 10 mL of contrast into stomach in right lateral decubitus position
    - If not emptying into duodenum, inject small puffs of air behind contrast to promote gastric emptying
    - If volvulus is seen, immediately notify referring clinicians
      - Longer time interval from diagnosis to operation makes intestinal ischemia & bowel loss more likely
    - Document duodenum in lateral & AP positions as per upper GI otherwise
  - US to exclude MGV in infants with bilious emesis
    - Trace course of duodenum from pylorus to D4 if possible
    - Trace superior to inferior course of SMV & SMA as far as possible
    - May need to scan at angle off of midline or alter patient position to keep bowel gas from obscuring view

DIFFERENTIAL DIAGNOSIS

Malrotation With Obstructing Ladd Bands

- May cause complete obstruction with beaking
- Cannot distinguish from MGV fluoroscopically if contrast does not pass beyond duodenal obstruction
  - US could help exclude MGV; otherwise, immediate surgery is required

Spectrum of Congenital Duodenal Obstruction

- Duodenal atresia, duodenal stenosis, annular pancreas, duodenal web
  - Atresia has double bubble sign: Marked stomach & proximal duodenal dilation with no distal gas
  - Stenosis or web usually has transition to normal distal duodenum & normal DJJ
    - Can mimic MGV fluoroscopically if contrast will not pass beyond obstruction

Redundant Duodenum

- Duodenum may make several retroperitoneal loops prior to extending leftward across spine to normal DJJ
- No duodenal dilation or obstruction

PATHOLOGY

General Features

- Etiology
  - With normal rotation, DJJ is positioned in left upper quadrant & cecum is positioned in right lower quadrant
    - Results in long, fixed mesenteric base between ligament of Treitz & cecum that keeps mesentery from twisting
  - If bowel is malrotated, DJJ to cecal length (mesenteric base) is short, predisposing to twisting (volvulus)
    - Wide range in degrees of malrotation
    - Complete nonrotation contribution is controversial; may be most common form in patients with MGV (if both DJJ & cecum lie in midline with short pedicle)
    - Isolated duodenal or colonic malrotation may also predispose to MGV
- Rarely, MGV has been reported in setting of normal rotation; some of these cases may be segmental volvulus
- Malrotation may also cause obstruction from
  - Ladd bands (abnormal fibrous peritoneal bands)
  - Paraduodenal hernias

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Classic presentation: Bilious vomiting in 1st month of life
    - But can occur at any age, even adulthood
- Other signs/symptoms
  - Acute abdominal pain
  - Intermittent, crampy abdominal pain
  - Failure to thrive
  - Shock

Demographics

- Age
  - 39% present within first 10 days of life
  - > 90% present within first 3 months of life
  - Can occur at any age
- Sex
  - Slightly higher incidence in boys
- Epidemiology
  - 2.86/10,000 new births

Natural History & Prognosis

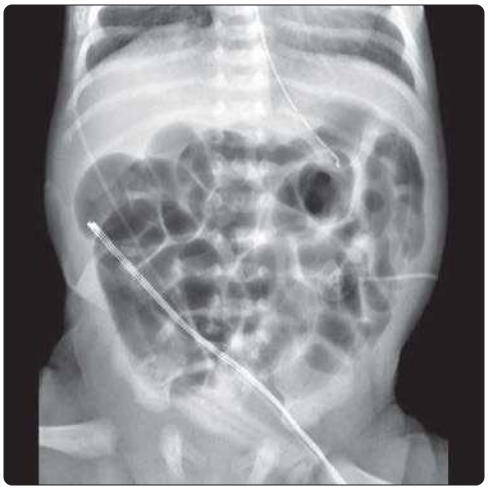
- May lead to to bowel necrosis, short gut, sepsis, death

Treatment

- Surgical emergency
- Ladd procedure: Reduce volvulus, resect nonviable bowel, transect Ladd bands (if present), place SB in right & colon in left abdomen

DIAGNOSTIC CHECKLIST

Consider



- Infant with bilious vomiting → emergent upper GI vs. US by expert sonographer
- Borderline cases of DJJ location on upper GI (suspicious for malrotation) → SBFT or contrast enema to document location of cecum

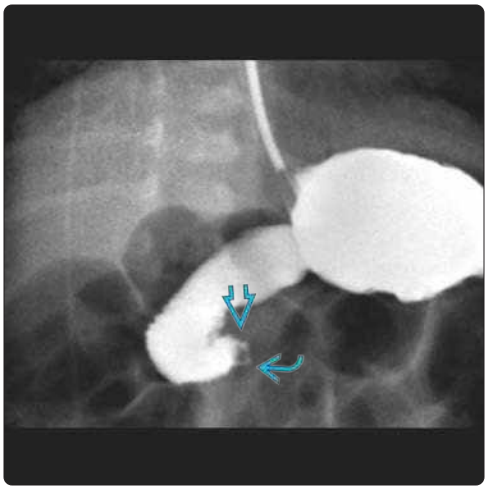


Image Interpretation Pearls

- High-grade duodenal obstruction at D2-D3 with beaking & no distal contrast passage is considered MGV until proven otherwise
  - Should not be confused with classic double bubble sign of duodenal atresia in newborn
    - Markedly dilated round or ovoid proximal duodenum with no distal bowel gas
- If patient has MGV by imaging, impression should read MGV
  - Must be communicated to clinician immediately

(Left) *AP radiograph in a newborn with bilious emesis shows multiple dilated, air-filled bowel loops suggestive of distal obstruction. However, prenatal imaging suggested malrotation, raising concern that this bowel dilation could be due to an ischemic ileus.* **(Right)** *LPO upper GI in the same newborn shows beaking of D3 ⇨ with a subtle twist ⇨ of MGV. In the OR, there was diffuse small bowel necrosis due to in utero MGV.*

(Left) *Frontal CT scout image in a 4-month-old with shock & abdominal distention shows gaseous distention of numerous bowel loops. Separation of the loops ⇨ could be due to wall thickening or interloop fluid.* **(Right)** *Coronal MIP CECT in the same patient shows absent enhancement ⇨ of much of the small bowel & proximal colon. There is a focal cutoff of the superior mesenteric artery (SMA) ⇨ at a site of bowel twisting. Bedside laparotomy showed MGV with ischemic bowel.*

(Left) *Transverse grayscale & color Doppler ultrasounds in a 21-month-old with vomiting show clockwise tapering & twisting of fluid-distended D3 & D4 segments ⇨ around the SMA ⇨, highly suggestive of MGV. These findings have a whirlpool configuration when sweeping from superior to inferior with the transducer.* **(Right)** *Lateral upper GI in the same patient (requested by the surgical service) confirms narrowing & twisting of the distal duodenum in a corkscrew pattern ⇨, consistent with MGV.*

Duodenal Atresia or Stenosis

KEY FACTS

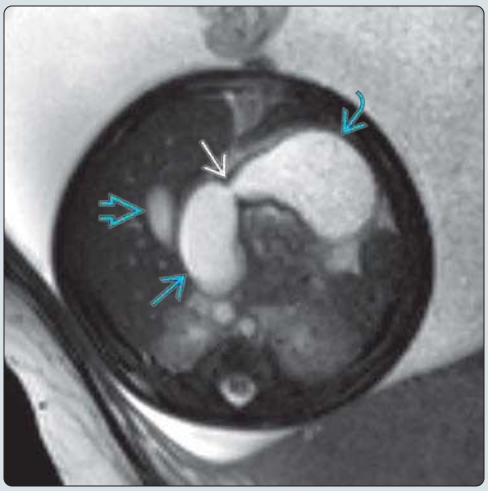
TERMINOLOGY

- Most common upper intestinal obstruction in neonate
- Atresia: Congenital occlusion of intestinal lumen
- Stenosis: Fixed narrowing of intestinal lumen

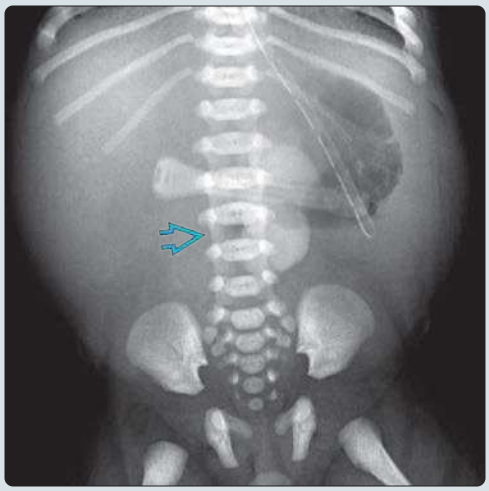
IMAGING

- Newborn radiographic double bubble appearance is essentially diagnostic
  - Markedly dilated duodenum implies chronic in utero obstruction (with duodenal atresia as most common cause), especially with no distal gas
  - May not be seen on initial radiographs if stomach or duodenum is decompressed by nasogastric tube or vomiting
- If duodenum is mildly to moderately dilated with some distal gas → emergent upper GI to exclude midgut volvulus, evaluate duodenal rotation
  - US may be useful adjunct in experienced hands

TOP DIFFERENTIAL DIAGNOSES

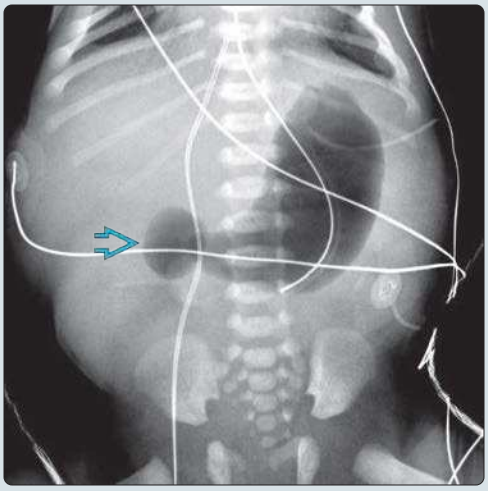


- Midgut volvulus
- Duodenal web
- Jejunal atresia
- Gastrointestinal duplication cyst
- Annular pancreas
- Hypertrophic pyloric stenosis

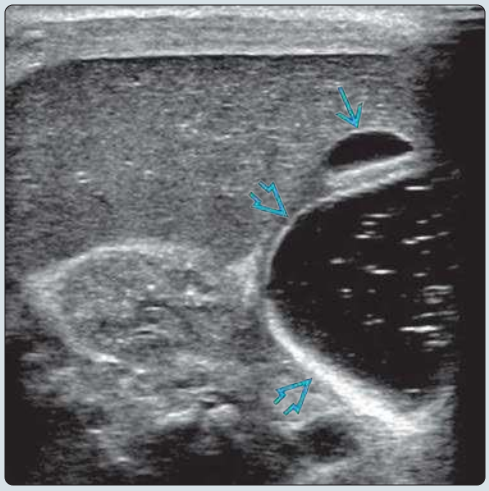


PATHOLOGY

- Associated anomalies in > 50% of patients
  - 30-46% have Down syndrome (trisomy 21)



CLINICAL ISSUES



- Diagnosis is often made prenatally by US
- With surgical treatment, survival rate is > 90%
- Duodenoduodenostomy is most common operation
- Postoperative complications: Megaduodenum, motility issues, adhesions

(Left) *Axial SSFSE T2 MR in a 36-weeks-gestation fetus shows a double bubble sign of duodenal atresia with dilation of the stomach, pylorus, & duodenal bulb. The gallbladder (GB) is noted for reference. The bowel distal to D2 is decompressed.* **(Right)** *AP radiograph immediately after delivery shows a nasogastric tube within the stomach, which can obscure the classic double bubble sign if suction is applied, as seen here. There is only minimal air in the duodenal bulb. Note the lack of distal bowel gas.*

(Left) *AP radiograph performed in the same patient on day 2 of life (after turning off the nasogastric suction) shows that air is starting to collect in the duodenal bulb with no distal gas, revealing a more classic double bubble appearance of duodenal atresia.* **(Right)** *Transverse US of the abdomen in the same patient shows a portion of the dilated, fluid-filled duodenum as well as a portion of the GB. Duodenal atresia was confirmed at surgery.*

TERMINOLOGY

Abbreviations

- Duodenal atresia (DA), duodenal stenosis (DS)

Definitions

- Atresia: Congenital occlusion of intestinal lumen
- Stenosis: Fixed narrowing of intestinal lumen
- Most common neonatal upper intestinal obstruction (40-50%)

IMAGING

General Features

- Best diagnostic clue
  - Double bubble sign
- Location
  - Usually 2nd duodenum (near ampulla of Vater)

Radiographic Findings

- Radiography
  - Double bubble sign: Classic
    - Gas-distended, dilated stomach & proximal duodenum without distal bowel gas
      - In this context, markedly dilated duodenum implies chronic in utero obstruction (with DA as most common cause)
    - If dilated stomach + duodenum in newborn with distal gas, think of
      - Acute midgut volvulus (MGV) (new onset since birth), though dilation is typically less severe
      - DA spectrum (stenosis, web, ± annular pancreas, etc.)
      - Variant biliary/pancreatic anatomy (collateral pathway around atretic segment)
    - If stomach is emptied by nasogastric tube (NGT) or vomiting, double bubble may not be seen on initial radiographs
  - Free air is very uncommon
    - Rare gastric perforation; may be related to NGT placement

Fluoroscopic Findings

- Upper GI
  - Not usually performed in DA (as radiographs are typically diagnostic with no distal gas)
    - Can inject air through NGT to look for distal passage of air
  - Needed urgently with dilated duodenum in setting of distal bowel gas (particularly with less bulbous duodenal dilation)
    - Must exclude MGV
      - Can only truly be done by visualizing normal duodenojejunal junction (DJJ)
    - DS: Focal or longer segment of fixed circumferential narrowing
    - DA with biliary/pancreatic duct variations: Biliary drainage above + below atresia → distal gas in bowel

Ultrasonographic Findings

- Grayscale ultrasound
  - Dilated fluid- & gas-filled stomach & duodenum
  - ↑ thickening & echogenicity of gastric & duodenal wall
  - Can potentially be used to confirm normal position of D3 posterior to SMA & absence of twisting ("whirlpool") of MGV
  - Prenatal sonography
    - Fluid double bubble appearance; polyhydramnios in 30-40%

MR Findings

- Fetal MR: Dilated, fluid-filled stomach + proximal duodenum ± polyhydramnios

Imaging Recommendations

- Best imaging tool
  - Radiographs for double bubble sign
  - Upper GI if distal gas is present
- Protocol advice
  - If upper GI is needed for diagnosis (due to distal gas), place NGT
    - Aspirate stomach, then inject small amounts of barium in right lateral decubitus position
    - Small puffs of air to advance barium
  - Postoperative upper GI: Low-osmotic/isosmotic nonionic water-soluble contrast
    - Is there anastomotic leak, obstruction, additional web, malrotation?

DIFFERENTIAL DIAGNOSIS

Midgut Volvulus

- Proximal duodenum is usually less dilated/bulbous in acute MGV than DA
  - Chronic in utero volvulus (rare) may cause greater duodenal dilation (than acute MGV) with absent distal gas
- Abrupt beak/taper with near-complete obstruction at D2-D3 of duodenum
- Corkscrew configuration of narrowed, twisted bowel + malpositioned DJJ
  - US or upper GI may be used
- Ladd bands may also cause proximal duodenal obstruction in malrotation

Duodenal Web

- Delayed clinical presentation; distal gas is present
- ± windsock appearance of web in midduodenum

Jejunal Atresia

- Dilated stomach + duodenum + several jejunal loops without distal gas
  - Triple or quadruple bubble, classically

Gastrointestinal Duplication Cysts

- Extrinsic mass effect on bowel on upper GI
- Sonographic gut signature to cyst wall
  - With dilated stomach, may mimic double bubble sign on prenatal US

Annular Pancreas

- Circumferential narrowing of mid-2nd duodenum
- Distal gas is present
- Often with DS at level of encircling pancreas

Hypertrophic Pyloric Stenosis

- Presents at 2-12 weeks of life (not 1st week)
- Projectile, nonbilious vomiting
- US: Thick, elongated, persistently closed pyloric muscle

Less Common Newborn Upper GI Obstructions

- Preduodenal portal vein, internal hernia, pyloric atresia

PATHOLOGY

General Features

- Etiology
  - Most accepted theory: Embryologic failure of duodenal recanalization in 12th gestational week
  - Unlike other intestinal atresias (due to vascular accidents)
- Genetics
  - Typically sporadic if isolated anomaly
  - Down syndrome (trisomy 21) in 30-46%
  - Feingold syndrome (autosomal dominant)
    - Hand/foot anomalies, microcephaly, tracheoesophageal fistula, esophageal/DA, short palpebral fissures, developmental delay
- Associated abnormalities
  - > 50% of patients with DA have other anomalies
  - 30-46% have Down syndrome (trisomy 21)
    - 11 pairs of ribs, macroglossia, flat acetabular angles, cardiomegaly with shunt vascularity
  - Malrotation: 28%
  - Annular pancreas: Up to 30%
  - Additional duodenal web: 1-3%
  - Choledochal cyst, other biliary anomalies
  - Preduodenal portal vein
  - Esophageal atresia + tracheoesophageal fistula: Up to 18%
  - Imperforate anus
  - Cardiac defects: 20-30% (less frequent without trisomy 21 but more likely cyanotic)
  - Situs anomalies; renal anomalies
  - VACTERL association

Staging, Grading, & Classification

- Type I DA (69-74%)
  - Intact intestinal wall & mesentery
  - Membranous luminal obstruction
- Type II DA (1-2%)
  - 2 blind ends separated by fibrous cord
- Type III DA (5-6%)
  - 2 blind ends without intervening cord
  - Biliary anomalies
- DS (18-23%)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Diagnosis is often made prenatally by US
  - Bilious > > nonbilious (80% vs. 20%) vomiting
    - Determined by site of atresia relative to ampulla of Vater
- Other signs/symptoms
  - Dehydration, weight loss, electrolyte imbalance

Demographics

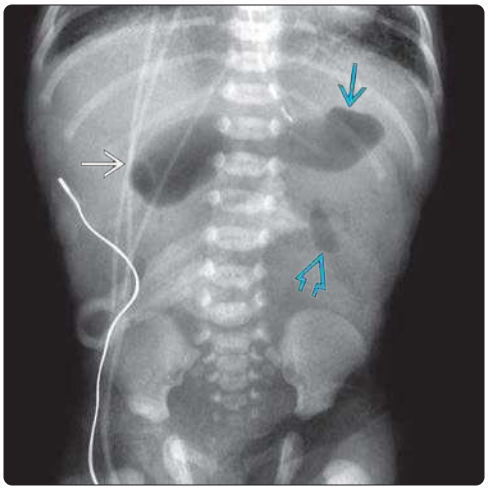
- Age
  - Newborn (21-45% are premature)
- Epidemiology
  - Incidence 1:5,000-10,000 live births

Natural History & Prognosis

- Untreated: Dehydration, severe electrolyte abnormalities, death
- With surgical treatment, survival rate is > 90%
  - Mortality is largely related to associated anomalies

Treatment

- Surgical repair
  - If radiographs are diagnostic of DA (classic double bubble sign), surgical repair is urgent but not emergent
  - In setting of distal gas, failure to demonstrate normal DJJ by upper GI requires emergent exploration (as MGV cannot be not excluded)
    - US may be useful adjunct
- Duodenoduodenostomy is most common operation
  - Bypasses obstruction to preserve ampulla of Vater
  - Diamond-shaped vs. side-to-side anastomosis
  - ± tapering enteroplasty of dilated duodenum
  - Rubber catheter is passed distally in duodenum & withdrawn with balloon inflated to exclude additional distal web (1-3%)
- Surgical repair may be delayed due to
  - Electrolyte or fluid balance disturbances
  - Severe cardiac defects
  - Severe respiratory insufficiency
- Long-term complications
  - Megaduodenum, motility issues, adhesions



DIAGNOSTIC CHECKLIST

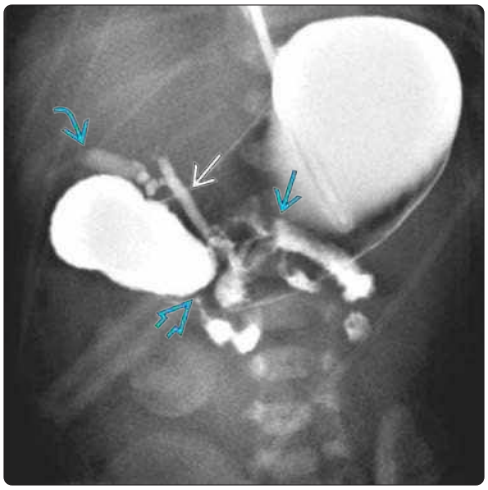


Image Interpretation Pearls

- True double bubble appearance with no distal bowel gas is essentially diagnostic for DA
- Upper GI or US is needed if distal bowel gas is present

(Left) *AP radiograph in a full-term infant boy at 1 day of age shows a dilated stomach ⇨ & duodenum ➡ with a small amount of distal gas ⇨. Main surgical diagnostic considerations include midgut volvulus, annular pancreas, & duodenal stenosis or web. Immediate upper GI is indicated.* **(Right)** *Upper GI in the same patient shows dilation of the duodenum to D2 with contrast passing through a stenotic orifice ⇨ & the remaining duodenum to a normal duodenojejunal junction ⇨. Note reflux into common bile duct ➡ & GB ⇨.*

(Left) *Coronal SSFSE T2 MR in a 24-weeks-gestation fetus shows a dilated stomach ➡ & proximal duodenum ⇨ with decompressed distal bowel, the classic double bubble appearance of the duodenal atresia spectrum.* **(Right)** *AP radiograph in the same patient upon delivery shows a classic double bubble sign ⇨ of duodenal atresia with no distal bowel gas. Duodenal atresia was confirmed surgically.*

(Left) *Supine frontal upper GI was performed in the same patient following operative repair of the duodenal atresia to exclude a leak. There was a nonretroperitoneal position of the duodenum (not shown) with the duodenojejunal junction in the midline ⇨, consistent with malrotation (which is associated with duodenal atresia).* **(Right)** *Frontal upper GI (converted to a small bowel follow-through) in the same patient shows most of small bowel on the right, confirming malrotation.*

Duodenal Web

KEY FACTS

TERMINOLOGY

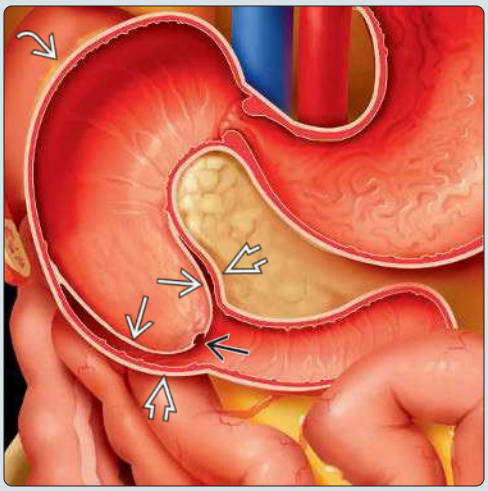
- Incomplete diaphragm of duodenal lumen causing partial or intermittent complete duodenal obstruction
- Duodenal atresia spectrum but with later clinical presentation

IMAGING

- Web lies at 2nd to 4th portion duodenum
  - Usually adjacent to ampulla of Vater
- Aperture size determines degree of obstruction, age of presentation, & imaging appearance
- Early presentation: Dilated stomach & proximal duodenum to D2/D3
- Late presentation: Thin, ballooned windsock in distal duodenum; variable duodenal caliber (based on orifice size)

TOP DIFFERENTIAL DIAGNOSES

- Duodenal atresia
- Midgut volvulus
- Gastrointestinal duplication cyst
- Annular pancreas
- Superior mesenteric artery syndrome

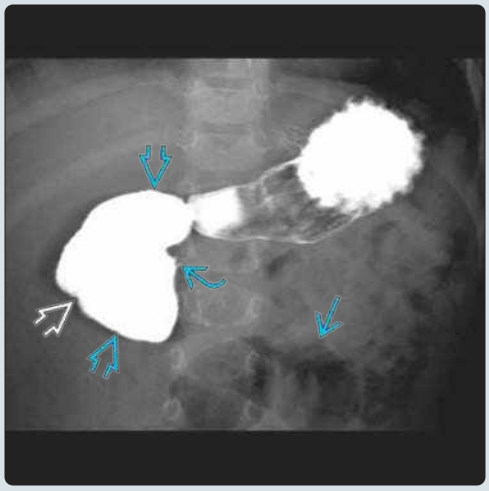


PATHOLOGY

- Failed duodenal recanalization: Spectrum of duodenal atresia
- Associated anomalies
  - Down syndrome: 30%
  - Malrotation: 28%
  - Annular pancreas: 33%

CLINICAL ISSUES

- Early presenters: Feeding intolerance, vomiting (bilious > nonbilious)
- Late presenters: Nausea, abdominal pain, progressive vomiting, acute pancreatitis
- Prognosis is excellent with treatment
  - Surgical vs. endoscopic excision



(Left) *Graphic shows a web with a windsock shape within the duodenal lumen with a pinhole opening distally. The proximal duodenum is moderately dilated from this partial obstruction.* **(Right)** *Transverse ultrasound performed for pyloric stenosis in a 3-week-old boy with recurrent emesis showed a normal pylorus. However, there is marked dilation of the duodenum to D2-D3 with no evidence of the swirl sign, Note the normal superior mesenteric artery /superior mesenteric vein relationship.*

(Left) *Lateral upper GI in the same patient immediately after the ultrasound shows no barium passing beyond the dilated proximal duodenum, but distal gas is seen. A tight duodenal web was found at surgery.* **(Right)** *Supine upper GI in an older patient shows a dilated duodenum with distal gas & a tiny orifice . Note also the dimple sign at the attachment of the proximal aspect of the web, which puckers when the web is stretched distally.*

KEY FACTS

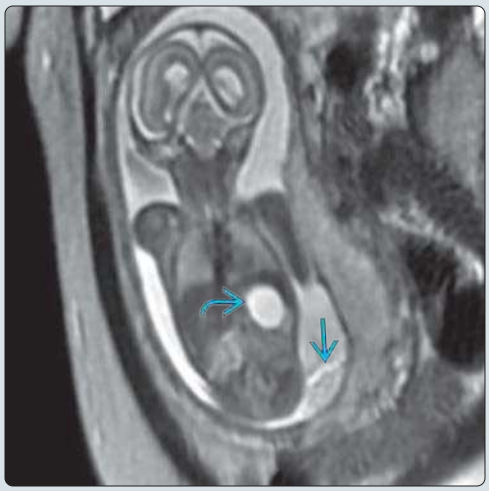
TERMINOLOGY

- Uncommon congenital gastric outlet obstruction
- Isolated vs. associated anomalies (30-50%)
  - Epidermolysis bullosa-pyloric atresia (EB-PA)
  - Hereditary multiple intestinal atresia or multiple intestinal atresia with immunodeficiency (HMIA/MIAI)

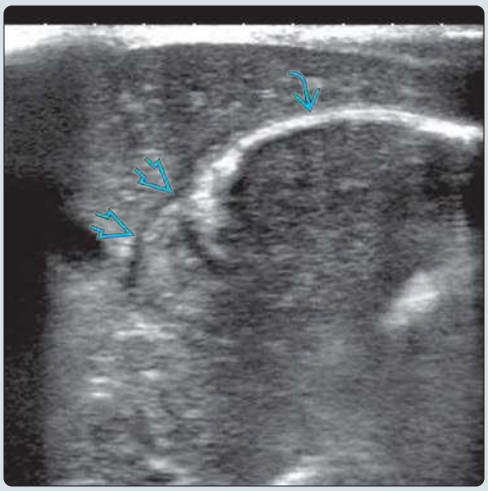
IMAGING

- Radiographs show "single bubble": Dilated, gas-filled stomach in newborn with no bowel gas otherwise
  - ± skin erosions (EB-PA)
  - ± intestinal Ca^{2+} (HMIA/MIAI)
- Ultrasound may show abnormal thin pyloric morphology + dilated gastric antrum = tennis racket appearance
  - Failure to visualize normal pyloric opening & antegrade passage of gastric contents into duodenal bulb

TOP DIFFERENTIAL DIAGNOSES

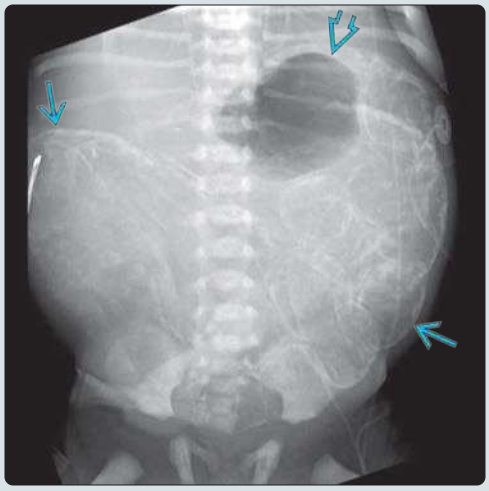


- Duodenal atresia
- Hypertrophic pyloric stenosis



PATHOLOGY

- Atresia may be web, solid cord, or discontinuous blind ends
- In MIAI: Atresias extend from pylorus to rectum (not just superior mesenteric artery territory)
  - Severe immunodeficiency → recurrent infections
- In EB-PA, clinical findings may include: Aplasia cutis, fusion/erosion/scarring with malformed protuberances (such as ears), small diameter orifices (such as nostrils), genitourinary anomalies, contractures



CLINICAL ISSUES

- Typical presentation for isolated PA: Nonbilious emesis
  - Perforated membrane may present later
- Isolated PA has excellent prognosis: Resection is curative
- Mortality approaches 100% in EB-PA or HMIA/MIAI
  - Infections & malnutrition in both

(Left) *Coronal T2 SSFSE MR at 21-weeks gestation shows dilation of the stomach (persisting throughout the exam) with no dilation of the bowel. Particulate debris was seen lying dependently in the amniotic cavity on multiple sequences, raising concern for the epidermolysis bullosa-pyloric atresia (EB-PA) association.* **(Right)** *Transverse oblique ultrasound through the newborn's right upper quadrant shows gastric distention with an abnormally thin, elongated, & persistently closed pylorus. Skin biopsy confirmed EB-PA.*

(Left) *AP abdominal radiograph in a newborn shows extensive Ca^{2+} throughout dilated bowel loops (which were fluid filled on prenatal ultrasound). The gas-filled stomach is moderately distended with no distal bowel gas identified.* **(Right)** *Lateral water-soluble contrast enema in the same patient shows a small, blind-ending rectal pouch. Surgery confirmed numerous atresias from the pylorus to the rectum, consistent with MIAI/HMIA in this patient found to have immunodeficiency.*

Jejunoileal Atresia

KEY FACTS

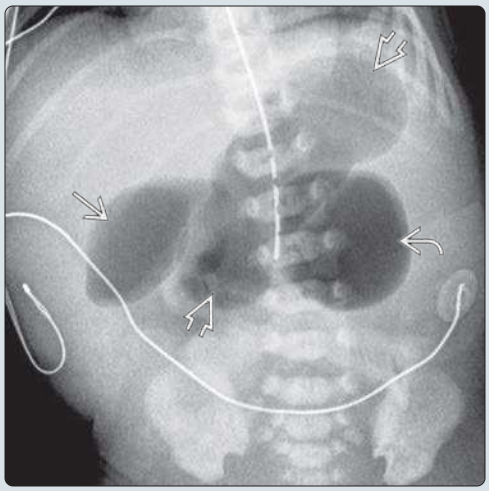
TERMINOLOGY

- Congenital occlusion of jejunal or ileal lumen
  - Ranges from focal membrane to long-segment intestinal & mesenteric gap

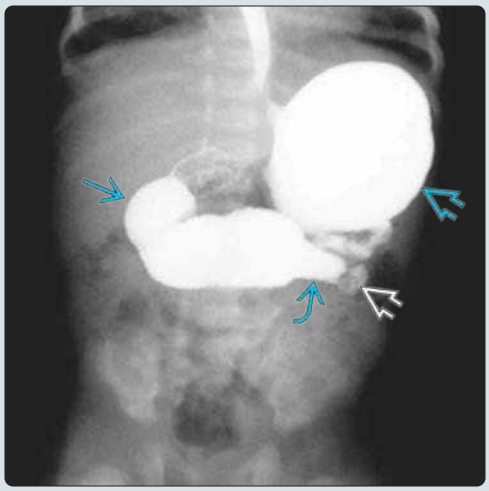
IMAGING

- Site of obstruction (atresia) determines radiographic & fluoroscopic patterns
- Proximal jejunal atresia
  - Dilated stomach + duodenum + 1-2 loops of jejunum; microcolon is less likely on enema
- Midjejunal to distal ileal atresia
  - Numerous dilated loops; enema often shows microcolon
- Protocol advice
  - Water-soluble contrast enema (low osmolality, nearly iso-osmotic to body fluids)
    - Avoids fluid shifts into or out of bowel
    - Barium is not used (may impede meconium passage)
  - If microcolon is seen, reflux into small bowel up to dilated loops (if possible)

TOP DIFFERENTIAL DIAGNOSES

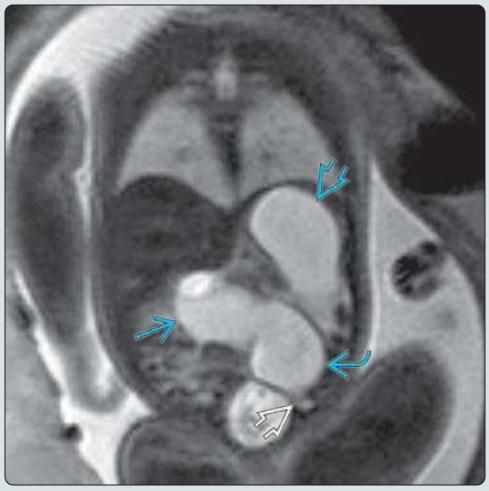


- Meconium ileus
- Meconium plug syndrome/small left colon
- Hirschsprung disease
- Anorectal malformation
- Inguinal hernia
- Necrotizing enterocolitis

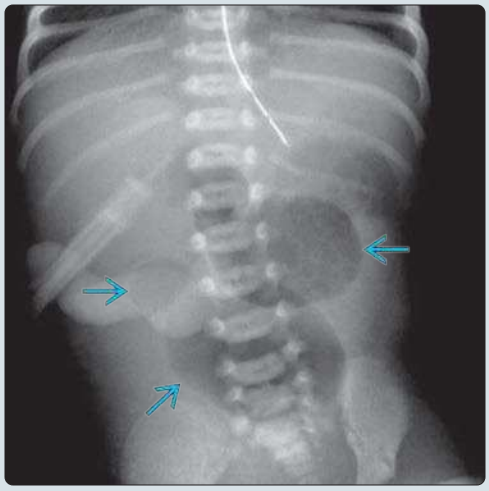


PATHOLOGY

- Associated anomalies in 10-52% of cases
  - Gastroschisis (up to 20%), meconium ileus/cystic fibrosis (up to 10%), malrotation, volvulus



CLINICAL ISSUES



- Prognosis depends on amount of residual functional bowel post repair + associated anomalies
- Mortality: 11-14%

(Left) *AP radiograph shows the classic triple bubble sign of jejunal atresia due to a dilated stomach, duodenum, & proximal jejunum with no distal bowel gas.* **(Right)** *Supine upper GI in a 13-day-old girl with several days of projectile yellow emesis shows dilation of the stomach, duodenum, & an initial jejunal segment with transition to a normal caliber jejunum just beyond the duodenojejunal junction, most consistent with jejunal stenosis (which was found at surgery).*

(Left) *Coronal T2 SSFSE fetal MR at 30-weeks gestation shows the triple bubble sign of jejunal atresia with a dilated, fluid-filled stomach, duodenum, & proximal jejunum. Note the abrupt blind end of the atresia.* **(Right)** *AP radiograph in the same patient upon delivery shows 3 or 4 air- & fluid-filled dilated bowel loops without other distal gas. Bilious material was aspirated from the Replogle tube. These findings are consistent with a proximal jejunal atresia, in agreement with the fetal MR.*

TERMINOLOGY

Definitions

- Congenital occlusion of jejunal or ileal lumen
- Ranges from focal membrane to long-segment intestinal atresia + mesenteric gap
- Stenosis, incomplete web: Forme fruste of atresia

IMAGING

General Features

- Best diagnostic clue
  - Contrast enema showing microcolon with reflux of contrast into blind-ending ileum or jejunum
- Location
  - Jejunum to distal ileum
- Morphology
  - Site of obstruction (atresia) determines radiographic & fluoroscopic patterns
    - Proximal jejunal atresia (classic high/proximal neonatal intestinal obstruction)
      - Dilated stomach + duodenum + 1-2 loops of jejunum; microcolon is less likely on enema
    - Midjejunal to distal ileal atresia (classic low/distal neonatal intestinal obstruction)
      - Numerous dilated bowel loops; enema shows microcolon
    - Multiple or long-segment intestinal atresias may have mixed imaging features
  - Appearance of microcolon on contrast enema is related to timing & level of obstruction
    - Smaller caliber colon from earlier or distal obstructions
      - Unused colon receives little succus entericus
    - Near-normal to normal-caliber colon from later or more proximal obstructions
      - Colonic succus entericus accumulation is less impaired

Radiographic Findings

- Radiography
  - Jejunal atresia: Proximal
    - Triple or quadruple bubble sign
      - Dilated stomach + duodenum + 1 (or few) proximal jejunal loop(s) without distal bowel gas
  - Ileal atresia
    - Multiple dilated bowel loops
      - Difficult to tell small bowel from colon in neonate
  - Soft tissue mass, ascites, &/or peritoneal Ca^{2+} suggest complicated obstruction
    - Perforation ± pseudocyst
    - Free intraperitoneal air is uncommon
  - Intraluminal Ca^{2+} in multiple atresias
  - Stenosis or web may have distal bowel gas beyond dilated loops

Fluoroscopic Findings

- Upper GI
  - Jejunal atresia
    - Dilated stomach, duodenum, proximal jejunum
      - Distal-most segment of bowel leading up to atresia may be very dilated & bulbous
    - Duodenojejunal junction may be displaced by dilated bowel loops in neonate (due to ↑ laxity of ligament of Treitz) despite normal rotation
  - Ileal atresia: Normal (in absence of multiple atresias)
- Water-soluble contrast enema (WSCE)
  - Jejunal atresia
    - Proximal atresia → normal or mildly small colon
    - Distal atresia → variable degrees of small colon
    - Long segment or multiple atresias → microcolon
  - Ileal atresia
    - Microcolon
    - Abrupt blind end to contrast flow at atresia
      - Contrast fails to reach dilated proximal bowel
    - Ileum distal to atresia is also small in caliber

Ultrasonographic Findings

- Grayscale ultrasound
  - Prenatal or post natal
    - Dilated, fluid-filled bowel loops
      - Echogenic, dilated loops prenatally may favor cystic fibrosis or gastroschisis ± atresia
    - Peritoneal Ca^{2+}, ascites (complex > simple), pseudocyst → suspect in utero perforation (meconium peritonitis)
    - Intraluminal Ca^{2+} is possible in multiple intestinal atresias
      - Must also consider anorectal malformation with rectourinary fistula or total colonic Hirschsprung disease
    - Whirlpool sign of twisting bowel loops has been described with "apple peel" atresia (but is classically associated with midgut or segmental volvulus)

MR Findings

- Depending on gestational age, fetal MR is better than prenatal US for detecting level of obstruction
  - Distribution of T1-bright meconium can evaluate length, caliber, & position of colon relative to abnormal small bowel loops

Imaging Recommendations

- Best imaging tool
  - For clinical + radiographic distal/low obstruction: WSCE
  - For clinical + radiographic proximal/high obstruction: Upper GI series (UGI)
    - For true triple or quadruple bubble with marked dilation & no distal gas, fluoroscopy may not be required prior to surgery
    - ± enema to exclude additional atresia preoperatively
  - If answer to obstruction site is not provided by 1st of these exams, be ready to perform 2nd
- Protocol advice
  - Enema is performed with low-osmolality, water-soluble contrast (nearly iso-osmotic to body fluids)
    - Avoids fluid shifts into or out of bowel
    - Barium is not used (may impede meconium passage)
  - If microcolon is seen, reflux contrast into small bowel until contrast reaches dilated loops or atresia

DIFFERENTIAL DIAGNOSIS

Meconium Ileus

- Microcolon on WSCE
- Meconium pellets obstruct distal ileum on enema
  - Refluxed contrast outlines ileal filling defects before passing into dilated loops

Small Left Colon/Meconium Plug Syndrome

- Small-caliber left colon up to splenic flexure on WSCE
- Normal to mildly dilated proximal colon
- ± meconium plugs in small left colon

Hirschsprung Disease

- Rectosigmoid ratio < 1 with colonic transition zone on WSCE; most of proximal colon is dilated
  - Entire colon is small in total colonic Hirschsprung disease

Anorectal Malformation

- No normal anal opening

Megacystis-Microcolon-Intestinal Hypoperistalsis

- Rare, often fatal syndrome with marked bladder dilation
- More common in female patients (4:1)

Colonic Atresia

- 1 or 2 disproportionately dilated loops on radiograph
- Small distal colon with proximal blind end on WSCE

Inguinal Hernia

- Dilated bowel with asymmetric inguinoscrotal fold
  - Gas in scrotum is essentially diagnostic

Necrotizing Enterocolitis

- Premature infants
- Uncommon in first 1-2 days of life
- Bowel separation, unchanging bowel loops, pneumatosis, portal venous gas, pneumoperitoneum
- Enema is not performed acutely

PATHOLOGY

General Features

- Etiology
  - Intrauterine vascular accident → necrosis with segmental stenosis/resorption
- Genetics
  - French Canadian ancestry was classically described in hereditary multiple intestinal atresias with immunodeficiency; has expanded
    - Specific atresias (often pyloric & sieve-like colon)
  - Autosomal recessive inheritance in some type 3b
- Associated abnormalities
  - 10-52% of jejunoileal atresia cases
    - Predisposing GI anomalies
      - Gastroschisis (up to 20%), meconium ileus/cystic fibrosis (up to 10%), malrotation, volvulus
    - Various cardiac, genitourinary, & brain anomalies

Staging, Grading, & Classification

- Atresia: Surgical grading system
  - Type 1: Membranous atresia, web/stenosis
    - No mesenteric defect, bowel is not short
  - Type 2: Blind ends are separated by fibrous cord
    - No mesenteric defect, bowel is not short
  - Type 3a: Blind ends with complete disconnection
    - V-shaped mesenteric gap, bowel is short
  - Type 3b: Apple peel or Christmas tree deformity
    - Large mesenteric defect, bowel is short
  - Type 4: Multiple small bowel atresias
    - 3-32% of jejunoileal atresias

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Distal ileal atresia: Failure to pass meconium + abdominal distention, bilious emesis
  - Jejunal or proximal ileal atresia: Bilious emesis
  - Stenosis or web: Early vs. delayed presentation with intermittent emesis, failure to thrive

Demographics

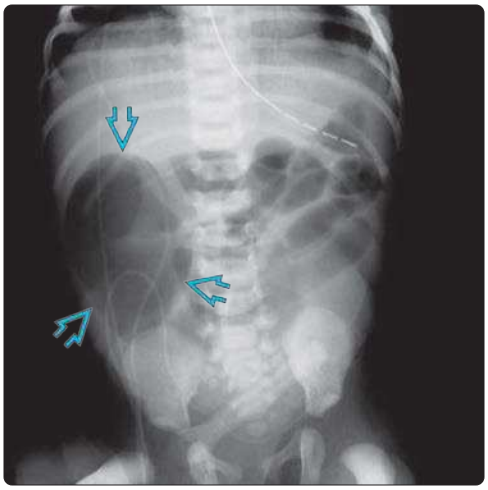
- Age: Atresia may present in utero or up to first 1-2 days after delivery

Natural History & Prognosis

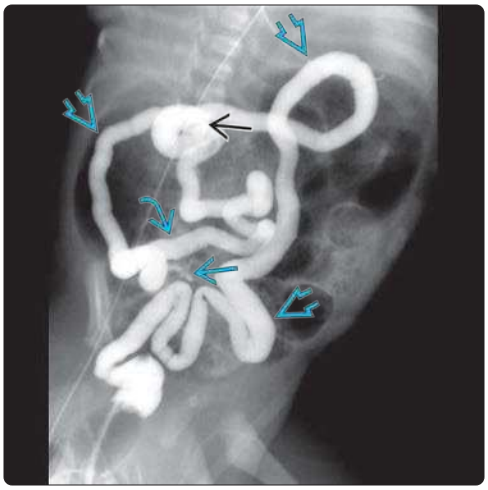
- Prognosis depends on amount of residual functional bowel post repair + associated anomalies
  - 40 cm of normal bowel length is considered functionally adequate to avoid treatment for short gut syndrome
- Mortality: 11-14%

Treatment

- Full resuscitation prior to surgical correction (unless perforation or volvulus requires emergent intervention)
- Surgical resection of atretic segment with anastomosis
  - Tapering vs. resection of very dilated proximal segment, depending on residual bowel length
- Complications: Short gut syndrome (14%), dysmotility, adhesions



DIAGNOSTIC CHECKLIST



Consider

- Bilious emesis can occur in neonatal distal or proximal obstructions
  - Radiograph determines initial fluoroscopic study in neonatal obstruction
    - WSCE 1st for distal vs. UGI for proximal

(Left) *AP radiograph in a 1-day-old term infant with abdominal distention & no meconium passage shows multiple dilated bowel loops, consistent with distal obstruction. A dominant dilated loop ⇨ suggests that there may be a distal ileal or colonic atresia.* **(Right)** *Supine water-soluble contrast enema (WSCE) in the same patient shows a microcolon ⇨ with reflux into the appendix ⇨ & terminal ileum ⇨, which curls & ends blindly ⇨, consistent with ileal atresia.*

(Left) *AP radiograph in a 1-day-old boy with bilious emesis shows several dilated loops of bowel, suggestive of an upper bowel obstruction, likely jejunal atresia.* **(Right)** *Supine WSCE in the same patient shows a microcolon, suggesting that there may be an additional distal atresia or a long-segment atresia. Surgery confirmed the former.*

(Left) *Surgical photograph in the same patient shows the dilated jejunum to the atretic segment ⇨; the distal bowel is decompressed ➡. A distal ileal atresia was also noted at surgery, explaining the microcolon.* **(Right)** *Supine WSCE in a 2-day-old shows a microcolon with reflux into appendix ⇨. However, contrast would not reflux into the terminal ileum. Considerations for this appearance include meconium ileus, ileal atresia, & total colonic Hirschsprung disease. At surgery, ileal atresia was found.*

Colonic Atresia

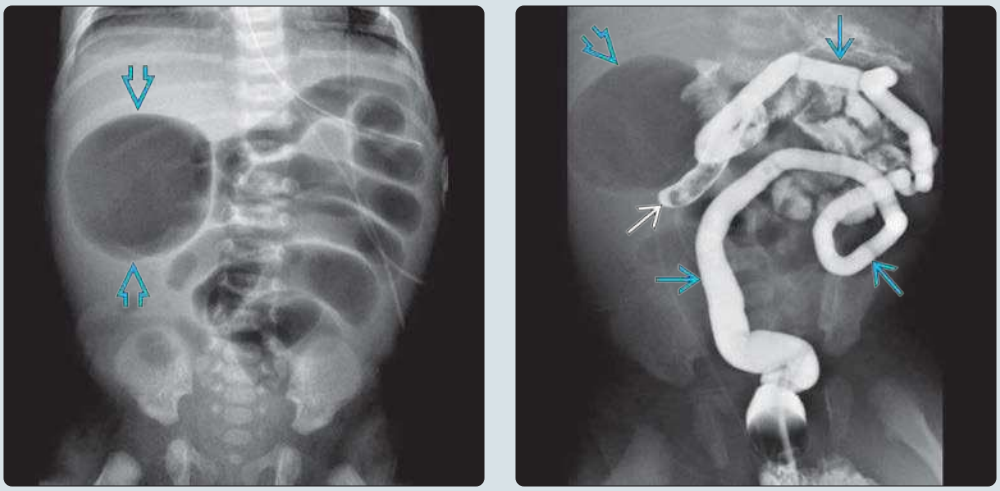
KEY FACTS

TERMINOLOGY

- Congenital colonic obstruction due to variable forms of interruption: Membrane (type I), fibrous cord (II), or complete separation with mesenteric defect (III)

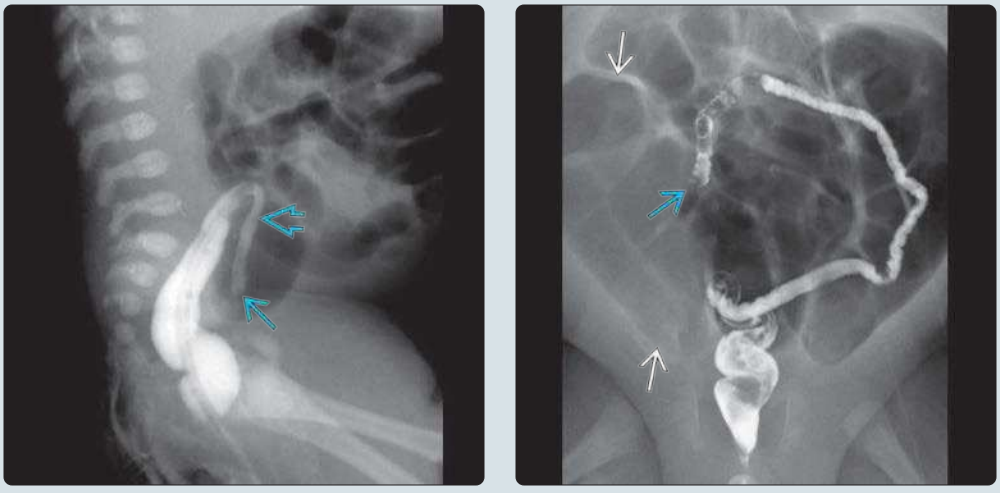
IMAGING

- Radiography: Multiple dilated, air-filled bowel loops ± 1 disproportionately dilated loop of colon proximal to atresia
- Contrast enema: Distal microcolon with abrupt termination to retrograde contrast flow proximally (at colonic blind end)
  - Contrast does not fill cecum/terminal ileum or dilated bowel loops
  - Atresia may affect any segment of colon



TOP DIFFERENTIAL DIAGNOSES

- Hirschsprung disease
- Meconium plug syndrome/neonatal small left colon
- Jejunoileal atresia
- Meconium ileus



CLINICAL ISSUES

- Presents similar to other congenital distal bowel obstructions
  - Newborn with failure to pass meconium, abdominal distention, ± bilious emesis
    - If initial abdominal radiograph shows distal bowel obstruction → water-soluble contrast enema
    - History of bilious emesis is frequent in distal obstructions; should not necessarily divert work-up to upper GI 1st (to rule out midgut volvulus) if clinical/radiologic picture suggests distal obstruction
  - May pass small amount of white or pale mucous rather than pigmented meconium
- Least common of all intestinal atresias (1.8-15%)
  - Very rare; incidence ~ 1:20,000 live births
- Treatment: Surgery to eliminate bowel obstruction & establish intestinal continuity

(Left) *AP supine abdominal radiograph in a 1-day-old full-term infant girl with bilious emesis shows multiple dilated gas-filled bowel loops in the left abdomen with a single, disproportionately dilated loop in the right upper quadrant, an appearance often seen in colonic atresia.* **(Right)** *Supine contrast enema in the same patient (after a normal upper GI) shows a microcolon with a blind end. The adjacent large dilated loop was due to an atretic proximal colon.*

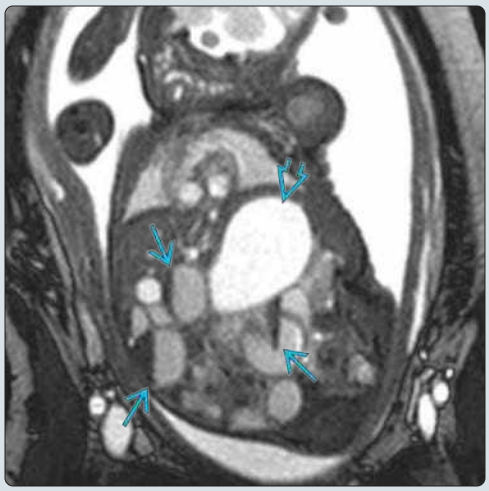
(Left) *Left-side down lateral contrast enema in a newborn with failure to pass meconium shows that the sigmoid colon is tiny & blind ending, consistent with colonic atresia at the sigmoid level.* **(Right)** *Supine contrast enema in a newborn boy with prior fetal MR imaging that demonstrated a distal bowel obstruction shows a diffusely small colon that abruptly terminates at the ascending colon, consistent with colonic atresia. The ascending colon is displaced medially by dilated colon & ileum proximal to atresia.*

KEY FACTS

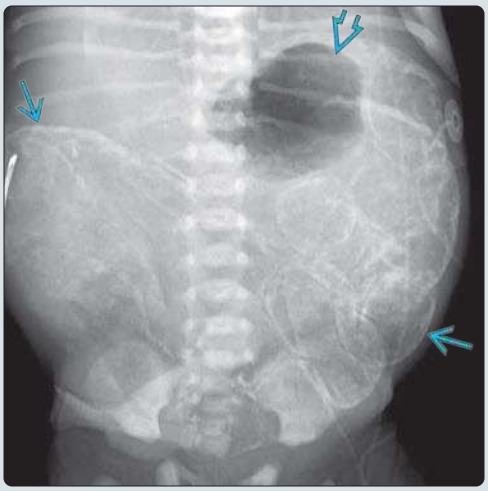
TERMINOLOGY

- Intestinal atresias are multifocal in 3-32%; 2 forms
  - Multiple intestinal atresia (MIA)
    - Atresias of types I, II, IIIa, IIIb; affects midduodenum to mid to distal transverse colon
      - Due to vascular insult to superior mesenteric artery territory (midgut)
  - Hereditary MIA (HMIA) or MIA with combined immunodeficiency (MIA-CID)
    - Atresias of types I & II only; affects pylorus to rectum, including long segments of occlusion
      - Multiple proposed etiologies
    - Develop severe infections from immunodeficiency

IMAGING



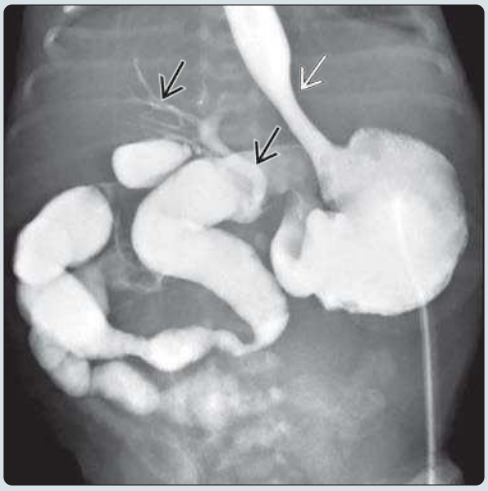
- No bowel gas beyond most proximal obstruction
- Ca^{2+} may develop in chronically obstructed, dilated closed loops of intestine
- Enema typically shows small, unused colonic segments distal to obstructions
- Ultrasound shows fluid-filled bowel ± echogenic Ca^{2+}, wall thickening; ± biliary dilation



PATHOLOGY

- Histology of HMIA/MIA-CID: Characteristic sieve-like occluded segments (multiple lumina in single cross section)
  - *TTC7A* mutations are implicated in HMIA/MIA-CID

CLINICAL ISSUES



- MIA: Operative repair is frequently curative; low mortality unless associated with gastroschisis or short gut syndrome
- HMIA/MIA-CID: Despite resection of atretic segments, patients have very high morbidity/mortality
  - Longstanding gut & biliary dysfunction
  - Immunocompromise with severe infections
    - Intestinal transplant may be curative with high level of immune system reconstitution by donor gut

(Left) *Coronal SSFP MR in a 33-weeks-gestation fetus shows numerous dilated bowel loops containing fluid-fluid levels. The distended stomach is of different signal intensity than the dilated bowel, which can suggest multiple intestinal atresias. No colonic meconium was seen on T1 MR.* **(Right)** *AP radiograph of the abdomen hours after birth shows extensive Ca^{2+} throughout the dilated bowel loops. The gas-filled stomach is moderately distended with no distal bowel gas identified.*

(Left) *Lateral view of a water-soluble contrast enema (with catheter balloon pressed externally against the anus) shows a small, blind-ending rectal pouch. Surgery confirmed numerous atresias at the pylorus, small bowel, & colon. This patient developed infections from a severe immunodeficiency & was diagnosed with hereditary multiple intestinal atresias.* **(Right)** *After resection of the atresias (same patient), upper GI (with contrast injected through the gastrostomy tube) shows free reflux into the esophagus & bile ducts.*

Meconium Ileus

KEY FACTS

TERMINOLOGY

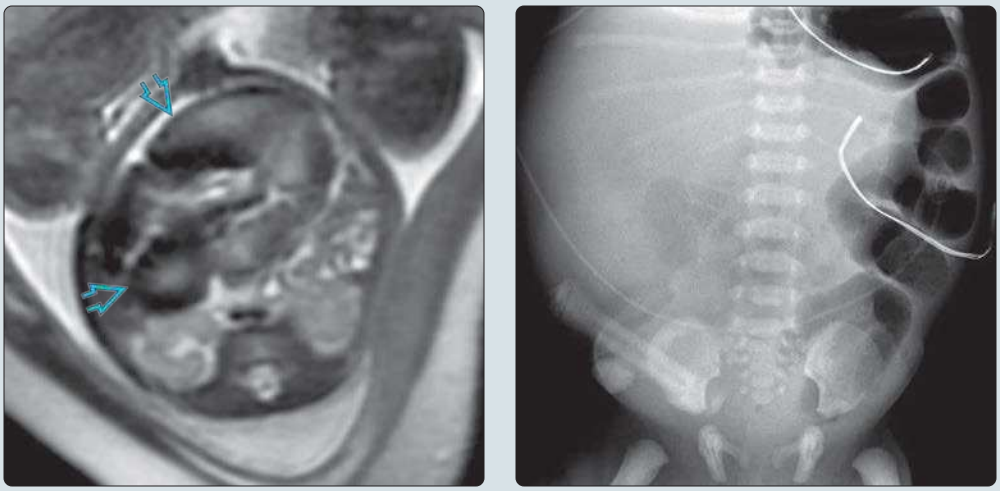
- Neonatal obstruction of terminal ileum (TI) due to abnormally thick, tenacious meconium
- Up to 90% of meconium ileus (MI) patients have cystic fibrosis (CF)
- MI is presenting illness in 10-20% of CF patients

IMAGING

- Uncomplicated MI (50%): Numerous dilated, gas-filled bowel loops on newborn radiographs
  - Microcolon + meconium-filled pellets in TI on water-soluble contrast enema (WSCE)
- Complicated MI (50%): Due to superimposed volvulus, atresia, necrosis, ± perforation with meconium peritonitis
  - Soft tissue mass or gasless abdomen
  - ± intrauterine perforation (Ca^{2+} of meconium peritonitis)

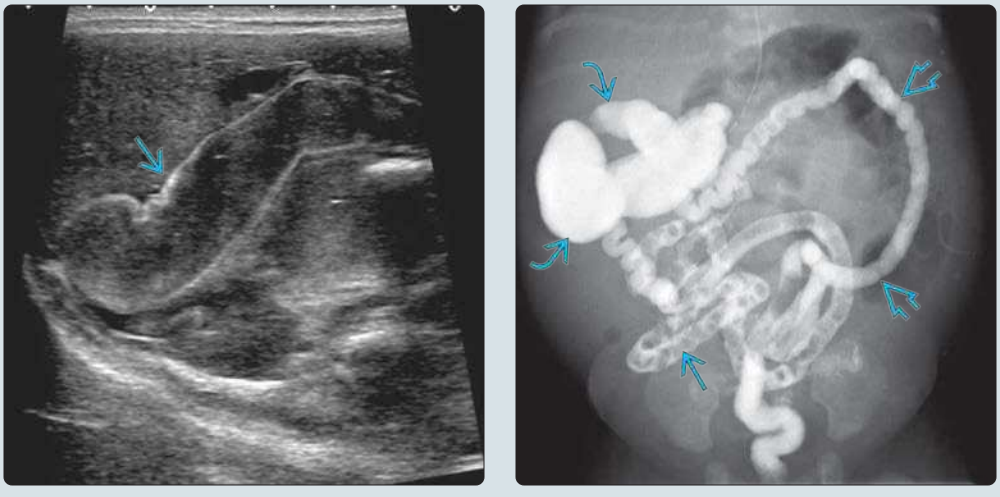
TOP DIFFERENTIAL DIAGNOSES

- Ileal atresia
- Hirschsprung disease
- Meconium plug syndrome
- Colonic atresia
- Megacystis-microcolon-intestinal hypoperistalsis
- Anorectal malformation
- Midgut volvulus



PATHOLOGY

- Mutation of *CFTR* gene (chromosome 7)



CLINICAL ISSUES

- CF incidence: 1:3,000 live births in White patients (much less common in other races)
- Most common signs/symptoms: Failure to pass meconium, abdominal distention, bilious emesis
- Serial hyperosmotic WSCE vs. surgery for treatment of uncomplicated MI
  - Surgery is usually required in complicated MI

(Left) *Axial SSFSE T2 fetal MR at 33-weeks gestation shows dilated small bowel (SB) filled with intermediate to low signal intensity meconium. A tiny-caliber colon was best seen on sagittal images (not shown), consistent with a SB obstruction. The mother was noted to be a carrier of the cystic fibrosis (CF) gene.* **(Right)** *Radiograph in the same patient several hours after birth shows a large soft tissue mass displacing dilated bowel towards the left, worrisome for a complicated meconium ileus (MI).*

(Left) *US immediately following the radiograph in the same patient shows dilated, debris-filled bowel with echogenic walls, consistent with bowel obstruction. Ascites was scattered in the abdomen. However, no pseudocyst or other sign of perforation was seen.* **(Right)** *Supine WSCE in the same patient shows a microcolon without significant colonic meconium. Reflux into the terminal ileum (TI) shows obstructing meconium pellets before reaching dilated SB, consistent with MI.*

TERMINOLOGY

Definitions

- Meconium ileus (MI): Neonatal obstruction of distal ileum due to abnormally thick, tenacious meconium
  - Up to 90% of MI patients have cystic fibrosis (CF)
  - Presenting illness in 10-20% of CF newborns
- Complicated MI: Superimposed ischemia, volvulus, atresia, &/or perforation in up to 50% of MI cases

IMAGING

General Features

- Best diagnostic clue
  - Microcolon + meconium-filled terminal ileum (TI) on water-soluble contrast enema (WSCE)
- Size
  - Microcolon (small, unused colon due to impaired passage of succus entericus through small bowel into colon in utero) varies in caliber
  - Varying degrees of proximal small bowel dilation

Radiographic Findings

- Radiography
  - Uncomplicated (or simple) MI
    - Multiple dilated bowel loops
    - ± bubbly lucencies in right lower quadrant
      - Air mixed with meconium
    - Few, if any, air-fluid levels ("sticky meconium")
    - WSCE to diagnose & treat
  - Complicated (or complex) MI
    - Soft tissue mass or gasless abdomen
    - ± intrauterine perforation → meconium peritonitis (MP)
      - Pseudocyst, Ca^{2+} lining peritoneum
    - Ultrasound &/or enema for further evaluation
      - Enema treatment usually fails (requiring surgery)

Fluoroscopic Findings

- Low osmolar WSCE for diagnosis; higher osmolar WSCE for therapy
  - Smallest of microcolons (often)
  - Contrast refluxed into TI outlines meconium pellets ("pearls on string")
    - Pellets may obstruct contrast passage proximally (mimicking ileal atresia)
    - Paucity of colonic meconium is common
  - Switching to higher osmolar WSCE can be therapeutic in uncomplicated MI
    - Up to 80% success in experienced hands
    - ± N-acetylcysteine added to WSCE for treatment

MR Findings

- Fetal MR
  - Microcolon containing little T1-bright meconium in later gestation
  - T1-bright signal is often seen in dilated, obstructed small bowel loops

Ultrasonographic Findings

- Grayscale ultrasound
  - Prenatally
    - Dilated, echogenic bowel
    - Echogenic ascites, peritoneal Ca^{2+}, pseudocyst from in utero perforation
  - Postnatally
    - Dilated, thick-walled small bowel loops containing heterogeneous meconium
      - Echogenic foci of gas in meconium
    - Echogenic ascites, peritoneal Ca^{2+}, pseudocyst from in utero perforation

Imaging Recommendations

- Best imaging tool
  - WSCE
- Protocol advice
  - With neonatal distal bowel obstruction on radiographs → WSCE for further investigation
    - Barium is not used (may impede meconium passage)
    - Nonballoon tip catheter is used (in general) due to possible risk of rectal injury
      - If using balloon-tipped Foley, inflate balloon outside & insert tip into rectum with balloon held up against anus to prevent leakage
      - Alternatively, carefully inflate balloon under fluoroscopy after visualizing normally distensible rectum with contrast (to prevent rectal injury)
      - Enema contrast gravity infusion vs. gentle pulsing of contrast by syringe injection
    - If microcolon is seen, attempt reflux into ileum
      - Visualization of meconium pellets is diagnostic
    - Switch to higher osmolality (600-900 mOsm) contrast for therapeutic enema
      - Reflux contrast up to dilated bowel if possible
      - Active fluid resuscitation during enema to balance fluid shifts into bowel: 1.5x maintenance
      - Have surgical team check electrolytes after each therapeutic enema
    - Serial enemas may be required to relieve meconium obstruction; usually 1 per day
    - Complications of enema
      - Perforation
      - Dehydration/intravascular volume depletion/hypotension
      - Electrolyte imbalances
      - Segmental volvulus of dilated proximal bowel if meconium does not clear
  - If bowel obstruction is present with soft tissue mass on radiographs (suggesting complicated MI ± MP), consider ultrasound ± enema
    - Ultrasound or MR in MP can help guide surgical management
  - If enema is normal (uncommon with numerous dilated loops), consider upper GI
    - Exclude midgut volvulus causing ischemic ileus

DIFFERENTIAL DIAGNOSIS

Ileal Atresia

- Microcolon on WSCE
- Contrast refluxing into ileum stops abruptly at atresia
- Opacified distal ileum is usually small & without meconium

Hirschsprung Disease

- Microcolon in some cases of total colonic Hirschsprung disease (HD) on WSCE
- More common: Short-segment HD
  - Low rectosigmoid (R/S) ratio (< 1), serrated mucosa
  - ± meconium plugs in colon above spasmodic rectum

Small Left Colon/Meconium Plug Syndrome

- Small distal colon; transition at splenic flexure on WSCE
- Nonobstructing meconium plugs in colon (not TI)
- Enema is often curative of this functional obstruction
- Not associated with CF

Colonic Atresia

- Microcolon up to level of atresia on WSCE
- Colon proximal to atresia is often dilated out of proportion to small bowel

Anorectal Malformation

- Distal obstruction without normal anus on exam

Megacystis-Microcolon-Intestinal Hypoperistalsis

- Microcolon on WSCE
- Very dilated bladder
- M:F = 1:4; often fatal disease

Midgut Volvulus

- Bowel loops may be dilated from ischemic ileus
- Upper GI vs. ultrasound for diagnosis

PATHOLOGY

General Features

- Genetics
  - CF: Autosomal recessive
  - Mutation of *CFTR* gene (chromosome 7)
    - > 2,000 mutations; ΔF508 mutation is most common overall & with MI
    - Faulty chloride transport across epithelium → ↓ water in luminal contents → dehydrated, thick secretions
      - Obstruction of glands & ducts
      - Pancreas, intestines, & lungs are most affected
    - Thick meconium → distal ileal obstruction
- Associated abnormalities
  - CF manifestations beyond neonatal period
    - Lung disease
    - Exocrine pancreas failure, biliary disease, chronic appendiceal dilation without inflammation, distal intestinal obstruction syndrome (DIOS)

Staging, Grading, & Classification

- Uncomplicated MI (50%)
- Complicated MI (50%): Superimposed segmental volvulus, necrosis, atresia, perforation with MP → ascites, peritoneal Ca^{2+}, pseudocyst (may be large)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Failure to pass meconium, abdominal distention, bilious emesis

Demographics

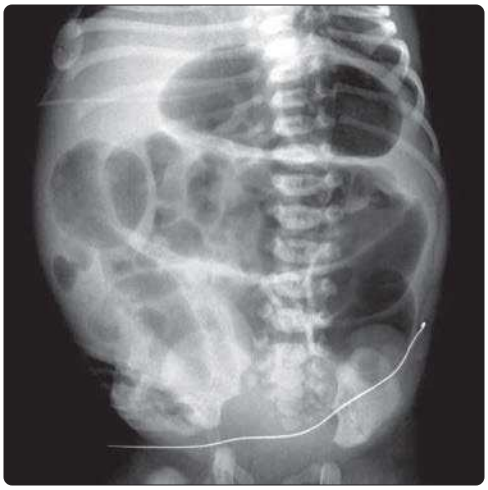
- Age: Newborn
- Sex: M = F
- Epidemiology: 1:3,000 live births in White patients have CF (much less common in other races)
  - Up to 90% of patients with MI have CF
    - Some reports that up to 50% of MI patients do not have CF
      - Complicated MI rate may be higher
      - Prematurity + low birth weights are more likely
  - 10-20% of CF patients present with MI

Natural History & Prognosis

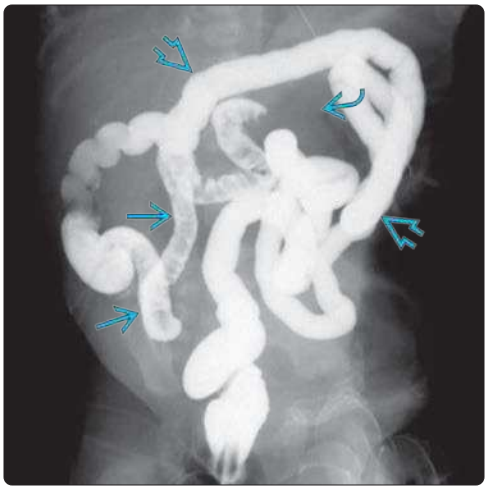
- MI patients classically have worse lung function, nutritional status, & survival vs. other CF patients
  - More recent papers show no difference
  - Earlier diagnosis of CF may be beneficial
- Recurrent bowel issues in CF
  - DIOS ("MI equivalent")
    - Older children with obstruction from thick stool in TI
  - Chronic constipation (may be 1st CF manifestation)

Treatment

- Uncomplicated MI: Serial hyperosmotic WSCE vs. surgery
  - Therapeutic enema success: Up to 83% (with experience)
    - Reported success rates vary widely (5-83%)
  - Perforation rate of enema 1-3%
    - Greatest with injection & use of rectal balloon
  - Surgery for patient decompensation, failed enemas, or perforation
    - Enterotomy, meconium removal, primary anastomosis vs. temporary enterostomy
- Complicated MI: Surgery
  - Resect abnormal bowel, meconium removal, primary anastomosis vs. temporary enterostomy
- Testing for CF



DIAGNOSTIC CHECKLIST



Consider

- Causes of distal obstruction & microcolon
- Diluted hyperosmolar WSCE for simple MI therapy
- Enema is rarely curative in complicated MI (requires surgery)

(Left) *AP radiograph in a full-term newborn with failure to pass meconium (& whose parents are CF gene carriers) shows a distal bowel obstruction without soft tissue mass effect or signs of meconium peritonitis. With this history, uncomplicated MI is the primary diagnostic consideration.* **(Right)** *Supine WSCE in the same patient shows a microcolon & reflux of contrast into the meconium-filled TI, most consistent with MI. Contrast did not reach the dilated bowel.*

(Left) *A 2nd supine WSCE was performed in the same patient. There is now reflux of the high osmolality 1:1 diluted Gastroview contrast (950 mOsm) into multiple dilated bowel loops proximal to the obstructing meconium.* **(Right)** *AP radiograph in the same patient 1 day after the 2nd enema shows much less dilation of the bowel proximal to the previously obstructed TI. There is mild residual contrast in the persistently small, unused colon. This is considered a successful treatment enema for MI.*

(Left) *Newborn AP radiograph shows Ca^{2+} in the right upper quadrant (RUQ), suggesting meconium peritonitis, + a distal bowel obstruction. Both parents were CF gene carriers.* **(Right)** *Transverse US shows a round fluid collection in the RUQ with punctate echogenic foci in the wall, likely corresponding to the radiographic Ca^{2+}. There is also a small amount of ascites. The WSCE (not shown) confirmed a microcolon with impacted TI pellets, giving a diagnosis of complicated MI.*

Neonatal Small Left Colon

KEY FACTS

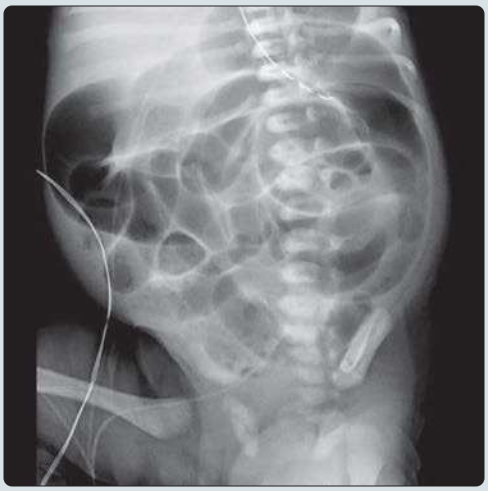
TERMINOLOGY

- Neonatal small left colon (NSLC): Transient functional colonic obstruction of newborn
  - Retained colonic plugs of normal meconium are secondary to functional obstruction in this scenario (not underlying cause of mechanical obstruction)
- Debate if meconium plug syndrome (MPS) is same as NSLC

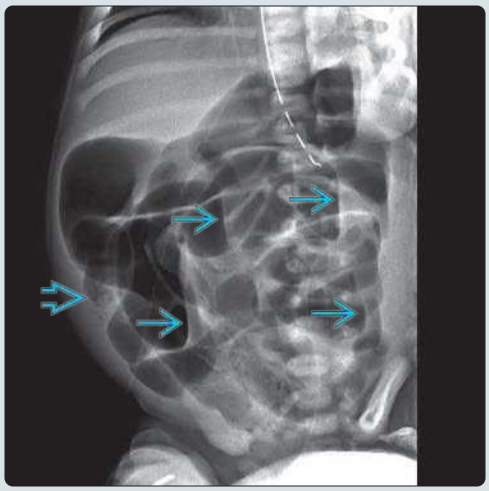
IMAGING

- Numerous dilated loops of bowel on newborn radiograph
  - Difficult to radiographically distinguish small vs. large bowel in neonate
- Water-soluble contrast enema (WSCE)
  - Normal rectosigmoid ratio
  - Small-caliber distal colon (sigmoid + descending segments) up to splenic flexure with abrupt or gradual transition to normal/mildly dilated transverse colon
  - Scattered meconium filling defects in colon
    - May be proximal or distal to level of caliber change

TOP DIFFERENTIAL DIAGNOSES

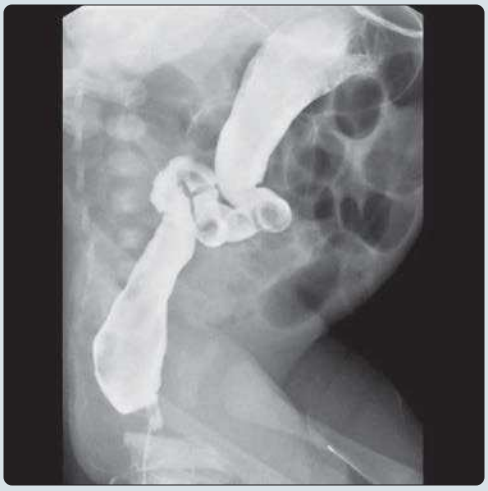


- Hirschsprung disease (HD)
- Ileal atresia
- Meconium ileus
- Anorectal malformation
- Ileus secondary to midgut volvulus or necrotizing enterocolitis

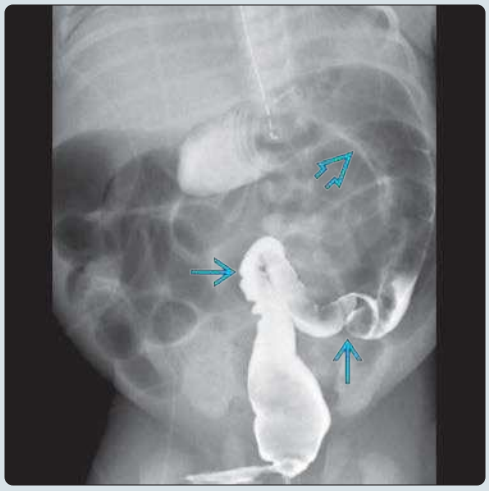


PATHOLOGY

- ↑ incidence in premature infants & infants of diabetic mothers or mothers who received magnesium sulfate



CLINICAL ISSUES



- Presents with abdominal distention, delayed passage of meconium, emesis
- Temporary phenomenon: Usually resolves within several days (hastened by enemas or rectal stimulation)
- Rectal biopsy to exclude HD if symptoms persist; some advocate biopsy for all as HD is ultimately found in 13-38%

(Left) *AP radiograph in a newborn with failure to pass meconium, abdominal distention, & emesis shows numerous dilated bowel loops throughout the abdomen, typical of a distal (or low) neonatal intestinal obstruction.* **(Right)** *Left side-down decubitus radiograph obtained simultaneously shows diffuse dilation of bowel with numerous air-fluid levels, consistent with a distal obstruction. There is no free air. A few bubbly lucencies are likely due to gas intermixed with retained meconium.*

(Left) *Lateral water-soluble contrast enema (WSCE) in the same patient shows a normal rectosigmoid ratio (> 1) with a small-caliber sigmoid & tapered descending colonic segments.* **(Right)** *Supine frontal WSCE in the same patient shows gradual transition from the small-caliber sigmoid colon to a more normal colonic caliber near the splenic flexure. This is a typical appearance for neonatal small left colon. A rectal biopsy ruled out Hirschsprung disease.*

TERMINOLOGY

Abbreviations

- Neonatal small left colon (NSLC)

Synonyms

- Meconium plug syndrome (MPS)
- Functional immaturity of colon

Definitions

- Transient functional obstruction of newborn colon
  - Retained colonic meconium/plug is likely secondary finding (not primary cause of mechanical obstruction)
- Debate exists if MPS & NSLC are same entity

IMAGING

Radiographic Findings

- Multiple dilated loops of bowel in newborn (i.e., neonatal distal bowel obstruction)
  - Note that dilated large & small bowel loops (from any cause) cannot be reliably differentiated in neonates by morphology or size

Fluoroscopic Findings

- Contrast enema
  - Rectosigmoid ratio is normal (> 1)
    - Rectum is of relatively normal caliber
  - Small-caliber distal colon (sigmoid & descending segments) up to splenic flexure
  - Abrupt or gradual transition to normal/mildly dilated proximal colon
  - Multiple filling defects of normal meconium may be scattered throughout colon & are often present in narrowed segment
    - May be displaced proximally during enema
  - Meconium plugs frequently pass during/after enema: Enema is often therapeutic

DIFFERENTIAL DIAGNOSIS

Hirschsprung Disease

- Distal aganglionic segment is small in caliber up to transition zone
  - Rectal caliber is typically smaller than sigmoid ± serrated mucosa/irregular contractions
  - Long-segment Hirschsprung disease (HD) with splenic flexure transition zone may mimic functional immaturity

Ileal Atresia

- Microcolon
- Contrast refluxed into ileum stops abruptly at atresia
- Cannot opacify proximal dilated small bowel

Meconium Ileus

- Microcolon
- Enema contrast outlines obstructive meconium pellets in distal ileum
- Contrast may or may not reach dilated small bowel proximal to impacted meconium
- Most have cystic fibrosis (CF)

Anorectal Malformation

- Distal obstruction with no normal anus present

Colonic Atresia

- Distal obstruction with disproportionately dilated loop
- Microcolon to level of atresia on enema

Midgut Volvulus

- Bowel loops may be diffusely dilated due to ischemic ileus in ill neonate
- Upper GI is study of choice in ill neonate with bilious emesis

PATHOLOGY

General Features

- Etiology
  - Unclear; probably due to immature ganglion cells or hormonal receptors resulting in transient functional obstruction of colon
  - ↑ incidence with
    - Infants of diabetic mothers (40-50% of MPS)
    - Infants of mothers who receive magnesium sulfate
    - Premature infants
  - Plugs of normal meconium do not cause obstruction in this diagnosis (unlike abnormal meconium in CF)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Abdominal distention
  - Delayed passage of meconium (> 24-48 hours)
  - Emesis

Natural History & Prognosis

- Temporary phenomenon: Usually resolves within few days
- Excellent prognosis, though HD is ultimately found in 13-38%

Treatment

- Condition resolves over time, hastened by rectal stimulation
  - Often resolves after diagnostic contrast enema
- Suction rectal biopsy to exclude HD if symptoms persist
  - Some advocate immediate biopsy regardless of symptom resolution
  - Wide variation exists in surgical practice; higher likelihood of biopsy with
    - Neonatal intestinal perforation
    - Delayed passage of meconium > 48 hours
  - Up to 25% with both HD & MPS do not get early biopsy, which may delay appropriate management

Hirschsprung Disease

KEY FACTS

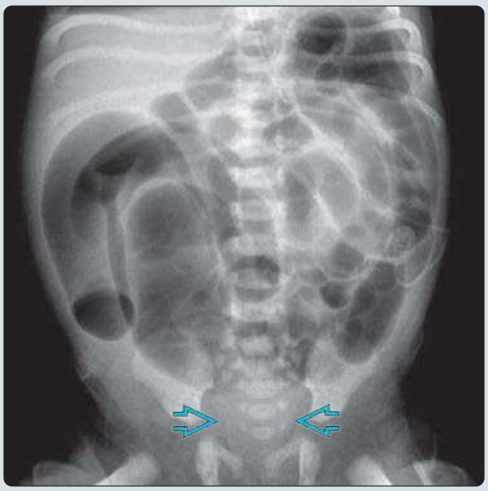
TERMINOLOGY

- Hirschsprung disease (HD): Congenital anomaly of enteric nervous system
  - Absence of ganglion cells in intestinal myenteric & submucosal plexus
  - Aganglionic segment extends retrograde from anus for variable length with gradual transition to normal innervation

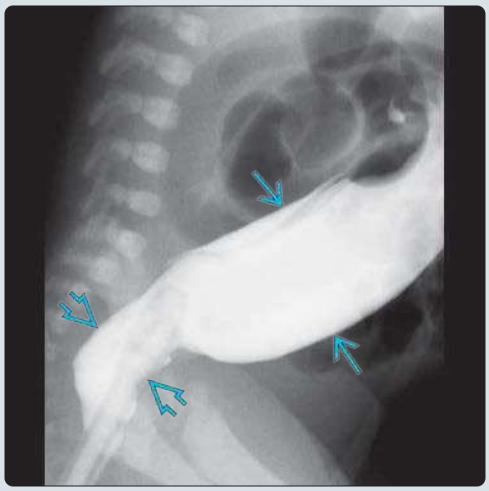
IMAGING

- Newborn radiograph: Numerous loops of dilated bowel
- Radiograph beyond neonatal period: Large stool burden with variable colonic dilation
- Contrast enema is especially useful in neonate with distal bowel obstruction; findings suggestive of HD include
  - Rectosigmoid ratio < 1
  - Transition zone from small distal colon to dilated proximal colon
  - Mucosal irregularity

TOP DIFFERENTIAL DIAGNOSES

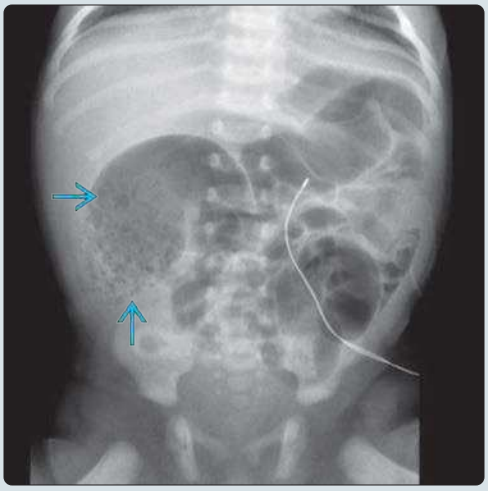


- Neonatal small left colon (meconium plug syndrome)
- Ileal atresia
- Meconium ileus
- Anorectal malformation
- Milk allergy colitis

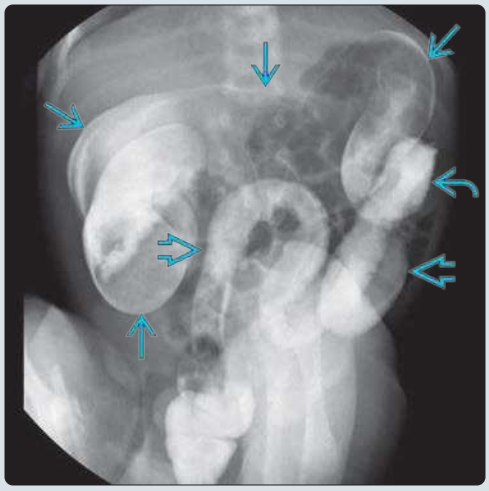


CLINICAL ISSUES

- Neonate: Failure to pass meconium, abdominal distention, bilious emesis, enterocolitis
- Older child: Constipation since birth, enterocolitis
- Diagnosis is made by rectal biopsy
- Treatment: Resect affected colon & pull-through of normal bowel to anus



DIAGNOSTIC CHECKLIST



- Contrast enema cannot rule out HD (but can suggest HD or other diagnoses)
- Frank colitis in term newborn → HD until proven otherwise

(Left) *AP radiograph in a 2-day-old with failure to pass meconium shows multiple dilated loops of bowel with no air seen in the rectum. One cannot differentiate small bowel (SB) from colonic loops on this exam. A contrast enema is required to elucidate the etiology of obstruction.* **(Right)** *Lateral view of a water-soluble contrast enema (WSCE) in the same patient shows a small-caliber rectum relative to the dilated sigmoid, suggesting short-segment Hirschsprung disease (HD). This was confirmed by rectal biopsy.*

(Left) *AP radiograph in a newborn with bilious emesis shows a disproportionately dilated loop in the right abdomen distended by meconium intermixed with gas. The number of gas-filled loops overall suggests a distal obstruction.* **(Right)** *Supine WSCE in the same patient shows a narrowed sigmoid & descending colon with transition at the splenic flexure to a dilated & meconium-filled transverse & ascending colon. Note the mucosal irregularity or spasm in the left colon. Biopsy confirmed long-segment HD.*

TERMINOLOGY

Synonyms

- Colonic aganglionosis

Definitions

- Hirschsprung disease (HD): Congenital anomaly of enteric nervous system
  - Absence of ganglion cells in myenteric & submucosal plexus of intestine
    - Lack of muscle relaxation → functional bowel obstruction
  - Aganglionic segment extends retrograde from anus for variable length with gradual transition to innervated proximal colon
    - Rectosigmoid: Short-segment HD (70-80%)
    - Proximal to rectosigmoid: Long-segment HD (15-25%)
    - Entire colon: Total colonic HD (4-13%)
    - Colon & small bowel (SB): Total intestinal HD (very rare)
    - Just above anorectal verge: Ultrashort-segment HD (very rare)

IMAGING

General Features

- Best diagnostic clue
  - Rectosigmoid (R/S) ratio < 1 on contrast enema
    - Requires well-distended lateral view from rectum to splenic flexure
- Morphology
  - Small caliber of aganglionic distal colon
  - Dilation of innervated proximal colon above transition

Radiographic Findings

- In newborn
  - Numerous dilated bowel loops suggesting distal obstruction
  - ± irregular, thickened bowel wall with enterocolitis
    - Rarely pneumatosis
  - Rarely intraluminal ileal Ca^{2+} in total colonic HD
- Outside neonatal period
  - Large stool burden with varying degrees of dilation
  - Paucity of gas with thick colonic wall: Question enterocolitis
  - Rarely free air from perforation in 1st year of life
    - Perforation usually at proximal colon or appendix

Fluoroscopic Findings

- Contrast enema
  - Short- or long-segment HD
    - R/S ratio is classically < 1 (but not always)
    - Transition zone: Level at which small distal colon becomes dilated proximally
    - ± sawtooth pattern of distal mucosa (spasm)
    - ± irregular mucosa/thickened wall of enterocolitis
      - Cobblestone appearance
    - Delayed (> 24-48 hours) evacuation of contrast
    - Near normal enema in ultrashort-segment HD
  - Total colonic HD
    - May appear normal vs. microcolon vs. shortened length with round flexures (question mark- or comma-shaped)
    - Rectum is often same caliber as rest of colon: R/S ratio ≤ 1
    - Ileocecal reflux is typically seen
      - Sensitivity/specificity is quite variable in isolation
    - SB proximal to colon may be dilated

Imaging Recommendations

- Best imaging tool
  - Water-soluble contrast enema (WSCE)
- Protocol advice
  - With clinical + radiographic suspicion for neonatal distal bowel obstruction → WSCE
    - Low osmolality water-soluble contrast
    - Lateral & AP views of maximally distended rectum up to splenic flexure on early images
      - Compare rectum to sigmoid + more proximal colon
      - Normal R/S ratio is > 1
    - WSCE is stopped once transition zone is reached
    - If WSCE is normal, consider upper GI to exclude midgut volvulus (MGV), as ischemic ileus can mimic obstruction

DIFFERENTIAL DIAGNOSIS

Neonatal Distal Intestinal Obstruction With Small Distal Colon

- Neonatal small left colon (meconium plug syndrome)
  - Nonpathologic transient functional obstruction
  - WSCE: R/S ratio is usually > 1 with transition at splenic flexure
  - ± rectal biopsy to exclude long-segment HD
- Colonic atresia
  - WSCE: Blind-ending, small-caliber distal colon
  - Dilated, air-filled proximal colon (larger as compared to dilated SB)

Neonatal Distal Intestinal Obstruction With Microcolon

- Ileal atresia
  - WSCE: Blind end of contrast column in ileum
- Meconium ileus
  - WSCE: Contrast outlines meconium pellets obstructing terminal ileum
- Megacystis microcolon intestinal hypoperistalsis
  - WSCE: Tiniest microcolon
  - Dilated, floppy bladder; most common in females

Neonatal Distal Intestinal Obstruction With Normal Colon

- Omphalomesenteric duct remnant
  - Various forms: Fibrous band, Meckel diverticulum
  - WSCE: May see medialization or beaking of cecum
- Inguinal hernia
  - May visualize gas in inguinal canal or scrotum
- MGV
  - Ischemic ileus in ill neonate mimics distal obstruction
  - Consider upper GI vs. ultrasound 1st in ill neonate with bilious emesis

- Necrotizing enterocolitis
  - In prematurity, most common etiology by far
  - Ischemic ileus mimics distal obstruction
  - Not typical in 1st few days after birth

Enterocolitis in Infant

- Milk allergy colitis
  - 1st weeks of life, usually with formula feeds
  - WSCE: R/S ratio < 1 ± colitis
  - Rectal biopsy: Eosinophils, normal ganglion cells

Intraluminal Calcifications

- Anorectal malformation
- Multiple intestinal atresias
- Total colonic HD

PATHOLOGY

General Features

- Etiology
  - Precise mechanism is unknown for sure
    - Defect in 1st-trimester migration of enteric ganglia
    - Normal migration but abnormal survival of ganglia
- Genetics
  - Most cases are sporadic
  - Numerous genetic mutations found
  - Familial HD in 8-10%
- Associated abnormalities
  - 5-32% of HD overall
    - Down syndrome (7-15%)
    - Neurocristopathy syndromes
    - Congenital central hypoventilation ("Ondine curse")
    - Colonic atresia
    - Other isolated anomalies

Microscopic Features

- Diagnosis by rectal biopsy
  - Suction biopsy: Bedside, less reliable
  - Full-thickness biopsy: In operating room, definitive
- Absent ganglia in myenteric & submucosal plexus
- Hypertrophic nerve fibers (acetylcholinesterase positive)
- Disease is most commonly contiguous without skip areas
  - Reported cases of segmental HD
    - May lead to incorrect diagnosis or inadequate resection/failed pull-through
- Radiologic-pathologic correlation of transition zone site
  - Short-segment (or low transition zone) HD: 75%
  - Long-segment (or high transition zone) HD: 25%

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Failure to pass meconium in first 24-48 hours of life (60-90%)
  - Abdominal distention (63-91%)
  - Bilious vomiting (19-37%)
  - Enterocolitis (5-44%)

Demographics

- 90% are diagnosed in newborn period
- 10% are diagnosed later, rarely adolescent or adult
- M > F = 4:1 (long-segment & total colonic HD → 1:1)

Natural History & Prognosis

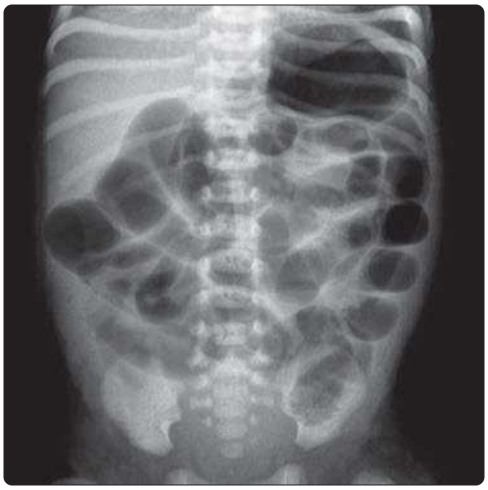
- Untreated HD may lead to constipation, enterocolitis, toxic megacolon, sepsis, death
- Treated: Up to 40% have chronic soiling, constipation
  - Must assess for failure of pull-through procedure
  - Poorer outcome: Down syndrome, total colonic HD

Treatment

- Resection of aganglionic colon
- Pull-through of normal bowel to anus
  - Swenson, Soave, Duhamel procedures are most common
  - Single-stage transanal endorectal pull-through ± laparoscopy is now common
- Complications
  - Early: Leak, infection, obstruction
  - Late: Bowel adhesion/obstruction, stricture, enterocolitis, constipation, incontinence
- Common etiologies for failed pull-through
  - Soave cuff, Duhamel pouch, ischemic stricture, residual HD, twisted pull-through

DIAGNOSTIC CHECKLIST

Consider



- Contrast enema cannot rule out HD
  - With clinical suspicion, must biopsy
- Contrast enema is most useful in assessing distal obstruction in neonates
  - Only up to 80% sensitive for HD in newborns

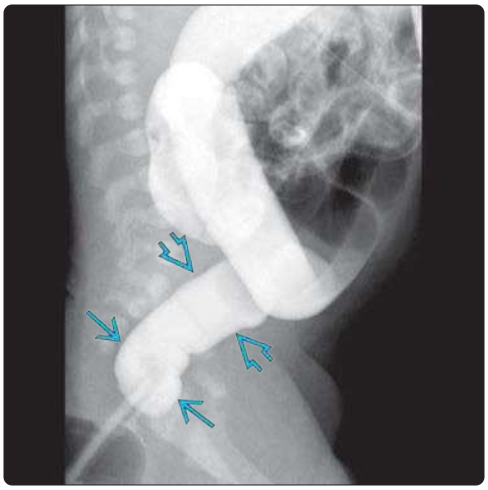


Image Interpretation Pearls

- R/S ratio < 1 & transition zone on WSCE → HD
- Frank colitis in term newborn → HD until proven otherwise

(Left) *AP radiograph of a 2-day-old with abdominal distention & failure to pass meconium shows multiple air-filled bowel loops diffusely, suggesting a distal intestinal obstruction. The next study should be a WSCE to elucidate the etiology of this obstruction.* **(Right)** *Lateral view of a WSCE in the same patient shows the rectum ⇨ to be slightly smaller in caliber as compared to sigmoid ⇨ & proximal colon without an abrupt transition. However, this appearance raised suspicion for HD, & biopsy was confirmatory.*

(Left) *AP radiograph in an 8-year-old with a long history of constipation & multiple episodes of colitis shows little stool after a clean out. There are dilated colonic & SB loops with possible wall thickening ⇨.* **(Right)** *Frontal supine WSCE in the same patient shows a fairly distended distal rectum. However, the colon was narrow & spastic almost to the splenic flexure ⇨, suggesting long-segment HD, which was confirmed at biopsy.*

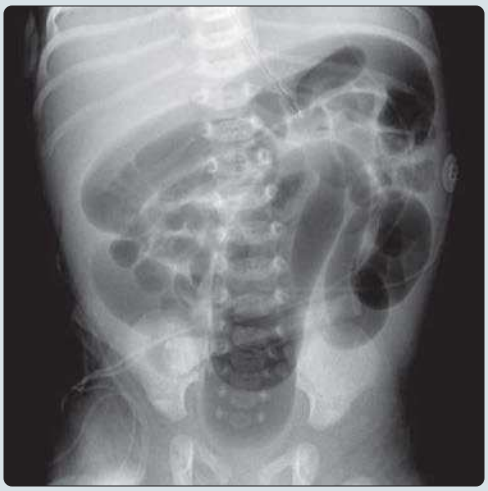
(Left) *Frontal supine WSCE in a newborn with total colonic HD shows a mildly small-caliber colon, which is fairly uniform throughout. The course of the colon is shortened with rounding of the flexures ⇨.* **(Right)** *Frontal supine WSCE in a newborn with bilious emesis shows severe mucosal irregularity ⇨ throughout most of the colon, suggesting colitis in HD. Biopsies showed total intestinal aganglionosis.*

KEY FACTS

IMAGING

- Neonatal clinical exam + AP abdominal radiograph
  - Many dilated bowel loops, ± rectal gas, ± bowel Ca^{2+}
  - Prone XTL view if fistula is not clinically evident (~ 5%)
- Renal, spine US; pelvic US for females with cloaca
  - Urgent drainage of hydrocolpos to prevent rupture & ureteral obstruction
- Evaluate additional anomalies (VACTERL or syndromes)
- Delayed distal colostogram for classification of ARM & preop planning: Fistula in ~ 95% of males
  - Perfect lateral view (superimposed femoral heads)
  - If bladder fills, fill until voiding; image distal colonic segment, bladder, urethra
- ± pelvic MR prior to, during, &/or after operative repair

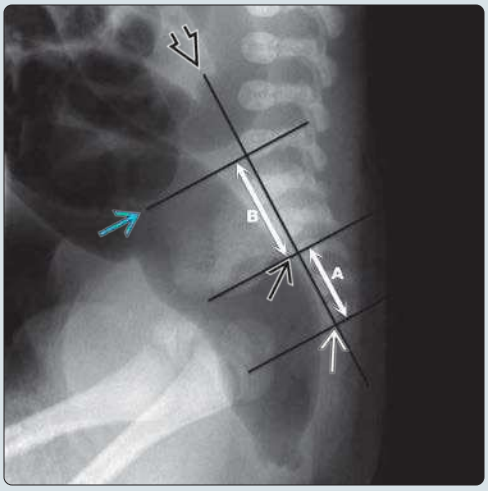
TOP DIFFERENTIAL DIAGNOSES



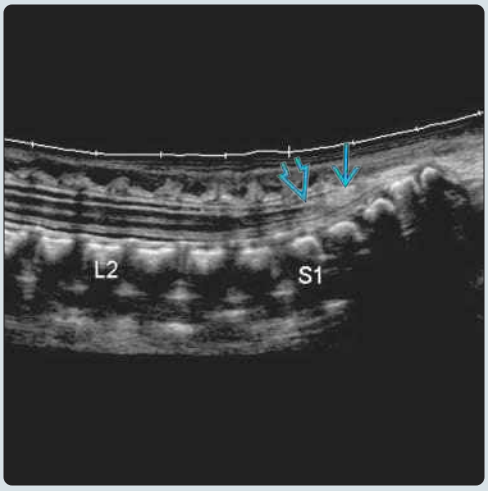
- Neonatal distal bowel obstruction (with normal anus)
  - Meconium plug syndrome, Hirschsprung disease, meconium ileus, jejunoileal atresia
- Neonatal intraluminal abdominal Ca^{2+}
  - Total colonic Hirschsprung, multiple intestinal atresia

PATHOLOGY

- Imperforate anus
  - Rectoperineal fistula (male or female)
  - Rectovestibular fistula: 25% of female ARMs
  - Rectourethral fistula: 50% of male ARMs
  - Rectobladder neck fistula: 10% of male ARMs
  - No fistula: 5% of ARMs (male or female)
  - Cloacal malformation: Only females
- Rectal atresia or stenosis: 1% of ARMs



CLINICAL ISSUES



- Goals: Maximize continence of feces & urine, sexual function
- Most ARMs require
  - Diverting colostomy within days of birth
  - PSARP for definitive repair months later

(Left) *AP radiograph in a newborn (24-hours-old) boy with imperforate anus & no clinical signs of a fistula (no meconium per urethra or perineum) shows multiple dilated bowel loops to the pelvis with a dilated rectum.* **(Right)** *Prone cross-table lateral view with a BB on the anus in the same patient shows the rectal pouch ⇨ adjacent to the anus, a type of low anorectal malformation (ARM) unlikely to have a rectourinary fistula that can be repaired as a neonate without colostomy.*

(Left) *Lateral radiograph in the same patient was taken to calculate the sacral ratio (A/B). The axis is drawn along the sacrum ⇨, then lines are drawn perpendicular to the sacral axis at the iliac crest ⇨, greater sciatic notch ⇨, & tip of the ossified sacrum/coccyx ⇨.* **(Right)** *Spinal US in a 2-day-old with a history of imperforate anus who had meconium per the urethra (clinical evidence of a rectourinary fistula) shows a low conus at the S1 level ⇨ with an echogenic terminus ⇨, which may represent a lipoma or lipomyelocele.*

TERMINOLOGY

Synonyms

- Imperforate anus

Definitions

- Anorectal malformation (ARM): Spectrum of congenital anomalies related to abnormal development of anorectal canal
- Diagnosis of ARM is made by clinical exam
- Imaging is used to identify associated anomalies, plan operations, & evaluate postoperative complications
- Evolution of ARM classification: Traditionally as high, intermediate, or low (relative to pubococcygeal line)
  - Current (Peña or Krickenbeck): By specific malformation with therapeutic & prognostic implications
- Cloaca: Subtype of ARM in girls; rectum, vagina, & bladder converge into common channel → single perineal orifice
- Posterior sagittal anorectoplasty (PSARP): Definitive surgical reconstruction for most ARMs

IMAGING

General Features

- Best diagnostic clue
  - Multiple dilated bowel loops in newborn without normal external anus
- Morphology
  - Rectal opening outside anal sphincter on perineum vs. no rectal opening on perineum

Radiographic Findings

- Radiography
  - Multiple dilated bowel loops of distal obstruction in newborn
  - Ca^{2+} → enteroliths (intraluminal Ca^{2+})
    - Mixing of urine & meconium via rectourinary fistula
  - Prone cross-table lateral (XTL) view of abdomen > 24-hours-old → measure pouch to anus distance
    - In ~ 5% of ARMs, fistula is **not** clinically apparent to help direct operative management
    - Rectal pouch close to anal region → neonatal repair; if not → diverting colostomy/delayed repair
  - ± hemisacrum/scimitar sacrum (different from truncated sacrum): Defect represents presacral mass
    - Teratoma, anterior meningocele, mixed lesion
  - Sacral ratio predicts potential for fecal continence; > 0.6 = normal; < 0.4 = ↓ probability of continence
  - ± esophageal atresia (EA), tracheoesophageal fistula (TEF), congenital heart disease
  - ± vertebral or radial ray anomalies

Fluoroscopic Findings

- Voiding cystourethrogram
  - Variable findings: Normal; vesicoureteral reflux (VUR); ± bladder thickening, trabecula, neurogenic bladder; fistula from bladder neck or urethra → rectum in males, reflux from urethra to vagina &/or rectum in female cloaca
- Fistulagram
  - a.k.a. augmented pressure distal colostogram using Foley catheter
    - Water-soluble contrast injection of mucous fistula
  - To be performed several weeks to months after colostomy, prior to definitive repair
    - Must opacify rectal pouch & rectourinary fistula
  - Lateral view (superimposed femoral heads) showing
    - Distal colonic segment length, fistula to bladder or urethra in boys, common channel in girls
      - Most boys (95%) have rectourinary fistula (except Down syndrome: 95% have **no** fistula)
      - **Adequate distention is needed to see fistula**
      - If bladder fills, fill until voiding; image distal colonic segment, bladder, urethra
    - Document relationship of rectal pouch to sacrum & anal sphincter (marked by BB)
    - Is presacral mass displacing rectal wall?
- ± cloacagram in females (usually performed prior to definitive repair)
  - Contrast injection of distal colostomy
  - Contrast into bladder &/or vagina via cloaca catheter
  - 3D imaging by rotational fluoroscopy, CT, or MR

MR Findings

- Prenatal: Absent T1-bright meconium posterior/inferior to bladder > 20-weeks gestation
- Post natal
  - Prerepair pelvic MR: Anal sphincter + pelvic floor musculature, rectal pouch, presacral mass, other GU anomalies
  - Intraoperative pelvic MR: Guide rectum through sphincter → novel approach
  - Postrepair pelvic MR (poor functional outcome): Look for misplaced rectum, entrapped fat, posterior urethral diverticulum
- Spine MR: Tethered cord, spinal dysraphism, sacral agenesis/dysgenesis

Ultrasonographic Findings

- Grayscale ultrasound
  - Perineal ultrasound: Assess distance of rectal pouch → perineum; not reliable
  - Assess neonate for renal + spine anomalies
  - Assess for hydrocolpos in newborn cloaca → if positive, urgent drainage is required to relieve secondary bladder/ureteral obstruction

Imaging Recommendations

- Best imaging tool
  - Neonate: Clinical exam + AP & prone XTL radiographs; renal, spine, & pelvic ultrasound (especially pelvis in cloaca)
  - Infant after colostomy: Distal colostogram for operative planning

DIFFERENTIAL DIAGNOSIS

Neonatal Distal Bowel Obstruction (Normal Anus)

- Small left colon/meconium plug syndrome
- Hirschsprung disease
- Meconium ileus
- Jejunoileal atresia

Abdominal Ca^{2+} in Newborn

- Intraluminal Ca^{2+}: ARM, total colonic Hirschsprung disease, multiple intestinal atresia

- Meconium peritonitis: Peritoneal Ca^{2+} due to in utero bowel perforation
- Visceral: TORCH, prior hemorrhage
- Mass: Teratoma, neuroblastoma, congenital hemangioma
- Vascular: Prior thrombosis

PATHOLOGY

General Features

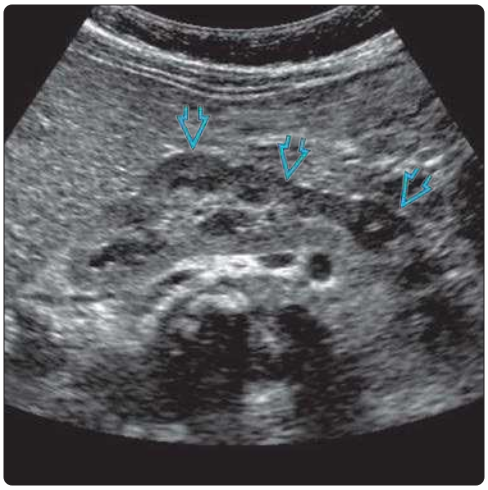
- Etiology
  - Abnormal separation of GU system from hindgut
- Genetics
  - No responsible gene identified; ↑ risk if sibling has ARM
  - Syndromic cases
    - Trisomy 21 (Down), Currarino (ARM, sacral deformity, presacral mass), VACTERL, OEIS, caudal regression, Pallister-Hall, Townes-Brocks
- Associated abnormalities
  - GU (50% of ARMs): Solitary/horseshoe kidney, VUR, bicornuate/didelphys uterus, hydrocolpos (50% of cloacas), hemivaginas
  - Spine: Tethered cord (25% of ARM, ↑ with more complex ARM), myelomeningocele, sacral anomalies (most affected bony structure)
  - Cardiac: Tetralogy of Fallot, ventricular septal defect
  - GI: EA ± TEF, duodenal atresia, Hirschsprung disease

Gross Pathologic & Surgical Features

- Imperforate anus
  - Rectoperineal fistula (male or female) → **no** colostomy → PSARP as newborn
    - Rectum opens to small, stenotic orifice anterior to normal anal sphincter complex; normal sacrum, muscles, sphincter
  - Rectovestibular fistula: 25% of female ARMs → **no** colostomy → PSARP as newborn
    - Rectum opens between hymen & perineal skin; most patients have good sacrum, sphincter
  - Rectourethral fistula: 50% of male ARMs → divided colostomy
    - Fistula to bulbar urethra: Normal/near-normal sacrum, muscles → delayed PSARP
    - Fistula to prostatic urethra: ± deficient sacrum, muscles → delayed PSARP ± lap procedure
  - Rectobladder neck fistula: 10% of male ARMs → divided colostomy → PSARP + lap procedure
    - Only true supralevator malformation; poor sacrum, sphincter, flat bottom (poorly developed gluteal crease)
  - No fistula: 5% of all ARM patients (male or female) with normal chromosomes → divided colostomy → PSARP
    - Rectum is usually ≤ 2 cm deep to perineum (if rectum is very close to skin on XTL → ± PSARP as neonate)
    - Usually good sacrum, sphincter
    - Frequent in Down syndrome (95%)
  - Rectal atresia or stenosis: 1% of ARMs (male or female) → different operative technique → colostomy
    - Atresia between normal anus & rectum; normal sacrum & sphincter
- Cloaca: Female with single perineal orifice (genitalia are frequently ambiguous)
  - Common channel drains rectum, vagina, urethra
  - Hydrocolpos in up to 50%
    - May cause urinary obstruction at distal ureters → requires neonatal drainage
    - Undrained hydrocolpos → renal insufficiency, vaginal perforation, sepsis, even death
  - Common channel length
    - < 3 cm: Divided colostomy → delayed PSARP, good prognosis
    - > 3 cm: Divided colostomy → delayed PSARP + lap procedure, poorer prognosis (more complex malformation, more associated anomalies)
  - Urethral length predicts urinary continence after cloacal repair

CLINICAL ISSUES

Presentation



- Most common signs/symptoms
  - Absent/misplaced rectal opening, abdominal distention
- Other signs/symptoms
  - Meconium per vestibule, urethra, or abnormal perineal opening; flat bottom, poorly developed gluteal crease

Treatment

- Goals: Maximize continence of feces & urine, sexual function
- Most ARMs require diverting colostomy within days of birth, PSARP months later
  - + laparotomy/laparoscopy for bladder neck & some prostatic fistulas + long common channel cloaca
- New MR-guided repair, avoids dividing anal sphincter
- Prognosis depends on type of malformation, sacral ratio, spine anomalies, meticulous surgical technique
  - 75% of ARMs will have voluntary bowel movements
  - 25% of ARM patients suffer incontinence, bowel management enemas daily to keep clean

(Left) *Transverse US in a 3-day-old boy with imperforate anus shows renal tissue ⇨ crossing anterior to the spine & great vessels, consistent with a horseshoe kidney.* **(Right)** *Colostogram in 3-month-old boy with an ARM shows a Foley balloon ⇨ inflated in the distal colonic segment. Contrast injection shows a rectoprostatic urethral fistula ⇨ located anterior to the spine, which will require laparoscopy as well as a posterior sagittal anorectoplasty (PSARP).*

(Left) *Colostogram in a 3-month-old boy with an ARM shows a rectobulbar urethral fistula ⇨ with a rectal pouch ⇨ well below the tip of spine ⇨. The distal colonic segment is adequate in length to bring the pouch to the anal region ⇨ by a PSARP.* **(Right)** *Colostogram in a 2-month-old with an ARM & poorly developed gluteal crease shows a rectobladder neck fistula ⇨. The rectal pouch lies above the spine tip at S3 & will only be reached by a laparoscopy or open abdominal approach prior to PSARP.*

(Left) *Axial T2 MR in a repaired ARM patient shows asymmetric positioning of the rectum ⇨ (containing a T2-bright catheter) within the asymmetric sphincter complex ⇨. Fat ⇨ is seen between the left rectal wall & sphincter muscle.* **(Right)** *Rotational fluoroscopy with 3D reconstruction was used to make this lateral view during a cloacagram in a 5-month-old girl with a history of cloaca. The urethra ⇨ length, amongst other criteria, has recently been found to correlate with the potential for urinary continence.*

Meconium Peritonitis

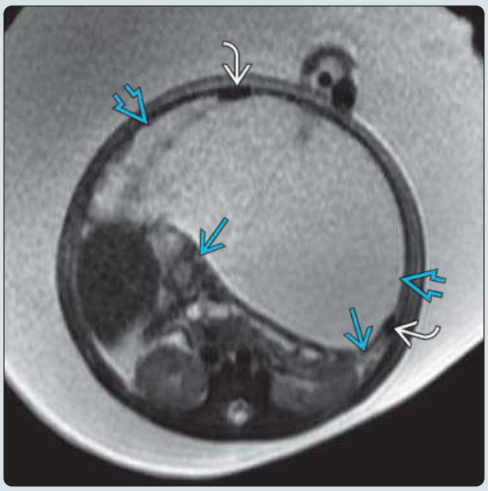
KEY FACTS

TERMINOLOGY

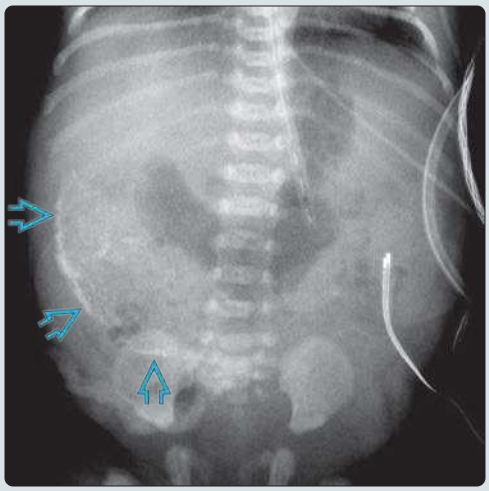
- Meconium peritonitis (MP): Chemical peritonitis from in utero bowel perforation with leakage of sterile meconium & digestive enzymes
- Meconium cyst: Meconium + fluid contained by fibrous membranes in setting of MP
- Meconium pseudocyst: Meconium + fluid contained by membranes partly derived from muscular layer of intestine

IMAGING

- Best diagnostic clue
  - Newborn abdominal radiograph showing linear, curvilinear, or punctate Ca^{2+} on peritoneal surfaces &/or cyst/mass causing bowel displacement
  - Pre- or postnatal US or prenatal MR showing peritoneal Ca^{2+}, complex ascites, dilated bowel, &/or cyst/pseudocyst
- Fluoroscopic contrast study can limit differential diagnosis



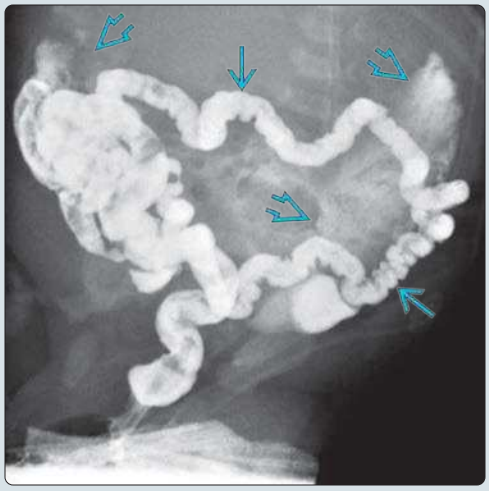
TOP DIFFERENTIAL DIAGNOSES



- Ileal atresia
- Meconium ileus
- Midgut volvulus
  - Much less common cause of MP

CLINICAL ISSUES

- Neonatal surgery is required in 50-90%
- Prenatal US prediction for neonatal surgery
  - Isolated Ca^{2+}: No surgery required
  - Ca^{2+} & 1 additional finding (ascites or pseudocyst or bowel dilation): > 50% require surgery
  - Ca^{2+} & 2-3 additional findings: 80-100% require surgery
- Newborn imaging predictors for surgery: Bowel obstruction, ascites, volvulus, pneumoperitoneum
- No treatment is required in asymptomatic patients with normal bowel function (i.e., healed perforation in utero)



(Left) *Axial SSFSE T2 fetal MR shows a large cystic lesion of the abdomen that contains scattered foci of debris, possibly meconium, & displaces decompressed bowel. Several low-signal foci suggest Ca^{2+}, raising the possibility of meconium peritonitis (MP).* **(Right)** *Newborn radiograph performed in the same patient delivered at 31-weeks gestation shows peritoneal or cyst wall Ca^{2+}, consistent with MP. No free intraperitoneal air is seen.*

(Left) *Abdominal US in the same patient shows a complex fluid collection with a thick, echogenic, calcified wall, correlating with the preceding radiograph. The bowel was decompressed (not shown).* **(Right)** *Supine WSCE was performed in the same patient to assess continuity of bowel in hopes of conservative initial management. Contrast first opacifies a microcolon & small bowel before leaking into the meconium pseudocyst. Three unexplained sites of perforation were found in the OR, but no atresia or thick meconium was seen.*

TERMINOLOGY

Definitions

- Meconium peritonitis (MP): Chemical peritonitis resulting from in utero bowel perforation that leaks sterile meconium & digestive enzymes into peritoneal cavity
- Meconium cyst: Meconium + fluid contained by fibrous membranes in setting of MP
- Meconium pseudocyst: Meconium + fluid contained by membranes partly derived from muscular layer of intestine

IMAGING

General Features

- Best diagnostic clue
  - Newborn abdominal radiograph showing linear, curvilinear, or punctate Ca^{2+} along peritoneal surfaces &/or cyst wall
    - Ca^{2+} begins within hours of meconium spillage
  - Pre- or postnatal US with peritoneal Ca^{2+}, complex ascites, dilated bowel, &/or cyst

Radiographic Findings

- Radiography
  - Abdominal soft tissue mass (cyst/pseudocyst)
    - May displace bowel loops
    - May have rim or internal Ca^{2+}
    - May cause gasless abdomen
  - Amorphous, linear, or curvilinear Ca^{2+} along peritoneal surfaces
    - Parietal layer lining abdominal cavity
    - Visceral layer along organ surfaces (liver, etc.)
    - Calcified meconium in bowel loops (enteroliths) may be difficult to differentiate from MP on radiographs
      - Consider: Total colonic aganglionosis, anorectal malformation, multiple bowel atresias
  - ± centralized bowel loops due to ascites
  - Multiple dilated bowel loops of bowel obstruction; 2 possible etiologies
    - In utero obstruction → perforation
    - Spontaneously sealed in utero perforation ± adhesions &/or atresia → obstruction
  - Free intraperitoneal air may occur from persistence of in utero perforation
    - More commonly, site of perforation seals in utero
  - Ca^{2+} in scrotum (meconium orchitis)
    - Due to intraperitoneal Ca^{2+} passing through patent processus vaginalis

Ultrasonographic Findings

- Grayscale ultrasound
  - Pre- or post natal
    - Hyperechoic punctate, linear echogenic foci along abdominal surfaces ± shadowing
      - Prenatal US is more sensitive than postnatal radiographs
    - Ascites: Complex fluid (from meconium) is very suggestive
    - Dilated bowel
    - Cystic mass ± wall nodularity, Ca^{2+}, debris
      - Mass effect may mimic abdominal tumor
    - Ca^{2+}, complex fluid (hydrocele) in scrotum

MR Findings

- Prenatal MR: Similar findings to prenatal US
  - Fetal ascites or cystic collection
    - Complex ± bright T1 signal debris (meconium) vs. simple fluid
  - Dilated bowel loops
  - ± polyhydramnios

Fluoroscopic Findings

- Upper GI
  - Can be normal or show variety of anomalies
    - Malrotation ± midgut volvulus
    - Duodenal jejunal junction may be displaced by adjacent dilated bowel loops or cyst/pseudocyst despite normal rotation
      - ↑ laxity of ligament (actually muscle) of Treitz in newborn
    - Small bowel obstruction (SBO) is frequent
- Contrast enema
  - Microcolon (small colon)
    - Strongly suggests distal in utero SBO
    - Most commonly due to
      - Ileal atresia: Contrast stops at blind-ending terminal ileum (TI)
      - Meconium ileus: Numerous filling defects in TI are outlined by contrast
  - Normal colon
    - Possible proximal or late SBO
  - Colonic obstruction is uncommon (i.e., MP is uncommonly seen with Hirschsprung disease, colonic atresia)

Imaging Recommendations

- Best imaging tool
  - Prenatal &/or postnatal sonography
  - Neonatal abdominal radiographs
- Protocol advice
  - Fluoroscopic contrast study can limit differential diagnosis
    - In face of distal obstruction, water-soluble contrast enema (WSCE) is most helpful
      - Usually meconium Ileus vs. ileal atresia

DIFFERENTIAL DIAGNOSIS

Neonatal Distal Bowel Obstruction

- Ileal atresia
- Meconium ileus
- Hirschsprung disease
- Small left colon/meconium plug syndrome
- Anorectal malformation
- Malrotation
  - Midgut volvulus
    - Much less common cause of MP than distal obstructions
    - Ischemic ileus may mimic distal obstruction due to multiple dilated loops
  - Congenital bands

Neonatal Abdominal Calcifications

- Enteroliths

- Anorectal malformation
- Multiple intestinal atresias
- Total colonic Hirschsprung disease

- Liver parenchyma
  - TORCH infections
  - Vascular Ca^{2+}
- Mass
  - Sacrococcygeal teratoma
  - Neuroblastoma
  - Hepatoblastoma
  - Congenital hepatic hemangioma

PATHOLOGY

General Features

- Etiology
  - In utero bowel perforation is most commonly due to
    - Meconium ileus
      - 8-40% have meconium ileus with cystic fibrosis
    - Jejunal/ileal atresia or stenosis
    - Volvulus
      - Malrotation with midgut volvulus
      - Other segmental volvulus
  - In utero bowel perforation is less commonly due to
    - Intussusception, vascular accident, congenital bands, internal hernia, Hirschsprung disease, colonic atresia, cloaca
  - Cause is unknown in 25-50% of cases
  - Meconium & digestive enzymes leak into peritoneal cavity → intense chemical peritonitis + inflammatory response → granulomatous response + Ca^{2+} within hours-days

Gross Pathologic & Surgical Features

- Subtypes at surgery
  - Fibroadhesive: Sealed off perforation → bowel obstruction
  - Cystic or pseudocystic (fibrous vs. partially muscular/bowel wall): Perforation does not seal off → inflammation → cystic cavity
  - Generalized: Late in utero perforation → more fibrinous than fibrous

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Prenatal: Polyhydramnios, bowel obstruction, Ca^{2+}, abdominal cyst, ascites
  - Post natal: Abdominal distention, mass, failure to pass meconium, bilious emesis, respiratory distress

Demographics

- Age: 2nd-trimester through birth
- Epidemiology: 1:35,000 live births

Natural History & Prognosis

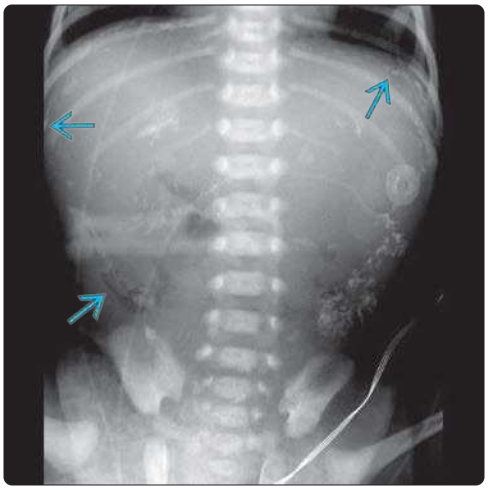
- Majority of cases do not resolve spontaneously in utero
- Prenatal US prediction for neonatal surgery
  - Isolated Ca^{2+}: No surgery required
  - Ca^{2+} & 1 additional finding (ascites or pseudocyst or bowel dilation): > 50% require surgery
  - Ca^{2+} & 2-3 additional findings: 80-100% require surgery
- Newborn imaging predictors for surgery: Bowel obstruction, ascites, volvulus, pneumoperitoneum
- No relation between prenatal diagnosis or type of MP & outcome
- Massive ascites or cyst may lead to hydrops, pulmonary hypoplasia in utero
  - Fetal paracentesis to ↓ fluid
  - Urinary trypsin inhibitor may ↓ inflammation
- 2-20% mortality in modern era
- Predicting factors for morbidity & mortality
  - Postnatal circulation deficiency, serum CRP, persistent ascites, persistent pulmonary hypertension

Treatment

- None in asymptomatic patients with normal bowel function (i.e., healed perforation)
- Neonatal surgery is required in 50-90%
  - Abdominal drainage
  - Relieve bowel obstruction
  - Resection of perforated &/or necrotic bowel
  - Anastomosis vs. temporizing bowel diversion with delayed anastomosis
- Cyst vs. pseudocyst may be important distinction to direct surgical treatment in recent series
  - Pseudocyst: Primary bowel anastomosis
  - Cyst: Bowel diversion with delayed anastomosis
- Complications: Sepsis, adhesions, short gut syndrome

DIAGNOSTIC CHECKLIST

Consider



- Most common causes of in utero bowel perforation
  - Complicated meconium ileus (cystic fibrosis)
  - Intestinal atresia

Image Interpretation Pearls

- Pre- or postnatal sonography: Polyhydramnios, abdominal cyst, ascites, peritoneal Ca^{2+}, dilated bowel
- Postnatal radiography: Ca^{2+} of peritoneal lining is diagnostic
  - Evaluate if Ca^{2+} could be in other locations
    - Intestinal lumen (enteroliths)
    - Hepatic, splenic parenchyma
    - Intraabdominal neoplasm

(Left) *AP radiograph in a 1-day-old girl with a prenatal concern for MP shows amorphous Ca^{2+} on peritoneal surfaces throughout the abdomen, which is consistent with MP. The paucity of bowel gas is suspicious for a collection, although US showed normal bowel & no cyst.* **(Right)** *Upper GI + small bowel follow-through in the same patient shows continuous bowel & no obstruction. MP with no cystic mass, ascites, or obstruction equals a healed in utero perforation.*

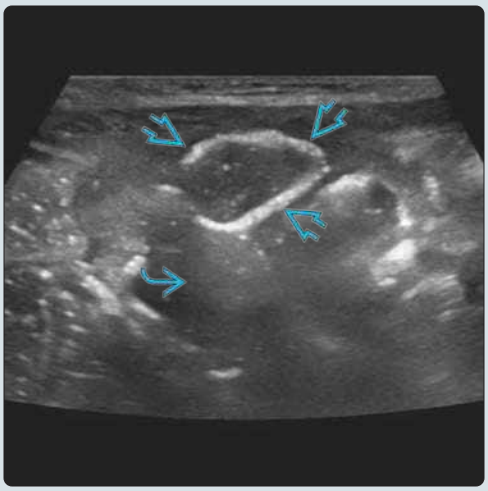
(Left) *Prenatal US shows complex ascites & somewhat thickened echogenic bowel loops, suggestive of MP. Echogenic bowel is nonspecific but can be seen in cystic fibrosis.* **(Right)** *AP radiograph in the same patient at delivery shows a gasless abdomen with curvilinear & amorphous subtle Ca^{2+}, suggestive of MP. The main diagnostic considerations include a bowel atresia or complicated meconium ileus, which is usually a manifestation of cystic fibrosis (CF).*

(Left) *Transverse US in the same patient confirms the presence of complex ascites, suggestive of MP (as well as echogenic bowel, as seen on the prenatal US).* **(Right)** *Supine WSCE in the same patient shows a microcolon devoid of significant meconium. The normal caliber terminal ileum is filled with meconium, consistent with meconium ileus, a common cause of MP. Genetic testing confirmed CF in this neonate.*

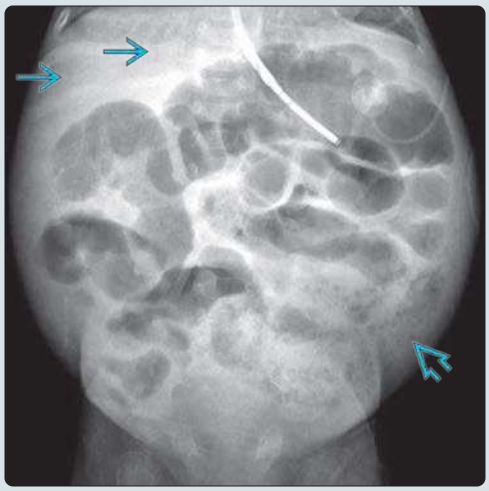
Necrotizing Enterocolitis

KEY FACTS

TERMINOLOGY

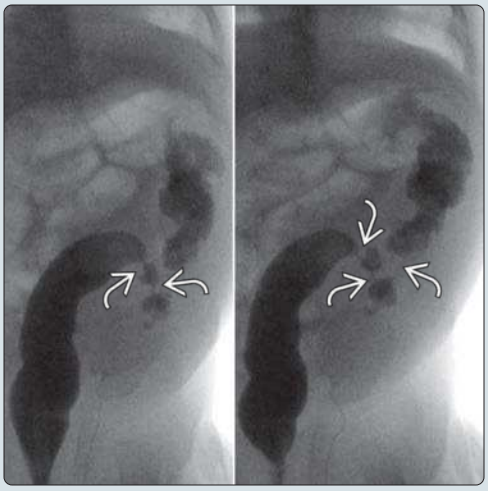


- Necrotizing enterocolitis (NEC): Life-threatening condition of neonatal GI tract characterized by inflammation, ischemia, & translocation of bacteria into bowel wall

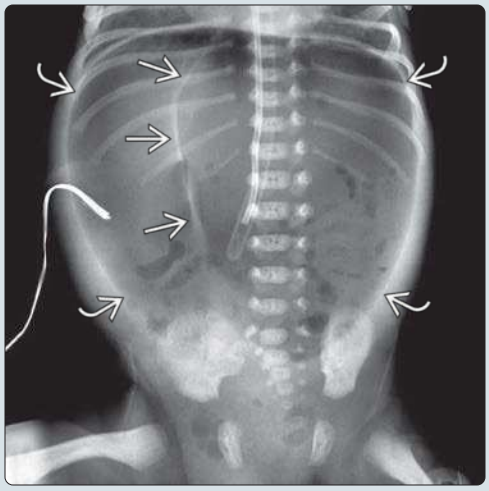


IMAGING

- Diagnosis is based on clinical & imaging findings
- Radiography is mainstay of imaging for suspected NEC
  - Findings range from nonspecific (gasless abdomen) to suggestive (thickened, dilated bowel loops) to diagnostic [pneumatosis, portal venous gas (PVG), free air]
  - Duke Abdominal Assessment Scale for radiographs
    - Standard lexicon for reporting NEC findings
    - Strong intraobserver & interobserver agreement
    - ↑ scores correlate with need for surgery
- Ultrasound is excellent adjunct
  - Predictors of radiographically occult necrosis &/or perforation requiring surgery vary by study but most commonly include complex collections & free air
  - Additional findings include ↑ (early) or ↓ (late) vascularity, ↓ peristalsis, ↑ bowel wall echogenicity, intramural gas, bowel wall thickening or thinning, & PVG
- Contrast enema is not used acutely; useful to localize strictures after treatment of acute episode



CLINICAL ISSUES



- Most common in very low birth weight (< 1,500 g) &/or premature infants, usually 2-3 weeks after delivery
  - 10% in term infants (usually with underlying diseases)
- Typical history: Feeding intolerance with emesis, ↑ gastric residuals, bloody stools
- Other frequent clinical findings include abdominal distention &/or discoloration, apnea & bradycardia, lethargy, temperature instability
- Treatment: IV nutrition + antibiotics ± surgery
- Overall mortality 10-50%
  - Death is secondary to sepsis from bowel perforation
- Delayed bowel strictures in 10-20% of survivors

(Left) *Transverse left lower quadrant US in a 5-week-old former premature infant shows bowel wall hyperechogenicity due to pneumatosis; this can be differentiated from intraluminal bowel gas by its circumferential distribution. Note the "dirty" posterior acoustic shadowing caused by gas in the bowel wall.* **(Right)** *Supine AP radiograph in the same patient shows "bubbly" lucencies of pneumatosis in the left lower quadrant. Subtle branching foci of portal venous gas (PVG) are seen in the liver.*

(Left) *Two weeks later, sequential frontal images from an enema in the same patient show several short-segment, high-grade colonic strictures in the same region that was imaged with US.* **(Right)** *Supine AP radiograph in a premature infant with necrotizing enterocolitis (NEC) shows a large amount of pneumoperitoneum causing abnormal lucency. The falciform ligament is outlined by air; this appearance resembles the laces of an American football (the football sign).*

TERMINOLOGY

Definitions

- Necrotizing enterocolitis (NEC): Poorly understood but life-threatening condition of neonatal GI tract characterized by inflammation, ischemia, & translocation of bacteria into bowel wall
- Very low birth weight (VLBW): < 1,500 g
- Extremely low birth weight (ELBW): < 1,000 g

IMAGING

General Features

- Best diagnostic clue
  - Dilated bowel loops with pneumatosis (intramural bowel gas), portal venous gas (PVG), & free intraperitoneal air
- Location
  - Affected bowel is most commonly in right lower quadrant
    - Ascending colon, terminal ileum
  - May occur anywhere from stomach to rectum

Radiographic Findings

- Nonspecific findings
  - Paucity of bowel gas
  - Loss of normal mosaic pattern of polygon-shaped bowel loops throughout abdomen
- Suggestive findings
  - Asymmetric bowel dilation
  - Fixed, "unfolded" bowel loops on serial radiographs
    - May be normal caliber or dilated
  - Separation of bowel loops
    - Due to bowel wall edema/hemorrhage or intervening collapsed or fluid-filled bowel or free fluid
- Definitive findings
  - Pneumatosis (50-75% of patients)
    - "Bubbly" (submucosal) or curvilinear (subserosal) lucencies
    - Mimics formed stool (not typically seen in unfed infants though enteric fluid may contain gas bubbles)
  - PVG
    - Branching lucencies over liver
    - Greater peripheral extension than biliary gas (with biliary gas being uncommon in newborns)
  - Free intraperitoneal air
    - Overall ↑ upper abdominal lucency on supine radiograph with liver appearing less opaque than heart
    - Football sign: Lucent, distended abdomen with gas outlining vertical falciform ligament on supine radiograph (like laces of American football)
    - Cupola sign: Gas under midline diaphragm on supine radiograph (with well-defined superior, but not inferior, borders)
    - Rigler sign: Gas outlining both sides of bowel wall
    - Crescentic lucency overlying right hepatic margin on left lateral decubitus view or anterior hepatic margin on cross-table lateral view
    - Triangles of lucency anteriorly on cross-table lateral view or peripherally on supine AP view

Ultrasonographic Findings

- Grayscale ultrasound
  - Focal fluid collections, echogenic ascites, aperistaltic bowel with thickening or thinning, & ↑ echogenicity of bowel wall all suggest NEC
    - Complex fluid collections suggest perforation
  - Pneumatosis: Nodular echogenicities around entire circumference of bowel wall ± "dirty shadowing" posteriorly
  - PVG: Branching linear & punctate echogenicities in liver periphery; may see echogenic foci coursing through portal veins in real time
  - Free intraperitoneal air: Linear echogenicities with "dirty shadowing" immediately deep to peritoneal surface
- Color Doppler
  - ↑ vascularity may be seen in earlier stages
  - ↓ vascularity indicates ischemia, potentially leading to necrosis/perforation
  - ↑ peak systolic velocity & resistive index in superior mesenteric artery
- Contrast-enhanced ultrasound
  - Can aid in assessing bowel perfusion

Fluoroscopic Findings

- Acute: Enema is contraindicated in acute NEC
- Chronic: Strictures create obstruction in "older" NICU infants; causative NEC episode not always clinically apparent
  - Single or multiple strictures found 4-8 weeks after NEC
  - Radiologically discovered strictures are usually left-sided, while most surgically discovered strictures are found in right colon (sometimes even small bowel)

Imaging Recommendations

- Best imaging tool
  - Serial radiography: Fixed, dilated loops are predictive of bowel ischemia/necrosis
  - Sonography is up to 100% sensitive & 95% specific for bowel necrosis or "surgical NEC," but specific findings vary by study

DIFFERENTIAL DIAGNOSIS

Newborn Bowel Obstruction

- Congenital bowel obstructions (e.g., atresias, meconium ileus) present within first 1-3 days after delivery, often with "bilious emesis" or "failure to pass meconium"

Newborn Spontaneous Intestinal Perforation

- Typically lacks pneumatosis & PVG
- Necrosis is focal, not extensive

Enterocolitis of Term Infants

- Milk allergy, cyanotic heart disease, maternal cocaine use, Hirschsprung disease (especially total colonic)

Nonspecific Gaseous Distention of Bowel

- Continuous positive airway pressure
- Bag ventilation at intubation

Hypertrophic Pyloric Stenosis

- Rarely associated with benign gastric pneumatosis

- Usually healthy term infants presenting with projectile vomiting at 2-12 weeks of life

Benign Pneumatosis in Older Children

- Often with complex medical history, including bone marrow transplant & steroid therapy
- Predominately colonic; may cause free air

PATHOLOGY

General Features

- Etiology
  - Different mechanisms in different newborn groups
    - Very premature: Dysregulated inflammatory response to stasis of feeds, incomplete or abnormal GI microbial colonization, & immunologic immaturity
    - Term & late preterm: Likely from hypoxia-ischemia
  - Multifactorial etiology in all patients
- Associated abnormalities
  - Lung disease of prematurity
  - Congenital heart disease
  - Intracranial hemorrhage, white matter injury

Staging, Grading, & Classification

- Duke Abdominal Assessment Scale: Standardized lexicon for reporting findings in newborns with suspected NEC
  - High intra- & interobserver agreement
  - Higher scores strongly correlate with disease severity/need for surgical intervention
    - 0: Normal gas pattern
    - 1: Mild bowel distention
    - 2: Moderate distention (or normal with nonspecific "bubbly" lucencies)
    - 3: Focal, moderate distention of bowel loops
    - 4: Separation or focal thickening of bowel loops
    - 5: Featureless or multiple separated bowel loops
    - 6: Possible pneumatosis with other abnormal findings
    - 7: Fixed or persistent dilation of bowel loops
    - 8: Pneumatosis (highly probable or definite)
    - 9: PVG
    - 10: Pneumoperitoneum

Gross Pathologic & Surgical Features

- Dilated, gray, hemorrhagic, friable bowel

Microscopic Features

- Mucosal coagulation, ulceration, submucosal hemorrhage, submucosal or subserosal gas (pneumatosis intestinalis), PVG, mesenteric gas
- Histopathologic features include coagulative & hemorrhagic necrosis, inflammation, bacterial overgrowth

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Signs of feeding intolerance (emesis, ↑ gastric residuals, bloody stools)
  - Abdomen may become distended, discolored, erythematous, &/or shiny
  - Apnea & bradycardia, lethargy, temperature instability
- Other signs/symptoms
  - 1/3 have fulminant course with bowel perforation
  - 1/3 develop septic shock

Demographics

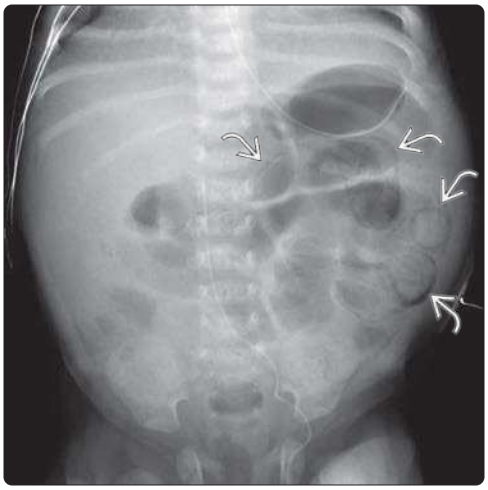
- Age
  - Premature VLBW or ELBW newborns have highest incidence (90% of cases)
    - Affects 3-13% < 1,500 g; rate in ELBW is 3x that of VLBW
    - Onset of NEC peaks at 29-31 weeks postmenstrual age, especially 2-3 weeks after delivery
  - Term newborns make up 10% of cases
    - Earlier age onset of NEC (1-3 days after delivery)
    - Often have ≥ 1 risk factors
- Epidemiology
  - Overall incidence: 1 per 1,000 live births
    - Varies by nursery/ICU
    - Outbreaks frequently follow epidemic pattern; no single causative infectious agent is known

Natural History & Prognosis

- Overall mortality: 10-50%
  - Death secondary to sepsis from bowel perforation
- Morbidity in survivors includes delayed bowel strictures (10-20%), short gut syndrome, & neurodevelopmental delays

Treatment

- Prevention: Probiotics ↓ NEC incidence & mortality in VLBW infants
- When NEC is suspected: IV nutrition + antibiotics
- Indications for surgery: Clinical ± radiologic findings
  - Perforation is considered absolute indication
  - Clinical deterioration, bowel necrosis



DIAGNOSTIC CHECKLIST

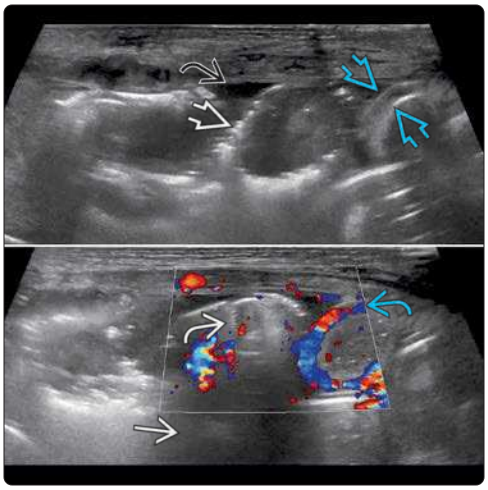


Image Interpretation Pearls

- NEC can be associated with adhesions, so intraperitoneal gas may be loculated rather than "free"
  - Strongly consider left lateral decubitus &/or cross-table lateral images to look for intraperitoneal gas

(Left) *Supine AP radiograph in a 5-week-old girl who was born prematurely shows extensive curvilinear pneumatosis throughout the left abdomen.* **(Right)** *Grayscale US (top) in 7-day-old premature infant shows ascites & segmental bowel wall abnormalities due to NEC, including pneumatosis & wall thinning compared to a normal bowel loop. Doppler US (bottom) reveals ↓ blood flow in the affected bowel compared to the normal segment. There is also shadowing from the pneumatosis.*

(Left) *Supine AP radiograph in a term infant with aortic coarctation, feeding intolerance, bloody stools, & spells of apnea/bradycardia shows a nearly gasless abdomen, a nonspecific finding of NEC.* **(Right)** *Supine AP radiograph shows a premature infant with NEC who has widespread pneumatosis intestinalis with curvilinear & "bubbly" lucencies seen in most of the intestinal walls, especially on the left.*

(Left) *Supine AP radiograph shows a dramatic case of NEC with PVG, pneumatosis, & free air causing numerous small & triangular lucencies. Also note the Rigler sign (with gas outlining both sides of the bowel wall), indicating pneumoperitoneum.* **(Right)** *Transverse US in a newborn with severe NEC shows extensive PVG throughout the liver parenchyma, affecting mainly the right lobe; note scattered bubbles in the left lobe. Gas within the main portal vein was much easier to see in real time.*

Spontaneous Intestinal Perforation in Neonates

KEY FACTS

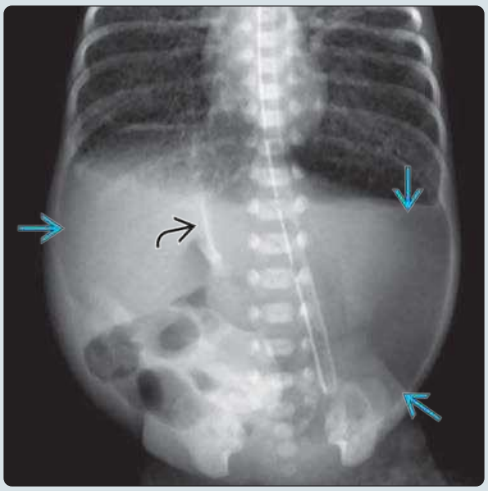
TERMINOLOGY

- Spontaneous intestinal perforation (SIP)

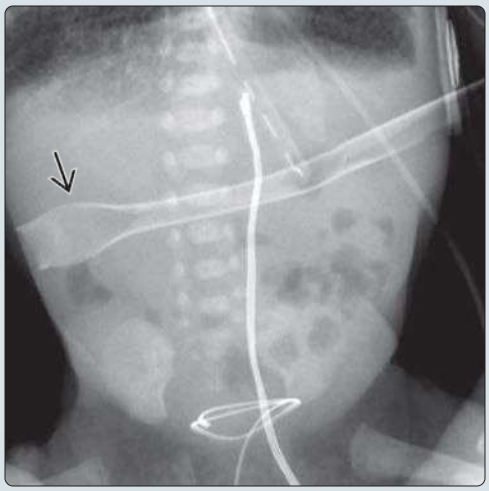
IMAGING

- Pneumoperitoneum on radiographs
  - Small volume of free air is best seen on left lateral decubitus or cross-table lateral views
- Occasionally gasless abdomen
- Absence of pneumatosis intestinalis or portal venous gas helps differentiate from necrotizing enterocolitis (NEC)
- Free fluid with echogenic debris on ultrasound

TOP DIFFERENTIAL DIAGNOSES

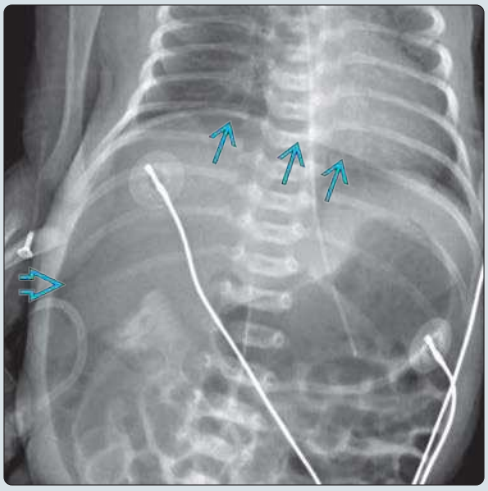


- NEC: Pneumatosis intestinalis ± portal venous gas, fixed dilated bowel loops, bowel wall thickening
  - More common > 15 days of life
- Distal intestinal obstruction: Numerous dilated bowel loops, pneumoperitoneum if perforation; presents in first 1-3 days of life
- Iatrogenic perforation: Feeding tube or gastric decompression tube

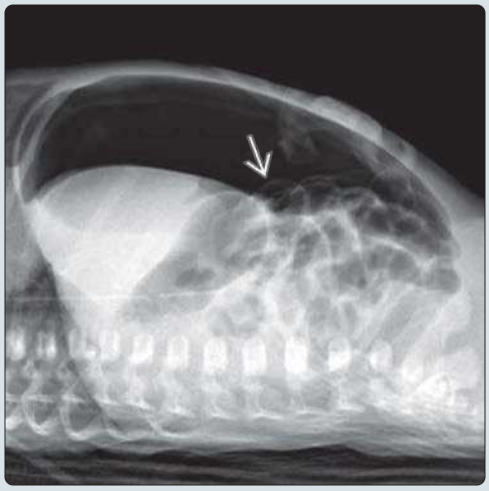


PATHOLOGY

- Exact etiology unknown
  - Several associations reported, causality elusive
  - Indomethacin, postnatal steroids, inotropes, sepsis
- Localized, focal necrosis & perforation
  - Lacks extensive necrosis seen in NEC
- Ileum is most common



CLINICAL ISSUES



- Disease of premature infants; ↑ risk with lower birth weight
- Mean age of 7 days, typically < 15 days
- Treatment: Surgical repair is definitive, peritoneal drainage as definitive vs. temporizing measure
- Mortality 9-24%

(Left) *AP radiograph in a 5-day-old, 25-weeks-gestation infant shows a large volume of pneumoperitoneum with generalized abdominal lucency & free air outlining the falciform ligament. Surgery showed ileal perforation with only mild focal ischemic changes, consistent with spontaneous intestinal perforation (SIP).* **(Right)** *Postoperative AP radiograph in the same infant shows an interval ↓ in pneumoperitoneum & placement of a peritoneal drainage catheter.*

(Left) *AP radiograph in a 30-week-gestation, very low birth weight newborn (1330g) obtained for tube placement incidentally revealed pneumoperitoneum with ↑ lucency & outline of the diaphragm. On pathology, a small perforation was found in the distal ileum with no significant associated inflammation, typical of SIP.* **(Right)** *Cross-table lateral radiograph in the same infant shows antidependent free air in the anterior abdomen. Note the Rigler sign with gas outlining both sides of the bowel wall.*

TERMINOLOGY

Abbreviations

- Spontaneous intestinal perforation (SIP)

Synonyms

- Focal intestinal perforation

Definitions

- Focal, isolated perforation of intestinal tract

IMAGING

General Features

- Best diagnostic clue
  - Pneumoperitoneum without pneumatosis intestinalis in premature infant in first 10 days of life

Radiographic Findings

- Absence of pneumatosis intestinalis & portal venous gas
  - Presence suggests perforated necrotizing enterocolitis (NEC) rather than SIP
- May have gasless abdomen
- Pneumoperitoneum

Ultrasonographic Findings

- Echogenic free fluid
  - Free fluid containing particulate matter
  - May precede radiographic pneumoperitoneum
- Extraluminal gas
  - Focal enhancement of peritoneal stripe with "dirty" shadowing
  - Moves with changes in patient position

Imaging Recommendations

- Best imaging tool
  - 2-view abdominal radiograph
    - Left lateral decubitus or cross-table lateral view ↑ sensitivity for pneumoperitoneum

DIFFERENTIAL DIAGNOSIS

Necrotizing Enterocolitis

- Necrosis involving large area of intestine
- Disease of premature infants
  - Tends to occur at later postnatal age vs. SIP; mean age: 15 days
- Pneumatosis intestinalis ± portal venous gas, fixed dilated bowel loops, bowel wall thickening
- Pneumoperitoneum from perforation

Distal Intestinal Obstruction

- Intestinal atresia, meconium ileus, Hirschsprung disease, etc.
  - Usually presents in first 1-3 days of life
- May present with abdominal distention, bilious emesis, &/or failure to pass meconium
- Numerous dilated bowel loops
- ± pneumoperitoneum from perforation
- Peritoneal Ca^{2+} suggests in utero perforation

Iatrogenic Perforation

- Feeding tube or gastric decompression tube ± predisposing factors affecting bowel integrity

PATHOLOGY

General Features

- Exact etiology remains unclear, may include
  - Focal ischemia
  - Altered trophism: Mucosal hyperplasia + thinned submucosa & muscularis propria
  - Impaired motility

Gross Pathologic & Surgical Features

- Localized focal necrosis & perforation
- Typically single perforation in antimesenteric bowel wall
- Ileum is most common site

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pneumoperitoneum on radiograph
  - Abdominal distention ± bluish abdominal wall discoloration
  - Hypotension

Demographics

- Premature infants, especially extremely low birth weight (< 1000 g)
  - Associations with indomethacin (debated in literature), postnatal steroids, inotrope requirement, sepsis
  - Causality not clearly established
- Sex: M > F; 2-3:1
- Incidence: 1% of infants < 32-weeks-gestational age
  - 2.3% < 28 weeks in same large cohort
- Most common ~ 7 days postnatal age (range 0-15 days)
  - NEC is classically in older neonates

Natural History & Prognosis

- Recent reported mortality of 9-24%
  - Mortality lower than perforated NEC
- Coexistent comorbidities of prematurity
- Lower rates of surgical morbidity vs. NEC
  - Stricture, adhesive bowel obstruction

Treatment

- Surgical repair
  - Resection with primary anastomosis vs. temporary stoma
- Peritoneal drainage
  - Definitive therapy or temporizing measure
- Successful conservative management has been described

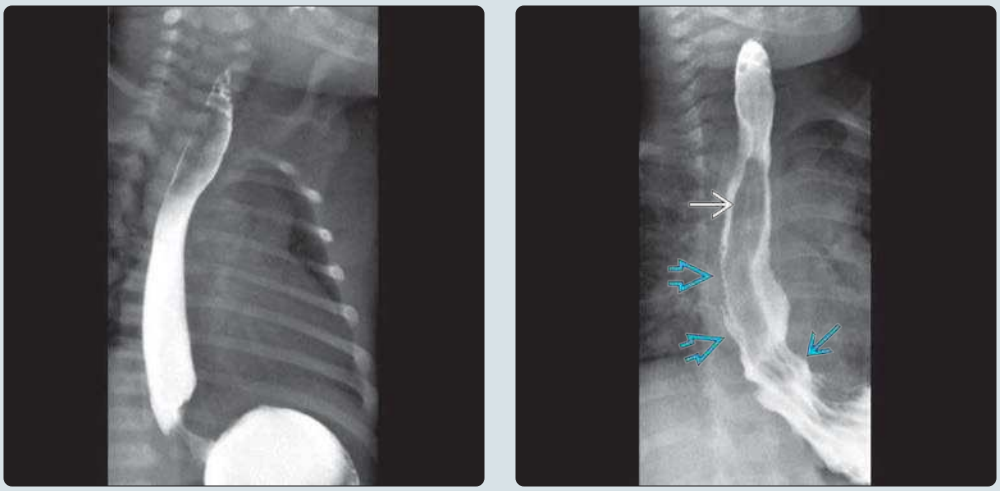
KEY FACTS

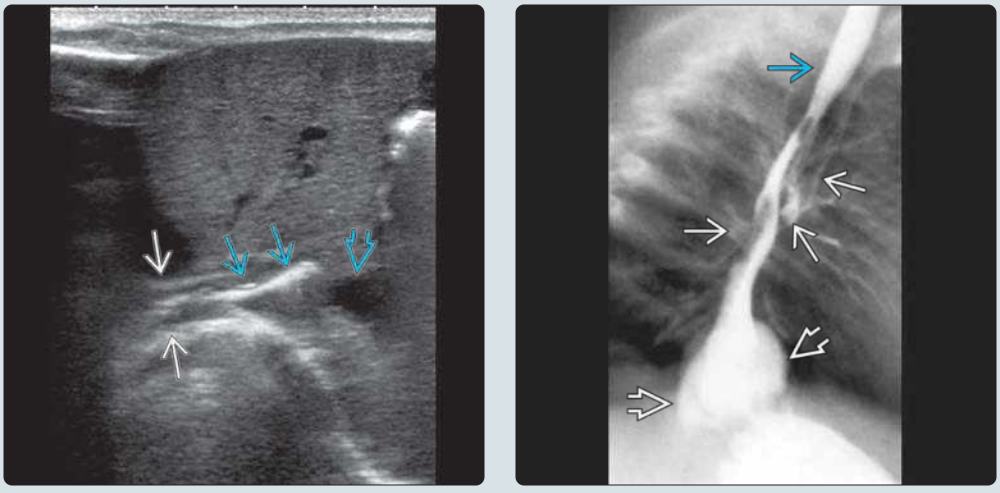
TERMINOLOGY

- Gastroesophageal reflux (GER): Retrograde flow of gastric contents into esophagus
- GER disease (GERD): GER that causes clinical symptoms or tissue damage



IMAGING

- Retrograde passage of gastric contents into esophagus
  - Can see on US, fluoroscopic upper GI, radionuclide scintigraphy, MR
- Reflux esophagitis (GERD)
  - Best seen fluoroscopically
  - Esophageal dysmotility is often earliest sign
  - Distal esophageal mucosal irregularity/thickening/stricture
  - Barrett esophagus (rare in children)
- Upper GI to exclude anatomic/functional abnormalities, not to identify GER
  - Esophageal dysmotility
  - Hiatal hernia
  - Gastric outlet/duodenal obstruction
  - Malrotation
- Radionuclide scintigraphy: Most sensitive imaging test to detect GER



CLINICAL ISSUES

- Symptoms
  - Recurrent vomiting/regurgitation
  - Poor weight gain/failure to thrive
  - Excessive irritability
  - Respiratory symptoms (e.g., wheezing, cough)
- Epidemiology
  - Most infantile GER resolves by 1-2 years of age
  - ~ 4% have persistent GER, 1% require surgical treatment
  - GER: 50% at 4 months, ↓ to 5-10% at 12 months
- Treatment
  - Nonsurgical: ~ 99% of refluxers
  - Surgical: Fundoplication

(Left) *LPO upper GI of a 3-day-old girl with severe regurgitation shows almost no peristalsis of an otherwise normal, completely distended esophagus. Hypomotility is the earliest finding in reflux esophagitis & gastroesophageal reflux disease (GERD).* **(Right)** *Upper GI in a 7-month-old with worsening GER shows a mild hiatal hernia (gastric folds above diaphragm ⇨) with thickened folds of the distal esophagus ⇨, consistent with reflux esophagitis & dysmotility. Note the air ➡ in the esophagus.*

(Left) *Longitudinal US of the gastroesophageal junction in a 20-day-old with recurrent nonbilious vomiting shows a column of echogenic air ⇨, which in real-time scanning was moving retrograde from the fluid-filled stomach ⇨ into the esophagus ➡.* **(Right)** *Lateral upper GI in a patient with a hiatal hernia ➡ demonstrates significant reflux of contrast ⇨, which the patient aspirated ➡, requiring placement of an enteric suction tube into the esophagus to prevent further aspiration of stomach contents.*

TERMINOLOGY

Abbreviations

- Gastroesophageal reflux (GER), GER disease (GERD)

Definitions

- GER: Retrograde flow of gastric contents into esophagus
  - Physiologic phenomenon, especially in young infants
- GERD: GER causes clinical symptoms or tissue damage

IMAGING

General Features

- Best diagnostic clue
  - Retrograde passage of contrast across gastroesophageal junction (GEJ) into esophagus
- Morphology
  - Normal GEJ or associated hiatal hernia, usually sliding type

Radiographic Findings

- Radiography
  - Usually normal; rarely shows round retrocardiac lucency (hiatal hernia)

Fluoroscopic Findings

- Upper GI
  - Retrograde flow of contrast into esophagus
  - Reflux esophagitis (GERD)
    - Esophageal dysmotility is often earliest sign
    - Distal esophageal mucosal irregularity/thickening/stricture
    - Barrett esophagus (rare in children)
  - Other potential findings with GER
    - Hiatal hernia, usually sliding type
    - Malrotation: Incidental in 4%
    - Gastric outlet/duodenal obstruction
      - Pyloric stenosis, gastric antral/duodenal web, etc.; delayed gastric emptying

Ultrasonographic Findings

- Retrograde flow of gastric contents at GEJ

Nuclear Medicine Findings

- Tc-99m sulfur colloid
  - Activity above GEJ during period of observation

Imaging Recommendations

- Best imaging tool
  - Tc-99m labeled sulfur colloid meal
  - Fluoroscopic upper GI evaluation for anatomic abnormality of GI tract
- Protocol advice
  - Upper GI to evaluate anatomy, not confirm reflux
    - Looking for GERD & GER causes: Evaluate swallow & motility, no provocative maneuvers
  - Radionuclide scintigraphy: Most sensitive imaging test for GER

DIFFERENTIAL DIAGNOSIS

Gastric/Duodenal Obstruction

- Pyloric stenosis, antral web, duodenal stenosis/web

Malrotation

- GER can be presenting symptom of malrotation without volvulus

Achalasia

- Rare; presents in childhood to adolescence

Esophagitis

- Many causes other than reflux

Esophageal Atresia (Repaired)

- Anastomotic stricture or GER is not uncommon after repair

PATHOLOGY

General Features

- Etiology
  - Potentially many physiologic & anatomic factors
    - Suboptimal angle of His

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Infants: Recurrent spit-up, irritability, feeding difficulty, poor weight gain, sleep disturbances
  - Children: Poorly localized abdominal or chest pain, heartburn, recurrent vomiting/regurgitation, dysphagia, respiratory (wheezing, cough)

Natural History & Prognosis

- Most infantile GER resolves by 1-2 years of age
- GER: 50% at 4 months, ↓ to 5-10% at 12 months
- ~ 4% have persistent GER, 1% require surgical treatment
- No treatment → pneumonia, asthma, laryngitis, otitis media, tooth decay
- Barrett esophagus, not usually seen in children

Treatment

- Nonsurgical: ~ 99% of refluxers
  - Lifestyle adjustment, diet/formula alteration
  - Prokinetic agents, antacids, & proton-pump inhibitors
- Surgical: ~ 1% of all refluxing patients
  - Fundoplication

DIAGNOSTIC CHECKLIST

Consider

- Potential anatomic causes of GER

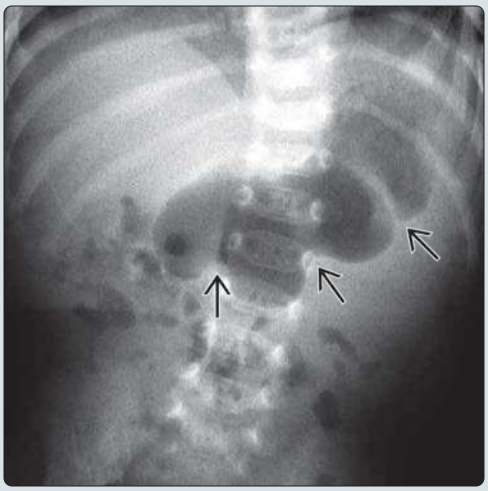
Hypertrophic Pyloric Stenosis

KEY FACTS

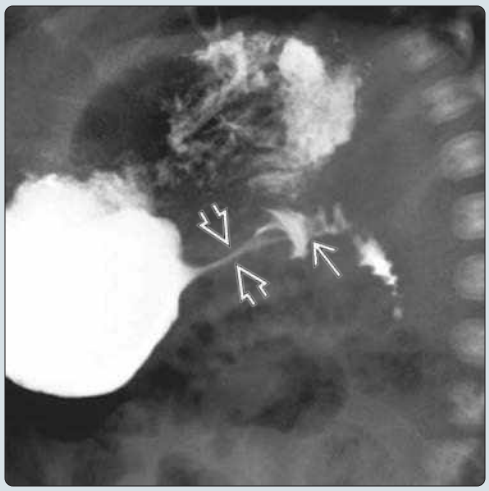
TERMINOLOGY

- Hypertrophic pyloric stenosis (HPS): Idiopathic pyloric muscle thickening in young infants → progressive gastric outlet obstruction

IMAGING

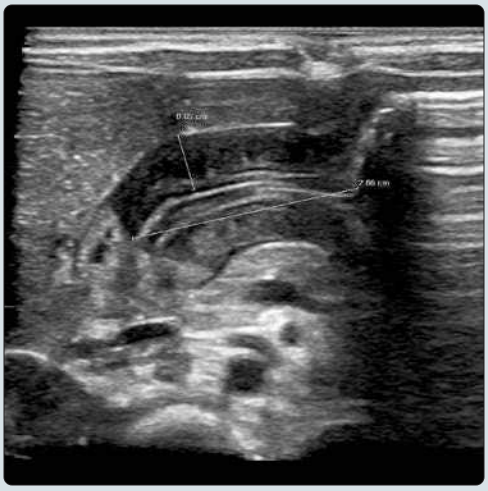


- Near-complete gastric outlet obstruction due to abnormally elongated & thickened pyloric muscle
  - Pylorus fails to relax/open → minimal gastric emptying → gastric overdistention → emesis
- Ultrasound shows hypertrophied circumferential hypoechoic muscle & elongated pyloric canal filled with echogenic mucosa
  - Commonly accepted sonographic criteria for HPS
    - Pyloric channel length > 15-16 mm
    - Single wall thickness of pyloric muscle > 3 mm
    - Failure of thickened pylorus to change during exam
      - May still see trickle of passage of gastric contents
- Upper GI shows minimal barium traversing narrowed & elongated pyloric channel, mass effect on gastric antrum & duodenum by hypertrophied muscle, hyperperistaltic gastric contractions, & gastroesophageal reflux/emesis

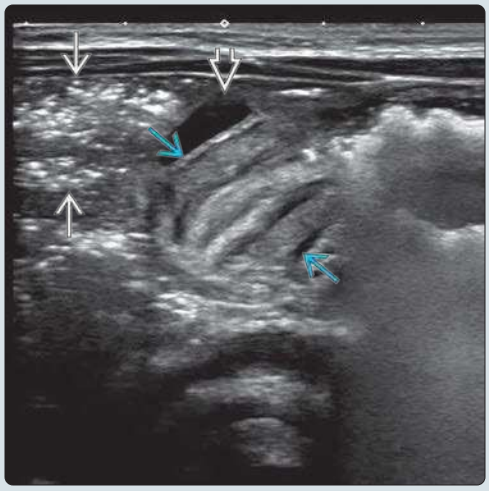


CLINICAL ISSUES

- Typically seen in infants 2-12 weeks old with progressive, nonbilious projectile vomiting
  - Feedings previously tolerated (i.e., HPS is not congenital)
- Incidence of 1.5-3 per 1,000 infants; M:F = 5:1
  - HPS in 1/5 of infants imaged for vomiting
    - Gastroesophageal reflux > > HPS
- Surgical treatment: Pyloromyotomy
- Nonsurgical alternative (rarely employed): Medications & frequent small feedings



DIAGNOSTIC CHECKLIST



- Pylorospasm mimics HPS (but typically transient)
- Avoid overdistending stomach during imaging exam (which displaces/obscures pylorus)

(Left) *AP radiograph in a vomiting infant with hypertrophic pyloric stenosis (HPS) shows hyperperistalsis of a gas-filled stomach with muscular contractions attempting to push gastric contents through the narrowed, hypertrophied pylorus.* **(Right)** *Lateral upper GI shows a thin "string" of barium extending through the narrowed, elongated pyloric channel, opacifying the duodenal bulb. The thickened pyloric muscle creates rounded indentations on the gastric antrum & base of the duodenal bulb.*

(Left) *Transverse oblique ultrasound shows yellow lines measuring the single wall thickness (6.5 mm) & length (26.6 mm) of the pyloric channel in a baby with HPS.* **(Right)** *Transverse oblique ultrasound shows echogenic foci in the left lobe of the liver, consistent with portal venous gas in a 1-month-old with HPS. The partially filled gallbladder is visible between the abnormal pylorus & liver.*

TERMINOLOGY

Abbreviations

- Pyloric stenosis, hypertrophic pyloric stenosis (HPS)

Definitions

- Idiopathic pyloric muscle thickening → progressive gastric outlet obstruction
- Typically seen in infants 2-12 weeks old with progressive, nonbilious projectile vomiting

IMAGING

General Features

- Best diagnostic clue
  - Near-complete gastric outlet obstruction due to elongated & thickened pyloric muscle
  - Ultrasound reveals hypertrophied muscle & ↓ gastric emptying on dynamic exam
  - Upper GI shows minimal contrast traversing narrowed & elongated pyloric channel with mass effect on antrum & duodenal bulb from thickened pyloric muscle
- Location
  - Near gallbladder in RUQ by ultrasound

Radiographic Findings

- Radiography
  - Overdistended stomach with ↓ distal bowel gas
    - Enlarged stomach containing gas & retained ingested material displaces adjacent bowel
  - Stomach may be collapsed if infant has recently vomited
  - Benign gastric pneumatosis & portal venous gas are rarely reported (< 2%) in association with HPS

Fluoroscopic Findings

- Overdistended "caterpillar stomach": Undulations of wall due to exaggerated gastric motility (hyperperistalsis)
- Tram-track or string sign of contrast within narrowed & elongated pyloric channel
- Shoulders of thickened pyloric muscle create impressions on distal antrum
- "Beak" where contrast encounters narrowed pyloric canal
- Contrast in duodenal bulb (covering hypertrophied muscle impressions at base of duodenal bulb) + contrast in narrowed & elongated pyloric channel: Mushroom sign

Ultrasonographic Findings

- Grayscale ultrasound
  - Threshold for abnormal measurements of pyloric muscle & channel length varies by study
    - In general, ↑ threshold measurements ↑ specificity but ↓ sensitivity
  - Commonly accepted threshold values for HPS
    - Single wall thickness of hypoechoic pyloric muscle > 3 mm
    - Pyloric channel length > 15-16 mm
    - Pyloric diameter > 15 mm
  - Hypertrophied & redundant echogenic mucosal lining
  - Gastric hyperperistalsis & persistently obliterated pyloric lumen on dynamic exam
  - If duodenal bulb is easily identified & distended with fluid, diagnosis of HPS is unlikely
  - Echogenic foci of gas in portal veins can be visible in adjacent left lobe of liver
- Color Doppler
  - ↑ flow in pyloric muscle & mucosa with HPS
  - Microvascular flow imaging shows trickle of enteric contents in channel

Imaging Recommendations

- Best imaging tool
  - Ultrasound when HPS is suspected
    - Excellent sensitivity & specificity; no ionizing radiation
  - Barium upper GI for atypical history (including bilious emesis)
- Protocol advice
  - Begin ultrasound scan with patient rolled onto right side in order to pool gastric fluids in antrum
  - Administer glucose water in small amounts
    - Avoid overdistending stomach, which will displace pyloric channel posteriorly or into right lower quadrant
  - Watch for pyloric channel to open with thinning of muscle & passage of fluid through channel
  - Vigorous gastric contractions of body & antrum that do not open pylorus suggest diagnosis of HPS
  - Formula or glucose water will "swirl" against thickened pylorus with each wave of gastric peristalsis in HPS

DIFFERENTIAL DIAGNOSIS

Pylorospasm

- Typically seen in irritable infants; resolves with time → wait & reimage
- Rarely as thick or elongated as true HPS

Gastroesophageal Reflux

- Cause of vomiting in 2/3 of infants referred to radiology
- Presumed diagnosis when pyloric ultrasound is normal
- Gastroesophageal junction can be mistaken for pylorus on ultrasound if transducer is too high
  - Heart should not be visible on longitudinal images of pylorus

Malrotation With Midgut Volvulus

- Emesis is classically bilious (greenish) from bile
- Surgical emergency due to risk of midgut ischemia
- Upper GI: Mildly dilated proximal duodenum with abrupt beaking near junction of 2nd-3rd duodenum
  - Distal contrast passage shows "corkscrew" or swirling contrast in typically narrowed bowel
- Ultrasound: Transverse superior to inferior sweep shows twisting of SMA/SMV & bowel in clockwise "whirlpool"
  - May lose Doppler flow & grayscale lumen of SMV & SMA

Gastric Bezoar

- Caused by accumulation of undigested matter in stomach
  - Trichobezoar: Composed of hair (& sometimes nails)
  - Phytobezoar: Composed of plant or vegetable fiber
- Contrast is seen in interstices of large filling defect on upper GI

Other Causes of Proximal Obstruction

- Duodenal stenosis or antral web

- Antral polyps, antritis, annular pancreas, choledochocele, RUQ mass
- Pyloric atresia

PATHOLOGY

General Features

- Etiology
  - Idiopathic hypertrophy of circular muscle bundles in pylorus
  - Slightly ↑ incidence in preterm infants vs. full term
    - Presents at later chronologic age in preemies
  - Higher incidence in mothers < 20 years old, nulliparous, smokers, & formula-fed babies
  - May be prostaglandin or erythromycin induced, neural mediated, familial
  - Associated with erythromycin & azithromycin (macrolide) exposure prenatally & postnatally via breast milk
  - Higher incidence of HPS in patients with cystic fibrosis
  - Abnormal muscle tone/electrophysiology of gastroduodenal junction in HPS
- Genetics
  - Tends to run in families; not truly inherited
  - Discordant incidence among monozygotic twins favors environmental factors over genetic predisposition
- Associated abnormalities
  - Eosinophilic gastritis, prostaglandin-induced antral mucosal hyperplasia, hypergastrinemia, nasoenteric tubes, erythromycin, esophageal atresia

Gross Pathologic & Surgical Features

- Hypertrophy of circular muscular layers of pylorus
- Thickening of mucosa in antrum & pylorus to ~ 1/3 diameter of pylorus

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Progressive vomiting in infant who previously tolerated feedings
  - Palpable "olive" on physical exam: 97% specific in experienced hands
    - Less common finding due to earlier imaging diagnosis
- Other signs/symptoms
  - Weight loss
  - Alkalosis & dehydration with prolonged course

Demographics

- Age
  - 2-12 weeks or even later in premature infants
  - Peak age of 5 weeks; 80% by 8 weeks
- Sex
  - M:F = 5:1
- Ethnicity
  - Slightly more common in White patients
- Epidemiology
  - Incidence of 1.5-3 per 1,000 infants
  - Incidence is ↓ worldwide
  - Vomiting caused by HPS in 1/5 of infants referred for imaging

Natural History & Prognosis

- Weight loss & parental concerns typically prompt imaging
- Gradual progression with spontaneous remission after weeks
- Excellent prognosis following surgery or conservative medical management
  - No significant GI disturbances seen in German study of infants treated surgically or medically 16-26 years after diagnosis
- Portal venous gas has no influence on prognosis

Treatment

- Surgical: Pyloromyotomy
  - Splits thickened muscle longitudinally (without breaching mucosa), opening channel
  - Laparoscopic pyloromyotomy & open procedures have equal success rates
  - Endoscopic pyloromyotomy & balloon dilation are alternatives
- Nonsurgical alternative: Medications & frequent small feedings
  - Requires several weeks before resuming normal feeding without medications
  - Medications used include Botox, atropine
  - Withdrawal of prostaglandins after corrective cardiac surgery → muscular hypertrophy regresses
- Complications
  - Failed surgery due to inadequate pyloromyotomy
  - Gastroduodenal myotomy or enterotomy

DIAGNOSTIC CHECKLIST

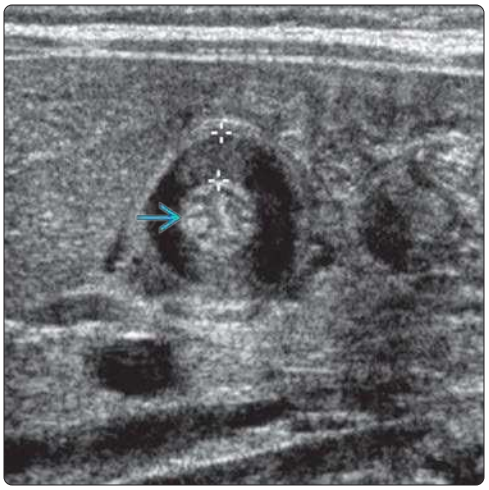


Image Interpretation Pearls

- Pylorospasm mimics HPS transiently
- Avoid overdistending stomach, which displaces pylorus

(Left) *Transverse oblique ultrasound in a 5-week-old boy with HPS shows elongation of the pyloric channel length. The hypoechoic muscle is thickened, & there is a small amount of anechoic fluid trying to enter the channel.* **(Right)** *Sonographic cross section of a hypertrophied pylorus shows the doughnut sign of HPS, consisting of a circumferentially thickened & hypoechoic muscle (calipers) + the central, redundant, echogenic mucosa.*

(Left) *Transverse oblique ultrasound in a different baby with HPS shows thickening of the pyloric muscle at 4.5 mm between the calipers. Note the normal relationship of the SMA & SMV.* **(Right)** *Delayed frontal upper GI shows a string sign of barium passing through a narrowed pylorus with reflux into the distal esophagus. Demonstrating barium in a tight pyloric channel requires patience & intermittent fluoroscopy.*

(Left) *Transverse ultrasound after a glucose water feeding in an infant with HPS shows how feeding can overdistend the stomach & push the pylorus posteriorly. The pylorus is thickened with the channel elongated at 27.6 mm.* **(Right)** *Transverse oblique postprandial ultrasound (left) shows how gas mixed with formula can interfere with visualization of structures. The insert (right) is a type of Doppler optimized for slow flow, showing a thin trickle of fluid passing through the hypertrophied channel.*

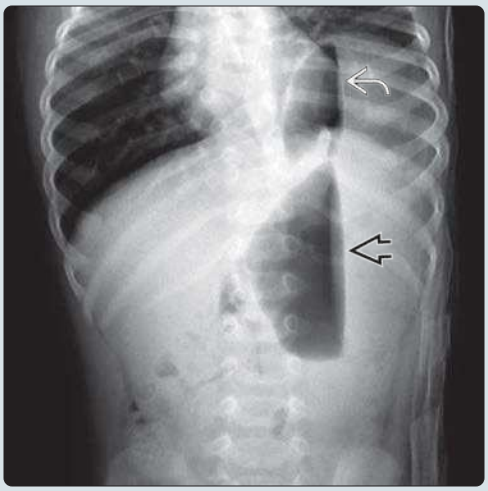
Gastric Volvulus

KEY FACTS

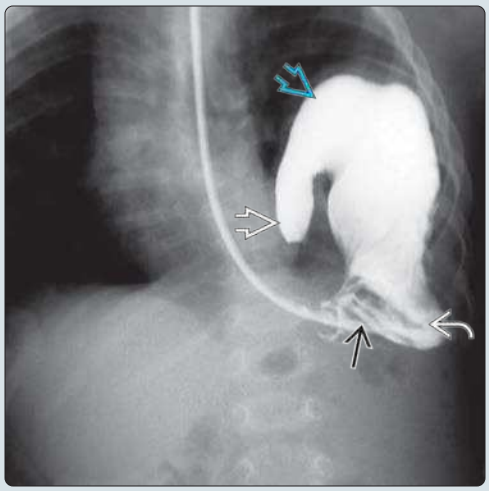
TERMINOLOGY

- Twisting of all or part of stomach on its axes by at least 180°
- Organoaxial volvulus (OAV): Rotation along long axis
- Mesenteroaxial volvulus (MAV): Rotation along short axis

IMAGING

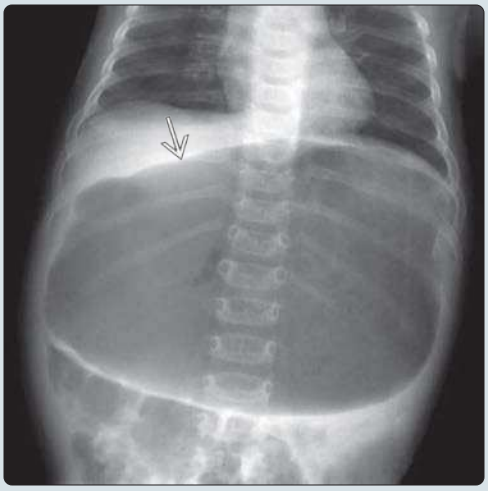


- Radiographic findings
  - Round, gas-distended viscus under &/or above left hemidiaphragm that decompresses with nasogastric (NG) tube
  - Upright image may show 2 air-fluid levels
- Upper GI vs. CECT to confirm diagnosis
  - OAV
    - Horizontal stomach with pylorus directed inferiorly
    - Greater curvature superior to lesser curvature
  - MAV
    - Vertical stomach with pylorus superior to fundus
    - Pylorus lies close to or overlaps gastroesophageal junction

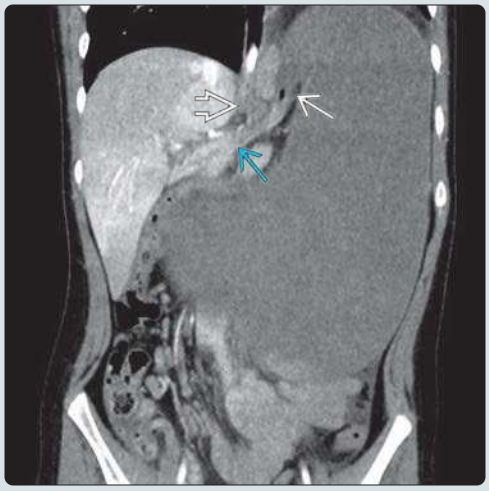


PATHOLOGY

- Primary volvulus: Absent, failed, or lax ligamentous fixation; chronic > acute
- Secondary volvulus: Disorder of gastric anatomy/function, often with diaphragm anomalies; acute > chronic



CLINICAL ISSUES



- 58% present within 1st year of life
- Symptoms: Retching, nonbilious emesis, pain, & distention
  - ± respiratory distress & cyanosis in acute setting
  - ± failure to thrive & colic in chronic setting
  - Complete Borchardt triad is uncommon (unproductive retching, epigastric distention, inability to pass NG tube)
- Treatment
  - Resuscitation required in 23-60% of acute presentations
  - Gastric decompression with NG tube
  - Open or laparoscopic reduction + gastropexy &/or gastrostomy tube
  - Repair of associated defects in secondary volvulus

(Left) *Left side down decubitus radiograph of a 6-month-old patient with vomiting shows 2 large air-fluid levels in the left lower hemithorax & left upper quadrant of the abdomen, respectively.* **(Right)** *Frontal upper GI in the same patient shows the stomach lying largely in the left hemithorax. The stomach is inverted with the antrum & gastric outlet lying above the fundus. Note the twisting of rugal folds in the cardia. An acute mesenteroaxial volvulus was found at surgery with a chronic diaphragmatic hernia.*

(Left) *Supine AP radiograph in a 4-month-old girl with abdominal distention & ↓ PO intake shows the stomach to be markedly distended & rounded. An organoaxial gastric volvulus was found at surgery.* **(Right)** *Coronal CECT in an 11-year-old with vomiting shows a narrow pylorus above the level of the gastroesophageal (GE) junction. The proximal duodenum is stretched. The abdominal contents extend abnormally into the lower left hemithorax. A mesenteroaxial gastric volvulus was found at surgery.*

TERMINOLOGY

Definitions

- Twisting of all or part of stomach on its long or short axis by at least 180°
- Organoaxial volvulus (OAV): Twisting along long axis [i.e., line drawn from gastroesophageal (GE) junction to pylorus]
- Mesenteroaxial volvulus (MAV): Twisting along short axis (perpendicular to long axis)
- Mixed volvulus: Rotation along both long & short axes
- Twisting of stomach on axes < 180°: Gastric torsion

IMAGING

Radiographic Findings

- Round, gas-distended viscus under &/or above diaphragm
  - ↓ in size after decompression by nasogastric (NG) tube
- Stomach lies horizontally (OAV) or vertically (MAV)
- 2 air-fluid levels on upright image (in fundus & antrum)
- Inability to pass or abnormal course of NG tube
- + elevation of left hemidiaphragm
- ± paucity of bowel gas distally

Fluoroscopic Findings

- Upper GI series
  - OAV
    - Horizontal stomach with pylorus at level of gastric cardia; pylorus is directed inferiorly
    - Greater curvature lies superior to lesser curvature
  - MAV
    - Vertical stomach with pylorus superior to fundus
    - Pylorus lies close to or overlaps GE junction
  - Beaking of contrast at sites of twisting
  - Partial or complete obstruction of contrast passage into or out of stomach

CT Findings

- Findings similar to upper GI series
- Multiplanar reformatted images are helpful
- Negative oral contrast allows for optimal gastric wall evaluation on CECT (if patient can tolerate)
- Can identify associated abnormalities

MR Findings

- Fetal MR of congenital diaphragmatic hernia often shows volvulus of intrathoracic stomach ± polyhydramnios

Imaging Recommendations

- Upper GI series vs. CECT

DIFFERENTIAL DIAGNOSIS

Air-Filled Thoracic Mass ± Air-Fluid Levels

- Sliding or paraesophageal hiatal hernia
- Postoperative anatomy (e.g., esophageal atresia repair with gastric pull-up vs. colonic interposition)
- Bronchopleural fistula
- Congenital pulmonary airway malformation

Massively Dilated Abdominal Viscus

- Hypertrophic pyloric stenosis
- Toxic megacolon ± Hirschsprung disease
- Colonic volvulus

PATHOLOGY

General Features

- Stomach is relatively fixed at ends: GE junction at esophageal hiatus & pylorus to retroperitoneal duodenum
- Stomach is also normally fixed by ligaments: Gastrophrenic, gastrosplenic, gastrocolic, gastrohepatic
- Primary volvulus
  - Absent, failed, or lax ligamentous fixation
  - 74% of chronic volvulus
- Secondary volvulus
  - Disorder of gastric anatomy/function (distention, peptic ulcer, neoplasm, prior gastric surgery) or abnormality of adjacent organ (diaphragmatic hernia or eventration, splenic anomalies, intestinal malrotation)
  - 69% of acute volvulus

Gross Pathologic & Surgical Features

- Acute: OAV 54%, MAV 41%, mixed 2%
- Chronic: OAV 85%, MAV 10%, mixed 3%

CLINICAL ISSUES

Presentation

- 58% present within 1st year of life
- Acute, chronic, or acute-on-chronic symptoms include
  - Retching, nonbilious emesis, pain, & distention
  - Respiratory distress & cyanosis may be seen acutely
  - Failure to thrive & colic are also seen chronically
  - Hematemesis in late stage occurs secondary to ischemia
- Complete Borchardt triad is uncommon (unproductive retching, epigastric distention, inability to pass NG tube)

Natural History & Prognosis

- Complications: Obstruction, ischemia, perforation
- Mortality: Acute 7.1%, chronic 2.7%
- In large review, 1 in 8 chronic volvulus cases developed acute symptoms with 60% requiring resuscitation

Treatment

- Resuscitation is required in 23-60% of acute presentations
- Gastric decompression with NG tube
- Open or laparoscopic reduction + gastropexy &/or gastrostomy tube
- Repair of associated defects in secondary volvulus
  - Controversial if gastropexy is required after repair of associated anomaly

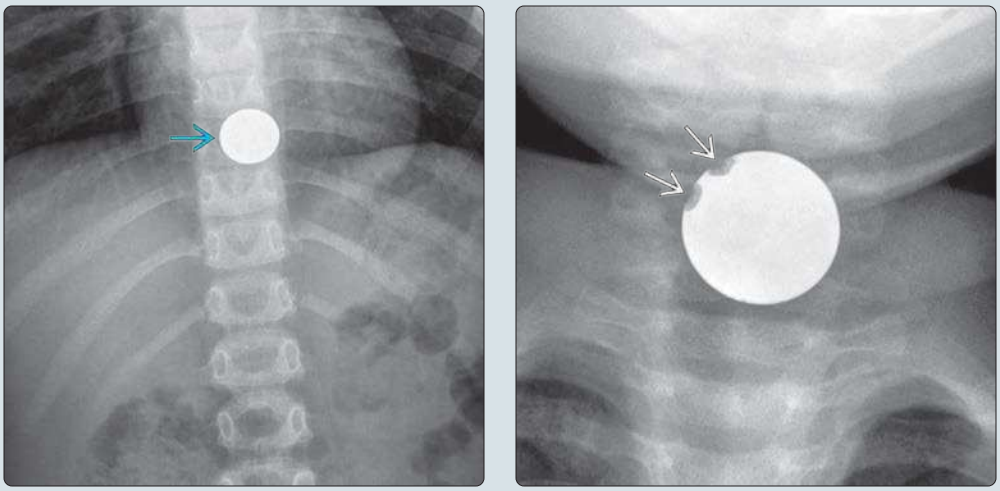
Ingested Coins

KEY FACTS

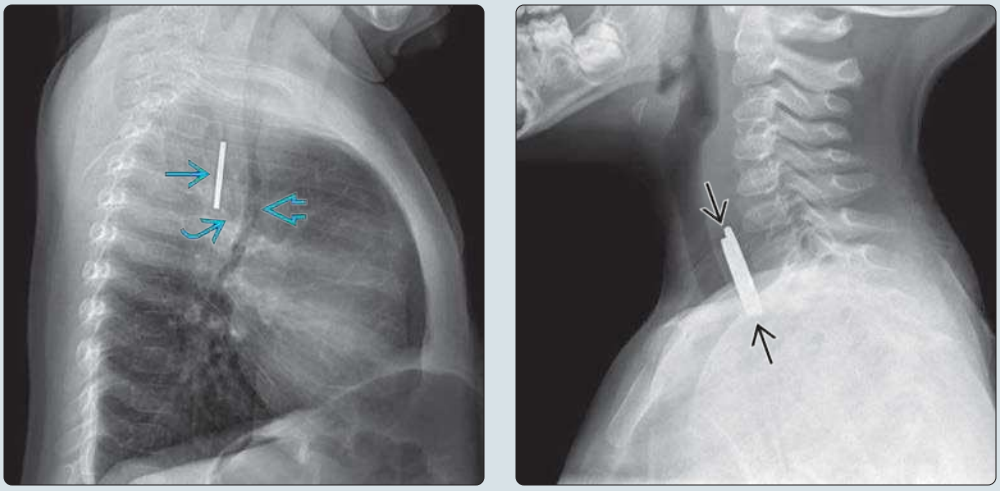
IMAGING

- Disc-shaped metallic density without circumferential beveled edge/step-off
- Most common sites of impaction
  - Upper esophagus at thoracic inlet
  - Midesophagus at aortic arch impression
  - Lower esophageal sphincter at gastroesophageal junction
- Other sites of impaction include pylorus, duodenum, ileocecal valve
- Imaging recommendations
  - Screening frontal radiographs of neck through pelvis ± lateral upper airway
  - Lateral radiograph if foreign body is identified



TOP DIFFERENTIAL DIAGNOSES

- Button battery ingestion
- Magnet ingestion
- Aspirated coin in trachea



CLINICAL ISSUES

- Majority of ingestions occur < 5 years of age
- Most common symptoms
  - Asymptomatic: Witnessed ingestion or incidental finding
  - Symptomatic: Drooling, chest/neck pain, vomiting, dysphagia, cough, respiratory distress, stridor
- Treatment of esophageal coins
  - Symptomatic: Urgent endoscopic removal
  - Asymptomatic: Endoscopic removal within 24 hours; repeat radiograph prior to endoscopy
- Treatment of coins in stomach
  - Monitor stools for passage; repeat radiograph in 2 weeks
  - Endoscopic removal if not passed in 2-4 weeks; repeat radiograph prior to endoscopy
- Treatment of small bowel coins
  - Observation
  - Enteroscopy/surgical removal if symptomatic

(Left) *Frontal radiograph of the upper abdomen of a 4-month-old with a witnessed ingestion of an American dime demonstrates a 19-mm metallic disc at the lower esophagus. Radiographic measurements do not allow for accurate coin identification.* **(Right)** *AP radiograph shows a coin lodged in the cervical esophagus. Note that the coin is wider than the trachea, indicative of an esophageal location. The erosions are due to gastroesophageal reflux reaching a zinc-based coin.*

(Left) *Lateral view of the chest of a 10-month-old shows a metallic foreign body at the upper thoracic esophagus compatible with a coin. There is soft tissue thickening anteriorly, bowing the trachea. Significant swelling was noted at endoscopy upon removal of a penny.* **(Right)** *Lateral airway radiograph in a 2-year-old after a witnessed ingestion shows 2 directly apposed coins projecting over the cervical esophagus at the thoracic inlet. This appearance can mimic the edge step-off of a button battery.*

IMAGING

General Features

- Location
  - Most common sites of impaction
    - Upper esophagus at thoracic inlet
    - Midesophagus at aortic arch impression
    - Lower esophageal sphincter (LES) at gastroesophageal junction
  - Other sites of impaction include pylorus, duodenum, ileocecal valve

Radiographic Findings

- Disc-shaped metallic foreign body without circumferential beveled edge/step-off/halo
- Typically seen en face (oriented in coronal plane) on frontal radiograph
- Rarely oriented in sagittal plane on frontal radiograph
- May exert mass effect on trachea secondary to size of coin or associated soft tissue swelling
- Ingestion of 2 or more coins can result in apposition that mimics button battery on tangential (usually lateral) view
  - Coins will generally be of similar density when viewed en face (usually frontal view), unlike halo margin of battery

Imaging Recommendations

- Ingested foreign body screening radiographs: Frontal views to include neck through pelvis ± lateral upper airway
- Lateral radiograph if foreign body is identified
  - Helps confirm location
    - Esophagus is much more likely than trachea
  - Helps determine type of foreign body

DIFFERENTIAL DIAGNOSIS

Button Battery Ingestion

- Disc-shaped metallic foreign body
  - Lateral view: Circumferential beveled edge/step-off
  - Frontal view: Circumferential halo or double ring sign
- Esophageal impaction requires emergent removal

Magnet Ingestion

- Metallic densities of variable shapes & sizes
- Multiple magnets or magnets with other metallic foreign bodies may attract through different bowel loops → fistulization, perforation, obstruction

Other Metallic Foreign Bodies

- Buttons, jewelry, toy parts

Aspirated Coin in Trachea

- Classic teaching that sagittally oriented coin on frontal radiograph is likely in trachea: Incorrect
  - Coin impacted in esophagus is much more likely regardless of orientation (coronal or sagittal)
  - Coin may lie in coronal or (rarely) sagittal plane in trachea or esophagus

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic: Witnessed ingestion or incidental finding
  - Symptomatic: Drooling, chest/neck pain, vomiting, dysphagia, cough, respiratory distress, stridor

Demographics

- Coin is most commonly ingested foreign body in children < 6 years old
  - Penny is most commonly ingested coin: 44%

Natural History & Prognosis

- 25-30% of esophageal coins pass spontaneously
  - Likelihood of spontaneous passage correlates with location in esophagus: Proximal 14%, middle 43%, distal 67%
- Complications are uncommon
  - Esophageal stricture, perforation, aortoesophageal or tracheoesophageal fistulas
  - Post-1982 copper-plated zinc penny is 97.5% zinc
    - Gastric acid may erode coin margins
    - Gastric acid reacts with zinc to form zinc-chloride
    - Ingestion of large number may cause zinc toxicity

Treatment

- North American Society for Pediatric Gastroenterology, Hepatology, & Nutrition (NASPGHAN) guidelines
  - Esophageal coin
    - Symptomatic: Urgent endoscopic removal
    - Asymptomatic: Endoscopic removal within 24 hours; repeat radiograph prior to endoscopy to look for interval progression
  - Gastric coin
    - Monitor stools for passage; repeat radiograph in 2 weeks
    - Endoscopic removal if not passed within 2-4 weeks
    - Repeat radiograph prior to endoscopy
  - Small bowel coin
    - Clinical observation
    - Enteroscopy/surgical removal if symptomatic
- Use of glucagon to relax LES & aid passage from esophagus is controversial: May cause vomiting & aspiration
- Fluoroscopic-guided retraction with Foley catheter may result in acute airway obstruction if coin moves into airway
- Pushing coin into stomach by dilator (bougienage) does not allow esophagus to be evaluated

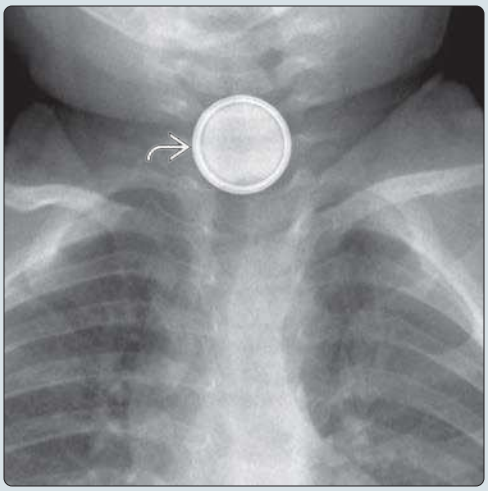
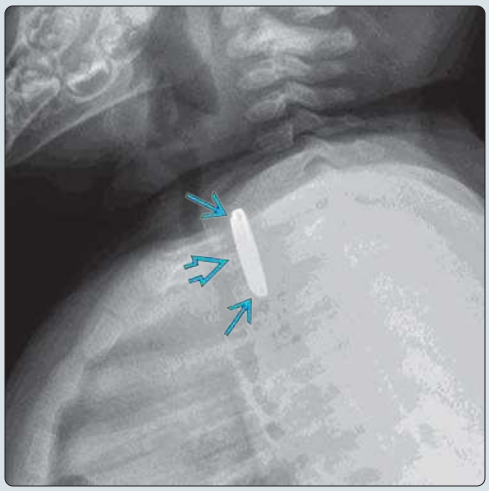
Ingested Button Batteries

KEY FACTS

TERMINOLOGY



- Ingestion of disc-shaped battery, typically by young child
- Esophagus is particularly susceptible to injury by lodged battery with potentially catastrophic consequences



IMAGING

- Frontal radiograph: Margin shows double halo/ring en face
- Lateral radiograph: Rim of step-off/beveled edge
- North American Society for Pediatric Gastroenterology, Hepatology, & Nutrition (NASPGHAN) imaging guidelines
  - Radiographic coverage from nasopharynx to anus
    - Lateral view at least at site of confirmed foreign body
  - After emergent removal of esophageal battery
    - CTA/MR if esophageal injury is present at endoscopy to evaluate proximity/involvement of vascular structures
      - CTA is most efficient vessel assessment
    - Esophagram to exclude leak prior to advancing diet
  - If battery is distal to esophagus, management varies based on battery size & patient age
    - Gastric location of battery at time of discovery does not exclude esophageal injury

CLINICAL ISSUES

- Caustic injury due to hydroxide radical production in tissues adjacent to negative pole (narrower side of step-off on lateral view)
- Unwitnessed ingestion is more likely to present in delayed fashion with nonspecific symptoms: Vomiting, difficulty feeding, cough, chest or abdominal pain, drooling, stridor
- ↑ risk of major complications: Unwitnessed ingestion, battery size ≥ 20 mm (majority are lithium), age < 5 years old, multiple batteries ingested
- Complications include tracheoesophageal fistula, esophageal perforation, esophageal stricture, vocal cord paralysis, aortoenteric fistula (high fatality rate)
  - Injury evolves weeks after battery removal, potentially resulting in delayed aortoenteric fistula

(Left) *Frontal radiograph in a 1-year-old demonstrates an ingested 23-mm, disc-shaped foreign body in the cervical esophagus above the thoracic inlet. Note the double ring/halo ➡ appearance, consistent with a button battery.* **(Right)** *Lateral radiograph in a 10-month-old with a witnessed foreign body ingestion & subsequent drooling & emesis shows the circumferential edge step-off ⇨ typical of a button battery. The negative pole is the narrower anterior side ⇨.*

(Left) *Supine view of the abdomen in a developmentally delayed 11-year-old shows a 13-mm diameter button battery with a faint, concentric radiolucent halo ⇨. Visualization of a halo is less reliable in batteries < 20 mm in size. A coin ⇨ is also present.* **(Right)** *Axial CTA in a patient status post button battery removal shows marked mediastinal inflammation ⇨ extending up to the aortic wall ➡ without contrast extravasation. Note the retained battery casing fragments ➡.*

IMAGING

General Features

- Most common sites of impaction in esophagus
  - Upper esophagus at thoracic inlet
  - Midesophagus at aortic arch
  - Lower esophageal sphincter at gastroesophageal (GE) junction

Radiographic Findings

- Metallic density disc of variable size
  - Size ≥ 20 mm: ↑ risk for esophageal impaction & injury
- Frontal view: Margin shows double halo/ring en face, but may not be visible if is size < 20 mm
- Lateral view: Rim of step-off/beveled edge in tangent
  - Step-off may not be visible on new thinner batteries
  - Negative pole: Narrower side on lateral view; site most likely for most severe injury
  - Soft tissue edema surrounding battery may cause anterior tracheal displacement or narrowing
- Complications may show mediastinal widening (from edema or fluid collections) &/or gas
- Metallic fragments may remain after battery removal

CT

- CTA to look for aortic/vascular injury
  - Mediastinal edema/fluid collections
  - Irregularity/outpouching or edema of aortic wall
  - Active extravasation
- No established findings are predictive of subsequent vascular catastrophes at this time

MR

- Likely more sensitive for soft tissue changes
- Multiple disadvantages relative to CTA
  - MR is not as readily available as CTA
  - MR exam time is much longer than CTA
  - Any retained metallic fragments may create MR safety &/or artifact issues

Esophagram

- Irregularity/edema of mucosa with luminal narrowing
- Leak of contrast into mediastinum or trachea
- Long-term stricturing

Imaging Recommendations

- Foreign body screening with radiographs
  - Frontal view to include neck through pelvis
  - Lateral view of upper airway with nasopharynx
  - Lateral view of foreign body site to identify negative pole & distinguish from coin
- Follow-up imaging as per NASPGHAN guidelines
  - CTA is most efficient tool to assess vessels

DIFFERENTIAL DIAGNOSIS

Coin Ingestion

- Flat metallic disc (no beveled edge or double ring sign)

Magnet Ingestion

- > 1 magnet or 1 magnet + other metallic foreign body may cause bowel injury by attraction through bowel walls

PATHOLOGY

General Features

- Lithium cell → caustic injury after impaction in esophagus
  - Mucosa contacts both poles, completes circuit
  - Electrolytic current generates hydroxide radicals in tissue adjacent to negative pole → ↑ pH
  - Injury evolves weeks after removal
- Nonlithium types injure mainly via alkaline leakage

CLINICAL ISSUES

Presentation

- Vomiting, difficulty feeding, cough, chest or abdominal pain, drooling, stridor, or asymptomatic
- Gastric location does not preclude esophageal injury
  - Gastric injury is more likely if removed > 12 hours after ingestion; may be asymptomatic

Natural History & Prognosis

- Unwitnessed ingestion accounts for 92% of associated fatalities & 56% of major outcome cases
- ↑ risk of major complications: Size ≥ 20 mm (majority are lithium), age < 5 years, multiple batteries ingested
- Major complications
  - Tracheoesophageal fistula in 48%
  - Esophageal perforation in 23%
  - Esophageal stricture in 38%
  - Vocal cord paralysis in 10%
  - Aortoenteric fistula in 46% of fatal cases (1977-2015)
    - Can occur weeks after battery removal

Treatment

- NASPGHAN guidelines are based on battery location & size, clinical stability, & patient age
  - Esophageal + stable: Immediate endoscopic removal
  - Esophageal + unstable/active bleeding: Immediate endoscopic removal in OR with surgery present
    - CTA or MR to evaluate involvement/proximity of aorta
    - Negative CTA, MR → esophagram to exclude leak
    - Injury close to aorta (≤ 3 mm) → serial CTA or MR every 5-7 days until injury recedes
  - Beyond esophagus + ≥ 20-mm battery size + < 5 years old
    - Assess for esophageal injury + endoscopic removal within 24-48 hours
    - If esophageal injury → CTA, MR
  - Beyond esophagus + < 20 mm &/or ≥ 5 years old
    - Consider outpatient observation + repeat radiograph (48 hours if ≥ 20 mm or 10-14 days if < 20 mm)
    - Endoscopic removal if GI symptoms develop or battery is not passed at time of repeat radiograph

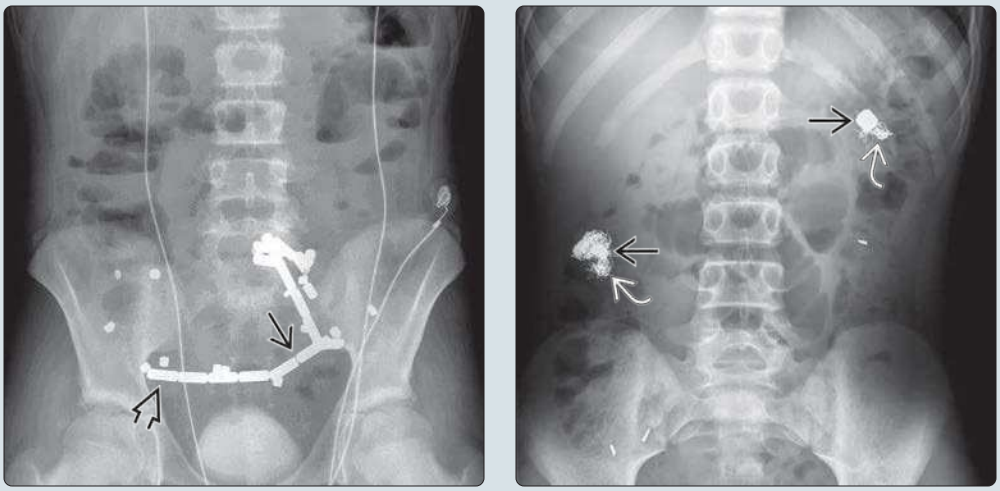
Ingested Multiple Magnets

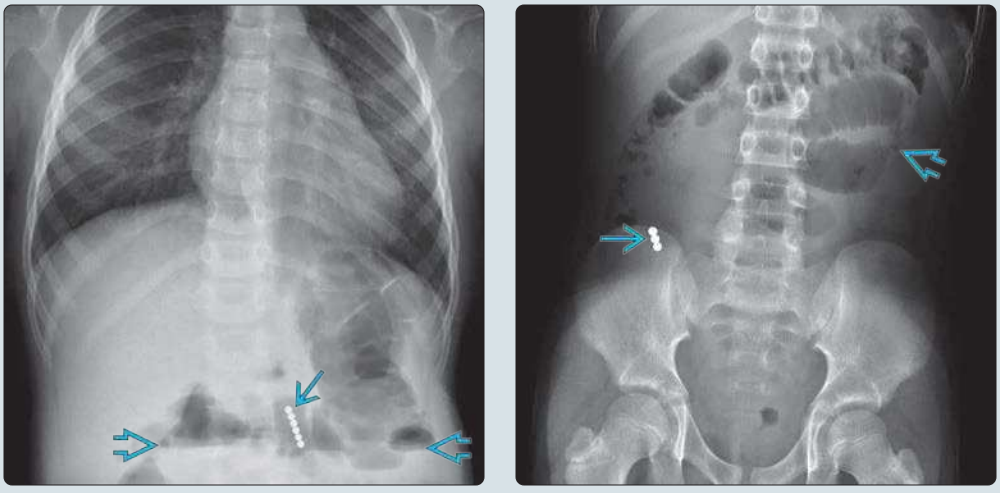
KEY FACTS

TERMINOLOGY



- Ingestion of multiple magnets or single magnet + additional metallic foreign bodies
  - Potential for significant bowel complications
- Rare-earth magnets: 5-10x stronger than traditional magnets

IMAGING



- Metallic density foreign bodies; shapes are variable
- Magnets attract through bowel walls
  - Multiple attracted "stacked" magnets may simulate single cylindrical foreign body
- Entrapment of interposed bowel wall is suggested by
  - Gap between otherwise closely apposed magnets or magnet & adjacent metallic foreign body
  - Failure of magnet to move on sequential radiographs
- Abnormal bowel gas patterns result from complications
  - Ulceration, perforation, fistulae, obstruction, volvulus
- Foreign body ingestion radiographic series includes
  - Frontal views of neck through anus
  - ± tangential views if foreign body is identified
  - ± lateral view of upper airway

CLINICAL ISSUES

- Management depends on number of magnets, location in GI tract, & symptoms
  - Single magnet: Remove vs. follow radiographic passage
  - Multiple magnets or magnet + metal in esophagus/stomach: Endoscopic or surgical removal
  - Multiple magnets or magnet + metal beyond stomach
    - With symptoms &/or abnormal bowel gas pattern: Operative exploration with magnet removal
    - Without symptoms or abnormal bowel gas pattern: Consider careful, frequent clinical & radiographic evaluation until passage vs. removal

(Left) *Frontal upright radiograph of a 12-year-old autistic boy with abdominal pain & bilious emesis shows multiple rod-shaped metallic foreign bodies, most of which appear linked. Small gaps between the magnets may represent entrapped intervening bowel. Numerous small bowel perforations & fistulae were found at surgery.* **(Right)** *Supine frontal radiograph shows 2 clusters of magnets, both of which attracted additional ingested metallic foreign bodies. Associated bowel perforations were present at surgery.*

(Left) *Frontal upright radiograph in a 5-year-old shows 6 metallic densities in the left abdomen with scattered air-fluid levels. The densities did not migrate over several hours. At surgery, multiple magnets were removed with identification of a jejunal perforation & a gastrojejunal fistula.* **(Right)** *Frontal supine view of a 12-year-old shows 3 metallic densities as well as dilated small bowel loops on the left. A small bowel perforation caused by adherent magnets in adjacent bowel loops was seen in surgery.*

TERMINOLOGY

Synonyms

- Postgastric magnetopathy

Definitions

- Ingestion of multiple magnets or single magnet + additional metallic foreign bodies
  - Potential for significant bowel complications due to attraction through bowel loops
- Newer rare-earth magnets are composed of iron, boron, & neodymium: 5-10x stronger than traditional magnets

IMAGING

Radiographic Findings

- Metallic density foreign bodies; variable shapes
  - Rods, discs, spheres/ball bearings, others
- May have larger nonradiopaque component
- Multiple attracted "stacked" magnets may simulate single cylindrical foreign body
  - Magnification helps delineate individual components
- Entrapment of interposed bowel wall is suggested with
  - Gap between otherwise closely apposed magnets or magnet & adjacent metallic foreign body
  - Failure of magnet to move on sequential radiographs
- Abnormal bowel gas patterns from complications
  - Ulceration, perforation, fistulae, obstruction, volvulus

Imaging Recommendations

- NASPGHAN guidelines recommend imaging if
  - Known magnet ingestion
  - Unexplained GI symptoms with rare-earth magnets in environment
- Screening foreign body ingestion radiographs
  - Frontal views from neck through anus, ± lateral view of upper airway
  - Tangential view if foreign body is identified
    - Assists in localization & characterization (such as attached metal or magnets not seen on one view)

DIFFERENTIAL DIAGNOSIS

Coin Ingestion

- Most common ingested radiopaque foreign body
- Metallic disc without beveled edge

Button Battery Ingestion

- Metallic disc with beveled edge/step-off on lateral view, double ring on frontal view
- Esophageal location requires emergent removal

PATHOLOGY

General Features

- Magnets attract to each other through bowel walls
  - Powerful rare-earth magnets attract through up to 6 bowel walls
    - Rare-earth magnets were temporarily banned from toys in USA
- Produce pressure ulcers, ischemic injury, fistulae, necrosis, perforations, &/or obstruction
  - Mucosal ulcerations may occur in < 8 hours

CLINICAL ISSUES

Presentation

- 54.7% < 5 years old
- Suspicion of magnet ingestion is critical: Only 1% of cases between 2000-2012 had witnessed ingestion [US Consumer Product Safety Commission (CPSC) data)]
- Common symptoms (single center study, 56 cases): None: 57.1%; abdominal pain/vomiting: 32.1%; choking: 10.7%

Natural History & Prognosis

- CPSC data: 72 cases in USA (2000-2012)
  - No adverse effect: 33%; > 1 perforation & necrosis: 34%; 1 perforation: 6%, ulcer: 5%, fistula: 3%, volvulus: 2%
  - Surgery: 70%; endoscopic removal: 8%; passed naturally: 21%, death: 1%

Treatment

- NASPGHAN published guideline algorithm
  - Single magnet
    - Esophagus/stomach: Remove with any risk of more ingestions or consider outpatient serial radiographs until passage is ensured
    - Beyond stomach: Removal if possible or outpatient serial radiographs until passage
  - > 1 magnet or 1 magnet + metal in esophagus/stomach
    - If < 12 hours: Pediatric GI consult for endoscopic removal
    - If > 12 hours: Consult surgery prior to endoscopic removal; surgical removal if endoscopy is unsuccessful
  - > 1 magnet or 1 magnet + metal beyond stomach
    - Consult pediatric GI & surgery
    - Symptomatic: Surgical removal
    - Asymptomatic & no obstruction/perforation on imaging
      - Entero-/colonoscopic removal or serial radiographs
      - Radiographs every 4-6 hours in emergency department
      - Progression on radiographs: Confirm passage (may educate parents & continue as outpatient)
      - No progression on radiographs: Admit → continue serial radiographs every 8-12 hours if asymptomatic or surgical/endoscopic removal
  - Parent education: No other metal or magnets near child

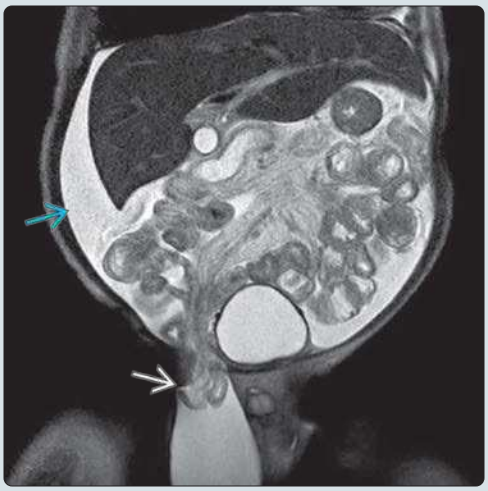
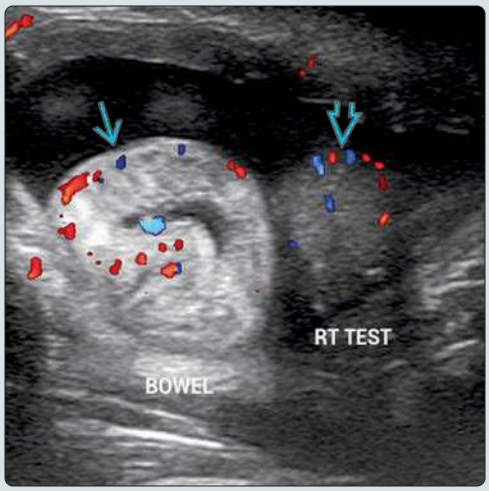
KEY FACTS

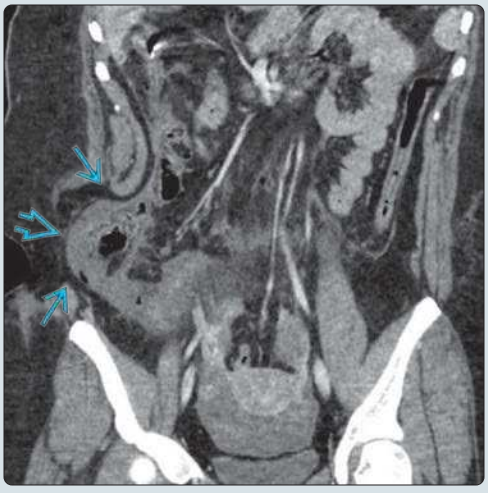


TERMINOLOGY

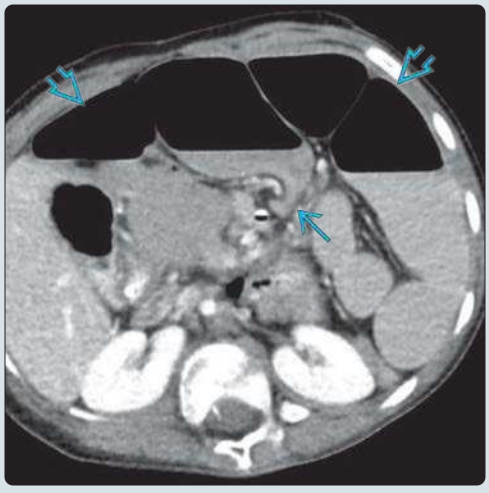


- Hernia: Protrusion of contents from normally encasing body cavity through normal or abnormal opening
- Inguinal hernia: Protrusion of abdominal contents through defect in inguinal region
  - Indirect inguinal hernia: Contents protrude into open deep inguinal ring, extend through patent processus vaginalis, & exit superficial inguinal ring
    - 15% of inguinal hernias are bilateral
    - In females, ovary may herniate through canal of Nuck
  - Direct inguinal hernia: Contents pass through wall of inguinal canal (due to weak abdominal musculature), exiting superficial inguinal ring
- Umbilical hernia: Contents extend into open umbilical ring
- Femoral hernia: Contents extend through femoral ring
- Littre hernia: Contains Meckel diverticulum; site varies
- Amyand hernia: Inguinal hernia contains appendix ± inflammation
- Internal hernia: Extends through defect in abdominal cavity
- Traumatic: Extends through posttraumatic abdominal wall defect
- Incarcerated hernia: Contents cannot be reduced without special maneuvers, sedation, anesthesia, or surgery
- Strangulated hernia: Contents are ischemic due to compression by hernia channel

IMAGING



- US is excellent modality to investigate palpable abnormality
  - Can characterize hernia contents & evaluate blood flow to contents & adjacent tissues
    - Bowel: Peristalsis, swirling contents, gut signature
  - Standing &/or Valsalva maneuver help reproduce reduced hernia to confirm diagnosis
- Obstructive hernia: Dilated bowel loop enters abdominal wall defect, decompressed bowel loop exits hernia defect
- Signs of strangulation: Bowel wall thickening &/or ↓ enhancement, engorged vasa recta, mesenteric stranding/fluid



(Left) *Coronal T2 FS MR in a patient with liver failure & a large volume of ascites shows a large right inguinal hernia containing bowel & ascites.* **(Right)** *Transverse color Doppler ultrasound in the same patient shows echogenic bowel & fluid adjacent to the right testis within the scrotum. Vascular flow is visible within both the herniated bowel & the testis.*

(Left) *Coronal CECT in an adolescent status post motor vehicle accident shows a large traumatic lumbar hernia. The peritoneum & bowel are herniating through the defect.* **(Right)** *Axial CECT in a patient with a history of multiple surgeries shows an internal hernia with a loop of decompressed bowel extending through a small mesenteric defect. Note the multiple dilated bowel loops containing gas & fluid due to obstruction.*

TERMINOLOGY

Definitions

- Hernia: Protrusion of contents from normally encasing body cavity through normal or abnormal opening
  - Inguinal hernia: Protrusion of abdominal contents through defect in inguinal region
    - Indirect inguinal hernia: Protrusion of abdominal contents into open deep inguinal ring, through patent processus vaginalis, exiting superficial inguinal ring
      - Canal of Nuck: Term for patent processus vaginalis in females; extends into labia majoris
      - Amyand hernia: Inguinal hernia containing appendix
    - Direct inguinal hernia: Abdominal contents pass through wall of inguinal canal (due to weak abdominal musculature), exiting superficial inguinal ring
  - Umbilical hernia: Protrusion of abdominal contents through open umbilical ring
  - Femoral hernia: Protrusion of abdominal contents through femoral ring
  - Littre hernia: Hernia contains Meckel diverticulum
  - Internal hernia: Hernia through fossa or foramen within abdominal cavity
    - Defect associated with internal hernia can be congenital or acquired
  - Traumatic: Hernia through traumatic abdominal wall defect
- Incarcerated hernia: Hernia in which contents cannot be reduced without special maneuvers, sedation, anesthesia, or surgery
- Strangulated hernia: Hernia in which contents become ischemic due to vascular compression by hernia channel

Associations

- Indirect inguinal hernia: Prematurity
- Umbilical hernia: Prematurity, Down syndrome, Beckwith-Wiedemann syndrome
- Acquired internal hernia: Abdominal surgery requiring Roux-en-Y reconstruction
- Recent repair of large congenital hernia: Omphalocele, gastroschisis, diaphragmatic hernia
  - ↑ intraabdominal pressure status post reduction of abdominal contents + defect repair can lead to recurrent or new hernias

IMAGING

General Features

- Best diagnostic clue
  - Protrusion of abdominal contents through defect in abdominal wall
- Location
  - Inguinal hernia: Extends to labia or scrotum
    - 60% of inguinal hernias occur on right side
    - 15% of inguinal hernias are bilateral
  - Umbilical hernia: Extends into umbilicus
  - Femoral hernia: Extends into femoral ring, lateral to lacunar ligament
    - More common on right side
  - Littre hernia: Occurs with inguinal (50%), umbilical (30%), & femoral (20%) hernias
  - Traumatic hernia: Right lower abdomen, lateral to rectus sheath
  - Left paraduodenal hernia: To left of inferior mesenteric vein & 4th duodenum within left mesocolon
- Size
  - Abdominal wall defect can vary in size from < 5 mm to > 10 cm depending on location, size of patient, & type of hernia

Radiographic Findings

- Signs of obstruction with dilated, air-filled loops of bowel & multiple air-fluid levels
- Inguinal hernia: Soft tissue or air-filled mass extending beyond pelvis inferiorly
- Umbilical hernia: Round soft tissue or air-filled mass within umbilicus
  - Best seen on cross-table lateral view

Fluoroscopic Findings

- Small bowel follow-through
  - Contrast entering loop of bowel within hernia
  - Obstructive hernia: Dilated loop of bowel entering abdominal wall defect & decompressed loop of bowel exiting hernia defect

CT Findings

- Protrusion of abdominal contents through defect in abdominal wall
- Obstructive hernia: Dilated loop of bowel entering abdominal wall defect & decompressed loop of bowel exiting hernia defect
- Signs of impending strangulation: Free fluid within hernia, bowel wall thickening, or luminal dilation
- Signs of strangulation: Bowel wall thickening, ↓ enhancement of bowel wall, engorged vasa recta, & mesenteric stranding
- Internal hernia: Cluster of small bowel loops, stretched mesenteric vessels
  - Left paraduodenal hernia: Bowel between stomach & pancreas or transverse colon
    - Bowel may appear to be contained by sac
    - Superior/anterior displacement of inferior mesenteric vein
- Traumatic hernia: Defect in abdominal musculature with soft tissue stranding ± injury of abdominal organs

Ultrasonographic Findings

- Inguinal hernia: Abdominal contents entering scrotum or labia
  - Confirm bowel presence with peristalsis, visualization of swirling bowel contents, gut signature in bowel wall
  - Use color Doppler to confirm blood flow to bowel
  - In females, may see herniated ovary
  - In male neonates, may see ↓ to absent color Doppler flow to ipsilateral testis

Imaging Recommendations

- Best imaging tool
  - Diagnosis is often based on clinical exam
  - US is used to diagnose etiology of unknown abdominal bulges

- Standing or Valsalva maneuver helps reproduce reduced hernia (by forcing abdominal contents through abdominal defect)
- Can characterize hernia contents
- Can evaluate blood supply to hernia contents & adjacent tissues compressed by hernia
- CT is useful to diagnose etiology of obstruction or abdominal pain

DIFFERENTIAL DIAGNOSIS

Hydrocele

- Can communicate through inguinal hernia defect
- May be confined to spermatic cord or extend into scrotum
  - Fluctuant mass of inguinal canal or scrotum
  - ↑ transillumination
  - ↑ in size late in day or during viral infection

Omphalocele

- Congenital midline abdominal wall defect into base of umbilicus
- Herniated contents are covered by sac

CLINICAL ISSUES

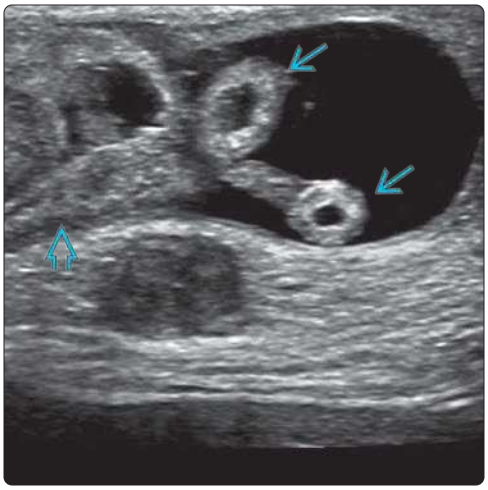
Presentation

- Most common signs/symptoms
  - Hernia: Painless easily reducible bulge
  - Incarcerated hernia: Hernia is not easily reduced
  - Obstructed hernia: Vomiting, abdominal distention
  - Strangulated hernia: Pain, peritonitis, shock

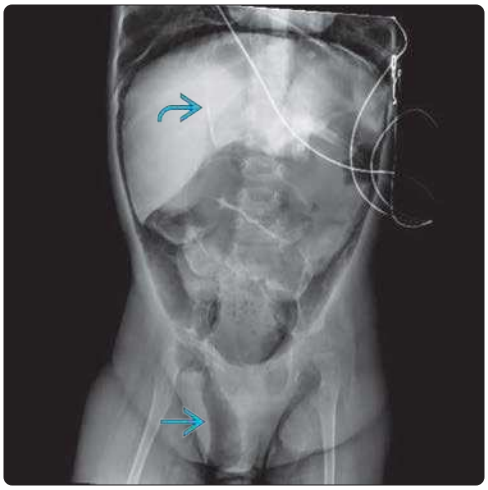
Demographics

- Age
  - Inguinal hernia: Occurs at any age; ↑ incidence in premature infants
  - Femoral hernia: Most commonly occurs 5-10 years
  - Umbilical hernia: Most common in infants & toddlers
    - 75% of infants < 1,500 g have umbilical hernia
  - Traumatic hernia: Mean age = 9.5 years
- Sex
  - Inguinal hernia: 9-10x more common in males
  - Femoral hernia: During childhood, slightly more common in males
    - In adults, femoral hernias are more common in females
  - Traumatic hernia: More common in males due to high-risk activities
- Ethnicity
  - Umbilical hernias are more common in children of African descent
- Epidemiology
  - Indirect inguinal hernias
    - Inguinal hernias in 0.8-4.4% of children
      - 13% of infants born < 32 weeks & 30% of infants weighing < 1,000 g will have inguinal hernia
    - Risk for inguinal hernia becoming incarcerated is ↑ in early infancy
      - 10-30% become incarcerated in premature infants
      - Up to 15% become incarcerated in older children
    - Inguinal hernia repair is one of most frequently performed surgeries in children
    - Incarcerated inguinal hernia is 2nd most common cause of bowel obstruction after postsurgical adhesions
  - Direct inguinal hernia
    - Accounts for 2-5% of groin hernias in children
  - Femoral hernias
    - Rare in children
    - Accounts for 0.1-1.1% of groin hernias
    - Become incarcerated in 15-20% of patients
    - Majority contain properitoneal fat
  - Umbilical hernia
    - 10-20% of all infants are born with umbilical hernia
  - Littre hernia
    - 0.3-0.8% of all hernias contain Meckel diverticulum
  - Amyand hernia
    - Appendix found in inguinal hernia in 1% at operation
    - Accompanied by acute appendicitis in 0.1%
  - Internal hernia
    - Left paraduodenal hernia is most common type of congenital internal hernia
  - Traumatic hernia
    - May be caused by bicycle handle bar injury

Natural History & Prognosis



- Indirect inguinal hernia occurs with patent processus vaginalis
  - 40% of patent processus vaginalis close during 1st months of life
  - 20% of boys have patent processus vaginalis at 2 years of age
  - Contralateral patent processus vaginalis in ~ 20%
    - Can lead to contralateral hernia in 3-15% of patients



Treatment

- Surgery is performed to treat most types of hernia due to risk of incarceration
- Umbilical hernia has low risk of incarceration
  - 90% of umbilical hernias close spontaneously before 6 years of age
  - Surgery is performed to close large hernias or hernias that fail to spontaneously close
- Complications of inguinal hernia repair include recurrence, infection, testicular atrophy, injury to vas deferens, & infertility

(Left) *Longitudinal ultrasound of the scrotum shows bowel & the appendix extending into the hernia, consistent with an Amyand hernia.* **(Right)** *AP radiograph of the abdomen in a young child with a large volume of intraperitoneal free air shows air extending through a right inguinal hernia. Note that the falciform ligament is visible, one of the multiple different signs of intraperitoneal free air on this radiograph.*

(Left) *Longitudinal ultrasound of the groin in an adolescent girl shows a left inguinal hernia containing the left ovary. This is termed a hernia of the canal of Nuck. The ovary may rarely torse in this scenario.* **(Right)** *Axial NECT in a patient with a history of a prior ostomy shows a Richter hernia at the site of the prior surgical defect.*

(Left) *Lateral radiograph of the abdomen shows a large umbilical hernia containing bowel.* **(Right)** *Lateral image from a water-soluble contrast enema in the same patient shows extension of the contrast-filled colon into the large umbilical hernia.*

Omphalocele

KEY FACTS

TERMINOLOGY

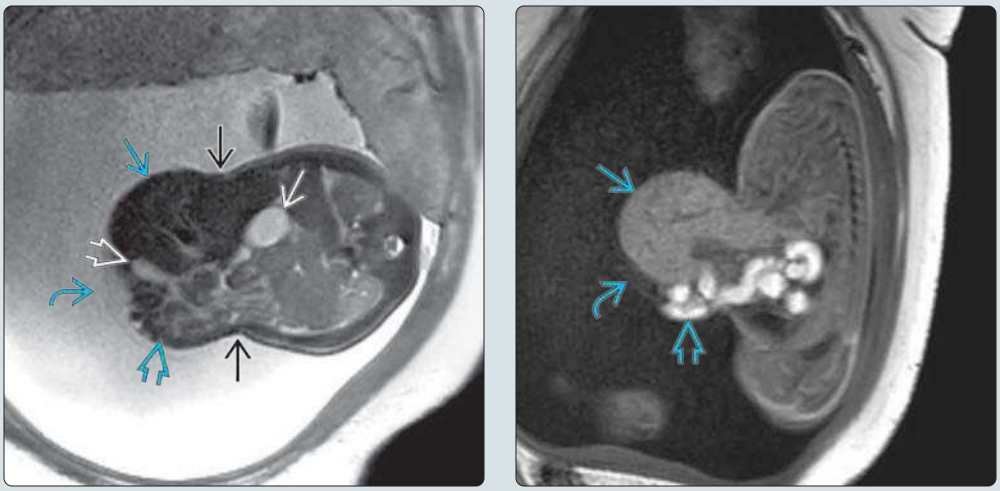
- Midline abdominal wall defect (AWD) with visceral extrusion into umbilical cord base
- AWD < 5 cm wide: Minor or small; > 5 cm: Giant

IMAGING

- Extruded abdominal contents are contained by round, membranous sac
  - Umbilical cord inserts on sac
- Small bowel & liver are more frequently herniated than spleen, stomach, bladder, colon, or gonads
- Bowel malrotation in virtually all cases
  - Postrepair risk of midgut volvulus is higher than gastroschisis as sac prevents bowel inflammation that incites "protective" adhesions
- Prenatal US/MR defines AWD location, size, covering, contents, & associated anomalies
- Postnatal radiographs demonstrate sac, which may contain gas-filled bowel loops

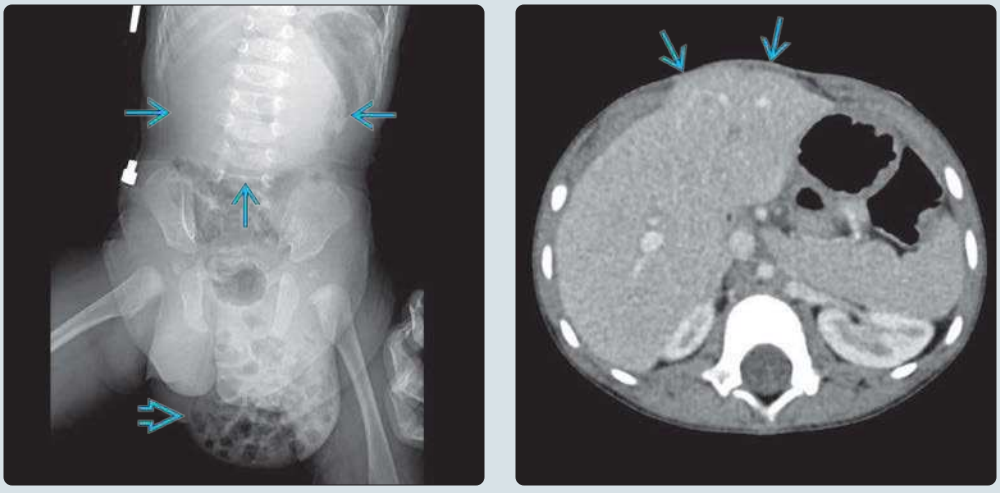
TOP DIFFERENTIAL DIAGNOSES

- Gastroschisis
- Umbilical hernia
- Bladder exstrophy
- Limb-body wall complex



PATHOLOGY

- High rates of associated structural & chromosomal anomalies: Beckwith-Wiedemann syndrome, OEIS complex, pentalogy of Cantrell, trisomy 18 > 21, 13; many others



CLINICAL ISSUES

- Repair technique & timing depend on size, contents, patient stability, & other anomalies
- With isolated omphalocele, survival of 75-95%
- Poor prognosis with
  - Associated structural &/or chromosomal abnormalities
  - Omphalocele rupture
  - Pulmonary hypoplasia

(Left) *Axial T2 SSFSE MR in a 34-weeks-gestation fetus shows a large abdominal wall defect (AWD) resulting in a giant omphalocele containing most of the liver, gallbladder, & bowel but not stomach. The umbilical cord could be seen inserting on the sac on other images (not shown).* **(Right)** *Sagittal T1 MR in the same fetus shows the liver & meconium-containing bowel herniated through the AWD but covered by a membrane.*

(Left) *AP radiograph in a 6-month-old shows a giant omphalocele that is undergoing sclerosis & epithelialization of the membrane ("paint & wait") after partial mesh closure. Note the large left inguinal hernia containing bowel.* **(Right)** *Axial CECT in the same patient at 33 months of age shows a relatively ↓ size of the omphalocele, which is now skin-covered. The liver has largely been incorporated into the abdomen at this point.*

TERMINOLOGY

Synonyms

- Exomphalos

Definitions

- Midline abdominal wall defect (AWD) with visceral extrusion into umbilical cord base

IMAGING

General Features

- Best diagnostic clue
  - Extruded abdominal contents are contained by sac
    - Small bowel & liver are more frequently herniated than spleen, stomach, bladder, colon, or gonads
  - Umbilical cord inserts on sac
- Size
  - AWD < 5 cm wide: Minor or small
    - Chromosomal abnormalities are more likely
    - Higher rate of intestinal, brain anomalies
  - AWD > 5 cm wide: Giant
    - Usually contains liver
    - Higher rate of cardiac, renal, pulmonary anomalies

Radiographic Findings

- Round mass protruding from abdominal midline
  - Gas-containing bowel may be seen in sac
- Giant omphalocele may lead to pulmonary hypoplasia
  - Pneumothorax, bell-shaped chest
- Ruptured omphalocele
  - Extruded bowel loops ± other viscera without sac
- Wide variety of associated anomalies

Fluoroscopic Findings

- Bowel malrotation in virtually all cases
  - Normal fixation never occurs for herniated bowel
  - Postrepair adhesions are not as frequent as gastroschisis (as covered/unexposed bowel not inflamed)
    - Risk of midgut volvulus may be greater

Ultrasonographic Findings

- Grayscale ultrasound
  - Prenatal scans
    - Transient physiologic bowel herniation into umbilical cord occurs before 12-weeks gestation
    - Omphalocele is confirmed with
      - Herniation of stomach or liver (not physiologic)
      - Bowel in umbilical cord > 12 weeks
    - Omphalocele circumference:abdominal circumference ratio (OC:AC) may predict type of surgical closure required
- Pulsed Doppler
  - Postnatal abdominal Doppler may be useful during reduction of abdominal viscera to evaluate flow
    - Abnormal high-resistance visceral waveforms are seen with ↑ abdominal pressures (i.e., compartment syndrome)

MR Findings

- Fetal MR is useful to
  - Characterize sac contents + associated anomalies
  - Calculate lung volumes to predict pulmonary hypoplasia

Imaging Recommendations

- Best imaging tool
  - Prenatal US detects & characterizes AWD (location, size, contents, covering)

DIFFERENTIAL DIAGNOSIS

Gastroschisis

- Small AWD to right (rarely left) of umbilical cord insertion
- No membrane covering herniated bowel loops
  - Chronic exposure to amniotic fluid → inflammation → dysmotility, adhesions
- Extruded contents are limited to bowel, stomach
  - Liver involvement is extremely rare
- Additional anomalies in < 20%
  - Intestinal atresias are most common

Umbilical Hernia

- Small (< 2 cm), skin-covered midline AWD
- May contain bowel or omentum

Bladder Exstrophy

- Lower AWD with superficial soft tissue mass (exposed bladder surface), wide pubic symphysis
- No normal bladder is visualized prenatally despite normal amniotic fluid

Limb-Body Wall Complex

- Lethal malformation complex
  - Large AWD with extruded abdominal viscera fused to placenta or uterine wall
  - Scoliosis, limb abnormalities, short umbilical cord

PATHOLOGY

General Features

- Genetics
  - Most cases are sporadic
  - Familial omphalocele is rare
    - Autosomal dominant or X-linked recessive trait
  - Chromosomal abnormalities in 30-50%
    - Trisomy 18 is most common
    - Less likely with larger, liver-containing AWD
- Associated abnormalities
  - Additional structural anomalies: 54-88%
    - More likely overall if omphalocele contains liver
    - Additional intestinal anomalies (especially Meckel diverticulum, intestinal atresias) & brain anomalies are more likely in small omphaloceles
  - Genitourinary anomalies: Up to 40%
    - Bladder exstrophy, cloacal exstrophy
    - Ureteropelvic junction obstruction, renal ectopia, solitary kidney, cryptorchidism
    - Prune-belly syndrome
  - Gastrointestinal anomalies: Up to 40%
    - Tracheoesophageal fistula, imperforate anus, absent gallbladder, enteric duplication, intestinal atresia, Meckel diverticulum
      - 7:1 likelihood of Meckel diverticulum in small vs. giant omphaloceles
  - Respiratory insufficiency

- Pulmonary hypoplasia with giant omphaloceles
  - Impaired diaphragm & thoracic cage development
  - Oligohydramnios occurs if fluid accumulates in omphalocele sac from bladder anomaly
- Congenital heart disease: Up to 50%
  - Septal defects, transposition, ectopia, tetralogy of Fallot, absent inferior vena cava
- Musculoskeletal anomalies: Up to 42%
  - Clubfoot, polydactyly, limb deficiency, rib anomalies
  - Scoliosis, vertebral abnormalities
  - Lymphatic malformation
- CNS anomalies: Up to 33%
  - Encephalocele, holoprosencephaly, cerebellar hypoplasia, myelomeningocele, anencephaly
- Specific associated syndromes
  - Beckwith-Wiedemann syndrome in 5-10%
    - Omphalocele, macroglossia, visceromegaly, hypoglycemia, embryonal tumors (hepatoblastoma, Wilms tumor)
  - OEIS complex (1:200,000 live births)
    - Omphalocele, exstrophy of cloaca/bladder, imperforate anus, spinal defects
  - Pentalogy of Cantrell
    - Cardiac anomalies, omphalocele, & defects of diaphragm, pericardium, sternum → often results in ectopia cordis

- Embryology
  - Failure of central migration of lateral mesodermal body folds in early gestation
  - Additional failure of migration of cephalic mesodermal folds: Ectopia cordis

Gross Pathologic & Surgical Features

- Omphalocele membrane is composed of peritoneum + amnion + intervening Wharton jelly
- Covered AWD protects bowel from inflammation, dilation
- Larger relative size of this AWD makes in utero vascular insults to bowel unlikely

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Detected by prenatal ultrasound
- Other signs/symptoms
  - ↑ maternal serum α-fetoprotein (70%)

Demographics

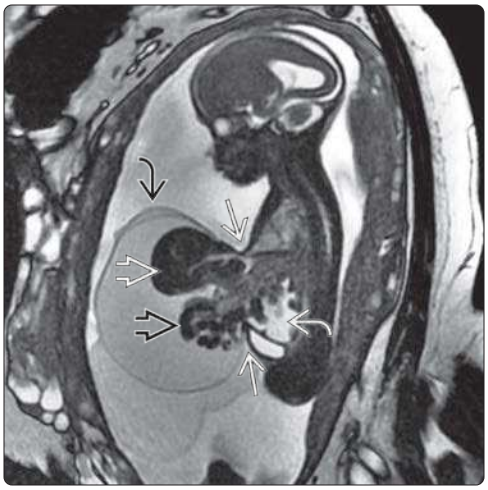
- Epidemiology
  - Incidence: 2-4.4/10,000
    - Multigestation:singleton pregnancies = 3:1

Natural History & Prognosis

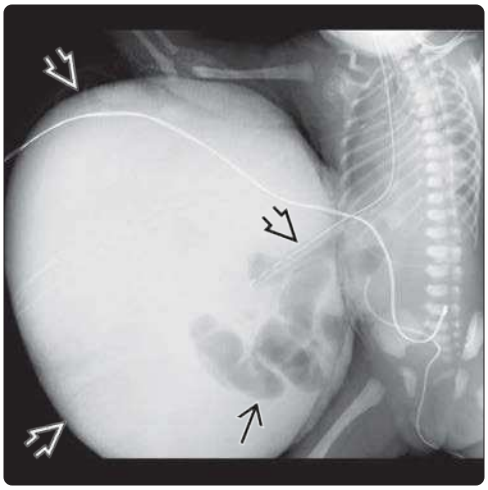
- Premature birth in up to 42%
- Survival is 75-95% with normal chromosomes & no other anomalies
- Overall survival beyond neonatal period
  - Small/minor: Up to 92%; giant: Up to 67%
- Poor prognosis with
  - Associated structural or chromosomal abnormalities: Mortality of 80-100%
  - Omphalocele rupture
  - Pulmonary hypoplasia

Treatment

- Fetus: Amniocentesis for karyotype; no intervention
- Birth: Delivery at tertiary facility
  - C-section for giant omphalocele to prevent dystocia, rupture
  - Respiratory support in giant omphalocele patients with pulmonary hypoplasia → pneumothorax, respiratory distress
  - Sac is covered to prevent fluid & heat loss, stabilized to prevent rupture
    - Urgent repair is not indicated unless sac ruptures
- Repair goal: Return viscera to abdomen with skin & fascial coverage
  - Abdominal compartment syndrome (ACS) develops if viscera are returned too quickly, causing ↑ intraabdominal pressures with impaired visceral blood flow, hypotension, respiratory distress (↓ diaphragm motion)
- Small/minor omphalocele: Initial direct repair
  - If bladder pressure ↑ intraoperatively by visceral reduction then temporizing measures are required to prevent ACS
    - Synthetic graft; skin-only closure; silo reduction
- Giant: Treatment is controversial, more complex
  - Staged: Gradual reduction by silo with gravity vs. synthetic graft + ↑ compression
  - Nonoperative (best for unstable patients): Topical agents promote epithelialization of sac (over ~ 3 months), which gradually incorporates to abdominal cavity
    - Subsequent hernia repair is required
- Postrepair issues
  - Pulmonary dysfunction
  - Inguinal or ventral hernia
  - Gastroesophageal reflux
    - May account for associated feeding intolerance as bowel functions normally
  - Complications of malrotation
    - Midgut volvulus risk is > repaired gastroschisis patients due to lack of bowel inflammation (which incites "protective" adhesions)



DIAGNOSTIC CHECKLIST



Consider

- Omphalocele is often associated with structural &/or chromosomal anomalies

(Left) *Sagittal SSFP MR in a 23-weeks-gestation fetus shows a large midline AWD with herniation of the entire liver & much of the bowel into a large sac, consistent with a giant omphalocele. Ascites is noted in the fetal abdomen as well as the sac.* **(Right)** *Oblique radiograph in the same patient after delivery shows the giant omphalocele sac containing the decompressed stomach & multiple gas-distended small bowel loops.*

(Left) *Axial CECT of an 18-month-old shows a giant omphalocele that has been closed by epithelialization (without fascia or muscle). There is continued protrusion of the liver into the abdominal wall defect (which is covered by skin).* **(Right)** *Frontal upper GI series 10-minute image in the same patient shows proximal small bowel loops in the right abdomen, typical of abnormal bowel fixation (i.e., malrotation) in these patients. The large abdominal protuberance is clearly visible.*

(Left) *AP radiograph in a newborn shows a lobular density overlying the central abdomen at the expected site of the umbilicus, corresponding to a small omphalocele. This protuberant mass is larger than the rounded opacity seen with an umbilical hernia.* **(Right)** *AP radiograph shows a silo enclosing a ruptured omphalocele. Note the characteristic appearances of the intraabdominal metallic coiled spring at the base of the silo as well as the overlying bar from which the silo bag is suspended.*

Gastroschisis

KEY FACTS

TERMINOLOGY

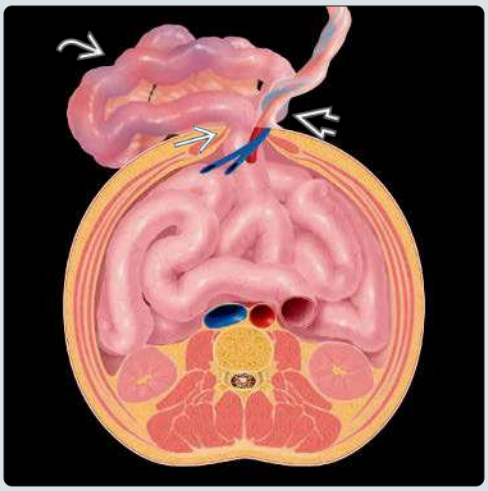
- Congenital abdominal wall defect (AWD) lateral (usually to right) of normal umbilicus
  - Bowel herniates freely into amniotic cavity without sac
- Simple gastroschisis (majority): No bowel complications
- Complex gastroschisis (10-20%): Presence of bowel atresia, necrosis, &/or perforation

IMAGING

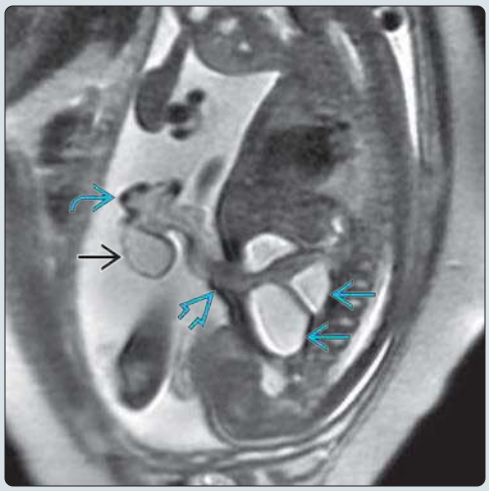
- Prenatal: Dilated bowel & polyhydramnios in complex cases
- Postnatal: Upper GI & small bowel follow-through after repair shows malrotation ± dysmotile dilated loops, obstruction, short gut

TOP DIFFERENTIAL DIAGNOSES

- Omphalocele
- Limb-body wall complex
- Cloacal exstrophy
- Amniotic band syndrome

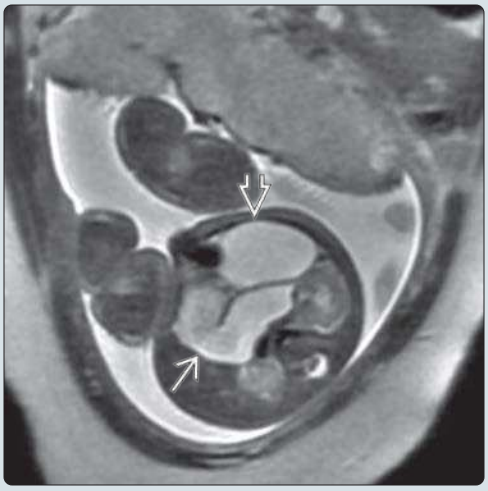


PATHOLOGY

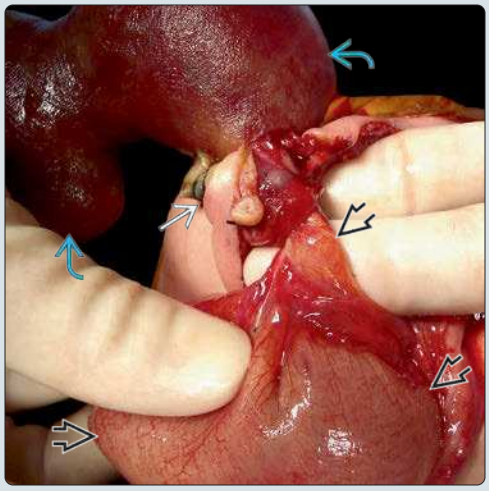


- Additional anomalies in up to 20%
  - Intestinal atresias are most common
- AWD may cause prenatal bowel injury
  - Chronic irritation by exposure to amniotic fluid → dysmotility, adhesions
  - Constriction at AWD → vascular injury with atresia, volvulus, necrosis, perforation
- Postrepair bowel insults
  - Necrotizing enterocolitis, hernias, obstruction by adhesions
  - Not at risk of midgut volvulus despite malrotation

CLINICAL ISSUES



- At delivery, herniated bowel is inflamed in ~ 33%
- Treatments include immediate primary repair vs. gradual bowel reduction with preformed silo to prevent compartment syndrome
- Overall infant survival > 90% (but ↓ in complex forms)



(Left) *Axial graphic shows a small abdominal wall defect (AWD) ➡ to the right of the umbilicus ➡ with herniation of bowel loops ➡. No covering membrane is seen. These features are typical of gastroschisis.* **(Right)** *Sagittal SSFSE T2 MR in a 31-weeks-gestation fetus shows a small AWD ➡ right of the umbilical cord insertion (not shown). Small-caliber, meconium-containing bowel ➡ protrudes with a cystic lesion ➡ into the amniotic fluid. Several dilated proximal small bowel loops ➡ remain in the abdomen.*

(Left) *Axial SSFSE T2 MR in the same patient shows dilated intraabdominal duodenum ➡ & proximal jejunum ➡.* **(Right)** *Intraoperative photograph of the same neonate shows a dilated atretic jejunum ➡ extending up to the AWD, which is right of the umbilicus ➡. A cystic mass of necrotic bowel ➡ protruded from the defect, consistent with a closed gastroschisis.*

TERMINOLOGY

Definitions

- Gastroschisis: Congenital abdominal wall defect (AWD) lateral to normal umbilicus
  - AWD almost always lies right of umbilical cord insertion
  - Bowel herniates into amniotic cavity without covering membrane
- Simple gastroschisis: Without bowel complications
- Complex gastroschisis: Presence of bowel atresia, necrosis, &/or perforation in ~ 10-20% of cases

IMAGING

General Features

- Best diagnostic clue
  - Prenatal ultrasound: AWD lies to right of umbilical cord with herniation of free-floating loops of bowel
    - Herniated viscera include
      - Small bowel (almost always)
      - Less frequently: Large bowel, stomach, gonads
      - Liver very rarely reported

Radiographic Findings

- Bowel loops protrude from AWD without covering sac
  - Bowel may be dilated & thick-walled
- Preformed silo: Intraabdominal metallic spring coil at base of overlying dense bag that contains herniated bowel
  - Only if utilizing gradual (rather than primary) reduction of bowel into abdomen
- Pneumatosis, portal venous gas, free air if necrotizing enterocolitis (NEC) develops

Fluoroscopic Findings

- Upper GI series + small bowel follow-through to demonstrate intestinal complications after repair
  - Malrotation (expected in all cases)
  - Dysmotility with dilated bowel loops → delayed small bowel transit time
  - Obstruction due to adhesions
  - Short gut with history of complicated gastroschisis & necrosis requiring resection

Ultrasonographic Findings

- Grayscale ultrasound
  - Prenatal ultrasound
    - Herniated bowel loops free floating in amniotic fluid without covering membrane
    - Bowel wall may be thickened, echogenic, nodular
    - Significance of bowel dilation is debated; intra- or extraabdominal loops may be dilated
      - Considerations include closing gastroschisis, volvulus, atresia, ischemia, chronic inflammation from amniotic fluid exposure
    - Oligohydramnios is more frequent than polyhydramnios
    - Intrauterine growth restriction (IUGR)
      - Overestimated by ↓ abdominal circumference due to bowel extrusion
    - Predictors of complex gastroschisis or adverse neonatal outcome: Polyhydramnios, bowel dilation, ↑ volume of herniated bowel, bowel wall thickening
      - Intraabdominal bowel dilation has been more consistently confirmed as predictive than extraabdominal dilation

MR Findings

- Fetal MR may be useful to evaluate associated anomalies
- Neonatal MR may be used to evaluate bowel motility & superior mesenteric artery (SMA) flow
  - ↑ SMA flow at time of AWD closure correlates with ↑ feeding tolerance

Imaging Recommendations

- Best imaging tool
  - Prenatal ultrasound

DIFFERENTIAL DIAGNOSIS

Omphalocele

- Viscera are herniated into base of umbilical cord with covering membranous sac
- Always contains bowel; often contains liver, other organs
- Ruptured omphalocele may mimic gastroschisis
- > 50% have associated malformations, chromosomal abnormalities

Limb-Body Wall Complex

- Lethal malformation with large AWD
- Herniated viscera are not covered by membrane
- Fetus is often fixed to placenta
- Abnormally short umbilical cord
- Scoliosis, limb anomalies

Cloacal Exstrophy

- Low AWD with nonvisualization of bladder
- Exposed bladder plates are divided by everted bowel
  - Prolapsed ileum resembles "elephant trunk"
- Low omphalocele forms upper part of AWD

Physiologic Gut Herniation

- Gut should not extend > 1 cm into cord
- Herniation is always midline
- Bowel returns to abdomen by 12-weeks gestation

Amniotic Band Syndrome

- Multiple body parts are affected (especially limbs, head)
- Random "slash" defects
- May visualize bands with extremity constriction ± distal edema/amputations

PATHOLOGY

General Features

- Etiology
  - Numerous theories
    - Incomplete lateral fold closure
    - Mesenchymal defect
    - Abnormal involution of right umbilical vein
    - Omphalomesenteric (vitelline) artery occlusion with necrosis at right side of umbilical ring
    - In utero rupture of umbilical hernia
  - Possible teratogens: Aspirin, pseudoephedrine, acetaminophen, cocaine, smoking, others
- Genetics

- No known genetic basis for gastroschisis
  - Chromosomal abnormalities in < 2%
- Familial cases are uncommon
  - 2-5% recurrence risk for siblings
- Associated abnormalities
  - Additional anomalies in up to 20%
    - Intestinal atresias in 5-20% (jejunoileal > colonic)
    - Rare
      - Gastrointestinal duplication, Meckel diverticulum
      - Hydronephrosis, bladder herniation into AWD
      - Congenital cardiac defects
      - Limb hypoplasia, arthrogryposis
      - Cryptorchidism

Gross Pathologic & Surgical Features

- Defect is usually < 2-4 cm
  - Tight, constricted defect, usually right of umbilicus
- In utero bowel injury mechanisms from AWD
  - Chronic irritation by exposure to amniotic fluid
    - Bowel thickening, coating by inflammatory fibrin peel
      - Dysmotility, ↑ risk of adhesions
    - Protein loss by bowel to amniotic fluid → IUGR
  - Constriction at AWD → complex gastroschisis (10-20%)
    - Vascular injury with necrosis, atresia, volvulus, perforation
      - Closed gastroschisis: AWD closes around prolapsed gut causing midgut infarction ± resorption (vanishing midgut); abdominal wall may be normal
    - ↑ rates of NEC, short gut
- Postrepair bowel insult
  - NEC
  - Malrotation with adhesions
    - No significant risk of midgut volvulus

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Recognized during prenatal ultrasound in 98% of cases in developed countries
    - ↑ α-fetoprotein in maternal serum (95%)
  - At delivery, herniated bowel is inflamed with fibrin coating ("peel") in ~ 33%; bowel is rarely necrotic

Demographics

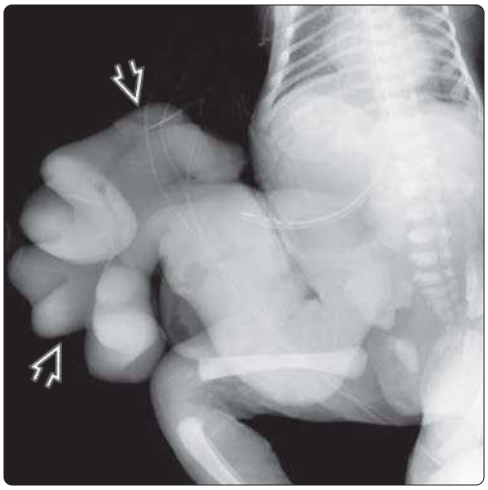
- Epidemiology
  - 1:2,000-4,000 live births
  - Maternal risk factors: Young age, low socioeconomic status, primigravida, poor nutrition, smoking, vasoconstrictive agents

Natural History & Prognosis

- Prematurity in up to 60%
- Overall infant survival > 90% (> 95% for simple, < 70% for complex)
  - Sepsis is most common cause of death
- 10-15% with persistent disability
  - Inguinal hernias due to ↑ intraabdominal pressure
  - Short-gut syndrome with malabsorption
  - Motility disorders
    - 10% incidence of hypoperistalsis syndrome
    - 50% have gastroesophageal reflux
  - Small bowel obstruction from adhesions post repair
    - 27% in 1st year; 37% by 10 years
  - Chronic abdominal pain

Treatment

- Antenatal
  - Close monitoring in 3rd trimester due to ↑ risk of intrauterine demise
  - Delivery at tertiary care center
  - Preterm delivery is not routinely recommended
  - Without other obstetric indications, cesarean section has no advantage over vaginal delivery
- Post natal
  - Protection of herniated bowel, IV fluid replacement & nutrition, IV antibiotics, thermoregulation
  - Prior to reduction, bowel must be inspected for atresias
  - Repair of AWD: Controversy over best method
    - Operative vs. sutureless umbilical cord flap
      - Sutureless method only if bowel is not inflamed
    - Primary closure
      - Possible if intraabdominal pressure < 20 mm Hg (measured in stomach or bladder) when external contents are returned to abdominal cavity
      - Excessive intraabdominal pressure (abdominal compartment syndrome) → hypotension, renal failure, bowel necrosis, respiratory compromise
    - Staged closure
      - Preformed silo provides gradual reduction of bowel to abdomen over 1st week of life
  - Rates of reported sepsis, NEC, reoperation, days on ventilator, & days until enteral feedings vary for each closure method depending on study
  - TPN is required until intestinal function returns



DIAGNOSTIC CHECKLIST

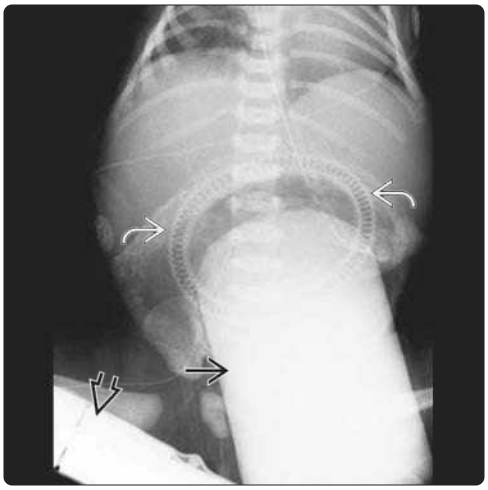


Image Interpretation Pearls

- Prenatally: Consider ruptured omphalocele if liver is herniated into defect without covering membrane (alters prognosis)
- Postnatally: Many possible causes for vomiting + dilated bowel in repaired gastroschisis patients

Note the characteristic metallic spring ⇨ within the AWD as well as the overlying bar ⇨ from which the bowel-containing silo is suspended.*

(Left) *AP radiograph in a newborn with gastroschisis shows numerous bowel loops ⇨ herniated from the abdominal cavity without a covering membrane.* **(Right)** *Frontal upper GI in the same patient after repair of the gastroschisis shows that the duodenojejunal junction ⇨ is abnormally positioned right of the midline & below the duodenal bulb ⇨. This is consistent with malrotation, which is typical in gastroschisis as the herniated bowel does not undergo normal fixation in utero.*

(Left) *Axial SSFSE T2 MR in a 30-weeks-gestation fetus shows numerous loops of uncovered bowel ⇨ herniated into the amniotic cavity. The loops lie between segments of the umbilical cord ⇨ & originated from an AWD at the right of the cord insertion (not shown). No dilated bowel is seen.* **(Right)** *Sagittal T1 MR in the same fetus with gastroschisis shows herniated meconium-containing sigmoid colon ⇨ coursing back into the abdomen with a normal rectal appearance noted ⇨. Herniated small bowel ⇨ is also seen superiorly.*

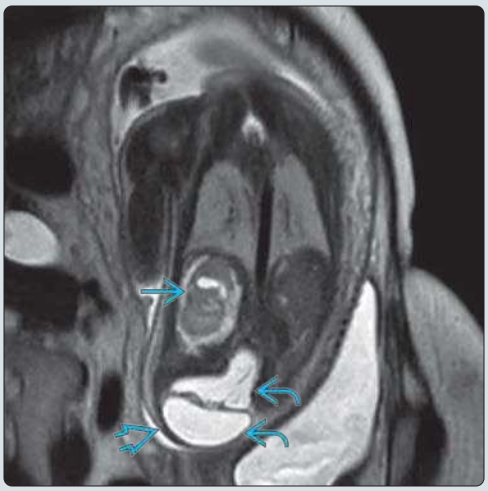
Cloacal Exstrophy/OEIS

KEY FACTS

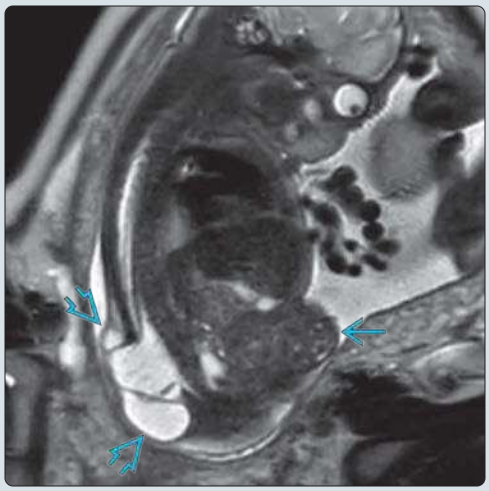
TERMINOLOGY

- Cloacal exstrophy: Complex abdominal wall defect (AWD) with exposed, abnormally persistent connection of genital, urinary, & intestinal tracts
- OEIS: Omphalocele, cloacal exstrophy, imperforate anus, spinal anomalies

IMAGING

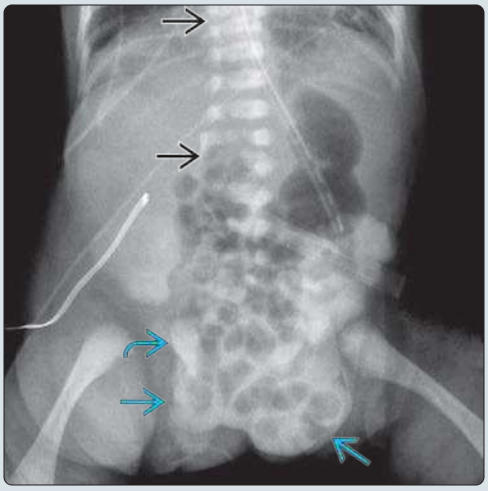


- Prenatal/prerepair findings
  - Absence of urinary bladder with normal to ↓ amniotic fluid volume (depending on renal/ureteral anomalies)
    - Protuberant exposed hemibladder plates at lower abdominal wall
    - Stenotic ureteral orifices may lead to hydroureteronephrosis
    - Additional genitourinary abnormalities: Various renal anomalies, hemiuteri/hemivaginas, + ambiguous &/or bifid genitals
  - Everted cecum splits bladder plates
    - ± elephant trunk appearance of prolapsed terminal ileum below umbilical cord
    - Short, blind-ending microcolon remains internal
      - Lacks normal T1-bright meconium signal
      - Imperforate anus is noted clinically
  - Omphalocele above bladder plates; typically low & small
  - Splayed anterior pelvic bones with abducted thighs
  - Neural tube defects are typically closed, not open
    - Terminal myelocystocele, lipomyelomeningocele
  - ± lower limb anomalies

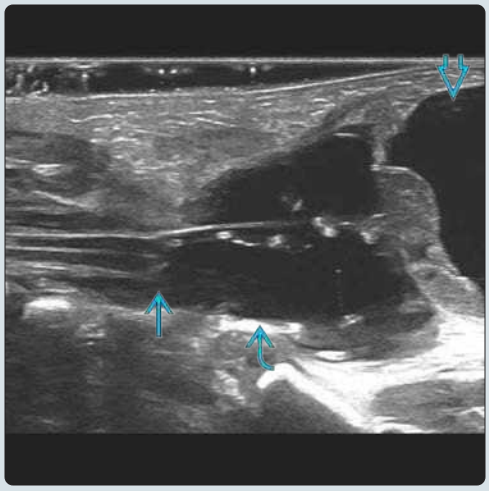


TOP DIFFERENTIAL DIAGNOSES

- Covered cloacal exstrophy
- Bladder exstrophy
- Limb body wall complex



CLINICAL ISSUES



- Survival is near 100%; long-term function/morbidity is related to severity of individual anomalies

(Left) *Coronal SSFSE T2 MR in a 31-weeks-gestation fetus shows a skin-covered lumbosacral dysraphism. Note the appearance of 2 fluid-containing sacs, typical of terminal myelocystocele. No normal left kidney was seen, & the right kidney showed hydroureteronephrosis.* **(Right)** *Sagittal SSFSE T2 MR in the same fetus shows the sac within a sac appearance of terminal myelocystocele as well as a low omphalocele. No bladder or normal rectal meconium was seen, consistent with OEIS complex.*

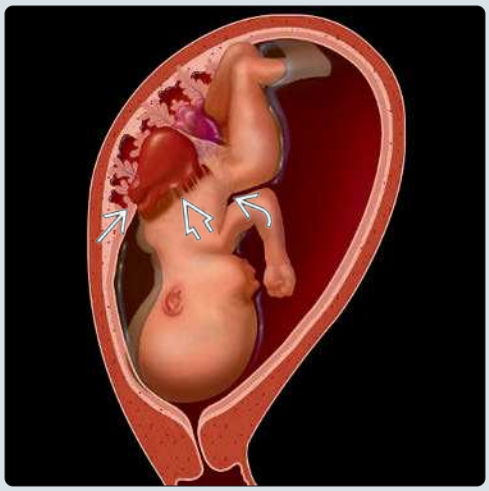
(Left) *AP radiograph in the same patient on day 1 of life shows a low omphalocele containing gas-filled bowel as well as splaying of the pelvic bones (best seen as overlap of the right pubic & ischial bones). Note also the spinal anomalies.* **(Right)** *Longitudinal US of the spine in the same newborn shows truncation of the lumbar spinal cord with a meningocele extending through the dysraphic bony elements into a second sac. Terminal myelocystocele is most commonly associated with OEIS.*

KEY FACTS

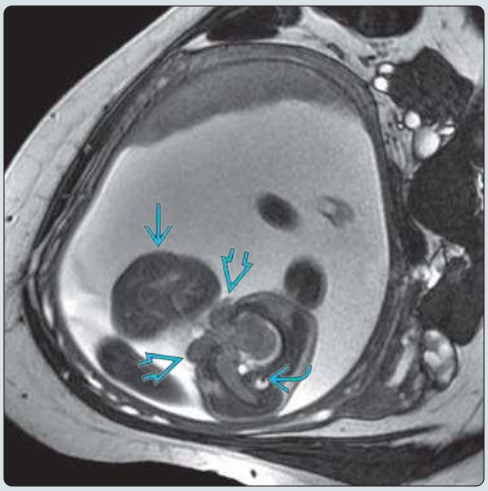
TERMINOLOGY

- Rare lethal malformation complex with large abdominal wall defect (AWD), limb anomalies, &/or craniofacial anomalies

IMAGING

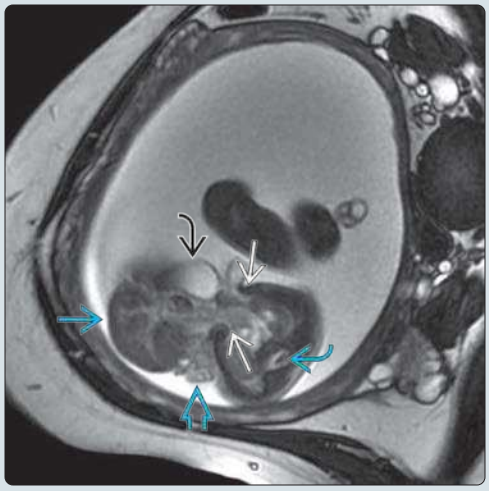


- Best imaging clue: Prenatal US/MR showing distorted fetus with AWD, fixation of extruded viscera to placenta, severe scoliosis, various limb anomalies, & short umbilical cord
- Spectrum of anomalies
  - Large AWD, may involve thorax
    - Herniated viscera include liver, bowel, stomach, bladder, ± kidney, spleen
    - Extruded organs are not contained by membrane
    - Viscera are often attached to placenta or uterine wall
  - Short or absent umbilical cord with 2 vessels
  - Severe scoliosis
  - Deformed, hypoplastic, or absent limb(s)
  - Persistent extraembryonic coelomic cavity
  - Craniofacial anomalies are considered as diagnostic component by some definitions
    - Encephalocele, exencephaly, facial clefts
  - Many other associated anomalies are reported
- Limited ex utero imaging: Typically autopsy radiographs



TOP DIFFERENTIAL DIAGNOSES

- Omphalocele
- Gastroschisis
- Amniotic band syndrome
- Pentalogy of Cantrell
- OEIS complex



PATHOLOGY

- Some classify 2 distinct LBWC phenotypes
  - Type 1: Placentocranial
  - Type 2: Placentoabdominal

(Left) *Graphic shows a large body wall defect with fixation of the abdominal viscera to the placenta. There is associated trunk distortion & scoliosis. No free-floating umbilical cord is seen.* **(Right)** *Axial SSFP MR in a 24-weeks-gestation fetus shows polyhydramnios & a large thoracoabdominal wall defect with herniation of the liver, lungs, & heart (superior to this plane). No covering membrane was seen. Note the eccentric position of the spinal cord, which was due to scoliosis.*

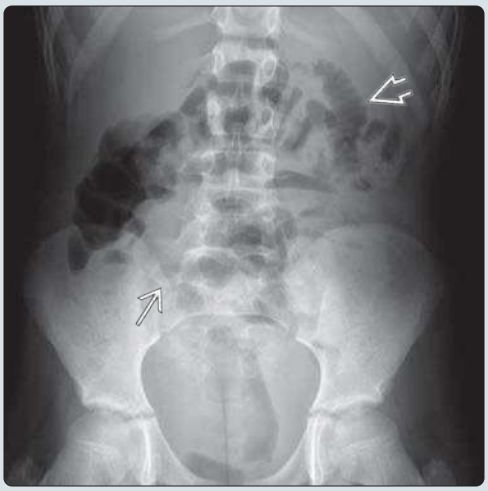
(Left) *Axial SSFP MR in the same fetus shows herniation of the liver, stomach, & bowel through the large thoracoabdominal wall defect. Note the distortion of the spinal cord due to scoliosis.* **(Right)** *Axial SSFP MR in the same fetus shows a relatively normal right thigh, while there is fixation & severe truncation of the lower leg & foot. The constellation of findings is consistent with limb body wall complex (LBWC).*

Appendicitis

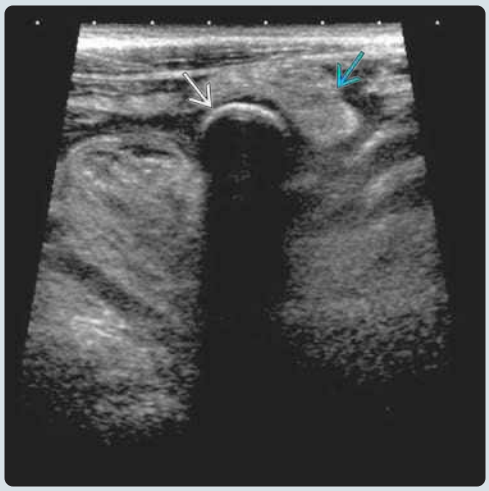
KEY FACTS

TERMINOLOGY

- Acute obstruction of appendiceal lumen → distention → ↑ intraluminal pressure → venous obstruction → ischemia → superimposed infection of appendiceal wall → eventual perforation

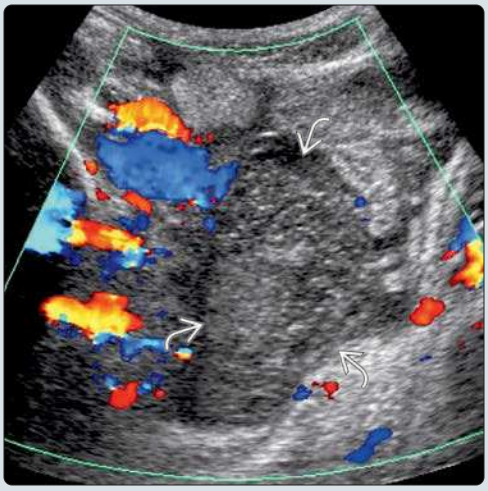


IMAGING



- US is 1st-line modality in child with suspected appendicitis
  - Noncompressible, dilated, tubular blind-ending structure (appendix) in RLQ with induration of surrounding fat
    - ± echogenic, shadowing appendicolith
  - US diameter of appendix ≥ 6 mm (during compression)
    - Caution if seen in isolation without secondary findings
- CT diameter of appendix > 6 mm is found in 40% of normal patients; look for other inflammatory features
  - Appendiceal wall thickening & hyperenhancement
  - Periappendiceal inflammation with fat stranding ± fluid
  - RLQ focal ileus
- MR findings are similar to CECT
- Features of perforation
  - Discontinuity of appendiceal wall
  - Appendicolith surrounded by inflammatory change but no well-defined appendix
  - Adjacent bowel wall thickening, moderate free fluid, localized complex collections
    - Even free fluid may be purulent
- Staged approach: US → CT or MR if US is indeterminate or equivocal

CLINICAL ISSUES



- Classic presentation: RLQ pain, anorexia, nausea, & vomiting
  - Periumbilical pain migrating to RLQ over 12-24 hours
  - Tenderness at McBurney point
  - Fever, guarding, rebound tenderness
- Clinical presentation is nonspecific in up to 1/3
  - Especially young children
- Typically benign course with prompt diagnosis & surgery; morbidity & mortality ↑ with perforation

(Left) *AP radiograph in a 9-year-old with right lower quadrant (RLQ) pain & vomiting shows an ovoid RLQ Ca^{2+} suggesting an appendicolith. A few mildly prominent small bowel loops with air-fluid levels are noted in the left upper quadrant (LUQ), concerning for focal ileus.* **(Right)** *Transverse RLQ ultrasound in the same patient shows the round echogenic appendicolith with complete posterior acoustic shadowing (typical of Ca^{2+}). Thickening & ↑ echogenicity of the surrounding fat is noted.*

(Left) *Transverse color Doppler ultrasound in the same patient shows a poorly defined, heterogeneous RLQ fluid collection concerning for abscess.* **(Right)** *Axial CECT in the same patient shows the appendicolith & a thick-walled rim-enhancing abscess with surrounding inflammation. A similar posterior collection was also seen along the rectum. Adjacent bowel loops are displaced with wall thickening. These findings are typical of perforated appendicitis.*

TERMINOLOGY

Definitions

- Acute obstruction of appendiceal lumen → distention → ↑ intraluminal pressure → venous obstruction → ischemia → superimposed infection of appendiceal wall → eventual perforation

IMAGING

General Features

- Best diagnostic clue
  - Noncompressible, dilated, tubular blind-ending structure (appendix) in right lower quadrant (RLQ) with surrounding inflammatory change
- Location
  - Various RLQ positions: Pelvic, retrocecal, subcecal, preileal, postileal
  - Underlying anomalies can lead to unusual locations
    - Other abdominal quadrants in setting of malrotation or situs inversus
    - Scrotum in setting of inguinal hernia (Amyand hernia)
    - Colonic lumen in setting of ileocolic intussusception (where inflamed appendix = pathologic lead point)
- Size
  - Mean diameter of normal pediatric appendix
    - ~ 4 mm on US, ~ 5.7 mm on CT, 5-6 mm on MR
  - US diameter of appendix is usually ≥ 6 mm (during compression) in acute appendicitis
    - Use with caution in absence of secondary signs
  - CT appendix diameter is > 6 mm in 40% of normal patients
  - Differences in normal appendiceal diameters between US, CT, & MR may be attributable to degree of compression normally applied during routine US
- Morphology
  - Normal
    - Smooth continuous wall with "gut signature" on US: Echogenic mucosa & serosa with intervening hypoechoic muscular layer
    - Lies dependently, minimally undulating, often collapsed; may be coiled
  - Abnormal
    - Distended, noncompressible lumen; often taut or straight configuration
    - Involvement of entire appendix vs. distal segment (tip)

Radiographic Findings

- May be normal
- ± calcified appendicolith
- Focal ileus with air-fluid levels or paucity of bowel gas in RLQ
- Loss of right psoas margin
- Abnormalities more likely with perforation
  - Obstruction or more diffuse ileus
  - RLQ extraluminal gas
  - Displacement of bowel loops from RLQ by abscess
  - RLQ bowel wall thickening

Ultrasonographic Findings

- Noncompressible blind-ending tubular structure extending from cecum; ≥ 6 mm in diameter
  - Growing evidence for 7 mm as threshold
- Echogenic thickened periappendiceal fat (may be best independent predictor)
- Echogenic appendicolith with posterior acoustic shadowing
- Free fluid in RLQ/pelvis (especially if complex) vs. localized complex phlegmon or abscess
  - Small amount of simple, anechoic fluid may be normal
- ± hyperemia of appendiceal wall on color Doppler
- Findings most suggestive of perforation include dilated or thick-walled adjacent bowel, loss of appendiceal wall integrity, fluid in at least 2 locations, complex fluid, & discrete abscess

CT Findings

- Dilated appendix (> 6-8 mm)
- Appendiceal wall thickening & hyperenhancement
- Periappendiceal inflammation with fat stranding & fluid
- Lack of appendiceal filling by enteric contrast despite contrast in cecum
- Calcified appendicolith
- RLQ lymphadenopathy
- RLQ focal ileus
- With perforation
  - Discontinuity of appendiceal wall
  - Appendicolith surrounded by inflammatory change without well-defined appendix
  - Localized phlegmon or fluid collection in RLQ or dependent pelvis ± rim enhancement to suggest abscess
  - Extraluminal gas
  - Adjacent bowel wall thickening
  - Small bowel obstruction or diffuse ileus
  - Moderate free fluid & peritoneal enhancement with generalized peritonitis
    - Even free fluid may be purulent
- Negative predictive value of normal CT with nonvisualized pediatric appendix ~ 99%

MR Findings

- Attractive alternative to CT due to lack of ionizing radiation
  - Growing use, particularly in larger pediatric centers
  - Short protocols ↓ need for sedation
- Dilated appendix ≥ 7 mm
- Appendiceal wall thickening & mural edema
- Periappendiceal edema
- Mural & periappendiceal restricted diffusion
- Mural & periappendiceal enhancement
- Appendicolith may appear as signal void
- Free fluid &/or localized phlegmon or fluid collections in RLQ or pelvis

Imaging Recommendations

- Best imaging tool
  - Staged approach with US as 1st modality
    - US is accurate in experienced hands, even if appendix is not visualized
    - No ionizing radiation exposure
    - Negative predictive value > 90% with visualized normal appendix or nonvisualization of appendix without secondary findings of inflammation
  - US → CT or MR depending on institutional or clinical factors: Similar sensitivity/specificity (> 94%)

- Protocol advice
  - US with high-frequency transducer & graded compression (to displace overlying bowel gas)
    - Must look in typical & variant locations
      - Start scanning where patient endorses pain
  - CT with IV contrast
    - ± oral contrast but may delay diagnosis without added value
    - CECT may be requested to determine extent of fluid collections prior to drainage procedure if perforation & fluid are detected by US
  - MR protocols vary
    - Multiplanar T2 ± FS, inversion recovery sequences
    - Sometimes used: DWI, pre- & postcontrast T1 + FS

DIFFERENTIAL DIAGNOSIS

Ovarian Pathology

- Hemorrhagic cyst, ovarian torsion, tuboovarian abscess

Meckel Diverticulum

- May become inflamed &/or cause obstruction

Inflammatory Bowel Disease

- Crohn disease & ulcerative colitis may primarily involve appendix (even in isolation)
- Bowel abnormalities are usually more extensive

Omental Infarct

- Focal infarction of omental fat: Nonsurgical disease
- Focal inflammatory changes in anterior RLQ near colon

Cystic Fibrosis

- Average noninflamed appendix in CF is > 8 mm, may be noncompressible
- No periappendiceal inflammation

Mucocele

- Dilated fluid-filled appendix

Fecal Impaction

- Appendiceal lumen distended by fecal material
- Nontender, no periappendiceal inflammation

Lymphoid Hyperplasia of Appendix

- Thickened hypoechoic lamina propria
- No periappendiceal inflammation

Ileocolic Intussusception

- En face ileocolic intussusception may (rarely) be difficult to distinguish from inflamed bowel & abscess in setting of perforated appendicitis
- Should be able to trace out involved bowel by US
- Tends to occur from 6 months to 3 years of age

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - RLQ abdominal pain, anorexia, nausea, & vomiting
- Other signs/symptoms
  - Classic symptoms in older children without perforation
    - Periumbilical pain migrating to RLQ over 12-24 hours
    - Tenderness at McBurney point
    - Fever, guarding, rebound tenderness
  - Clinical presentation is nonspecific in up to 1/3
    - Delay of diagnosis, higher perforation rate
    - More common in younger children

Demographics

- Any age; ↑ incidence from ages 5-15 years
- Most common reason for emergent surgery in children

Natural History & Prognosis

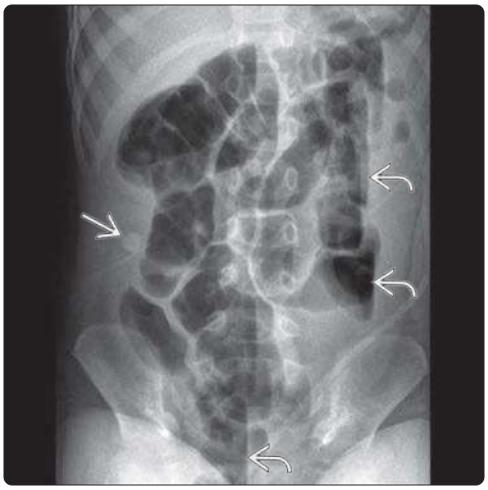
- Typically benign course if classic history leads to prompt diagnosis & surgery
- Morbidity & mortality ↑ with perforation
  - Up to 40% are perforated at presentation; risk ↑ with delay in diagnosis
  - Adjacent abscesses form over days
- Delayed abscesses may present weeks to years later with retained infected appendicoliths

Treatment

- For early uncomplicated appendicitis, perform laparoscopic appendectomy
  - Nonoperative management with IV antibiotics is being increasingly studied
- For perforated appendicitis with abscess, treat with IV antibiotics, percutaneous drainage, delayed appendectomy
  - Must remove appendicolith to prevent future abscess
- Open laparotomy for peritoneal washout if frank peritonitis

DIAGNOSTIC CHECKLIST

Consider



- US 1st modality, then CT or MR if US is indeterminate/equivocal

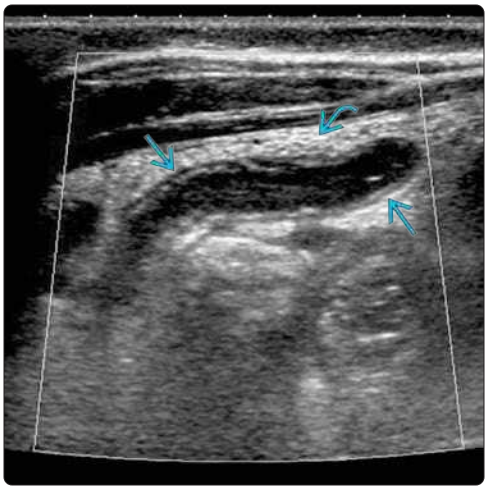


Image Interpretation Pearls

- Caution using appendiceal diameter in isolation
- Periappendiceal inflammation is particularly useful in making diagnosis on US, CT, & MR

(Left) *Left side down decubitus abdominal radiograph in a 2-year-old with RLQ pain & fever shows a large appendicolith ➡ with medial displacement of adjacent bowel loops. The bowel is mildly dilated diffusely & contains numerous air-fluid levels ➡, suggesting ileus.* **(Right)** *Longitudinal ultrasound of the RLQ in the same patient shows dilation (12 mm) of a noncompressible appendix ➡ with thickening & ↑ echogenicity of the periappendiceal fat ➡, typical of acute appendicitis.*

(Left) *Axial CECT in an 8-year-old with RLQ pain & nonvisualization of the appendix on US shows a thickened retrocecal appendix ➡ with surrounding fat stranding ➡. A retrocecal appendix may be more difficult to visualize on US.* **(Right)** *Transverse grayscale & color Doppler ultrasounds in a 9-year-old with pain show a dilated appendix with a thickened, irregular, & hyperemic wall ➡. The periappendiceal fat is indurated ➡ in this patient with acute appendicitis.*

(Left) *Axial T2 SSFSE (top) & FS T2 (bottom) MR images in an 8-year-old with pain show a dilated (9-mm), thick-walled appendix ➡ with surrounding fat edema. Adjacent bowel wall thickening ➡ & a localized fluid collection (not shown) confirmed perforated appendicitis.* **(Right)** *Axial T2 SSFSE in the same patient shows a signal void ➡ in the proximal appendiceal lumen corresponding to an appendicolith. Signal voids are also seen corresponding to air ➡ within bowel loops & flowing blood ➡ in the iliac vessels.*

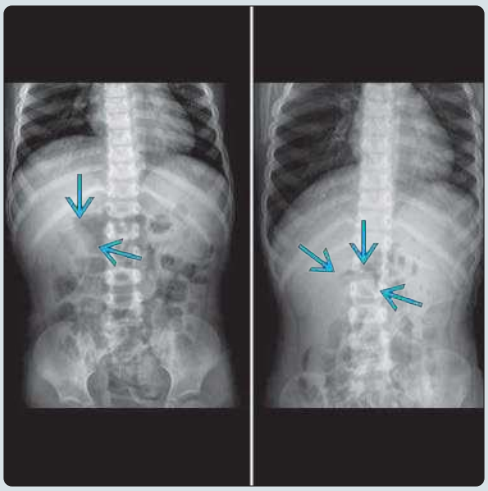
Ileocolic Intussusception

KEY FACTS

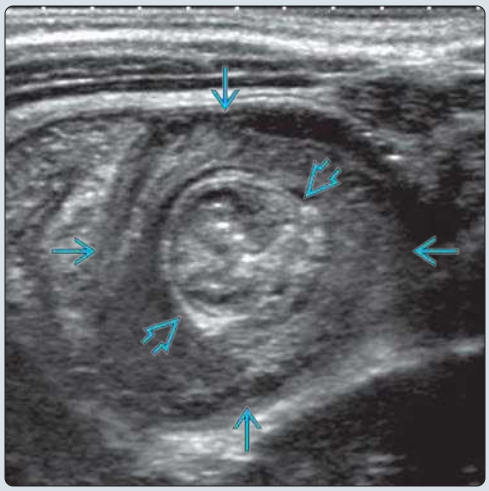
TERMINOLOGY

- Invagination of distal small bowel (SB) (intussusceptum) into colon (intussuscipiens) in telescope-like manner

IMAGING

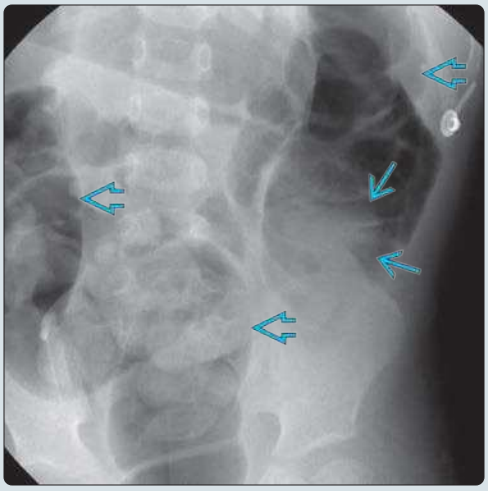


- Radiography: Often abnormal, not always perceived
  - Paucity of right abdominal colonic gas ± round mass
    - ± fat density (from entrapped mesentery) in mass
  - Crescent sign: Curvilinear mass-gas interface
  - Lateralization of ileum to expected cecal location
  - ± SB obstruction
- US: Best diagnostic modality if clinically suspected
  - Round mass with target sign in right abdomen
  - Mean diameter of 2.6 cm vs. 1.5 cm for purely SB intussusceptions
  - Echogenic core contains fat, lymph nodes, & SB
    - May also see normal appendix or pathologic lead point (such as duplication cyst, juvenile polyp)
  - Sweeping transducer proximal & distal shows relationship to small & large intestine
  - Entrapped fluid: ↑ failure rate of enema reduction
  - ↓ vascularity is associated with ↑ likelihood of bowel necrosis & ↑ failure rate of reduction

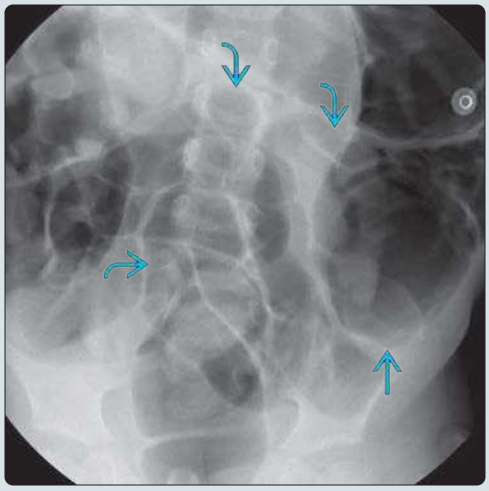


PATHOLOGY

- ~ 90% are idiopathic (due to lymphoid hypertrophy)
- ~ 5-10% from pathologic lead points



CLINICAL ISSUES



- Most common from ages 3 months to 3 years
- Presents with vomiting, alternating lethargy & irritability, "currant jelly" (bloody) stools
- Treat with enema reduction (as bowel can infarct if not reduced): Air enema under fluoroscopy vs. hydrostatic with US guidance
- Intussusception recurs after reduction in ~ 5-15%
- Surgery is reserved for cases of enema reduction failure or when enema is contraindicated

(Left) *Supine (L) & left decubitus (R) radiographs in a 3-year-old with intermittent pain show a soft tissue mass partially outlined by gas in the abdominal RUQ ⇨ (the crescent sign). There is a paucity of colonic gas in the right abdomen with lateralization of small bowel gas.* **(Right)** *Transverse US of the RUQ in the same patient shows the classic target sign of an ileocolic (IC) intussusception ⇨, measuring > 3 cm in diameter. The echogenic core ⇨ contains bowel, fat, vessels, & lymph nodes.*

(Left) *Prone fluoroscopic image in the same patient during an air enema reduction shows gas filling the colon ⇨ to the level of the cecum. Only a small component of intussusceptum ⇨ remains in the cecum at this point. There is minimal small bowel gas at this time.* **(Right)** *Subsequent prone fluoroscopic image in the same patient after further air introduction shows that the intussusceptum is no longer visualized in the cecum ⇨ & gas has freely refluxed into the small bowel ⇨, confirming a successful reduction.*

TERMINOLOGY

Definitions

- Ileocolic (IC) intussusception: Invagination of distal small bowel (SB) (intussusceptum) into colon (intussuscipiens) in telescope-like manner

IMAGING

General Features

- Best diagnostic clue
  - US: Round target sign in right abdomen at expected level of colon
  - Radiography: Paucity of colonic gas in right abdomen + gas outlining left margin of rounded soft tissue density in RUQ (crescent sign in colon)
- Location
  - Always involves right/proximal colon; extends distally to variable degrees but usually involves some length of transverse colon
- Size
  - Mean diameter of 2.6 cm (vs. 1.5 cm for purely SB intussusceptions)
    - > 3 cm strongly favors IC; < 2 cm strongly favors SB-SB

Radiographic Findings

- Paucity of colonic gas in right abdomen
- Round mass in right abdomen: May see layers of fat density (from intussuscepted mesentery)
- Crescent sign: Curvilinear gas outlining left aspect of round soft tissue mass (intussusceptum) within colon
- ± SB obstruction
- Pneumoperitoneum before air enema is extremely rare

Ultrasonographic Findings

- Grayscale ultrasound
  - Target sign: Cross section of intussusception shows round mass with alternating concentric rings of hyper- & hypoechogenicity from bowel walls & mesenteric fat
    - Mean diameter of 2.6 cm
    - Sweeping transducer proximal & distal shows relationship to small & large intestine
      - May see entrapped lymph nodes, appendix, other pathologic lead points (such as intestinal duplication cyst, juvenile polyp, or lipoma)
    - Fatty core to wall index: Never < 1.0 in IC intussusception; mean of 2.3 (vs. 0.16 for SB-SB)
      - Outer wall thickness: Mean of 0.6 cm in IC vs. 0.42 in SB-SB
      - Echogenic fat core: Mean of 1.3-1.5 cm in IC vs. 0.1-0.3 in SB-SB
  - Pseudokidney or sandwich sign: Longitudinal or oblique image showing ovoid mass with alternating layers of hyper- & hypoechogenicity
  - Often not located in right lower quadrant (RLQ) due to distal progression of intussusception (or in setting of underlying malrotation)
    - Need to scan all 4 quadrants
    - Absence of normal ileocecal region in RLQ
  - Trapped fluid within intussusception → ↑ failure rate of enema reduction
  - May be used to guide hydrostatic reduction
- Color Doppler
  - ↓ internal vascular flow → ↑ likelihood of bowel necrosis, ↑ failure rate of enema reduction

CT Findings

- CECT
  - Incidentally seen on abdominal CT performed for nonspecific abdominal pain when intussusception is not suspected or if US findings are unclear
    - Not primary modality for diagnosis
  - Abdominal mass with alternating rings of high & low attenuation (target or sandwich sign)

Fluoroscopic Findings

- Air-contrast enema
  - Apex of intussusceptum projects as round soft tissue mass against distal colonic air column
  - Multilobular intussusceptum in right colon/cecum suggests irreducibility
  - Dissection sign: Air surrounding length of intussusceptum predicts irreducibility
- Liquid contrast enema
  - Apex of intussusceptum projects as round soft tissue/lucent defect against distal colonic positive contrast column
  - Dissection or coiled spring sign: Contrast surrounding length of intussusceptum predicts irreducibility

Imaging Recommendations

- Best imaging tool
  - US for diagnosis
  - Fluoroscopic air enema vs. US-guided hydrostatic reduction for treatment

DIFFERENTIAL DIAGNOSIS

Small Bowel-Small Bowel Intussusception

- Smaller cross-sectional diameter than IC
  - Smaller or absent echogenic core lacking lymph nodes
  - Outer wall is less thick
- Location is more variable than IC
- Often able to trace SB into & out of intussusception

Appendicitis

- More common > 3 years of age
- Identification of appendicolith is helpful
- In cases of perforation, inflammatory collection can mimic soft tissue mass

Ovarian Torsion

- US may show avascular mass with peripheral cysts in midline with only 1 normal ovary visualized

Gastroenteritis

- Air-fluid levels throughout colon suggest gastroenteritis

Meckel Diverticulum

- Round or tubular, rim-enhancing mass ± surrounding inflammation
  - May also cause obstruction or GI bleed
- May serve as lead point for intussusception

PATHOLOGY

General Features

- Etiology
  - ~ 90% are idiopathic (likely secondary to reactive lymphoid hyperplasia)
    - May be preceded by viral illness
  - ~ 5-10% are caused by pathologic lead points in children
    - Meckel diverticulum > duplication cyst > polyp > lymphoma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Vomiting; may be bilious
  - Alternating lethargy & irritability
  - Colic or "intermittent fussiness"
- Other signs/symptoms
  - Bloody diarrhea ("red currant jelly" stools are classic)
  - Palpable right-sided abdominal mass

Demographics

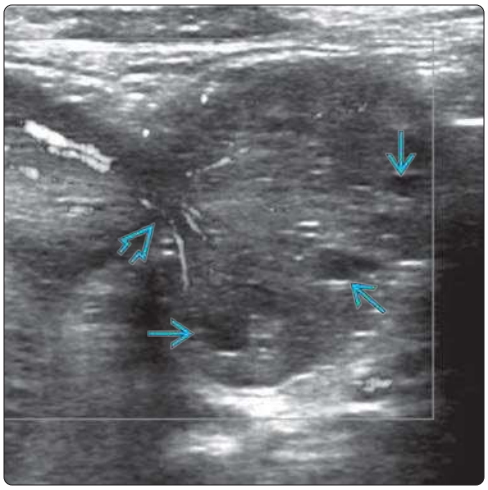
- Classic age: 3 months to 3 years
  - If < 3 months or > 3 years, question pathologic lead point
- Sex: More common in males (3:2)
- Epidemiology: ~ 56 per 100,000 children annually
  - Most common cause of pediatric SB obstruction
  - Classically reported seasonal occurrence (winter, spring) with viral illnesses

Natural History & Prognosis

- Medical urgency: Bowel can infarct if not reduced
  - Bowel necrosis → perforation → peritonitis, shock, & death
- May spontaneously reduce
- Intussusception recurs after successful reduction in ~ 5-15%
  - Most recurrences occur within 48-72 hours

Treatment

- Imaging-guided pressure reduction; options include
  - Air insufflation with fluoroscopic guidance
    - Liquid contrast under fluoroscopy is used much less commonly in current era
  - US-guided hydrostatic reduction
- Contraindications: Peritonitis (relative), pneumoperitoneum
  - In resource-rich countries, pneumoperitoneum prior to reduction attempt is rare
    - Likely due to prompt presentation to medical facility
- US findings associated with ↓ success rate of enema reduction (but not contraindications)
  - Trapped fluid within intussusception, ↓ intussusceptum vascularity, presence of pathologic lead point, SB obstruction, younger age, rectal bleeding, prolonged duration of symptoms (> 24-72 hours)
- Preparation guidelines: Adequate hydration, IV access, physical examination, surgery consultation
- Air enema guidelines
  - Good rectal seal without leak
  - Maximum of 120 mm Hg sustained colonic pressure at rest (though greater pressure spikes are usually seen during crying or Valsalva)
- Intussusception is encountered as round mass that moves retrograde toward cecum with air insufflation
- Intussusceptum is most likely to get "stuck" at ileocecal valve
- Success: Retrograde rush of gas into SB + resolution of soft tissue mass
  - Edematous ileocecal valve may protrude into cecum, mimicking persistent intussusception: Follow clinically or by US
- If mass progresses on initial attempts but does not reduce beyond ileocecal valve, period of ~ 60 minutes may ↓ edema & ↑ chance of success
  - Repeat attempts with interval of 1 hour of waiting are acceptable as long as patient is stable & head of intussusception is progressing more toward cecum with each attempt
  - Recurrences are typically treated by enema up to 5x prior to considering surgical exploration for potential pathologic lead point
- Success rates of ~ 80-90% with enema reduction
- Risk of perforation is 0.5-1.0% with air
- Surgery is reserved for cases of enema reduction failure or when enema is contraindicated



DIAGNOSTIC CHECKLIST

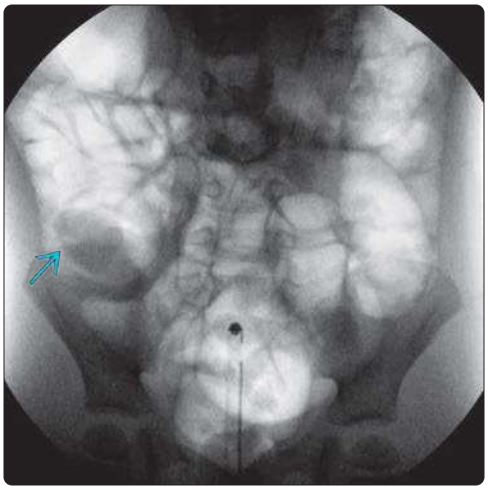


Image Interpretation Pearls

- Radiographs: Often abnormal, but signs of intussusception are not always perceived
  - Lateralized ileum or redundant sigmoid may mimic air in cecum with false exclusion of intussusception
    - Sigmoid colon in RLQ on radiographs 43% of time
  - Left side down decubitus radiograph can help evaluate cecum (& exclude free air)
- US: Best test if intussusception is suspected clinically

(Left) *Longitudinal US in a 3-year-old shows a pedunculated lead point mass at the head of an intussusceptum. The mostly solid mass contains peripheral cysts ⇨ & a vascular stalk ⇨, strongly suggesting a juvenile polyp (which was confirmed upon resection).* **(Right)** *Supine air enema image in the same patient demonstrates a persistent filling defect ⇨ in the cecum status post reduction, consistent with the juvenile polyp. An edematous ileocecal valve is typically more round & medial.*

(Left) *Supine AP radiograph in a 5-month-old after multiple air enema reduction attempts shows a large, multilobular residual soft tissue mass at the cecum ⇨. A multilobular configuration can suggest irreducibility of the IC intussusception by enema, potentially due to a lead point mass.* **(Right)** *Axial CECT of a 3-year-old child with a small bowel obstruction & clinical findings suggestive of appendicitis shows an enhancing target sign ⇨ in the right abdomen, consistent with an IC intussusception.*

(Left) *Transverse color Doppler US in a 4-month-old with lethargy & recurrent abdominal pain shows trapped fluid ⇨ & no blood flow within the IC intussusception, suggesting that it will be more difficult to reduce without surgery.* **(Right)** *Left decubitus radiograph in a 7-month-old immediately after an unsuccessful air enema IC intussusception reduction attempt shows pneumoperitoneum ⇨, consistent with bowel perforation. Note the Rigler sign ⇨ (with gas outlining both sides of the bowel wall).*

Meckel Diverticulum

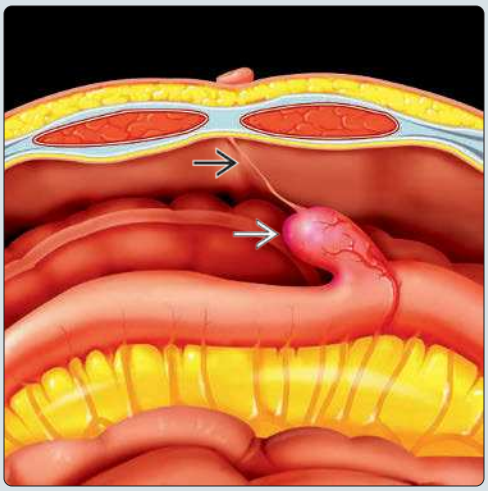
KEY FACTS

TERMINOLOGY

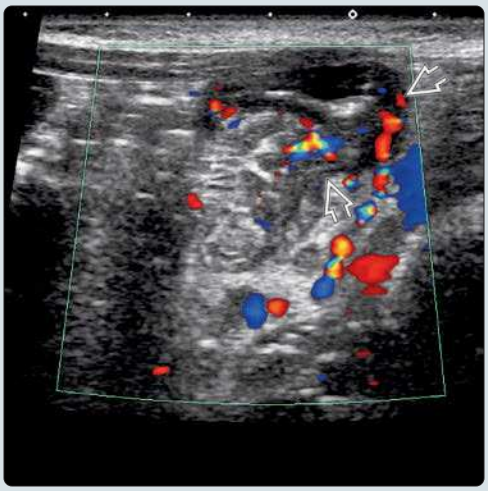
- Most common omphalomesenteric duct remnant
- Presents with bleeding, inflammation, intussusception, bowel obstruction, or perforation
  - ~ 65% of symptomatic Meckel diverticula contain ectopic gastric mucosa
- Rule of 2s: 2% of general population, found within 2 feet of ileocecal valve, most have symptoms < 2 years of age

IMAGING

- Classic imaging appearance (in patient with GI bleeding): Focal persistent accumulation of radiotracer in right lower quadrant (RLQ) on nuclear pertechnetate scan
  - Coincident with & isointense to gastric uptake
  - ↑ in visibility with time
- Other modalities (US, CT, MR)
  - Blind-ending, tubular structure may be inconspicuous
  - May present as cyst, even with gut signature
  - With inflammation, findings are similar to appendicitis
    - Thick-walled, tubular structure, hyperemic bowel loops; rare perforation
  - Intraluminal mass as lead point in intussusception
  - May see bowel obstruction without obvious cause

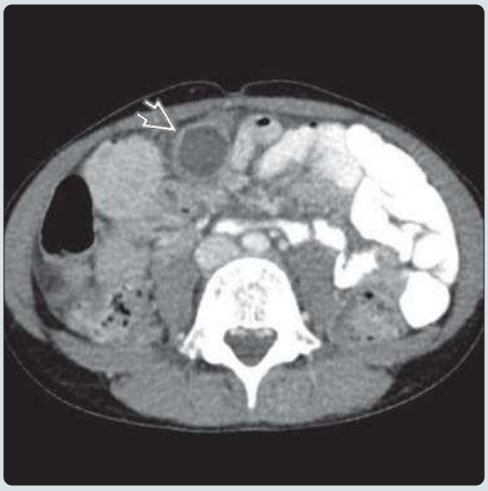


TOP DIFFERENTIAL DIAGNOSES



- GI bleeding with positive pertechnetate scan
  - Strong accumulation in GI duplication cyst
  - Hyperemia of Crohn disease, appendicitis, or vascular lesion may cause mild accumulation
- Small bowel obstruction
  - Appendicitis, adhesions, intussusception, inguinal hernia, malrotation, + Meckel (mnemonic of AAIIMM)
- RLQ inflammation
  - Appendicitis, Crohn disease, omental infarct, mesenteric adenitis, ovarian torsion

CLINICAL ISSUES



- Treated surgically

(Left) *Axial graphic shows an inflamed Meckel diverticulum ➡ growing off of the antimesenteric border of the intestine with the obliterated remnant of the omphalomesenteric duct ⇨ extending from its tip.* **(Right)** *Longitudinal US in a 14-year-old boy with right lower quadrant (RLQ) pain demonstrated a normal appendix (not shown) + a thickened, hyperemic tubular structure ➡ just above the bladder. An inflamed Meckel diverticulum was removed at surgery.*

(Left) *Axial CECT in a 10-year-old boy with vague, intermittent abdominal pain shows a rim-enhancing cystic lesion ➡ just deep to the umbilicus. This cyst did not appear to communicate with the bowel.* **(Right)** *Coronal reformatted CECT in the same boy shows mild inflammation ⇨ surrounding the cystic lesion ➡, which was found to be a Meckel diverticulum distended with secretions at surgery.*

TERMINOLOGY

Definitions

- Remnant of omphalomesenteric duct
- Presents with bleeding (when containing ectopic gastric mucosa), inflammation, intussusception, bowel obstruction, or perforation
- Rule of 2s
  - Incidence: 2% of general population
  - Found within 2 feet of ileocecal valve
  - Most have clinical symptoms before 2 years of age

IMAGING

General Features

- Best diagnostic clue
  - Radiologic appearance varies by type of presentation
  - Classic imaging appearance on nuclear pertechnetate scan in patient with GI bleeding
    - Persistent, focal accumulation of radiotracer in right lower quadrant (RLQ) due to ectopic gastric mucosa in Meckel diverticulum
      - Coincident with & isointense to gastric uptake
      - Increasingly visible with time
- Location
  - RLQ or midline/periumbilical in location
  - Most within 2 feet of ileocecal valve
- Size
  - Variable; often small if uninflamed, large if inflamed or intussuscepted

Radiographic Findings

- Abdominal films may be normal or show
  - RLQ mass
  - Displacement of bowel loops
  - Small bowel obstruction
  - Enteroliths & ingested foreign bodies have been reported

Fluoroscopic Findings

- Often normal; variable communication with bowel lumen
- Contrast studies may show indirect evidence of mass & inflammatory changes in adjacent bowel
- May serve as lead point for intussusception
  - Often not reducible with air enema

Ultrasonographic Findings

- Grayscale ultrasound
  - Thick-walled, tubular structure or hyperemic bowel loops in RLQ
  - Heterogeneous echotexture mass in RLQ, may mimic appendicitis
    - Look for normal appendix
  - Meckel diverticulum may present as cyst, even with gut signature
    - Walls are more heterogeneous & thick with inflammation vs. enteric duplication cyst
  - Intraluminal mass as lead point in intussusception, inverted Meckel
- Color Doppler
  - Hyperemia related to inflammatory process

CT Findings

- CECT
  - Incidentally, may be collapsed & blind-ending or appear cystic with trapped secretions
  - CT enterography technique may be helpful
  - If inflamed, similar to appendicitis: Thick-walled blind-ending structure near cecum with surrounding inflammation
    - If perforated, may see abscess & free air
    - Normal appendix is clue to diagnosis
  - May cause small bowel obstruction with no clear explanation on imaging
  - If intussuscepted, may be occult
  - If bleeding, CTA may show ↑ flow locally

MR Findings

- Follows CECT findings; enterography may help visualize

Nuclear Medicine Findings

- Tc-99m pertechnetate scan
  - Most specific test for Meckel diverticulum: ~ 90% accuracy
  - Pertechnetate accumulates in mucous cells in acidic environment
    - Ectopic gastric mucosa of most Meckel diverticula
  - Diverticulum typically does not communicate with bowel lumen, so radiotracer does not appear to move downstream in bowel unless there is active bleeding
  - Pharmacologic enhancement of pertechnetate scans by using
    - Pentagastrin subcutaneously
    - Ranitidine or cimetidine, oral or intravenous
    - Glucagon intramuscularly
  - Given high sensitivity otherwise, additional medications may be reserved for repeat studies in patients with high clinical suspicion of Meckel diverticular disease & normal initial scans
  - False-negative pertechnetate scans
    - Lack of any or sufficient gastric mucosa to localize radiotracer
      - ~ 65% of symptomatic Meckel diverticula have ectopic gastric mucosa
    - Secondary ischemia due to volvulus or intussusception
    - ~ 50% of scans repeated for high clinical suspicion are positive on 2nd study

Imaging Recommendations

- Best imaging tool
  - Tc-99m pertechnetate scan or US for GI bleeding
    - Recent literature shows US is > 90% sensitive & specific for Meckel diverticulum in setting of GI bleeding
  - US or CECT for other presentations
- Protocol advice
  - Lateral & postvoid images should be obtained before conclusion of pertechnetate scan to look for Meckel diverticulum behind urinary bladder

DIFFERENTIAL DIAGNOSIS

GI Bleeding With Positive Pertechnetate Scan

- Strong accumulation in GI duplication cyst

- Hyperemia of Crohn disease, appendicitis, or vascular lesion may cause mild accumulation

Small Bowel Obstruction

- Appendicitis, adhesions, intussusception, inguinal hernia, malrotation
  - With Meckel diverticulum → AAIIMM mnemonic

Inflammatory Bowel Disease

- Crohn disease & other enteritis

Right Lower Quadrant Inflammation

- Appendicitis, ileitis, omental infarct, epiploic appendagitis, mesenteric adenitis, ovarian torsion

PATHOLOGY

General Features

- Form of omphalomesenteric duct remnant (OMDR) is found in 2-3% of autopsy series
  - Connection between yolk sac & primitive digestive tract in early fetal life
  - Meckel diverticulum is most common end of spectrum of OMDRs, which also include umbilicoileal fistula, umbilical sinus or cyst, & fibrous cord connecting ileum to umbilicus
- Small percentage of Meckel diverticula becomes symptomatic, typically due to presence of ectopic gastric mucosa
  - Rarely, diverticulum contains rests of pancreatic tissue
  - Can entrap fish bones, seeds, pits, ingested foreign bodies, etc.

Microscopic Features

- Composed of same layers as adjacent small bowel but with addition of heterotopic gastric or pancreatic rests
- Risk of cancer: Malignant carcinoid & adenocarcinoma in older patients

CLINICAL ISSUES

Presentation

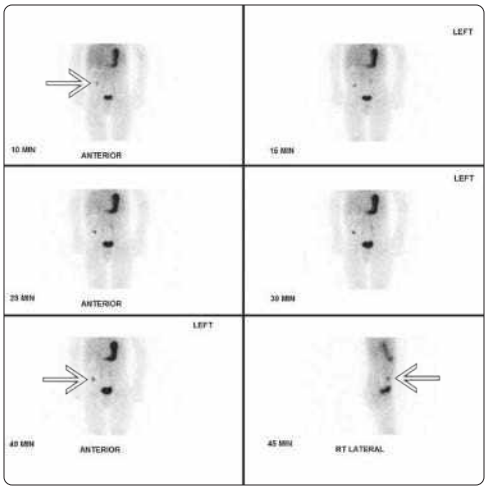
- Most common signs/symptoms
  - GI bleeding: Bleeding can be occult or frank
- Other signs/symptoms
  - Abdominal pain with small bowel obstruction, intussusception, volvulus (including torsion of diverticulum), bowel perforation
    - Perforations reported from ingested fish bone, phytobezoar, button battery, etc.
  - Capsule endoscopy may visualize inflamed Meckel or capsule can become entrapped
  - Hemoperitoneum from necrosis & perforation is possible

Demographics

- Age
  - Most become symptomatic before 2 years of age
    - 60% come to medical attention before 10 years of age, with remainder of cases manifesting in adolescence & adulthood
    - Older patients are more likely to present with intussusception or small bowel obstruction than with GI bleeding
- Sex
  - M = F in true incidence
  - Bleeding & other symptoms/complications are more common in male patients

Treatment

- Surgical resection; incidental appendectomy is usually also performed
- Meckel diverticula are generally removed when found incidentally on imaging or in operating room
  - ↑ detection on double-balloon (push pull) endoscopy



DIAGNOSTIC CHECKLIST

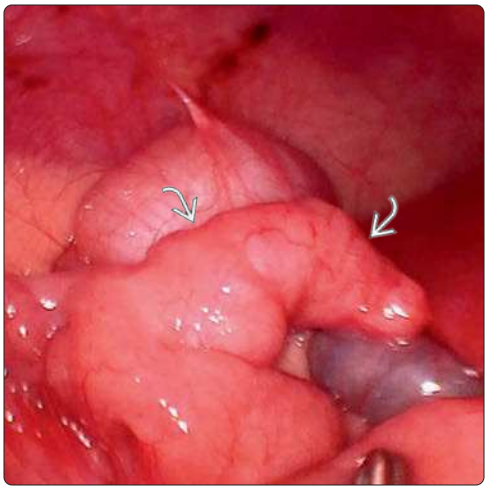


Image Interpretation Pearls

- Tc-99m pertechnetate scan: Positive in Meckel diverticula containing gastric mucosa
- Consider Meckel diverticula in atypical cases of RLQ pain
- Consider some form of OMDR in small bowel obstruction otherwise unexplained on imaging & history

(Left) *Anterior images of a 2-year-old with intermittent bloody stools show a persistent focus of radiotracer accumulation in the RLQ, surgically confirmed to be a Meckel diverticulum containing gastric mucosa.* **(Right)** *Intraoperative photograph in a patient with a history of GI bleeding shows an inflamed, blind-ending Meckel diverticulum.*

(Left) *Coronal CECT in a 10-year-old child with mild abdominal pain & no prior surgical history shows metal artifact in the RLQ, just superior to a normal appendix. At surgery, an ingested metal BB was found in a mildly inflamed Meckel diverticulum (which was resected).* **(Right)** *AP radiograph in a young child shows dilated small bowel loops with differential air-fluid levels & a paucity of colonic gas, consistent with a small bowel obstruction. An obstructing omphalomesenteric duct remnant was found at surgery.*

(Left) *Transverse color Doppler US shows a Meckel diverticulum creating a lead point in a 5-month-old with intussusception. Note the entrapped fluid surrounding the Meckel diverticulum. Air reduction enema failed to reduce the intussusception; therefore, the Meckel & adjacent bowel were resected surgically.* **(Right)** *Split-screen transverse & longitudinal US images of the left lower quadrant show an intussusception containing a Meckel diverticulum in an 11-month-old girl.*

Colonic Volvulus

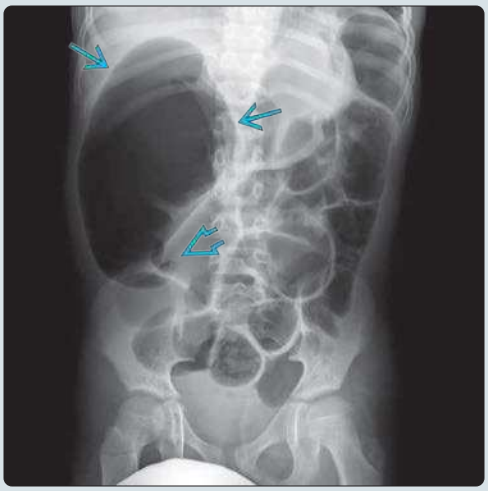
KEY FACTS

TERMINOLOGY

- Colonic volvulus: Twisting of mobile segment of colon → obstruction → vascular compromise → ischemia
  - Frequency: Sigmoid > cecum >>> transverse colon

IMAGING

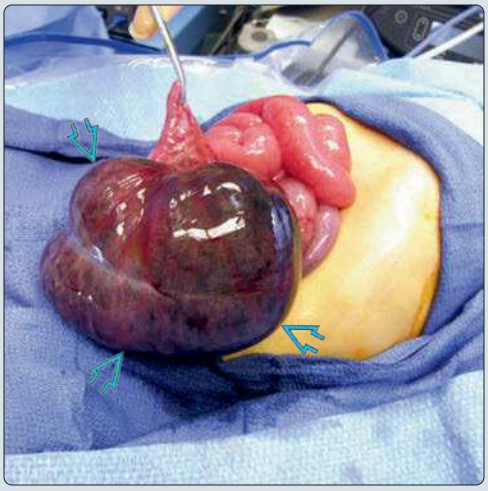
- Radiographs: Upper abdominal dilated loop of unusual size & shape for small bowel
  - Cecal volvulus: Often rounded (kidney bean sign)
  - Sigmoid volvulus: Often coffee bean-shaped (1/3)
  - Paucity of distal colonic gas
- Water-soluble contrast enema (WSCE): Bird's beak shape to proximal contrast at site of colonic twisting
  - Contrast fails to pass proximal to twist
    - Does not opacify dilated loop
- CECT: Whirl sign of twisted mesocolon encircling vascular pedicle that serves affected colonic segment
  - Look for abrupt change in course & caliber of veins
  - May have ↓ enhancement of involved segment due to vascular compromise
    - ± bowel wall thickening, pneumatosis, mesenteric edema, free or trapped fluid
- Protocol advice: If initial radiographs are worrisome for colonic volvulus → WSCE for definitive diagnosis; if pneumatosis &/or ill patient → CECT



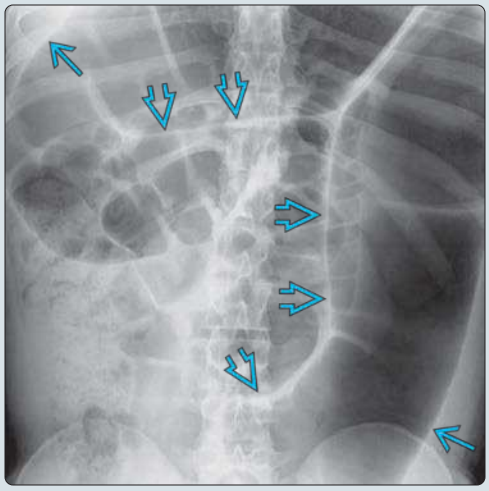
CLINICAL ISSUES

- Nonspecific abdominal distention & pain, vomiting

DIAGNOSTIC CHECKLIST



- Predisposed patients often have chronic constipation &/or chronically dilated bowel loops
- Suspicion for volvulus requires careful assessment of new radiograph for changes compared to prior radiographs that showed chronic bowel dilation



(Left) *AP radiograph in a 12-year-old developmentally delayed boy with acute abdominal pain shows a very dilated bowel loop in the right upper quadrant. The loop has a beak configuration at its inferior aspect, highly suggestive of a colonic volvulus. A contrast enema was recommended.* **(Right)** *Frontal radiograph in the same patient after a water-soluble contrast enema shows narrowing of the ascending colon, which ends proximally in a twist, leading to upstream dilation in this cecal volvulus.*

(Left) *Surgical photograph of a 2-year-old with cerebral palsy & acute abdominal pain who had a preceding enema (not shown) worrisome for cecal volvulus shows a large necrotic cecum, which was extracted from the left upper quadrant & resected.* **(Right)** *AP radiograph of a 14-year-old with acute abdominal pain shows a dilated closed loop of sigmoid colon. The centrally apposed colonic walls create the coffee bean sign. This appearance can be seen in almost 1/3 of sigmoid volvulus cases.*

TERMINOLOGY

Synonyms

- Cecal volvulus, sigmoid volvulus, transverse colon volvulus

Definitions

- Colonic volvulus: Twisting of mobile segment of colon
- Very rare in children

IMAGING

General Features

- Best diagnostic clue
  - Radiographs: Upper abdominal dilated loop of unusual size & shape for small bowel
    - Cecal volvulus is often kidney bean-shaped
    - Sigmoid volvulus is often coffee bean-shaped
  - Water-soluble contrast enema (WSCE): Bird's beak shape to proximal contrast at site of colonic twisting
- Location
  - Sigmoid colon > cecum >>> transverse colon

Radiographic Findings

- Cecal volvulus: Abnormally positioned, focally dilated & rounded cecum (kidney bean)
  - ± small bowel air-fluid levels & paucity of distal colonic gas
- Transverse colon volvulus: Gas-distended central colonic segment with paucity of distal colonic gas
- Sigmoid volvulus: Distended, twisted, ovoid closed loop; characteristic coffee bean sign in up to 1/3 of cases

Fluoroscopic Findings

- Contrast enema
  - Bird's beak shape to proximal contrast head at site of twisting on WSCE
  - Contrast fails to pass proximal to twist to opacify dilated loop

CT Findings

- CECT
  - Whirl sign: Twisted mesocolon encircling vascular pedicle that serves affected colonic segment
    - Look for abrupt change in caliber (e.g., narrowing, cut-off) or course of supplying vessels (especially veins)
      - Helpful to review in 3 planes
      - Veins beyond point of narrowing may be distended
  - Dilated & obstructed segment of colon
    - Transverse & sigmoid segments usually show closed loop obstruction
    - Cecum shows twisted tubular segment
  - Colon distal to obstruction is decompressed
  - May have ↓ enhancement of involved segment due to vascular compromise
    - ± bowel thickening, pneumatosis, mesenteric edema, free or trapped fluid

Imaging Recommendations

- Best imaging tool
  - WSCE or CECT
- Protocol advice
  - If radiographs suggest colonic obstruction with possible volvulus → WSCE for definitive diagnosis
  - If pneumatosis present, patient is ill-appearing, or diagnosis is not suggested on radiography, consider CECT

DIFFERENTIAL DIAGNOSIS

Ileosigmoid Knot

- Ileum & sigmoid become entangled, leading to knot & vascular compromise
- Acute abdominal pain & rapid shock

Colonic Pseudoobstruction

- Acutely or chronically dilated large > small bowel without identifiable mechanical obstruction

Toxic Megacolon

- Ill patient with dilated, thick-walled colon
- Infectious causes or ulcerative colitis is classic

PATHOLOGY

General Features

- Etiology
  - Predisposition in redundant & dilated mobile segments
  - ↑ risk with ↑ colonic distention, constipation, prior surgery, or malrotation
- Associated abnormalities
  - Sigmoid volvulus
    - Hirschsprung disease (18%), omphalomesenteric abnormalities, bowel malrotation, anal stenosis, chronic constipation, postoperative adhesions, prune-belly syndrome, & developmental delay

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Nonspecific abdominal distention & pain
- Other signs/symptoms
  - Vomiting, constipation, diarrhea

Treatment

- Endoscopic reduction success: Sigmoid > > cecal volvulus
- Even with endoscopic detorsion, affected colonic segment is typically resected to prevent recurrence
  - High recurrence rate with pexy procedures

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Predisposed patients often have chronic constipation &/or chronically dilated bowel loops
- Suspicion for volvulus requires careful assessment of new radiograph for changes compared to prior radiographs that showed chronic bowel dilation

Internal Hernia

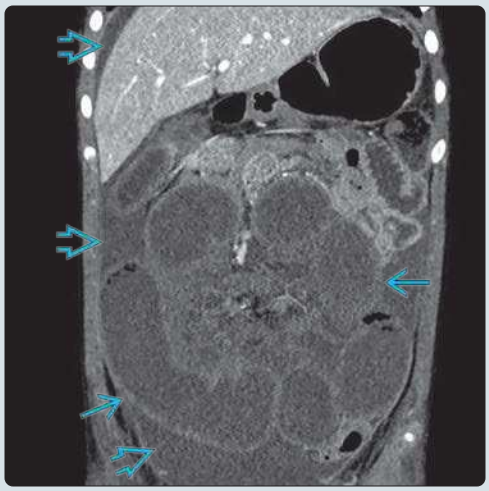
KEY FACTS

TERMINOLOGY

- Herniation of bowel through mesenteric defect, congenital band, or normal anatomic opening
- Transmesenteric hernia: Congenital mesenteric defect, usually near ileocecal valve or ligament of Treitz
  - Most common in children
- Acquired: Post surgical (iatrogenic) or post traumatic
- Other types are more common in adults
  - Foramen of Winslow, paraduodenal, pericecal, transomental

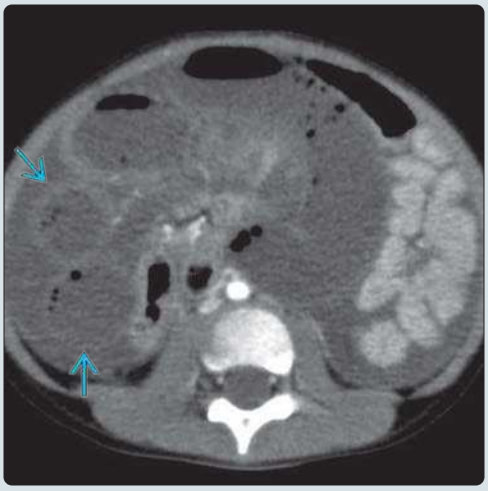
IMAGING

- Best imaging modality: CECT
  - Dilated small bowel loops, often localized to 1 region of abdomen
    - Look for abnormal position &/or configuration
  - Closed loop obstruction is suggested by decompressed distal & proximal bowel loops
  - Vascular compromise/ischemia is suggested by
    - Mesenteric edema, free fluid (nonspecific)
    - ↓ bowel wall enhancement, pneumatosis (more specific)
    - ± swirling/twisting with narrowing &/or engorgement of vessels
- Finding exact location of obstruction is less important than recognizing signs of vascular compromise

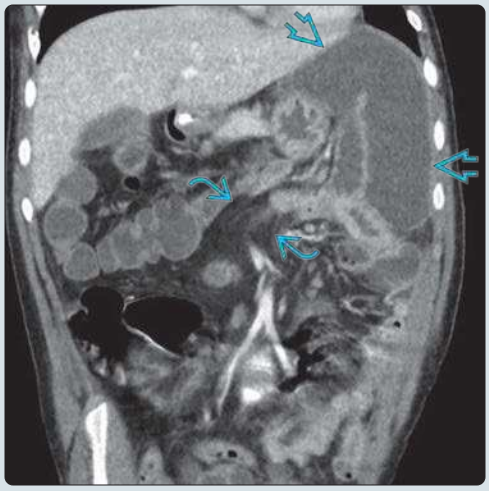


TOP DIFFERENTIAL DIAGNOSES

- Obstruction from other causes [appendicitis, adhesions, intussusception, inguinal hernia, malrotation, + Meckel diverticulum (AAIIMM mnemonic)]
- Ileus; bowel injury



CLINICAL ISSUES



- Presents with vomiting, distention, & other clinical signs of small bowel obstruction
  - May be intermittent as bowel moves in & out of hernia
  - Vascular compromise & bowel necrosis → shock
- Treatment is surgical

(Left) *Upright abdominal radiograph in a 7-year-old boy with vomiting shows dilated small bowel loops with air-fluid levels, consistent with a bowel obstruction.* **(Right)** *Coronal CECT in the same patient shows dilated small bowel loops with hypoenhancing walls & extensive intraabdominal free fluid, consistent with a bowel obstruction complicated by ischemia. A congenital mesenteric defect with internal hernia was found at surgery.*

(Left) *Axial CECT in a 4-year-old girl with abdominal distention demonstrates free fluid & dilated small bowel loops (with wall hypoenhancement) clustered in the right lower quadrant. These findings suggest ischemic bowel, & a transmesenteric internal hernia was found at surgery.* **(Right)** *Coronal CECT in a 13-year-old with nausea & vomiting shows dilated loops of small bowel in the left upper quadrant with fat & vessels passing through a mesenteric defect.*

KEY FACTS

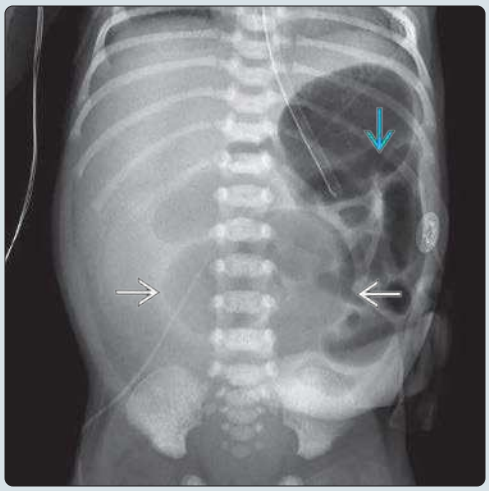
TERMINOLOGY

- Twisting of bowel segment (ileum > jejunum) resulting in obstruction ± ischemia
- Volvulus that is not due to malrotation
  - Can be due to bowel twisting around mesentery in neonates
  - Often from lead point or adhesions in older children

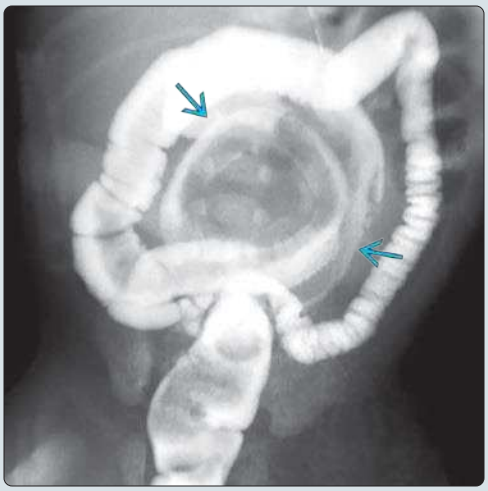
IMAGING

- Best clue: Dilated small bowel loops tapering into twist/swirl of collapsed bowel & vessels
- Radiographs
  - Dilated bowel loops with air-fluid levels
  - ± pneumatosis, pneumoperitoneum
- UGI/SBFT or water-soluble contrast enema
  - Spiral appearance of bowel loops at transition point, indicating volvulus
- CECT or ultrasound
  - Dilated proximal small bowel
  - Tapering of dilated bowel into "whirlpool" or "swirl" of collapsed small bowel & vessels
  - Bowel wall ischemia is suggested by bowel wall thickening, ↓ enhancement (CT) or color flow (Doppler), mesenteric edema, ascites, pneumatosis, pneumoperitoneum

PATHOLOGY

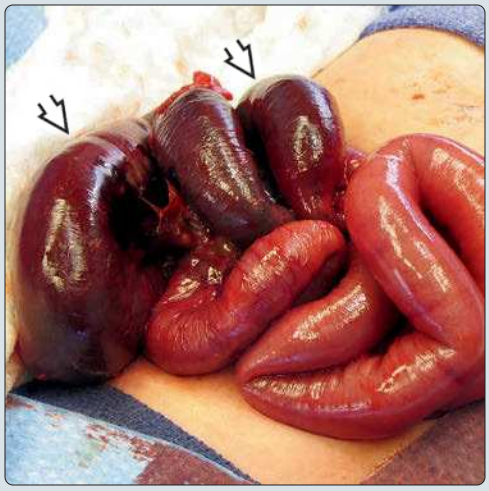


- Underlying lead points: Congenital band, meconium ileus, duplication cyst, Meckel diverticulum, lipoma, lymphatic malformation, postoperative adhesion, foreign body

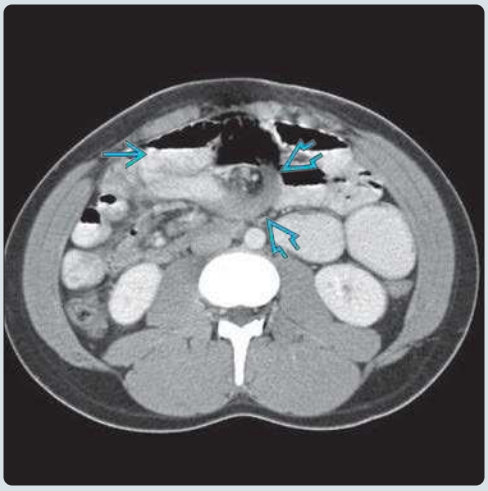


CLINICAL ISSUES

- Presentation: Abdominal pain, distention, nausea/vomiting
- Most common in neonates but can occur at any age
- Treatment is surgical



DIAGNOSTIC CHECKLIST



- Look for signs of bowel ischemia
- Look for lead point, especially in older children

(Left) *Supine abdominal radiograph in a 3-day-old girl with vomiting shows dilated, gas-filled small bowel loops being displaced into the left abdomen ⇨ by a cluster of mildly lucent dilated bowel loops in the central abdomen ⇨. There is no bowel gas in the right abdomen. These features suggest a distal obstruction.* **(Right)** *Water-soluble contrast enema in the same patient shows swirling of opacified distal small bowel loops in the midabdomen ⇨. Surgery confirmed an ileal volvulus around a congenital band.*

(Left) *Intraoperative photograph in the same 3-day-old girl shows twisting of the necrotic dilated small bowel loops ⇨. This ileal volvulus was due to a congenital band.* **(Right)** *Axial CECT in a 17-year-old boy with a history of neonatal repair of a proximal intestinal atresia, now presenting with vomiting, shows tapering & twisting/swirling ⇨ of small bowel loops at the transition point from dilated ⇨ to decompressed small intestine. At surgery, this volvulus was found to be secondary to an adhesion.*

Hepatoblastoma

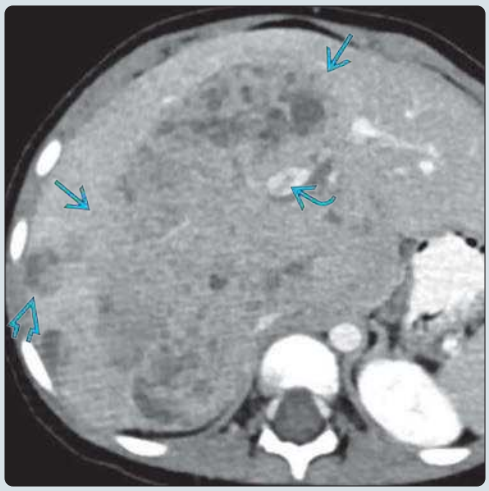
KEY FACTS

TERMINOLOGY

- Malignant embryonal hepatic tumor

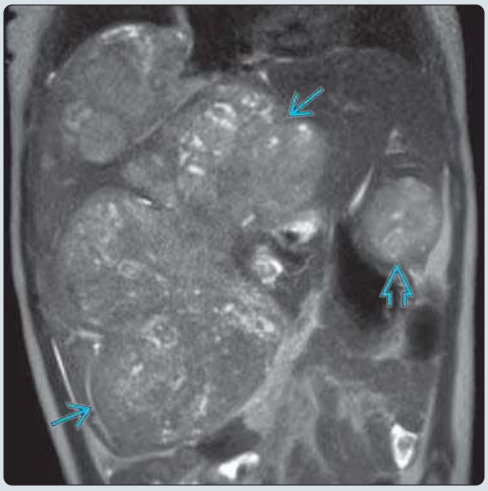
IMAGING

- Large, well-defined, solid but heterogeneous liver mass in child < 4 years of age with high α-fetoprotein (AFP) levels
  - Heterogeneity due to hemorrhage, necrosis, Ca^{2+}, or mixed histologies
- Single round, lobulated mass (80%), usually > 10 cm
  - May be multifocal (20%)
- Displacement/compression/effacement of adjacent vessels vs. true vascular invasion
- Usually enhances less than normal liver on all phases
- Pediatric LI-RADS workgroup recommends MR with hepatobiliary contrast agent at all imaging time points
- Chest CT to evaluate for pulmonary metastases
  - Metastases in 20% at presentation

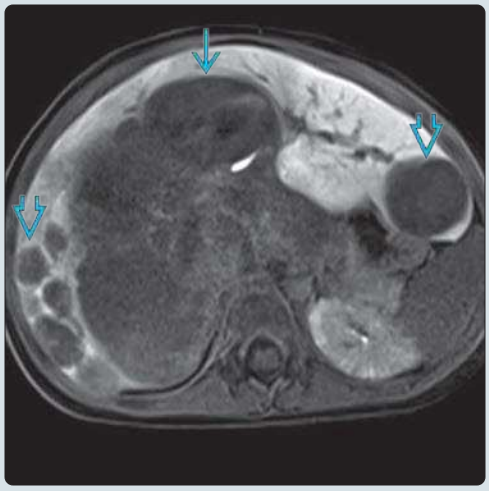


PATHOLOGY

- Risk factors: Very low birth weight, Beckwith-Wiedemann syndrome, familial adenomatous polyposis
- Epithelial type is more common than mixed epithelial & mesenchymal type
- **Pret**reatment **ext**ent of disease (PRETEXT) system is used to stage all pediatric liver tumors



CLINICAL ISSUES



- Most common primary liver tumor of childhood
- Presents as painless abdominal mass or hepatomegaly
- Median age: 19 months
  - Only 5-10% occur in children > 4 years of age
- Surgical resection ± neoadjuvant chemotherapy
  - Resection alone can be curative
  - Transplant if unresectable after neoadjuvant therapy
- Posttherapy AFP levels serve as tumor marker for surveillance

(Left) *Longitudinal US in a child with hepatoblastoma shows a large, heterogeneous, lobulated mass. No normal liver parenchyma is visible.* **(Right)** *Axial CECT of the same patient obtained in the portal venous phase of imaging shows a dominant tumor occupying the right side of the liver. Thrombus is present in the adjacent left portal vein. Additional satellite lesions are also noted.*

(Left) *Coronal T2 MR in the same patient shows that this tumor is multifocal with the dominant mass in the right lobe but a separate lesion in the left lateral section. Because this tumor involved all liver sections, it was considered PRETEXT IV.* **(Right)** *Axial T1 C+ FS MR during the hepatobiliary phase in the same patient highlights the multifocal tumor against the normal contrast-retaining hepatic parenchyma. The dominant mass involves the right lobe of the liver, but additional lesions are present in both lobes.*

TERMINOLOGY

Definitions

- Malignant embryonal hepatic tumor

IMAGING

General Features

- Best diagnostic clue
  - Large, well-defined, solid, heterogeneous liver mass in child < 4 years of age with high α-fetoprotein (AFP) levels
    - Heterogeneity due to hemorrhage, necrosis, or mixed histologies; Ca^{2+} in 50%
- Location
  - More common in right lobe of liver
- Size
  - Usually > 10 cm
- Morphology
  - Single round, lobulated mass (80%)
    - May be multifocal (20%)
  - Displaces, compresses, & effaces adjacent hepatic structures (vessels, falciform ligament)
  - May invade portal or hepatic veins
    - Tumor thrombus is favored over bland thrombus if
      - Vessel is dilated
      - Thrombus is contiguous with mass
      - Thrombus shows enhancement with contrast or internal arterial flow on color Doppler ultrasound
  - Large unusual veins may surround tumor

Radiographic Findings

- Homogeneous soft tissue mass in right upper quadrant
  - Displaces bowel inferiorly
  - May mimic generalized hepatomegaly
- Ca^{2+} is uncommonly seen on radiographs

Ultrasonographic Findings

- Grayscale ultrasound
  - Solid, well-defined mass
  - Usually hyperechoic to liver, often heterogeneous
    - Acoustic shadowing due to echogenic Ca^{2+}
    - Hypoechoic/anechoic foci from necrosis, hemorrhage
  - May have spoke-wheel appearance
- Pulsed Doppler
  - Portal or hepatic venous tumor thrombus may show arterial waveforms in venous lumen
- Color Doppler
  - Tumor is often hypovascular
    - Variable amount of disorganized vascularity in tumor

MR Findings

- T1WI
  - Generally hypointense to normal liver
  - High signal intensity foci of intratumoral hemorrhage
- T2WI
  - Heterogeneous intermediate signal intensity but usually hyperintense to normal liver
    - ± hypointense fibrous bands, hemorrhage
    - ± internal hyperintense cystic/necrotic foci
- T1WI C+ FS
  - Pediatric LI-RADS workgroup recommends MR with hepatobiliary contrast agent at all imaging time points
  - Heterogeneous enhancement, usually less than background liver on all phases
  - Hepatobiliary phase (≥ 20-minute delay) is useful for
    - Characterizing tumor
    - Establishing relationship to biliary system & vessels
    - Detecting multifocal lesions

CT Findings

- NECT
  - Not recommended for liver mass evaluation
- CECT
  - Well-defined, heterogeneous mass
  - Most enhance < background liver
    - Pediatric LI-RADS workgroup recommends dual-phase CT with imaging during late arterial & portal venous phases
    - ± arterial phase enhancement in rim & septa

Imaging Recommendations

- Best imaging tool
  - Ultrasound is best initial imaging modality in child with palpable abdominal mass
    - Determines organ of origin, helping to protocol subsequent cross-sectional imaging study
    - ± visualization of vessel involvement
  - MR with hepatobiliary contrast agent is preferred at all imaging time points
    - Pediatric LI-RADS workgroup recommends CT only if MR is contraindicated, if pediatric anesthesia is not available, or if multiple anesthesia events would be required to image chest & abdomen
  - Chest CT to look for pulmonary metastases

DIFFERENTIAL DIAGNOSIS

Hepatocellular Carcinoma

- Most common malignant hepatic tumor in children > 10 years of age
  - Pediatric hepatocellular carcinoma (HCC) differs from adult disease
    - Underlying liver disease in 30-50%
    - Associated with glycogen storage diseases, tyrosinemia, hemochromatosis, α-1 antitrypsin deficiency, biliary atresia, hepatitis B
- AFP levels are elevated < hepatoblastoma

Mesenchymal Hamartoma

- Benign hepatic tumor, usually < 2 years of age
- Large multicystic or mixed solid-cystic mass

Undifferentiated Embryonal Sarcoma

- Rare, usually 6-10 years of age, normal AFP
- May arise from mesenchymal hamartoma
- Large mass appears solid on US but cystic at CT/MR due to myxoid stroma

Hepatic Hemangioma

- Can be congenital or infantile type
- Congenital: Typically large & solitary; may cause heart failure with shunting
  - Detected in perinatal period

- Heterogeneous mass with vigorous peripheral enhancement but central areas of persistent nonenhancement
- Often regresses in 1st few months of life

- Infantile type: Multifocal or diffuse; small to moderate size
  - Develops in 1st weeks to months of life
  - Gradual complete enhancement (periphery to center)
  - Slowly regresses after 6-24 months

Hepatic Metastases

- Most commonly caused by neuroblastoma or Wilms tumor
- Delayed hepatocyte phase MR may be most sensitive

PATHOLOGY

General Features

- Etiology
  - Unknown
  - Risk factors & predisposing conditions
    - Very low birth weight (20x risk)
    - Beckwith-Wiedemann syndrome (2,280x risk)
    - Familial adenomatous polyposis (847x risk)

Staging, Grading, & Classification

- **Pret**reatment **ext**ent of disease (PRETEXT) staging system is used to characterize pediatric liver tumors & risk stratify patients
  - Image-based system to guide surgical management
  - PRETEXT group is determined by number of contiguous hepatic sections that must be resected to remove tumor
    - PRETEXT I: Tumor only involves 1 section (left lateral or right posterior) → 3 contiguous sections free of tumor
    - PRETEXT II: 2 contiguous sections free of tumor
    - PRETEXT III: 1 section free of tumor
    - PRETEXT IV: All sections involved with tumor
  - PRETEXT annotation factors for vascular involvement (portal veins & hepatic veins), multifocality, metastases, extrahepatic spread, tumor rupture, & nodal involvement
    - Strict definitions for each annotation factor
    - Vascular invasion & metastases are most common annotation factors
    - Vascular involvement is determined by presence of thrombus, vascular encasement, or obliteration
- POSTTEXT (**postt**reatment **ext**ent of tumor) is determined using same method

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Painless abdominal mass
  - Hepatomegaly
  - Markedly elevated AFP levels (90%)

Demographics

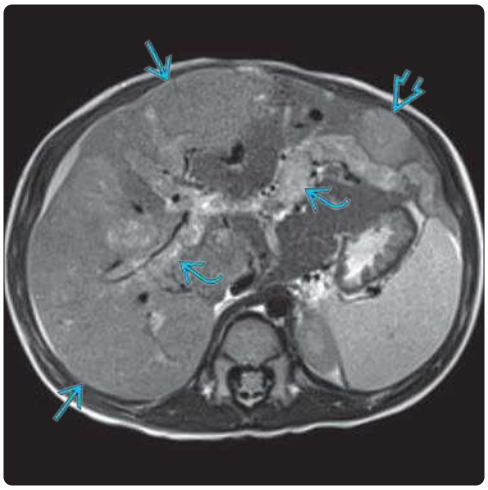
- Age
  - Diagnosed in young children
    - Median age at diagnosis: 19 months
    - 4% congenital
    - Only 5-10% occur beyond 4 years of age
- Sex
  - 60% male
- Epidemiology
  - Most common primary liver tumor of childhood
    - 91% of hepatic malignancies < 5 years of age
  - Incidence
    - 10.5 cases per million in children < 1 year of age
    - 5.2 cases per million in children 1-4 years of age
  - 3rd most common pediatric abdominal malignancy after Wilms tumor & neuroblastoma

Natural History & Prognosis

- Event-free survival/overall survival
  - Standard risk: Up to 83%/95%
    - Standard risk: Tumor confined to liver, ≤ 3 sections
  - High risk: Up to 65%/69%
    - High risk: Tumor in 4 sections, metastatic disease, low AFP levels
- Metastatic disease in 20% at diagnosis
  - Lung is most common location for metastases
- Poor prognostic factors
  - Positive annotation factors, low AFP level (< 100 ng/mL), ≥ 8 years of age, PRETEXT III or IV
- Fractures present in ~18% of patients at diagnosis
  - Most common in ribs & spine
  - May be paraneoplastic effect

Treatment

- Surgical resection can be curative
  - Up to 60% are unresectable initially
- Chemotherapy
  - Neoadjuvant therapy improves resectability
- Liver transplantation for unresectable tumor
  - 75-87% disease-free survival for primary transplant
- Posttherapy AFP serves as surveillance tumor marker



DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Large, well-defined, heterogeneous liver mass in infant
  - May have vascular invasion
    - Can be difficult initially to distinguish vascular invasion from compression

(Left) *Axial T2 MR in a child with hepatoblastoma shows a dominant tumor ⇨ spanning both the right & left lobes of the liver. The tumor is multifocal with a distinct mass ⇨ in the left lateral section. Tumor thrombus ⇨ fills the right & left portal veins.* **(Right)** *Axial CECT in the portal venous phase shows a PRETEXT III hepatoblastoma ⇨ occupying the right anterior & left medial sections of the liver. The tumor was marginated by the right hepatic vein & the umbilical segment of the left portal vein (not shown).*

(Left) *Axial CECT obtained in the portal venous phase shows a large tumor ⇨ occupying the left lobe of the liver. The tumor does not cross beyond the middle hepatic vein ⇨, making this a PRETEXT II tumor.* **(Right)** *Coronal CECT obtained in the portal venous phase in the same patient shows that the large tumor ⇨ of the left lobe of the liver lies entirely to the left of the middle hepatic vein & gallbladder ⇨.*

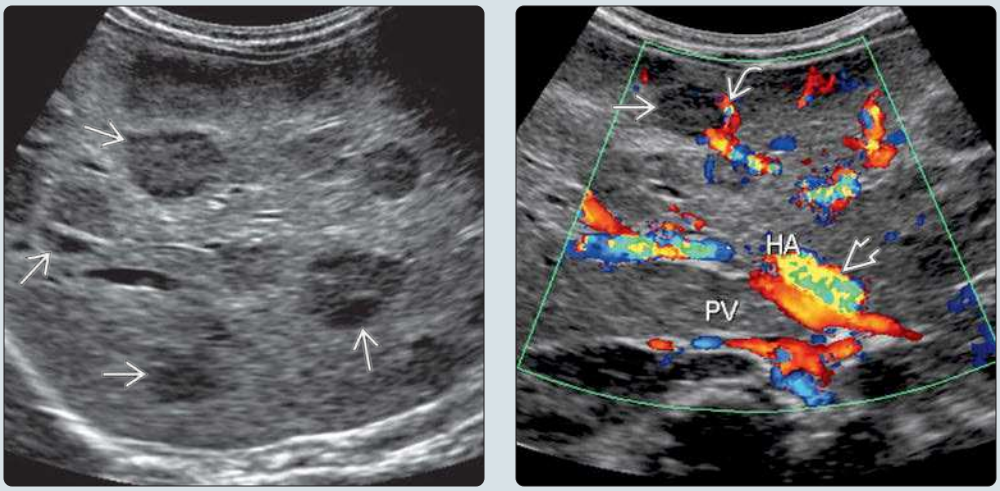
(Left) *Longitudinal US of the left lobe of the liver shows a mildly heterogeneous solid mass ⇨ arising from the inferior liver.* **(Right)** *Coronal T2 MR in the same patient shows the mass ⇨ arising from the inferior aspect of the left lobe of the liver. The tumor is multifocal with additional masses ⇨ scattered throughout the hepatic parenchyma.*

Hepatic Hemangiomas, Infantile and Congenital

KEY FACTS

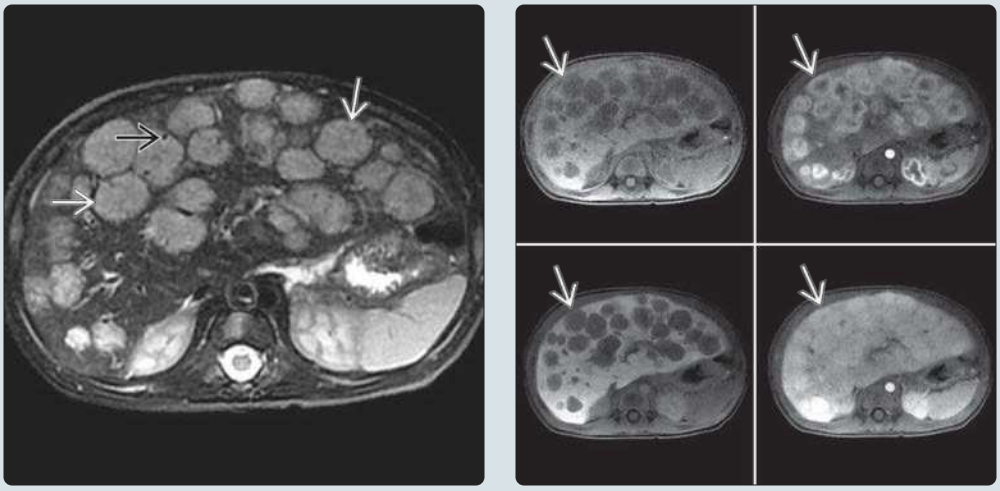
TERMINOLOGY

- Hemangioma: Benign endothelial neoplasm of neonates/infants in soft tissues or viscera (especially liver)
  - **Not** hemangioendothelioma (more aggressive tumor)
  - **Not** cavernous hemangioma (venous malformation)
- Congenital hemangioma (CH): Found in perinatal period, does not proliferate beyond birth; stains GLUT1 negative
  - Rapidly involuting subtype is more common in liver than noninvoluting
- Infantile hemangioma (IH): Develops in 1st few weeks of life with characteristic proliferating & involuting phases; stains GLUT1 positive



IMAGING

- 3 types of pediatric hepatic hemangiomas
  - Focal (CH): Solitary large heterogeneous mass
  - Multifocal (IH): Multiple small to moderate homogeneous masses
  - Diffuse (IH): Liver is enlarged & replaced by masses
- Focal hepatic CH: T2 heterogeneity; early peripheral enhancement + persistent foci of central nonenhancement
- Multifocal/diffuse IHs: T2-hyperintense lesions with gradual complete central filling after early peripheral enhancement
  - Often found in infants with ≥ 5 cutaneous IHs
- CH & IH often have enlarged feeding arteries/draining veins



CLINICAL ISSUES

- Hepatic CHs & IHs may be asymptomatic or can present with hepatomegaly, heart failure
- CHs may have anemia & mild, transient, consumptive coagulopathy (not Kasabach-Merritt phenomenon)
- Diffuse IHs may also present with hypothyroidism, liver failure, abdominal compartment syndrome
- Treatment is required if complications develop (< 10%)
  - CHs: Embolization, resection
  - IHs: Medical therapies initially (propranolol, steroids; rarely vincristine); embolization, liver transplant in extreme cases

(Left) *Longitudinal US in a 7-month-old with a history of cutaneous infantile hemangiomas (IHs) shows multiple, round, well-circumscribed, hypoechoic masses throughout the liver.* **(Right)** *Transverse color Doppler US in the same patient shows ↑ vascularity along the hypoechoic masses. Note the enlarged hepatic artery with color aliasing (compared to the normal color Doppler appearance of the portal vein) due to undersampling of high-velocity flow supplying the lesions.*

(Left) *Axial T2 FS MR in this patient shows the typical appearance of IHs: Multiple, round, well-circumscribed, small to moderate-sized, hyperintense (but not fluid-bright) lesions, some of which contain flow voids.* **(Right)** *Axial dynamic T1 C+ FS MR images with a hepatocyte-specific agent in (clockwise from top left) precontrast, arterial, portal venous, & delayed hepatocyte phases show a typical appearance of IHs with early peripheral enhancement, complete venous filling, & washout.*

TERMINOLOGY

Synonyms

- **Not** hemangioendothelioma (more aggressive vascular tumor, not typically found in infantile liver)
- **Not** cavernous hemangioma (venous malformation, not typically found in infantile liver)

Definitions

- Hemangioma: Benign endothelial neoplasm occurring in soft tissues or viscera (especially liver: Most common benign hepatic tumor of infants)
  - 70% of 2009 publications used term hemangioma incorrectly
- Congenital hemangioma (CH): Found in perinatal period; does not proliferate beyond birth
  - Rapidly involuting (RICH) vs. noninvoluting (NICH) vs. partially involuting subtypes
    - Only follow-up imaging or biopsy can determine subtype
- Infantile hemangioma (IH)
  - Usually not present at birth
  - Proliferating phase: Lesion(s) develop during 1st few weeks of life with rapid growth over next few months
  - Involuting phase: Slow regression of lesion(s) over years, usually beginning by 12 months of age

IMAGING

General Features

- Best diagnostic clue
  - CH: Large, solitary, heterogeneous hypervascular hepatic mass in fetus/newborn
  - IHs: Multiple small to moderate T2-hyperintense hepatic lesions with progressive peripheral to central enhancement in infant with ≥ 5 cutaneous IHs
- Morphology
  - Hepatic hemangiomas of young children are characterized as focal, multifocal, or diffuse
    - Focal hepatic hemangioma = true CH (usually RICH)
      - Large, solitary, well-defined mass
      - Multifocal CHs are very rare
    - Multifocal/diffuse hepatic hemangiomas = IHs
      - Multifocal IHs (most common): Multiple small to moderate-sized round lesions
      - Diffuse IHs: Liver is enlarged & nearly completely replaced by lesions
      - Very rarely infiltrate along portal veins, typically in syndromic cases [e.g., PHACE(S)]
  - Enlarged feeding arteries/draining veins may be seen with either CH or IHs

Radiographic Findings

- Radiography
  - Hepatomegaly or right upper quadrant mass
    - Depends on size/number of lesions
  - Ca^{2+} can be seen in ~ 15% of CH cases
  - ± heart failure with cardiomegaly, pulmonary edema

Ultrasonographic Findings

- Grayscale ultrasound
  - Prenatal US
    - CH: Heterogeneous mass ± ↑ vascularity, hydrops
    - IHs: Not present
  - Postnatal US
    - CH: Solitary heterogeneous mass
    - IHs: Multiple, round, well-defined lesions of variable echogenicity, most frequently hypoechoic & homogeneous
- Pulsed Doppler
  - IHs: Elevated hepatic artery velocities during proliferation, ↓ with involution
- Color Doppler
  - CH: ↑ peripheral vascularity ± arteriovenous shunts; little to no central vascularity
  - IHs: Variable ↑ vascularity within/along lesions; low-resistance arterial waveforms during proliferative phase
  - Hepatic arteries & veins frequently are enlarged
- Contrast-enhanced US
  - CH: Early arterial & portal venous hyperenhancement (relative to liver); no washout
  - IHs: Early arterial hyperenhancement; isoenhancement on portal venous phase; variable washout

CT Findings

- NECT
  - Well-defined hypodense mass(es)
  - CH: ± hyperdense foci of hemorrhage, Ca^{2+}
- CECT
  - Typical enhancement patterns
    - CH: Increasingly confluent early nodular peripheral enhancement on dynamic imaging; large central areas do not fill in/enhance over time
    - IHs: Early peripheral enhancement with gradual complete central fill in

MR Findings

- T1WI
  - Hypointense mass(es) compared to unaffected liver
  - CH: Hyperintense foci of hemorrhage
- T2WI
  - CH: Very heterogeneous internally with mixed hyper-/hypointense foci
  - IHs: Relatively homogeneous, hyperintense lesions compared to unaffected liver (but not as bright as fluid); small septa; scattered prominent flow voids
- T1WI C+
  - Enhancement patterns are similar to CT
  - Washout is expected with hepatocyte-specific agents
- MRA/MRV
  - ± enlargement of
    - Upper abdominal aorta, celiac axis, hepatic arteries
    - Hepatic veins, inferior vena cava
    - Arterial & venous branches along periphery of lesions (especially CH)

Imaging Recommendations

- Best imaging tool
  - US is best screening tool for palpable abdominal mass, hepatomegaly, or infant with multiple cutaneous IHs
  - MR for further characterization, extent determination

DIFFERENTIAL DIAGNOSIS

Hepatoblastoma

- Usually large, well-defined, solitary mass
- Uncommon in newborns
- Rarely hypervascular; usually hypoenhancing
  - Peripheral enhancement is not typical
- Markedly elevated & rising α-fetoprotein (AFP)

Neuroblastoma Metastasis

- Multiple masses vs. diffuse liver heterogeneity & enlargement
- Adrenal or paraspinal mass is typically present

Mesenchymal Hamartoma

- Can be solid & highly vascular with similar enhancement to CH (but continues to grow)

Umbilical Catheter Complication

- Vascular/hepatic perforation by umbilical venous catheter may lead to hemorrhage &/or parenchymal infusion of fluid

Venous Malformation

- Uncommon in pediatric liver outside of syndromes
- Lobulated fluid-signal intensity lesions ± layering fluid-fluid levels, phleboliths
- Gradual puddling of contrast into lesion over time

Arterioportal Fistula

- Enlargement & early enhancement of portal vein branch without discrete mass

PATHOLOGY

Microscopic Features

- Clusters of thin-walled capillaries lined by plump endothelium without cellular atypia
- IH
  - Densely packed capillaries with little intervening stroma
  - Cellular proliferation is present during early stages
  - GLUT1-positive endothelium
  - Fatty infiltration is not usually seen with involution in hepatic IHs (unlike soft tissue IHs)
- CH
  - Varying-sized lobules of capillaries surrounded by dense myxoid stroma & large malformed vessels
  - Foci of hemorrhage, necrosis, fibrosis, extramedullary hematopoiesis, Ca^{2+}
  - GLUT1-negative endothelium

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hepatic CH & IHs may be asymptomatic
  - CH, IHs can present with hepatomegaly, heart failure
- Other signs/symptoms
  - CH may have anemia & mild, transient consumptive coagulopathy
  - Diffuse IHs may also present with
    - Hypothyroidism (due to production of enzyme type 3 iodothyronine deiodinase)
      - 100% of diffuse IHs vs. 21% of multifocal IHs
    - Liver failure
    - Abdominal compartment syndrome
  - Cutaneous IHs are found in
    - 50-75% of multifocal/diffuse hepatic IHs
    - 15% of focal hepatic CH
  - AFP is not produced by CH or IHs
    - AFP is normally high in newborns but ↓ over 1st months of life

Demographics

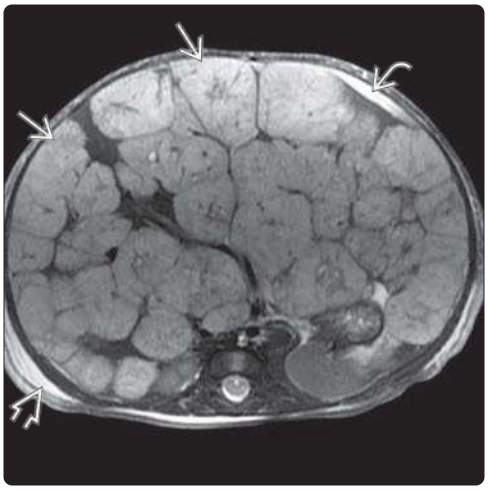
- Age
  - CH is usually detected in perinatal period
  - IHs develop in 1st few weeks of life
    - More common in premature infants
- Sex
  - CH, M:F = 1:1; in IH, M:F = 1:3-4
- Ethnicity
  - IH is much more common in White patients

Natural History & Prognosis

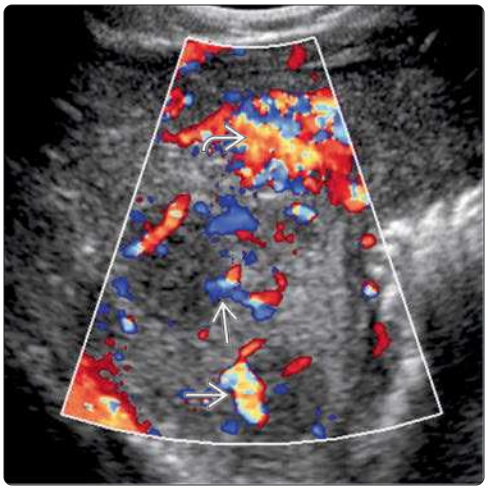
- Focal hepatic CH
  - Can enlarge from hemorrhage
  - RICH will mostly involute by 14 months of age
  - Mortality is widely variable in literature
- Multifocal/diffuse IHs
  - May grow after detection, depending on age
  - After 1st year of life, gradually involute over years
  - Mortality: 16% overall, higher for diffuse pattern; median age of death = 115 days

Treatment

- Treatment is required if complications develop
  - < 10% of pediatric hepatic hemangiomas require therapy
- CH: Embolization, resection; medical therapies have not proven effective
- IHs: Medical therapies initially (propranolol, steroids; rarely vincristine); embolization, liver transplant in extreme cases



DIAGNOSTIC CHECKLIST



Consider

- Liver US screening in patients with ≥ 5 cutaneous IHs
- Biopsy of hepatic lesions should be performed if diagnosis is unclear by combination of clinical history/exam, initial imaging, & lesion behavior over appropriate timeframe
  - Safely performed percutaneously in experienced hands

(Left) *Axial T2 FS MR in a patient with cutaneous IHs & abdominal distention shows near-total replacement of the hepatic parenchyma by innumerable hyperintense lesions. Note the ascites & body wall edema secondary to liver failure.* **(Right)** *Transverse color Doppler US in a 2-month-old with cutaneous IHs shows variable vascularity within the hypoechoic hepatic lesions, ranging from moderate peripheral vascularity to diffusely ↑ internal flow.*

(Left) *Pulsed Doppler US in a newborn with hydrops shows a large, solid, mildly heterogeneous mass in the right hepatic lobe with ↑ peripheral vascularity. Interrogation of an enlarged artery shows elevated velocities wrapping around the scale.* **(Right)** *Axial CECT shows irregular heterogeneous enhancement of the lesion periphery on arterial phase. Central portions of the mass did not enhance on delayed images (not shown), typical of a focal hepatic congenital hemangioma (CH).*

(Left) *Coronal T2 FS MR in a 4-day-old with a palpable abnormality shows a large exophytic mass arising from the inferior right hepatic lobe. The lesion shows marked internal heterogeneity.* **(Right)** *Axial T1 C+ FS MR images of the same patient at (clockwise from top left) precontrast, 90-second, 180-second, & 5-minute times show irregular peripheral enhancement with large areas of persistent central nonenhancement, typical of a focal CH of the liver.*

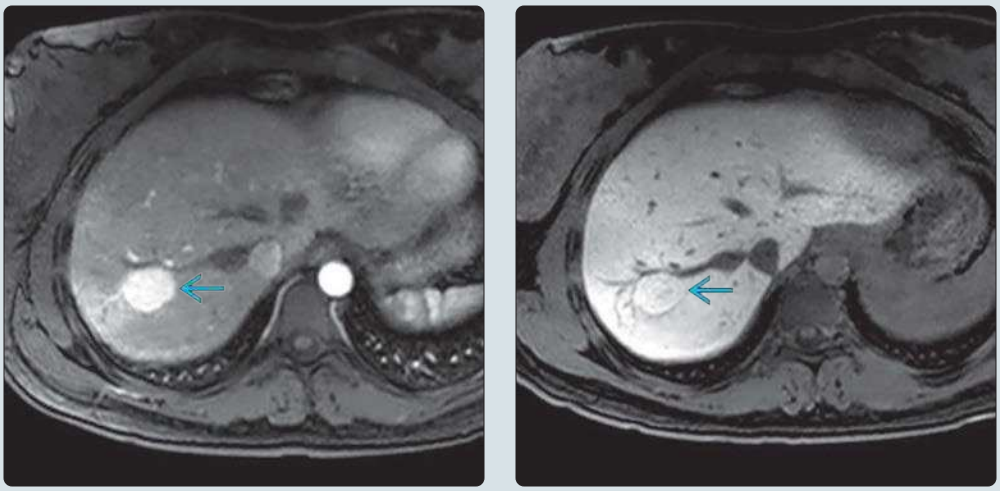
Focal Nodular Hyperplasia

KEY FACTS

TERMINOLOGY

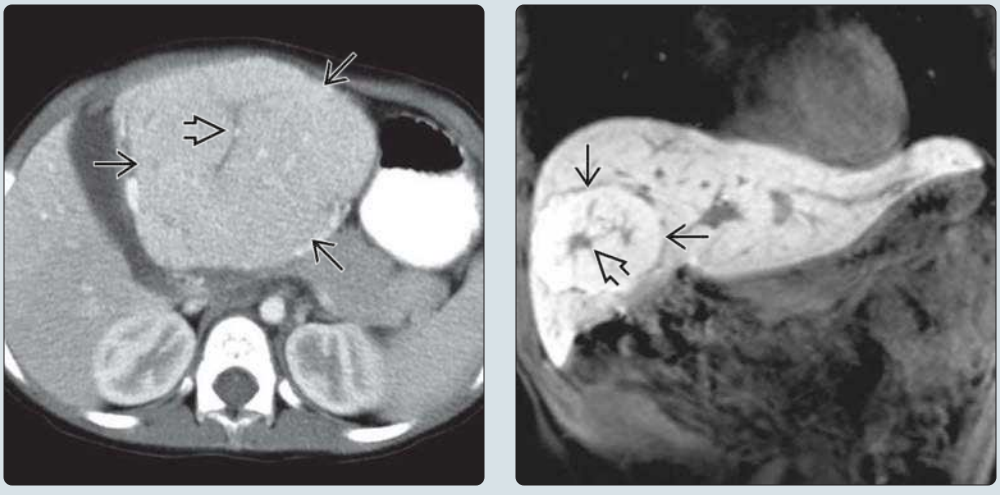
- Benign epithelial tumor composed of hepatocytes, Kupffer cells, abnormal bile ducts, & vessels
  - Central scar is present in 50-70%

IMAGING



- CECT: Homogeneous arterial enhancement ± hypoenhancing central scar
- MR with hepatobiliary-phase contrast agent (best tool)
  - T1: Iso- to slightly hypointense; ± hypointense scar
  - T2: Slightly hyperintense; ± hyperintense scar
  - Arterial phase: Hyperenhancing mass ± central scar
  - Venous phase: Iso- to slight hyperenhancement of mass ± hyperenhancing central scar
  - Hepatobiliary phase: Mild hyperenhancement but can be isoenhancing
    - Usually homogeneous (can be heterogeneous in larger lesions)
- US: ↑, ↓, or ↔ echogenicity relative to liver
  - Doppler shows spoke-wheel pattern with hypervascular central scar & radiating vessels
  - Contrast-enhanced US: Early hyperenhancement, ± spoke-wheel pattern

PATHOLOGY



- Hyperplastic response to preexisting vascular malformation within central scar
- Abnormal bile ducts → hepatobiliary phase hyperenhancement (↓ clearance of contrast agent)
- ↑ prevalence after chemotherapy &/or stem cell transplant
  - Often multiple small lesions with no central scar

CLINICAL ISSUES

- 2% of primary hepatic tumors in children
- Often asymptomatic; occasionally causes palpable mass &/or vague abdominal pain
- Managed conservatively in asymptomatic patients & surgically in symptomatic patients

(Left) *Axial arterial-phase T1 C+ FS MR in a 16-year-old girl with an incidentally discovered liver mass demonstrates a homogeneously hyperenhancing lesion ⇨ typical of focal nodular hyperplasia (FNH).* **(Right)** *Axial T1 C+ FS MR 20 minutes after the injection of a hepatocyte-specific contrast agent in the same patient shows mild homogeneous hyperenhancement of the lesion ⇨ relative to the normal enhancing background liver, consistent with FNH.*

(Left) *Axial CECT in a 3-year-old boy with a palpable mass demonstrates a well-defined, homogeneously enhancing left lobe liver mass ⇨ with a central hypodense scar ⇨, typical of FNH. The lesion enhancement is similar to normal liver in portal venous phase.* **(Right)** *Coronal T1 C+ FS MR using a hepatocyte-specific contrast agent in a patient with a liver mass demonstrates slight hyperenhancement of the mass ⇨ on the 20-minute delayed image. Note the nonenhancing central scar ⇨, typical of FNH.*

TERMINOLOGY

Abbreviations

- Focal nodular hyperplasia (FNH)

Definitions

- Benign epithelial tumor composed of hepatocytes, abnormal bile ducts, & vascular structures
- 2% of primary hepatic tumors in children

IMAGING

General Features

- Best diagnostic clue
  - Homogeneous, arterially enhancing mass on CT or MR with delayed enhancement of central scar
  - Central scar is present in 50-70%
    - Scar is more likely in larger lesions
- Morphology
  - Well-defined, round or ovoid mass
  - Smooth vs. mildly lobulated margins

Ultrasonographic Findings

- Grayscale ultrasound
  - Iso-, hypo-, or hyperechoic mass ± central scar
- Color Doppler
  - Spoke-wheel pattern with hypervascular central scar & radiating vessels extending to periphery
- Contrast-enhanced US: Early phase hyperenhancement; ↔ to ↑ on later phases
  - Can see spoke-wheel pattern of enhancement

CT Findings

- CECT
  - Arterial phase
    - Hyperenhancing hepatic lesion ± ↓ attenuation central scar
  - Portal venous & delayed phases
    - Becomes isoattenuating relative to normal liver
    - Enhancement of central scar (if present)
  - May be impossible to distinguish from normal liver on NECT or postcontrast portal venous & delayed phases

MR Findings

- T1WI
  - Iso- to hypointense lesion; ± hypointense central scar
- T2WI
  - Iso- to slightly hyperintense; ± hyperintense central scar
- T1WI C+
  - Arterial phase
    - ↑ enhancement relative to normal liver; ± ↓ enhancing scar
  - Portal venous phase
    - Becomes isointense to liver; ± ↑ enhancing scar
  - Hepatobiliary phase (e.g., gadoxetate disodium)
    - Most common: Mildly ↑ enhancement of mass relative to normal liver; ± ↓ enhancing scar
    - Different patterns of enhancement are reported: Homogeneous, heterogeneous, peripheral, or isointense to liver
      - Rare ↓ enhancement has been described

Imaging Recommendations

- Best imaging tool
  - Dynamic MR with hepatobiliary contrast agent

DIFFERENTIAL DIAGNOSIS

Fibrolamellar Hepatocellular Carcinoma

- Central scar is hypointense on both T1 & T2 MR

Hepatocellular Carcinoma

- ± underlying liver disease in children
- Typically ↓ enhancement on hepatobiliary-phase MR

Hepatic Adenoma

- Oral contraceptive use or history of liver disease

PATHOLOGY

General Features

- Hyperplastic response to preexisting vascular malformation within central scar
  - Leads to proliferation of functional hepatocytes, vascular structures, & abnormal bile ducts
    - Abnormal bile ducts → hepatobiliary-phase hyperenhancement (↓ clearance of contrast agent)
- ↑ prevalence after chemotherapy &/or stem cell transplant
  - Usually multiple & smaller lesions with no central scar

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Often asymptomatic; occasionally causes abdominal pain due to mass effect
- Other signs/symptoms
  - Normal lab values, including α-fetoprotein

Natural History & Prognosis

- No known malignant potential

Treatment

- Managed conservatively in asymptomatic patients vs. surgically in symptomatic patients

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Homogeneous, arterially enhancing mass on CT or MR, ± central scar
- ↑ enhancement relative to normal liver with delayed hepatobiliary-phase contrast MR

SELECTED REFERENCES

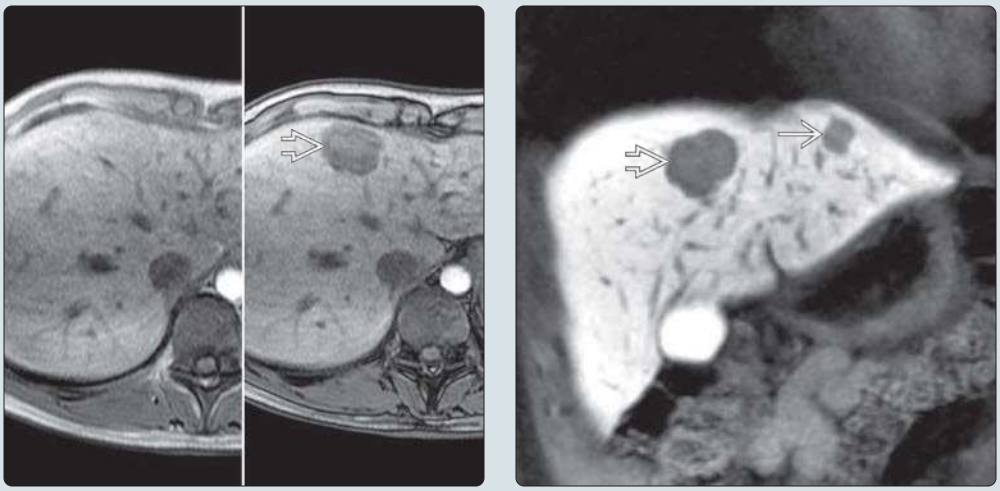
Hepatic Adenoma

KEY FACTS

TERMINOLOGY

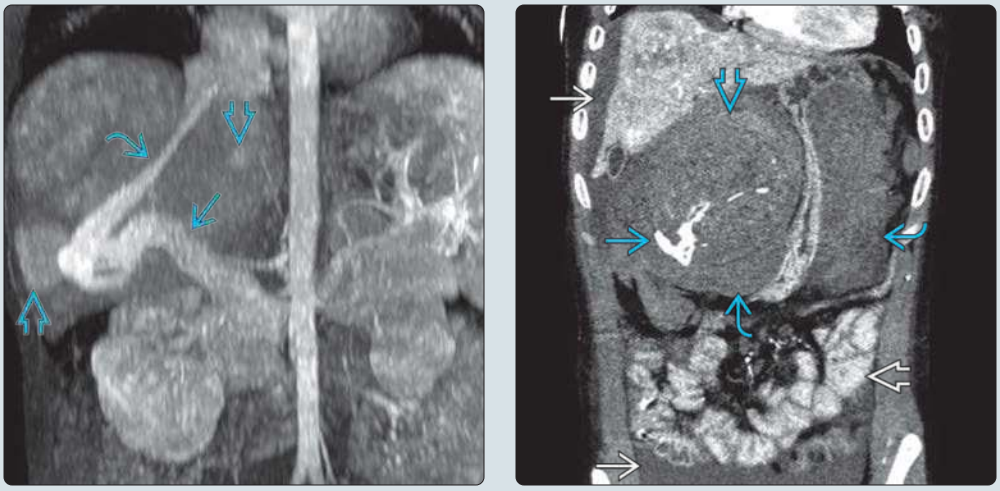
- Benign neoplasm arising from hepatocytes
- May hemorrhage/rupture
- Pathologic subtypes
  - Inflammatory ~ 40-50%
  - Hepatocyte nuclear factor 1α (*HNF1α*) mutated ~ 30-35%
  - β-catenin activated ~ 10-15%
    - ↑ malignant potential
  - Unclassified ~ 5-10%

IMAGING



- Variable patterns of hyperenhancement on arterial phase
  - May contain fat, hemorrhage, necrosis, Ca^{2+}
- Subtypes may have different MR features
  - Inflammatory: ↑ on T2, ↑ arterial enhancement
  - *HNF1α:* ↓ on T1 opposed phase (lipid), ↑ to ↔ arterial enhancement
  - β-catenin & undifferentiated subtypes: Variable
- Hepatobiliary-phase MR contrast agents help characterize lesions & ↑ detection of small lesions
- US: Heterogeneous, ± ↑ echogenicity due to lipid or hemorrhage
- CT: Arterial phase → typical hyperenhancement
  - ↑ attenuation subcapsular or peritoneal fluid if tumor rupture/hemorrhage occurs

TOP DIFFERENTIAL DIAGNOSES



- Focal nodular hyperplasia
- Hepatocellular carcinoma

CLINICAL ISSUES

- Adenomas are more likely with exogenous steroids, glycogen storage disease, underlying liver disease, congenital portosystemic shunts (Abernethy malformation vs. intrahepatic shunt)
- May regress if oral contraceptives are discontinued
- Surgical excision: Male (↑ β-catenin subtype), symptomatic, suspicious imaging features, or large size

(Left) *Axial in- & opposed-phase MR images in a teenage girl with a liver mass demonstrate marked signal dropout within the mass on the opposed-phase image, indicating intracellular lipid typical of adenoma. The mass is isointense to normal liver on in-phase imaging.* **(Right)** *Hepatocyte-phase coronal T1 C+ FS MR using a hepatobiliary contrast agent (gadoxetate disodium) in the same patient shows no contrast retention by the mass relative to the surrounding normal liver. Note a 2nd similar lesion in the left hepatic lobe.*

(Left) *Coronal T1 C+ FS MR MIP in a 16-year-old with an intrahepatic portosystemic shunt shows an aberrant connection of the interrupted portal vein to a hepatic vein. Biopsy of the hyperenhancing lesions confirmed inflammatory adenomas.* **(Right)** *Coronal CECT in the same patient 6 months later shows active arterial extravasation from a large adenoma with hemoperitoneum & large foci of clotted blood. There is profound bowel wall hyperenhancement due to hypoperfusion complex.*

TERMINOLOGY

Definitions

- Benign neoplasm arising from hepatocytes
- Different subtypes with different imaging features & clinical significance
  - Inflammatory ~ 40-50%
  - Hepatocyte nuclear factor 1α (*HNF1α*) mutated ~ 30-35%
    - More frequently have fat content
  - β-catenin activated ~ 10-15%
    - ↑ malignant potential
    - More common in males
  - Unclassified ~ 5-10%

IMAGING

General Features

- Best diagnostic clue
  - Arterial-phase enhancing liver mass in patient on oral contraceptives or with underlying liver disease

Ultrasonographic Findings

- Heterogeneous, well-defined mass; may be hyperechoic due to lipid content or hemorrhage
- Contrast-enhanced US
  - Similar enhancement to background liver on early & late phases
  - Can be heterogeneous

CT Findings

- NECT
  - Typically ↓ attenuation compared to liver (due to lipid)
  - ± ↑ attenuation due to Ca^{2+} or hemorrhage
- CECT
  - Arterial phase → variable patterns of hyperenhancement
  - Venous phase → ± heterogeneous enhancement

MR Findings

- Most common MR appearance
  - ↓ to ↔ on T1, mildly ↑ on T2
    - May be ↓ on T2 FS due to intracellular lipid
  - ± signal loss on T1 opposed-phase images due to lipid
  - ↑ arterial enhancement, ± heterogeneity
  - Most commonly hypoenhancing on hepatobiliary phase if hepatocyte specific contrast is used
- Different subtypes may have differentiating features
  - *HNF1α* subtype
    - ↑ or ↓ on T1, ↓ signal on T1 opposed phase due to lipid
    - Moderate arterial enhancement, ↓ enhancement on delayed phases
  - Inflammatory subtype
    - ↔ to mild ↑ on T1
    - Typically ↑ on T2
    - ↑ arterial enhancement, remains hyperenhancing on later phases
  - β-catenin activated & unclassified subtypes
    - Variable, can be heterogeneous
- Hepatobiliary-phase MR contrast agent
  - Variable, most commonly hypoenhancing on hepatobiliary phase
  - Can be iso- to hyperenhancing
    - Most common with β-catenin subtype

Imaging Recommendations

- Best imaging tool
  - Multiphasic MR with hepatobiliary contrast agent, in-/opposed-phase T1 imaging

DIFFERENTIAL DIAGNOSIS

Focal Nodular Hyperplasia

- Homogeneous arterial enhancement ± central scar
- No intracellular lipid
- Iso- or hyperintense to liver on hepatocyte phase with hepatobiliary contrast agent

Hepatocellular Carcinoma

- Can be indistinguishable from hepatic adenoma on imaging

Hypervascular Metastasis

- Uncommon in children
- No intracellular lipid

PATHOLOGY

General Features

- Associated with oral contraceptives, exogenous steroids, glycogen storage diseases, liver disease (e.g., cardiogenic cirrhosis), congenital portosystemic shunts (Abernethy malformation vs. intrahepatic shunt)

Gross Pathologic & Surgical Features

- ± fat, necrosis, & hemorrhage
- Can be solitary or multiple (adenomatosis)

CLINICAL ISSUES

Natural History & Prognosis

- ↑ risk of hemorrhage with ↑ size of mass
- Risk of malignant transformation to hepatocellular carcinoma ~ 5%
  - ↑ risk with β-catenin subtype

Treatment

- Discontinuation of oral contraceptives can lead to ↓ in size or even complete regression
- Surgical excision if male, suspicious/atypical imaging features, or large size

Hepatocellular Carcinoma

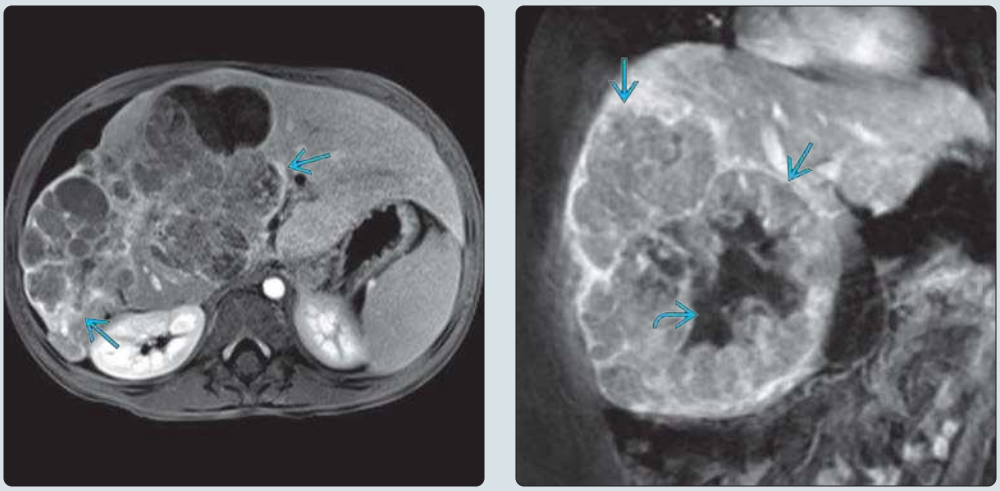
KEY FACTS

TERMINOLOGY

- Hepatocellular carcinoma (HCC): Malignant tumor of hepatocytes
- Hepatobiliary agent (HBA): MR contrast agent with substantial hepatocyte uptake & retention with biliary excretion

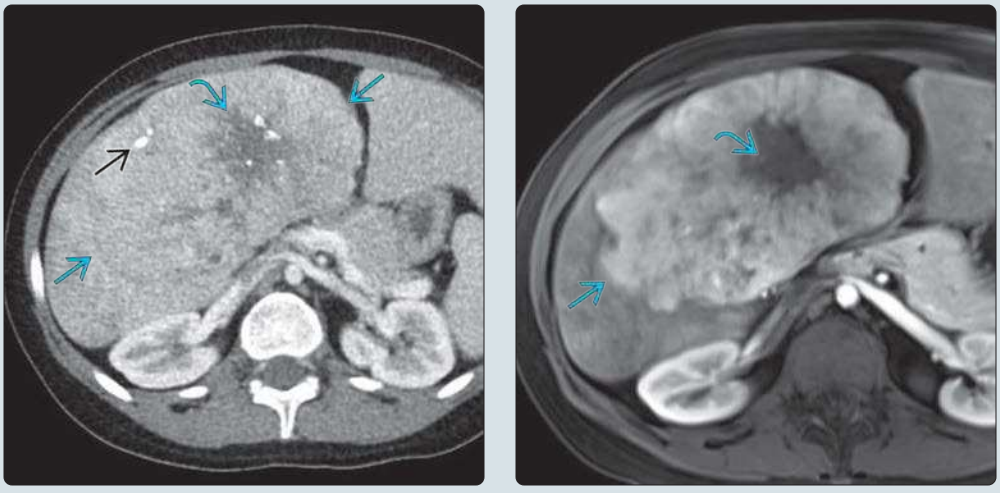
IMAGING

- Pediatric LI-RADS work group recommends MR with HBA at all imaging time points
  - CT is not recommended unless MR is contraindicated or if pediatric anesthesia is required but unavailable
- MR imaging findings
  - Variable precontrast signal intensity
  - Typically hyperenhancing on arterial phase
  - Washout on portal venous & delayed phases
  - Typically has no delayed hepatobiliary-phase contrast retention



TOP DIFFERENTIAL DIAGNOSES

- Fibrolamellar HCC
- Hepatoblastoma
- Hepatic adenoma
- Focal nodular hyperplasia
- Undifferentiated embryonal sarcoma



CLINICAL ISSUES

- 2nd most common primary hepatic malignancy in children after hepatoblastoma
- Typical age: 10-19 years
- Preexisting liver disease in 30-50% of patients
- Best therapy: Complete resection
  - 2/3 are unresectable at diagnosis due to multifocality, vascular invasion, size, or metastases (25-50%)
    - May become resectable with neoadjuvant therapy
    - Transplant may be curative for localized disease
- Overall survival rate of ~ 10-30%

(Left) *Axial T1 C+ FS MR imaged in the hepatic arterial phase shows a large hepatocellular carcinoma (HCC) within the right lobe of the liver. The tumor is heterogeneous with some foci that enhance more than the background liver while many regions enhance less.* **(Right)** *Coronal T1 C+ FS MR during the portal venous phase shows a large HCC arising from the inferior aspect of the right lobe of the liver. The tumor has a central area of necrosis.*

(Left) *Axial CECT in an adolescent with fibrolamellar HCC shows a large tumor with a central scar & scattered calcifications. Most of the mass shows similar enhancement to the liver parenchyma.* **(Right)** *Axial T1 C+ FS MR obtained during the portal venous phase in the same patient shows the HCC to enhance more than the background liver. The central scar does not enhance, typical of the fibrolamellar variant.*

KEY FACTS

TERMINOLOGY

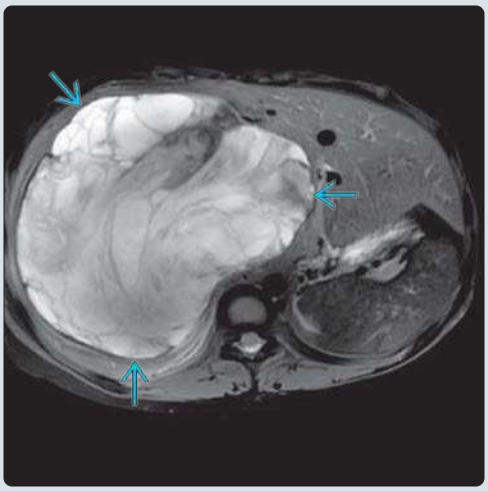
- Malignant hepatic mesenchymal tumor with undifferentiated cells

IMAGING

- Well-circumscribed, solitary liver mass in 6- to 10-year-old child
- Typically > 10 cm in size; mean: 14 cm
- Mass appears cystic on CT/MR but solid on ultrasound due to myxoid components
  - Septations & mural nodules may be present
  - Minimal enhancement during arterial phase
  - ± peripheral enhancement on delayed phases
  - Central hyperdense foci & fluid-debris levels suggest hemorrhage; Ca^{2+} is uncommon

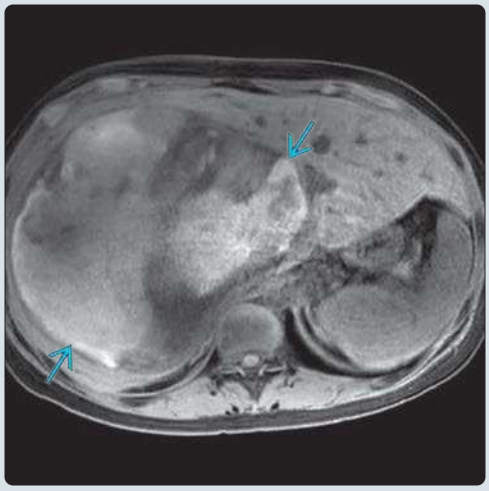
TOP DIFFERENTIAL DIAGNOSES

- Hepatoblastoma
- Mesenchymal hamartoma
- Hepatocellular carcinoma
- Hepatic pyogenic abscess

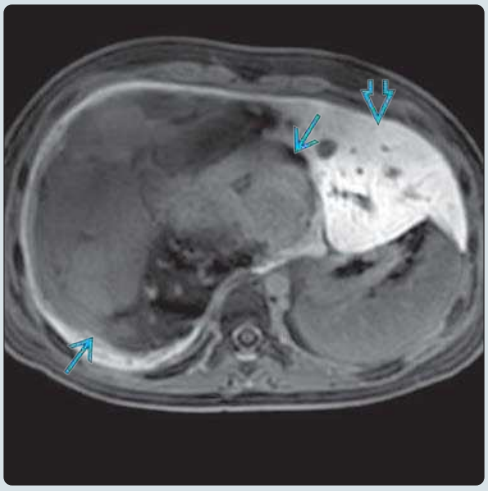


PATHOLOGY

- May arise from mesenchymal hamartoma



CLINICAL ISSUES



- 3rd most common pediatric hepatic malignancy after hepatoblastoma & hepatocellular carcinoma
- Most frequently occurs between 6-10 years of age
- Most commonly presents with abdominal mass ± abdominal pain; normal α-fetoprotein (AFP) levels
  - Fever, weight loss, anorexia, vomiting, diarrhea, lethargy, constipation, & respiratory distress are less common
- 86% 5-year overall survival
  - Multimodal therapy (including chemotherapy & resection or transplant) are key for ↑ survival
- Metastases are present in 15%: Most common in lungs, pleura, & peritoneum

(Left) *Transverse US of the liver in an adolescent with an undifferentiated embryonal sarcoma shows a heterogeneous but predominantly solid mass ⇨ involving the right lobe of the liver.* **(Right)** *Axial T2 FS MR in the same patient shows a complex hyperintense mass ⇨ of the right lobe of the liver. Hepatic undifferentiated embryonal sarcoma often has fluid signal on MR (due to myxoid components) but is solid on ultrasound.*

(Left) *Axial T1 FS MR in the same patient shows that the heterogeneous mass ⇨ has regions of hyperintense T1 signal, suggesting that internal hemorrhage has occurred.* **(Right)** *Axial T1 C+ FS MR obtained in the hepatobiliary phase (while using a hepatobiliary contrast agent) in the same patient shows that the tumor ⇨ does not retain the hepatobiliary contrast media. Note the retention of contrast by the normal liver ⇨.*

Mesenchymal Hamartoma

KEY FACTS

TERMINOLOGY

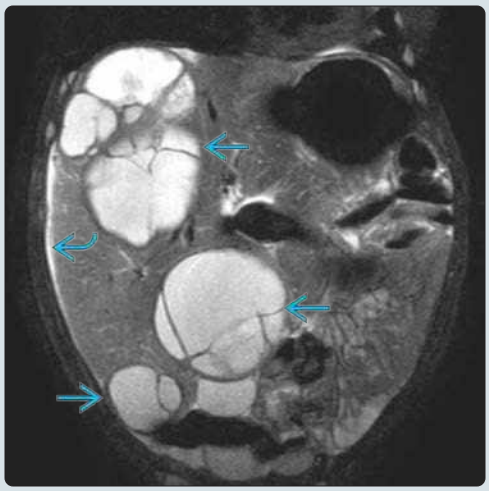
- Mesenchymal hamartoma (MH): Benign liver tumor of infants due to primitive mesenchymal proliferation

IMAGING

- Spectrum from mostly cystic to mostly solid masses
  - Amount of solid stromal tissue determines appearance
  - Cysts found (to some degree) in up to 85%
    - Septations may be thin or thick
- Typically unifocal; rarely multifocal or diffuse
  - Right hepatic lobe: 75%
- Up to 30 cm in size; mean: 16 cm
- Ca^{2+} & hemorrhage are uncommon

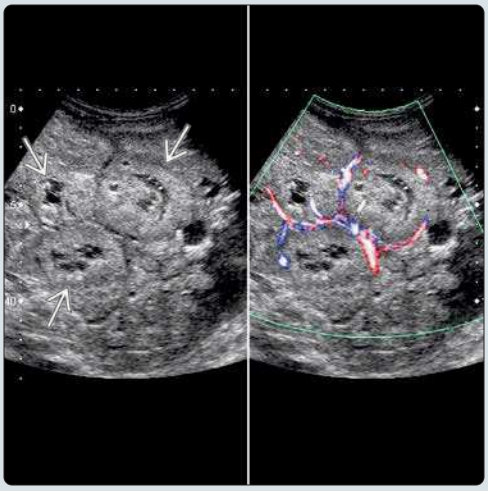
TOP DIFFERENTIAL DIAGNOSES

- Hepatoblastoma
- Congenital hemangioma (CH)
- Umbilical venous catheter (UVC) extravasation
- Undifferentiated embryonal sarcoma (UES)

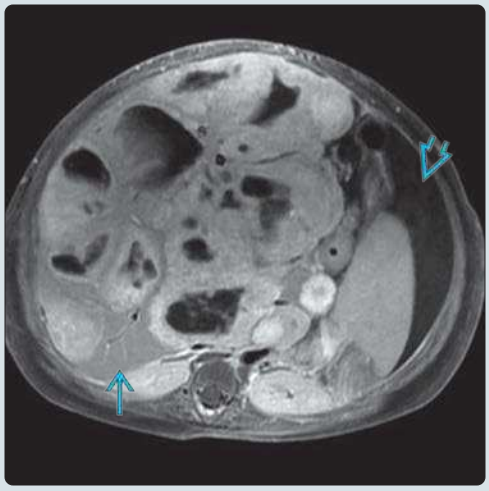


CLINICAL ISSUES

- Typically < 2 years old; 5% > 5 years old
- Grow slowly or rapidly in perinatal period
  - Prenatal: May cause polyhydramnios, hydrops
  - Postnatal: May cause respiratory distress
- Subsequent stabilization vs. partial regression
- > 90% long-term survival
- Complete excision is required due to rare malignant potential: Reports of UES arising in background MH
- Cyst aspiration may be required emergently (pre- or postnatally) to alleviate compression



DIAGNOSTIC CHECKLIST



- Most likely hepatic neoplasms in young children
  - Largely cystic in neonate/infant → MH
  - Solid, hypovascular in infant/toddler → hepatoblastoma
  - Solid, heterogeneous, hypervascular in newborn → CH
- In neonate with recent UVC infusion & newly discovered "cystic hepatic mass," consider extravasation (not tumor)

(Left) *Coronal T2 FS MR in a 6-month-old shows a large multicystic mass ➡ replacing the right lobe of the liver & filling much of the abdomen. Mesenchymal hamartoma (MH) was confirmed at resection.* **(Right)** *Coronal T2 FS MR in a 13-month-old shows multiple loculated cystic masses ⇨ in the liver + a small amount of ascites ⇨. There was no enhancement of the lesions after contrast (not shown). Transplant was required as all hepatic sectors were involved (not shown). (Courtesy P. Masand, MD.)*

(Left) *Transverse grayscale & color Doppler US images in a 6-month-old with new-onset liver failure show numerous mixed solid & cystic masses ➡ filling the visible liver & splaying the hepatic vessels. Scant internal vascularity is seen in the lesions.* **(Right)** *Axial T1 C+ FS MR in the same patient shows heterogeneously enhancing masses replacing all but a small volume of normal liver parenchyma ⇨. Note the ascites ⇨ secondary to liver failure. A liver transplant was ultimately required for diffuse MHs.*

KEY FACTS

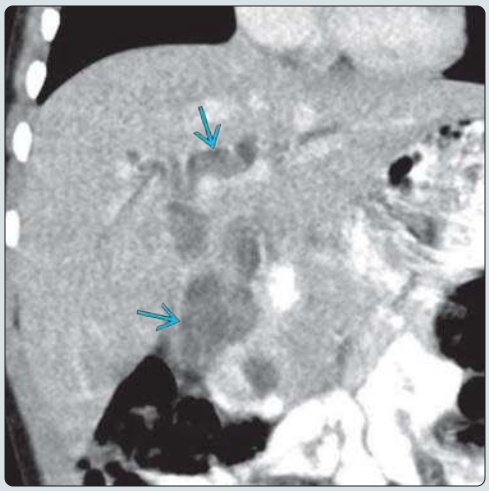
IMAGING

- Expansile intraductal biliary mass in young child
  - Most commonly arises in common bile duct
  - Dilated upstream intrahepatic bile ducts are caused by downstream biliary obstruction
  - May be difficult to distinguish tumor from dilated/obstructed bile ducts
- CT: Isodense to slightly hypodense compared to liver
- MR: Hypointense on T1, hyperintense on T2, heterogeneous enhancement, restricted diffusion
- US: Heterogeneous hypoechoic mass expanding bile duct with variable degree of internal vascularity
- ERCP: Lobulated intraductal filling defect

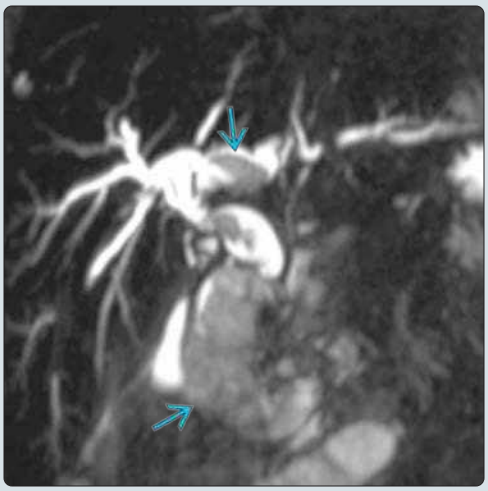
TOP DIFFERENTIAL DIAGNOSES

- Choledochal cyst: Spectrum of malformations involving extrahepatic & intrahepatic bile ducts
- Cholangiocarcinoma: Malignancy arising from bile duct epithelium; extremely rare in children

PATHOLOGY

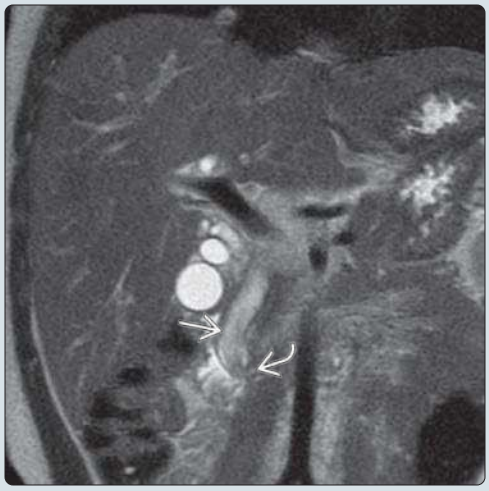


- 2 subtypes: Embryonal & alveolar
- Botryoides is variant of embryonal subtype

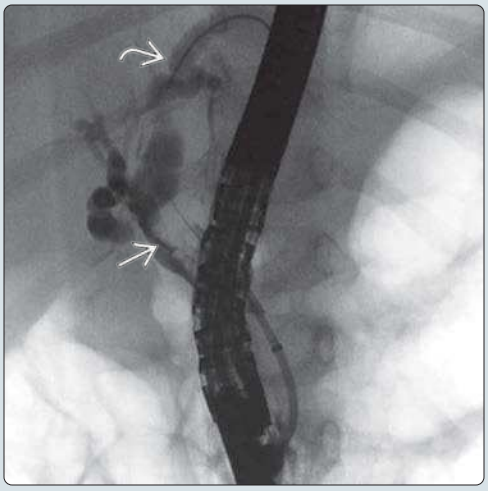


CLINICAL ISSUES

- Most common presentation: Jaundice (60-80%)
- Other presenting signs/symptoms: Abdominal distention, fever, hepatomegaly, nausea, & vomiting
- Most common pediatric biliary malignancy
  - 75% are diagnosed before 5 years of age
  - Overall survival: 55-75%
- Metastases present in 30%



DIAGNOSTIC CHECKLIST



- Mass may follow fluid appearance on CT & MR, making it difficult to differentiate tumor from dilated ducts
- Biliary rhabdomyosarcoma may be misdiagnosed as choledochal cyst

(Left) *Coronal CECT in a 3-year-old child shows a mildly enhancing solid mass ⇨ filling & distending the common & intrahepatic bile ducts. While uncommon, biliary rhabdomyosarcoma is the most common biliary mass in children.* **(Right)** *Coronal MIP image from an MRCP in a 3-year-old child shows a mass ⇨ filling & distending the common & intrahepatic bile ducts with dilation of the obstructed upstream ducts.*

(Left) *Coronal T2 MR in another 3-year-old patient shows a heterogeneous solid mass ⇨ filling & distending the common bile duct. The mass extends to the sphincter of Oddi ⇨.* **(Right)** *AP image from an ERCP shows a filling defect ⇨ within the common bile duct. The upstream intrahepatic ducts ⇨ are dilated, suggesting that the intraductal mass is at least partially obstructive.*

Biliary Atresia

KEY FACTS

TERMINOLOGY

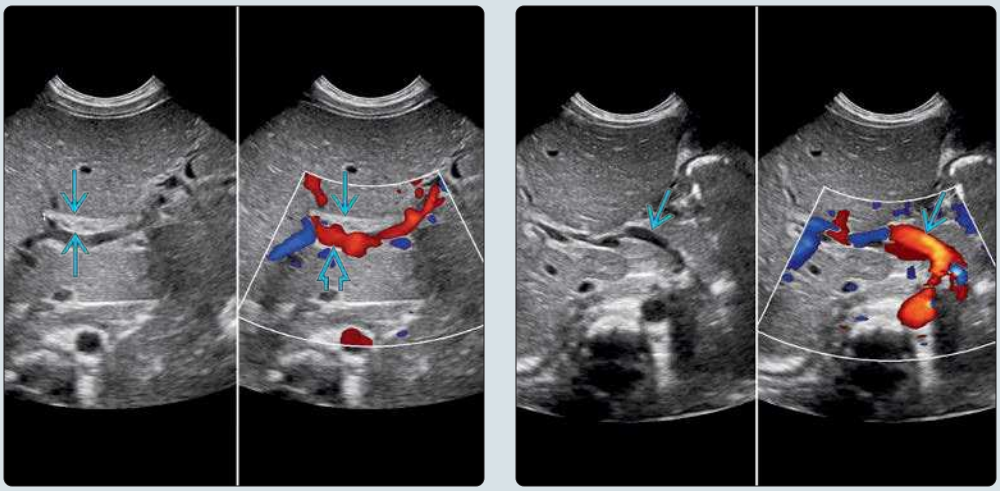
- Biliary atresia (BA): Absent or severely deficient extrahepatic biliary tree
  - Lengths & sites of ductal involvement vary

IMAGING

- US to exclude other causes of neonatal jaundice; characteristic findings can be very suggestive of BA
  - Absent or small irregular gallbladder with discontinuous echogenic wall in vast majority (gallbladder ghost sign)
  - Echogenic fibrous tissue (triangular cord sign) anterior to right portal vein at site of obliterated bile duct
  - No biliary ductal dilation; rare hilar cyst
  - Liver echotexture is typically normal early
  - Elevated shear wave velocities on elastography
- Hepatobiliary scan: No radiotracer excretion into intestines; gallbladder is visible in up to 25%
- Intraoperative cholangiogram: Absence of contiguous extrahepatic biliary system; segments may be visualized

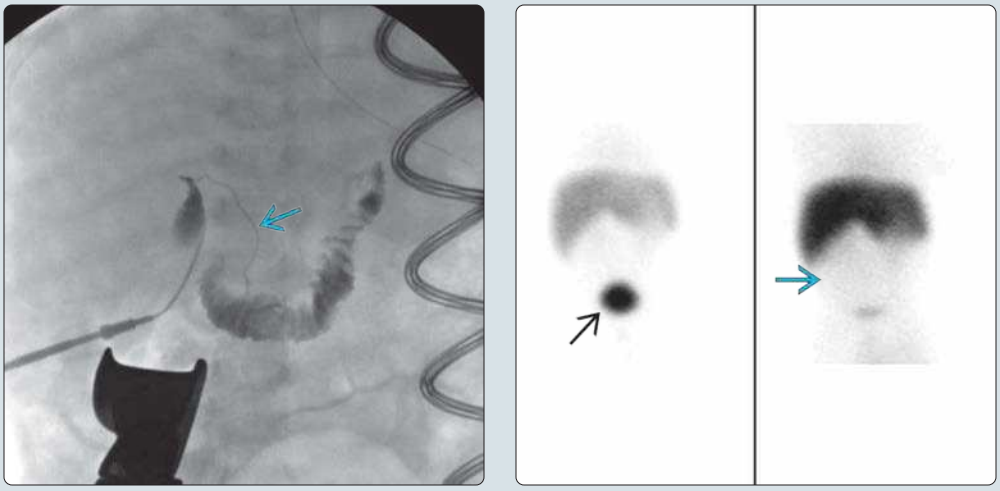
TOP DIFFERENTIAL DIAGNOSES

- Neonatal hepatitis
- Bile-plug syndrome
- Alagille syndrome
- Choledochal cyst



PATHOLOGY

- Associations: Preduodenal portal vein, interrupted IVC, situs anomalies, congenital heart disease, polysplenia (or asplenia), midgut malrotation in 10-20% (BASM syndrome)



CLINICAL ISSUES

- Neonatal jaundice with direct hyperbilirubinemia
  - ↑ GGT & ↑ MMP-7 are more specific for BA
- Gradual deterioration of hepatocyte function
- Kasai portoenterostomy is temporarily effective in 90% if performed < 2 months of age; ↓ to < 50% if > 3 months
- Liver transplant is ultimately required in most by adulthood, even with prompt Kasai

(Left) *Transverse grayscale & color Doppler liver ultrasounds in a 1-month-old with acholic stools, hyperbilirubinemia, & elevated GGT & MMP-7 show a thick (4-mm), echogenic focus ⇨ anterior to the right portal vein ⇨, the classic triangular cord sign.* **(Right)** *Transverse grayscale & color Doppler ultrasounds in same neonate show enlargement of main hepatic artery ⇨ at 3 mm, just above plane of partially visualized main portal vein. Biliary atresia (BA) was confirmed on biopsy.*

(Left) *Intraoperative cholangiogram in the same patient (through a normal gallbladder) shows a patent common bile duct ⇨ to the duodenum. However, even with occlusion of this segment during injection, no hepatic ducts could be visualized, consistent with BA.* **(Right)** *Hepatobiliary scintigraphy in a jaundiced infant shows no intestinal excretion of mebrofenin. The hepatic radiotracer is slowly excreted by the kidneys into the urinary bladder ⇨. A 24-hour delayed image also shows no intestinal radiotracer ⇨, typical of BA.*

TERMINOLOGY

Definitions

- Biliary atresia (BA): Inflammatory cholangiopathy of fetal life/infancy → progressive fibrosis & obliteration of extra- & intrahepatic bile ducts
  - Variable degrees of extrahepatic involvement

IMAGING

General Features

- Best diagnostic clue
  - US shows small & irregular or absent gallbladder (GB) with obliterated/fibrosed bile duct anterior to portal vein
  - Elevated shear wave elastography velocities
  - Hepatobiliary scan shows lack of radiotracer excretion into intestines
  - Intraoperative cholangiogram shows absence of contiguous biliary system from liver to duodenum

Ultrasonographic Findings

- Grayscale ultrasound
  - Liver echotexture is typically normal in neonatal period, though liver may be enlarged
  - GB is typically absent or abnormal
    - GB ghost triad: Small (< 15-19 mm in length), irregular shape, & discontinuous echogenic wall
    - GB length to width ratio of > 5.2
  - Extrahepatic bile ducts are usually not visible
    - Triangular cord sign: Echogenic obliterated/fibrotic remnant of hepatic duct anterior to right portal vein near porta hepatis
      - Thickness of cord at 3 mm vs. 4 mm influences sensitivity/specificity of sign
    - Dilated bile ducts (intra- or extrahepatic) are not present
      - Rare cystic BA form with hilar cyst
  - Main hepatic artery diameter > 2 mm
  - Associated anomalies of BA-splenic malformation (BASM) syndrome (in 20% of BA)
    - Polysplenia
    - Preduodenal portal vein
    - Transverse liver (showing continuity of portal veins in leftward hepatic tissue)
    - Malrotation of midgut
    - Interrupted inferior vena cava (IVC)
    - Cardiac anomalies
  - Post-Kasai procedure, liver often shows gradual fibrosis/cirrhosis with portal hypertension (HTN), splenomegaly, & varices
- Color Doppler
  - Useful to demonstrate main portal vein & hepatic artery when searching for echogenic triangular cord
  - ± ↑ subcapsular flow, telangiectatic capsular/subcapsular small vessels
- Shear wave elastography
  - Evaluates liver stiffness; shear wave velocity is significantly ↑ in BA
    - Recommended cutoff values range from 1.6-2.2 m/s
    - Helps differentiate BA from other causes of neonatal jaundice

MR Findings

- MRCP
  - Technically more challenging than ultrasound
  - Features: Abnormal GB, triangular cord > 5 mm, absent common bile duct
    - Note that complete biliary tree is only visible in 60-75% of normal patients < 3 months old
- T1, T2
  - Post-Kasai procedure, liver often shows gradual fibrosis/cirrhosis with portal HTN, splenomegaly, & varices

Nuclear Medicine Findings

- Hepatobiliary scan
  - Tc-99m disofenin (DISIDA) & mebrofenin (BRIDA) have highest hepatic extraction rates & shortest transit times of hepatobiliary radiotracers
  - Pretreat with oral phenobarbital (5 mg/kg/day in divided doses x 5 days)
    - Potent inducer of hepatic microsomal enzymes: Enhances biliary excretion & improves scintigraphic accuracy
    - Ursodeoxycholic acid has also been used as choleretic prescintigraphy (20 mg/kg every 12 hours for 48-72 hours) with good results
  - Hepatocyte uptake & extraction of radiotracer from blood pool is usually preserved in first 2-3 months of life, later deteriorates
  - Lack of excretion into intestines on 24-hour delayed images highly suggestive of BA or other extrahepatic occlusion
    - Excretion into intestines effectively excludes BA
  - Visualization of GB is not helpful; seen in 25%
  - High sensitivity (~ 100%) with 87% specificity, 91% accuracy

Other Modality Findings

- ERCP: Invasive, requires general anesthesia, uses ionizing radiation, & has significant morbidity (1-7%) & failure (3-14%) rates
- Intraoperative cholangiogram: Cannulation of any GB seen by US in attempt to opacify entire biliary system
  - May show segments of extrahepatic biliary system but will not show patency from liver to duodenum in BA
- Analysis of duodenal drainage is difficult to perform, not yet standardized; sensitivity of ~ 97%, specificity of ~ 93%

Imaging Recommendations

- Best imaging tool
  - US is performed 1st
    - Traditionally to exclude other causes of jaundice
    - Combination of characteristic findings can strongly suggest BA
  - If any GB is seen by US, some surgeons proceed directly to intraoperative cholangiogram with liver biopsy; if patent ducts are not demonstrated by cholangiogram, definitive surgery is performed

DIFFERENTIAL DIAGNOSIS

Neonatal Hepatitis

- Very common entity; usually self-limited medical disease but can be caused by hepatitis A, hepatitis B, cytomegalovirus, rubella, toxoplasmosis, α-1-antitrypsin deficiency, familial recurrent cholestasis, or other metabolic disorders

Bile-Plug Syndrome

- Due to cystic fibrosis, dehydration, sepsis, hemolytic disorders, or total parenteral nutrition

Alagille Syndrome

- Intrahepatic ducts are sparse & malformed
- Pulmonic stenosis, characteristic facies, butterfly vertebra, CNS arterial anomalies

Choledochal Cyst

- Localized dilation of extrahepatic biliary tree
- ± dilated intrahepatic ducts

PATHOLOGY

General Features

- Etiology
  - Hypoplastic, atretic, or fibrosed extrahepatic ducts that worsen in perinatal period
    - Variable sites/lengths of involvement
  - May result from prenatal biliary duct inflammation of unknown etiology
  - Proposed mechanism involves initial virus-induced, progressive T-cell-mediated inflammatory obliteration of bile ducts
- Associated abnormalities
  - Preduodenal portal vein, interrupted IVC, congenital heart disease, situs anomalies, & polysplenia (or asplenia) in BASM (10-20%)
  - Another 10-25% have other anomalies, most commonly involving abdomen & genitourinary tract
  - Molecular disorders involving bile formation, canalicular transporters, tight junction proteins, & inborn errors of metabolism are increasingly recognized

Gross Pathologic & Surgical Features

- Abnormal intra- & extrahepatic ducts; cirrhosis if diagnosis is delayed
- Most common form (~ 2/3): Complete atresia of extrahepatic ducts & GB
- ~ 12% of BA patients have patent proximal ducts & can have simple reanastomosis surgery; 88% require Kasai procedure

CLINICAL ISSUES

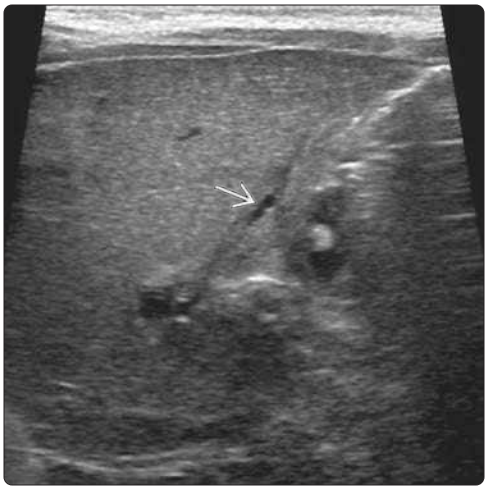
Presentation

- Most common signs/symptoms
  - Progressive conjugated (direct) hyperbilirubinemia in neonatal period
    - Bilirubin is unconjugated in sepsis, hepatitis, & metabolic hepatocellular diseases
- Other signs/symptoms
  - ↑ gamma-glutamyl transpeptidase (GGT)
  - ↑ matrix metalloproteinase-7 (MMP-7)
    - Suggested cutoff of 52.85 ng/mL has high sensitivity/specificity

Demographics

- Affects 1 in 10,000-13,000 newborn infants
- Jaundice is evident in immediate perinatal period
- Full-term infants > premature infants
- No sex or racial predilection

Natural History & Prognosis



- Prompt diagnosis is crucial to surgical success
  - Initially, hepatocyte function is preserved; hepatocyte function gradually deteriorates
- Kasai portoenterostomy is temporarily effective in 90% if performed < 2 months of age; ↓ to < 50% if > 3 months of age
  - Poor prognosis if total bilirubin is not < 2 mg/dL within 3 months of Kasai procedure
  - Steroid treatment post Kasai hastens clearance of jaundice; long-term effects are unclear
- Most patients ultimately require liver transplantation
  - < 18% who have prompt Kasai procedures avoid liver transplantation ≥ 20 years later
  - BA is most common reason for pediatric liver transplant

Treatment

- Kasai portoenterostomy: Intestinal loop is anastomosed to dissected surface of porta hepatis
- Liver transplant

(Left) *Transverse US in a jaundiced infant shows a small, irregularly shaped gallbladder ➡ despite an adequate fast. In addition to the gallbladder ghost, this patient also had a triangular cord sign of BA (not shown).* **(Right)** *Intraoperative cholangiogram through a hypoplastic gallbladder shows a short segment of common hepatic duct ➡ but no intestinal drainage, confirming BA. A portoenterostomy (Kasai procedure) followed.*

(Left) *Shear wave elastography US in an infant liver shows ↑ stiffness with a shear wave speed measuring 1.81 m/s (1 of 6-10 measurements obtained as part of the exam). Normal median values in the neonate/young infant are generally < 1.6 m/s.* **(Right)** *Intraoperative photograph during a Kasai procedure shows the discolored liver (related to chronic cholestasis), tiny spider angiomata ⇨, & lack of a common bile duct in the porta hepatis ➡ in this patient with BA.*

(Left) *Coronal T2 MR shows the cystic variant ➡ of BA in a 2-month-old with jaundice. No patent common bile duct or normal gallbladder was seen on MR.* **(Right)** *Paramidline US shows a preduodenal portal vein ➡ along the liver margin in an infant with BA & polysplenia, suggesting BA-splenic malformation syndrome. Look for other findings of heterotaxy in these patients, including congenital heart disease & midgut malrotation.*

Choledochal Cyst

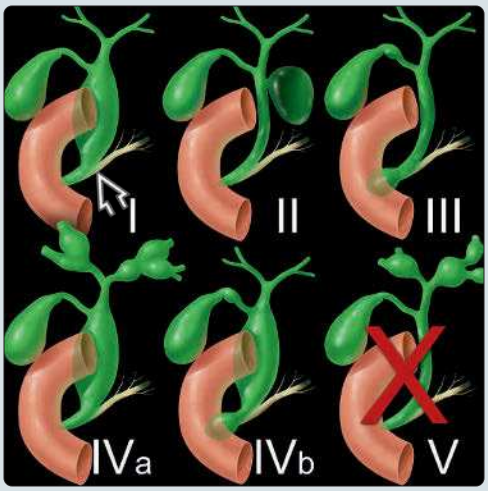
KEY FACTS

TERMINOLOGY

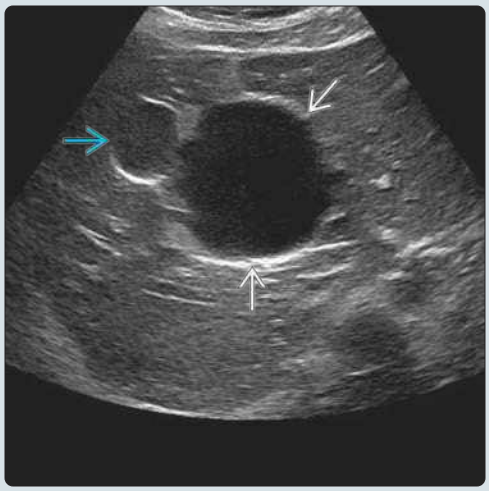
- Choledochal cyst: Spectrum of malformations involving extrahepatic & intrahepatic bile ducts
- Etiology may be due to pancreaticobiliary maljunction
  - Pancreatic duct joins common bile duct (CBD) proximal to sphincter of Oddi → reflux of pancreatic enzymes
- High risk (in long term) of cholangiocarcinoma if choledochal malformation is not resected

IMAGING

- US in child with jaundice & elevated liver enzymes
  - Round or tubular, cystic right upper quadrant mass separate from gallbladder
    - CBD dilation > 10 mm is very suggestive in child
- MRCP for detailed preoperative assessment of ductal anatomy & pancreaticobiliary maljunction
  - Delayed scan with hepatobiliary contrast agent may confirm connection of cyst to biliary tree

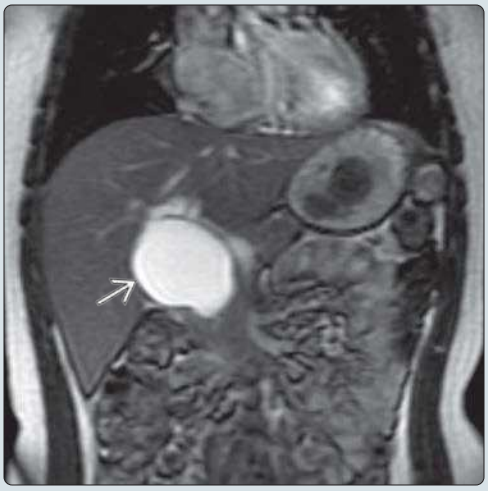


TOP DIFFERENTIAL DIAGNOSES



- Obstructing choledocholithiasis
- Cystic biliary atresia
- Gastrointestinal duplication cyst
- Primary sclerosing cholangitis
- Pancreatic pseudocyst

CLINICAL ISSUES



- Classification modified by Todani in 1977
  - Type I: Dilated CBD; most common (75-95%)
  - Type II: Diverticulum of duct
  - Type III: Choledochocele protruding into duodenum
  - Type IV: Discontinuous extrahepatic bile duct cysts, isolated (type IVb) or with intrahepatic cysts (type IVa)
  - Type V: Intrahepatic cystic dilations (Caroli disease); not considered choledochal cyst in modern era
- General treatment: Cyst resection & biliary diversion/hepatobiliary enterostomy

(Left) *Graphic shows the choledochal malformation classification by Todani, with type V now considered a separate ductal plate malformation (Caroli disease). Note the anomalous pancreaticobiliary junction with the pancreatic duct inserting into the common bile duct proximal to the sphincter of Oddi.* **(Right)** *Transverse ultrasound of the liver in a 9-year-old shows a large, simple-appearing cyst adjacent to a normal-appearing gallbladder.*

(Left) *Coronal SSFP MR in the same patient shows the elliptical cyst in the porta hepatis extending into the pancreatic head, typical of a choledochal cyst.* **(Right)** *Coronal MIP from an MRCP in the same patient shows a severely enlarged common hepatic duct & focally dilated central intrahepatic bile ducts in this case of a type IVa choledochal cyst.*

TERMINOLOGY

Synonyms

- Choledochal malformations, common bile duct (CBD) cyst or diverticulum, choledochocele, congenital biliary dilation

Definitions

- Choledochal cyst: Spectrum of malformations involving extrahepatic & intrahepatic bile ducts
- Etiology may be due to pancreaticobiliary maljunction
  - Pancreatic duct joins CBD proximal to sphincter of Oddi → biliary reflux of pancreatic enzymes
- ↑ cholangiocarcinoma risk in patients with choledochal malformations

IMAGING

General Features

- Best diagnostic clue
  - Marked dilation of biliary tree, focal or diffuse
- Location
  - May involve intrahepatic bile ducts, extrahepatic ducts, or both
- Size
  - Bile duct dilation > 10 mm is very suggestive in child
- Morphology
  - Ductal dilation may be continuous or multifocal

Ultrasonographic Findings

- Grayscale ultrasound
  - Round or tubular cystic right upper quadrant lesion separate from normal gallbladder
  - ± intrahepatic ductal dilation
- Color Doppler
  - Shows lack of flow in anechoic round/tubular mass, confirming cyst rather than abnormal vessel
  - Useful to demonstrate position & displacement of adjacent vessels

MR Findings

- T2, MR cholangiogram to show
  - Anatomy of dilated ducts & variants
  - Pancreaticobiliary maljunction
- T1 C+ with hepatocyte-specific contrast agent
  - Delayed images can confirm biliary connection of cyst

Nuclear Medicine Findings

- Hepatobiliary scan shows early photopenia at hilum with delayed filling
- Can help show bile leak after resection

Other Modality Findings

- ERCP & PTC are usually reserved for complex cases or intervention

Imaging Recommendations

- Best imaging tool
  - US in child with jaundice & elevated liver enzymes
    - Shows dilated biliary tree & extent of ductal involvement
  - MRCP for detailed preoperative assessment of ductal anatomy
    - Position/length of common channel to pancreatic duct
    - Has replaced preoperative percutaneous cholangiogram
  - Hepatobiliary nuclear scans for functional evaluation

DIFFERENTIAL DIAGNOSIS

Obstructing Choledocholithiasis

- Stone disease may cause obstruction at several levels
- Ductal dilation is typically < 10 mm

Cystic Biliary Atresia

- Uncommon biliary atresia form with hilar cyst
- No intrahepatic duct dilation
- Hypoplastic or absent gallbladder
- Echogenic cord anterior to right portal vein

Gastrointestinal Duplication Cyst

- Duodenal cyst can involve porta hepatis
- Look for wall gut signature sign & peristalsis of cyst

Primary Sclerosing Cholangitis

- Irregular beading with dilation & stenosis of bile ducts
- Look for findings of ulcerative colitis

Pancreatic Pseudocyst

- Round pancreatic head collection can mimic dilated CBD
- History/findings of recent pancreatitis

Caroli Disease

- Localized saccular ectasia of intrahepatic bile ducts
- Central dot sign of encased portal radicles

PATHOLOGY

General Features

- Etiology
  - Primary theory: Anomalous junction of common biliary & pancreatic ducts → conduit for mixing (& reflux) of pancreatic enzymes & bile
    - Dilation & structural weakness of CBD (with destruction of elastic fibers) after reflux of pancreatic secretions in animal models
    - Unclear that this leads to marked duct dilation
    - Pancreaticobiliary maljunction can occur ± congenital biliary dilation
    - Consider pancreaticobiliary maljunction in cases of pediatric pancreatitis
  - Additional theories: ↓ in ganglion cells in narrow portion of bile duct causing ↑ intraluminal pressure; preceding viral infection; familial pattern of inheritance; failure of recanalization
- Genetics
  - Autosomal recessive polycystic kidney disease is often associated with Caroli syndrome
    - Ciliopathy underlies these disorders (different etiology from remaining choledochal malformations)

Staging, Grading, & Classification

- Classification modified by Todani in 1977

- Type I: Segmental or diffuse fusiform dilation of CBD; most common variety (75-95% of cases); IA is unilocular saccular dilation of entire CBD; IB is unilocular saccular dilation of distal CBD; IC is unilocular fusiform CBD & hepatic duct dilation
- Type II: Diverticulum of duct, usually protruding from lateral wall
- Type III: Choledochocele, most often of duodenal wall (protruding into duodenal lumen)
- Type IV: Multiple discontinuous extrahepatic bile duct cysts, isolated (type IVb) or with Caroli-type intrahepatic biliary cysts (type IVa)
- Type V: Ductal plate malformation with multifocal cystic dilations of intrahepatic bile ducts (Caroli disease); **not** considered type of choledochal cyst in modern era
  - Caroli syndrome (large & small bile duct ectasia with congenital hepatic fibrosis) > > Caroli disease (large bile duct ectasia only)
- Additional proposed modifications
  - Type ID: Dilated cystic duct + dilated CBD & common hepatic duct (CHD)
  - Type VI: Isolated dilation of cystic duct
- Intrahepatic ductal dilation preoperatively may resolve postoperatively, changing cyst classification

Gross Pathologic & Surgical Features

- Range in diameter from few centimeters to > 15 cm
- Cyst wall is thickened, fibrotic, & occasionally calcified in adults

Microscopic Features

- Varying degrees of chronic inflammation
- Biliary epithelium lining cyst is often intact in infants
- Type III cysts (choledochocele) are often lined by duodenal mucosa but occasionally have biliary epithelium
- Goblet-cell metaplasia & epithelial dysplasia with nuclear hyperchromasia, irregularity, & loss of polarity have been described
  - May play role in subsequent development of carcinoma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Prolonged neonatal cholestasis, so-called infantile obstructive cholangiopathy
  - Infants: Jaundice, acholic stools, hepatomegaly, & palpable abdominal mass
  - Adults: Upper abdominal pain, jaundice, cholangitis, & pancreatitis

Demographics

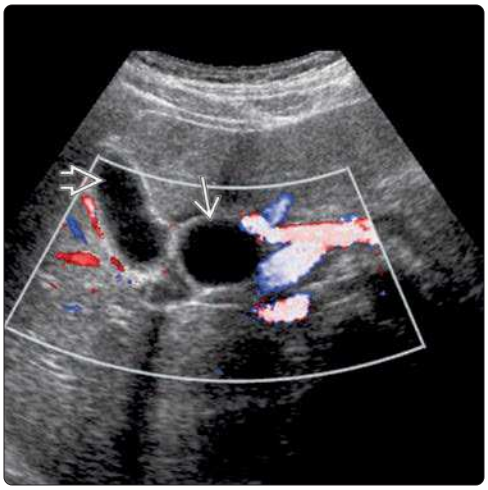
- Age
  - 2/3 diagnosed before 10 years of age
  - Only 20% diagnosed in adults
- Sex
  - M:F = 1:3-4
- Epidemiology
  - More common in Asian than Western countries
    - 1 in 2,000,000 live births in USA vs. 1 in 1,000 live births in Japan

Natural History & Prognosis

- Low-grade biliary obstruction may develop cirrhosis & portal hypertension (HTN)
- Complications: Bile duct perforation, biliary stone formation, bacterial cholangitis with subsequent hepatic abscess & sepsis, biliary strictures, low-grade biliary obstruction → cirrhosis & portal HTN, development of bile duct carcinomas
  - Prevalence of cancer (adenocarcinoma) in choledochal cysts: 2-18% (5-35x ↑ risk)
  - Caroli disease & Caroli syndrome are associated with risk of cholangiocarcinoma (100x that of general population)

Treatment

- Type I: Complete surgical excision + biliary drainage procedure, typically Roux-en-Y choledochojejunostomy
  - Excision with hepaticoduodenostomy has higher rate of bile reflux/gastritis
- Type II: Usually excised entirely; defect in CBD is closed primarily over T tube
  - Type II is usually diverticula of bile duct
- Type III: Choledochocele with diameter < 3 cm may be approached endoscopically with sphincterotomy
  - Cysts > 3 cm are often associated with some degree of duodenal obstruction → excised surgically using transduodenal approach
- Type IV: Dilated extrahepatic duct is completely excised + biliary-enteric drainage procedure
  - No surgery specifically directed at intrahepatic ductal disease
- Type V: Caroli disease (no longer considered type of choledochal cyst), when limited to single hepatic lobe (usually left), may be resected
  - Liver transplantation is necessary in diffuse disease with liver failure
- Internal & external drainage, without cyst excision → unacceptably high rate of cholangitis, does not alter malignant potential
- After resection of choledochal cysts
  - < 0.5% develop cancer before 18 years
  - 11% develop cancer as adult; mean age: 42 years



DIAGNOSTIC CHECKLIST

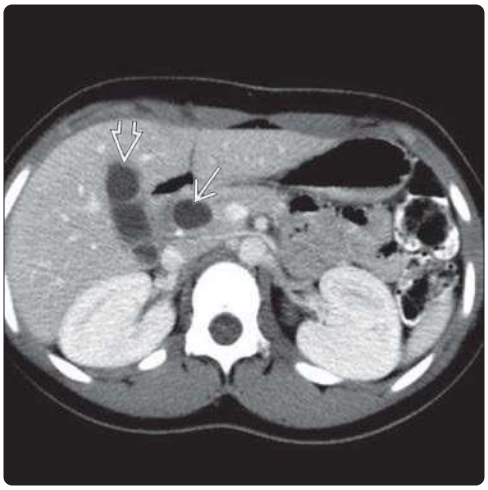


Image Interpretation Pearls

- Bile duct measuring > 10 mm in childhood is nearly always due to choledochal malformation

(Left) *Transverse color Doppler ultrasound through the right upper quadrant in a 12-year-old shows a normal gallbladder ⇨ with diffuse, marked dilation of the common bile duct ⇨.* **(Right)** *Axial CECT in the same patient shows marked dilation of the common bile duct ⇨ with a normal gallbladder ⇨. Mild intrahepatic ductal dilation was also noted (not shown).*

(Left) *Intraoperative cholangiogram in the same patient shows moderate intrahepatic ⇨ & marked extrahepatic ⇨ ductal dilation. However, the biliary tree still drained into the duodenum ⇨. This patient had a type I choledochal malformation repaired surgically.* **(Right)** *Axial T2 FS MR images in a 10-year-old girl with acute pancreatitis ⇨ show a type III choledochal cyst (choledochocele) ⇨ protruding into the duodenal lumen.*

(Left) *Longitudinal split screen grayscale & color Doppler ultrasounds in a 4-year-old girl show focal dilation of the common bile duct ⇨, measuring 10.6 mm, without intrahepatic biliary dilation.* **(Right)** *Coronal MIP from an MRCP in the same patient shows focal dilation of the common bile duct ⇨ with a normal gallbladder ⇨ & no intrahepatic biliary dilation.*

Caroli Disease

KEY FACTS

TERMINOLOGY

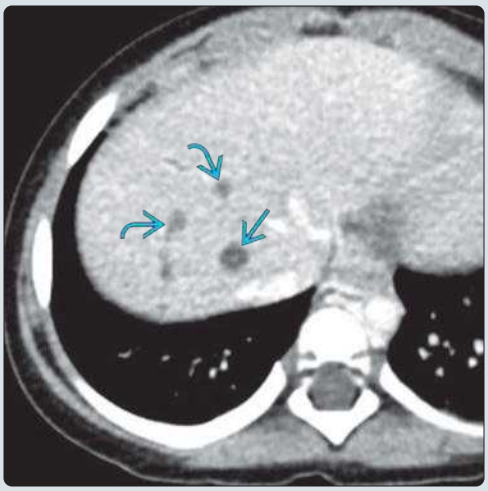
- Caroli disease (CD): Saccular dilation of large intrahepatic bile ducts (IHBD)
- Congenital hepatic fibrosis (CHF): Presence of fibrotic tissue between portal tracts with persistent intralobular ducts
- Caroli syndrome (CS): CD + CHF &/or autosomal recessive polycystic kidney disease (ARPKD)

IMAGING

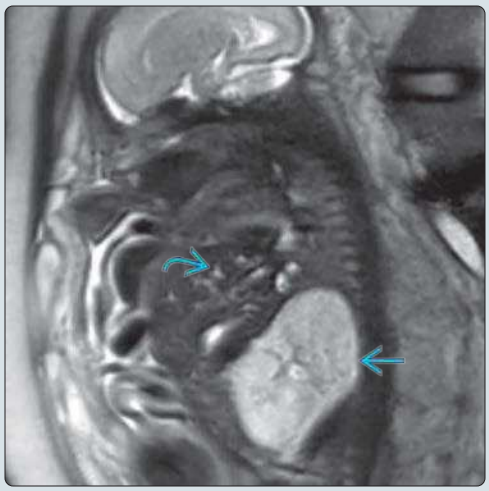
- Multiple intrahepatic "cysts" connected to biliary tree
- Central dot sign: Cross section of dilated IHBD surrounds portal vein radicle
- Hepatic involvement can be segmental, lobar, or diffuse

TOP DIFFERENTIAL DIAGNOSES

- Choledochal cyst
- Primary sclerosing cholangitis

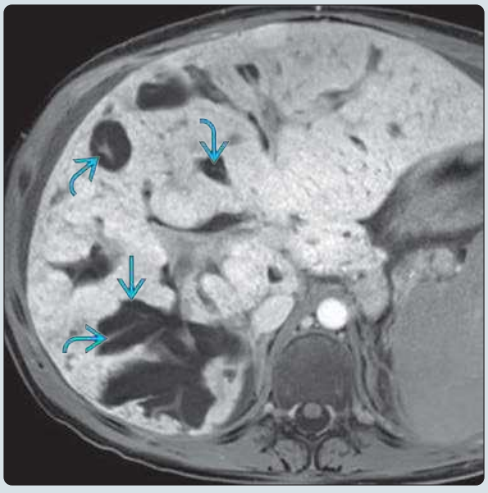


PATHOLOGY

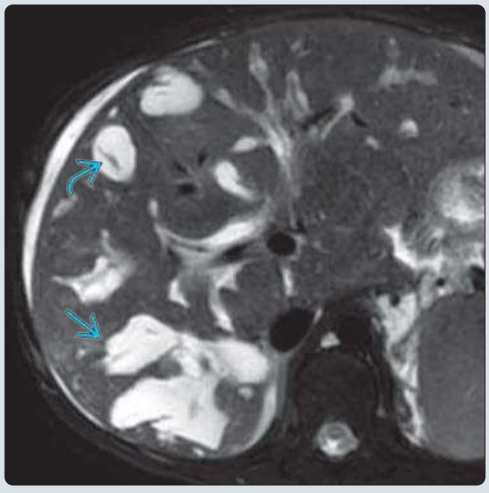


- CD, CS, & ARPKD are caused by impaired ciliary function (ciliopathy)

CLINICAL ISSUES



- Rare (1:1 million of general population)
- Patients can be diagnosed at any age
- Symptoms/complications
  - RUQ pain, fever, & jaundice
  - Stone formation (95%), recurrent cholangitis
  - Hepatic fibrosis with portal hypertension → hepatosplenomegaly & gastrointestinal tract bleeding
  - Cholangiocarcinoma ultimately develops in 7% of patients (100x ↑ risk compared to general population)
- Treatment
  - Ursodeoxycholic acid to ↓ bile duct stones; broad-spectrum antibiotics for cholangitis
  - Biliary decompression
  - Resection ranging from segmentectomy to transplant



(Left) *Axial CECT shows dilated intrahepatic bile ducts. The largest dilated bile duct has a central dot characteristic of Caroli disease. This image highlights that Caroli disease may only affect a portion of the liver.* **(Right)** *Sagittal T2 SSFSE fetal MR shows abnormal dilated intrahepatic bile ducts, a markedly enlarged hyperintense kidney, & oligohydramnios. The constellation of findings is consistent with Caroli disease associated with autosomal recessive polycystic kidney disease (ARPKD).*

(Left) *Axial T1 FS MR in a patient with Caroli disease shows massively dilated intrahepatic bile ducts. The portal radicle is visible within the center of the dilated ducts.* **(Right)** *Axial T2 FS MR in the same patient shows massively dilated intrahepatic bile ducts. Because of the plane of imaging, the central dot of the portal radicles appears more linear.*

TERMINOLOGY

Definitions

- Caroli disease (CD): Saccular dilation of large intrahepatic bile ducts (IHBD)
- Congenital hepatic fibrosis (CHF): Presence of fibrotic tissue between portal tracts with persistent intralobular ducts
- Caroli syndrome (CS): CD + CHF &/or autosomal recessive polycystic kidney disease (ARPKD)

IMAGING

General Features

- Best diagnostic clue
  - Central dot sign: Portal radicle encased by dilated IHBD
  - Cholangiography confirms direct communication of segmental saccular ductal ectasia with IHBDs
- Location
  - Hepatic involvement can be segmental, lobar, or diffuse
  - Common bile duct is classically spared; dilation (in up to 50%) due to cholangitis, stones
- Size
  - Varying diameters of cystic-appearing dilated IHBDs in same patient (ranging from millimeters to centimeters)

Ultrasonographic Findings

- Grayscale ultrasound
  - Numerous "cysts" scattered throughout liver ± visible biliary communication
  - Intraluminal portal vein sign = central dot sign
    - Portal radicle surrounded by cystic-appearing IHBD
  - Intraductal bridging septa: Echogenic septa completely or incompletely traversing dilated IHBDs
- Color Doppler
  - Flow within central dot (portal vein radicle)

MR Findings

- T2WI
  - Numerous "cysts" in segmental, lobar, or diffuse distribution
  - Small, round, hypointense central dots are visible in dilated, hyperintense cystic-appearing IHBDs
    - Due to flow void of portal radicle in IHBD cross section
    - ± larger biliary filling defects from stones, sludge
  - Renal involvement in 60% with CS
    - Enlarged hyperintense kidneys
      - Due to diffuse medullary or corticomedullary cysts/tubular ectasia
- T1WI C+
  - Central dot of enhancement (of portal vein radicle) is surrounded by dilated IHBD
  - Heterogeneous enhancement of liver parenchyma from hepatic fibrosis
- MRCP
  - Direct communication of segmental saccular ductal ectasia with IHBDs
  - ± intraluminal filling defects of sludge or calculi within dilated IHBDs

DIFFERENTIAL DIAGNOSIS

Choledochal Cyst

- Extrahepatic bile ducts are affected in 90%
- Type IV: Cystic dilation of common bile duct ± intrahepatic ducts (type IVa has intrahepatic biliary cysts)
- Not inherited; no renal disease

Primary Sclerosing Cholangitis

- Dilation of both IHBD & extrahepatic bile ducts with multiple irregular strictures
- ± history of ulcerative colitis

PATHOLOGY

General Features

- Etiology
  - CD, CS, & ARPKD are caused by impaired ciliary function (ciliopathy)
    - Ciliopathy during fetal development leads to ductal plate malformation

Staging, Grading, & Classification

- CD is no longer considered as type of choledochal cyst

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Intermittent abdominal/right upper quadrant pain
- Other signs/symptoms
  - Recurrent cholangitis, fever, & jaundice
  - Hepatic fibrosis with portal hypertension → hepatosplenomegaly & GI bleeding
  - Renal failure may dominate clinical picture in infants
- Complications
  - Stone formation (95%), recurrent cholangitis, end-stage liver disease
  - Cholangiocarcinoma (ultimately) in 7% of patients
    - 100x ↑ risk compared to general population

Demographics

- Age
  - Patients can be diagnosed at any age
  - Patients diagnosed in infancy have more severe disease
- Epidemiology
  - Rare; 1:1 million of general population

Treatment

- Ursodeoxycholic acid (to ↓ biliary stones) & broad-spectrum antibiotics (for cholangitis)
- Biliary decompression: External drainage & biliary-enteric anastomosis are effective but with ↑ risk of infection
- Resection ranging from segmentectomy to transplant

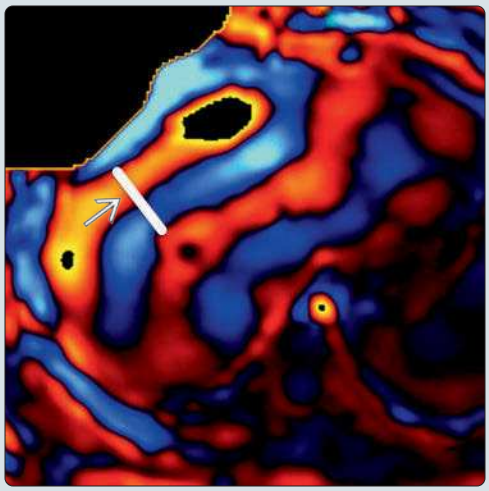
KEY FACTS

TERMINOLOGY

- Cirrhosis: Liver disease characterized by bridging fibrosis
  - Variety of underlying disorders may lead to cirrhosis

IMAGING



- Nodular contour of liver; easiest to see along free margin
- US: Liver has coarsened echotexture
- MR: Lace-like signal of fibrosis
  - MR can detect underlying deposition (fat, iron, etc.)
  - Hepatocyte-specific contrast agents allow characterization of nodules
- MR or US elastography can determine liver stiffness as marker of fibrosis
- Progressive fibrosis leads to ↓ hepatic size
- Signs of portal hypertension: Ascites, splenomegaly, varices

CLINICAL ISSUES

- Symptoms & treatment depend on underlying condition; potential etiologies include
  - Biliary atresia
  - Choledochal cyst
  - Alagille syndrome
  - Progressive familial intrahepatic cholestasis
  - Viral hepatitis
  - α-1 antitrypsin deficiency
  - Cystic fibrosis
  - Wilson disease
  - Nonalcoholic fatty liver disease
  - Autoimmune hepatitis
  - Primary sclerosing cholangitis
  - Total parenteral nutrition cholestasis
  - Post-Fontan physiology
- Early stages of fibrosis can be reversed by treating underlying condition
- Treatment for end-stage liver disease: Liver transplant
- Cirrhotic patients are typically screened every 6 months for hepatocellular carcinoma

(Left) *Axial T2 FS MR in a patient with congenital hepatic fibrosis shows lace-like ↑ signal at the periphery of the liver, consistent with hepatic fibrosis. The spleen is enlarged, suggesting portal hypertension.* **(Right)** *Axial image from MR elastography shows abnormal ↑ thickness ➡ of the sound wave traversing the liver. The liver stiffness was measured at 8.5 kPa in this patient (normal is < 2.7).*

(Left) *Transverse ultrasound in an adolescent with cystic fibrosis shows a small, nodular appearance of the liver. The liver nodularity ➡ is best seen on the free edge of the liver. The underlying hepatic echotexture is coarsened.* **(Right)** *Axial T1 opposed-phase MR in an adolescent with autoimmune hepatitis shows an abnormal lace-like pattern of fibrosis throughout the liver.*

TERMINOLOGY

Definitions

- Cirrhosis: Liver disease characterized by bridging fibrosis

IMAGING

Ultrasonographic Findings

- Liver has coarsened echotexture
- Nodular contour is easier to see on free margin
- Doppler US to evaluate portal flow

CT Findings

- Morphologic changes of liver on CT or MR
  - ↓ in liver size with progressive fibrosis
  - Atrophy of right lobe & left medial section
  - Hypertrophy of caudate & left lateral section
  - Widening of porta hepatis & hepatic fissure
  - Enlargement of gallbladder fossa
  - Nodular contour of liver
  - Changes related to portal hypertension: Splenomegaly, ascites, varices

MR Findings

- Fibrosis may appear as lace-like ↓ T1 & ↑ T2 signal
- Elastography can determine liver stiffness
- Hepatocyte-specific contrast agent: Characterizes nodules
- Detects potential causes of fibrosis, such as fat or iron deposition
- MR venogram can determine portal venous flow direction & reveal varices

Imaging Recommendations

- Best imaging tool
  - MR provides complete evaluation: Fat or iron deposition, liver stiffness, vascular supply, & tumor screening

CLINICAL ISSUES

Treatment

- Depends on underlying condition
- Early stages of fibrosis can be reversed by treating underlying condition
- Treatment for end-stage liver disease: Liver transplant

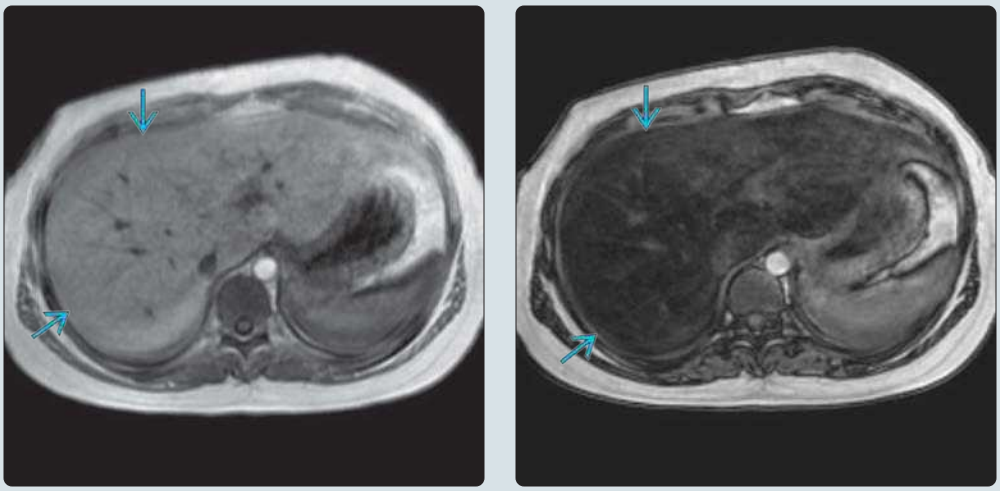
Common Causes of Cirrhosis in Children

Disease	Key Facts
Biliary Obstruction	
Biliary atresia	Presents in 1st weeks of life; early diagnosis is essential; ultrasound, serum MMP7, & biopsy are replacing HIDA scan for diagnosis
Choledochal cyst	Types classified via Todani classification system
Intrahepatic Cholestasis	
Alagille syndrome	Bile ducts are malformed & reduced in number; associated with tetralogy of Fallot, vertebral anomalies, & abnormal facies
Progressive familial intrahepatic cholestasis	Autosomal recessive disorder of intrahepatic cholestasis; presents in neonatal period
Genetic	
α-1 antitrypsin deficiency	Liver disease occurs in 10-15%; onset of lung disease is usually between 20-50 years of age
Cystic fibrosis	Liver disease occurs in 25%; caused by plugging of bile ducts
Wilson disease	Caused by defect in copper transport; copper accumulates in liver, brain, & eyes
Other	
Nonalcoholic fatty liver disease	Associated with obesity & metabolic syndrome; can measure excess fat content in liver with MR
Hepatitis B	Most common cause of viral cirrhosis in children & adolescents
Autoimmune hepatitis	Hepatocellular inflammation of unknown cause; elevated levels of serum IgG
Primary sclerosing cholangitis	Associated with inflammatory bowel disease (particularly ulcerative colitis)
TPN	TPN-associated cholestasis can occur rapidly; more common in infants after bowel resection
Post-Fontan physiology	Caused by chronic passive venous congestion & volume overload

KEY FACTS

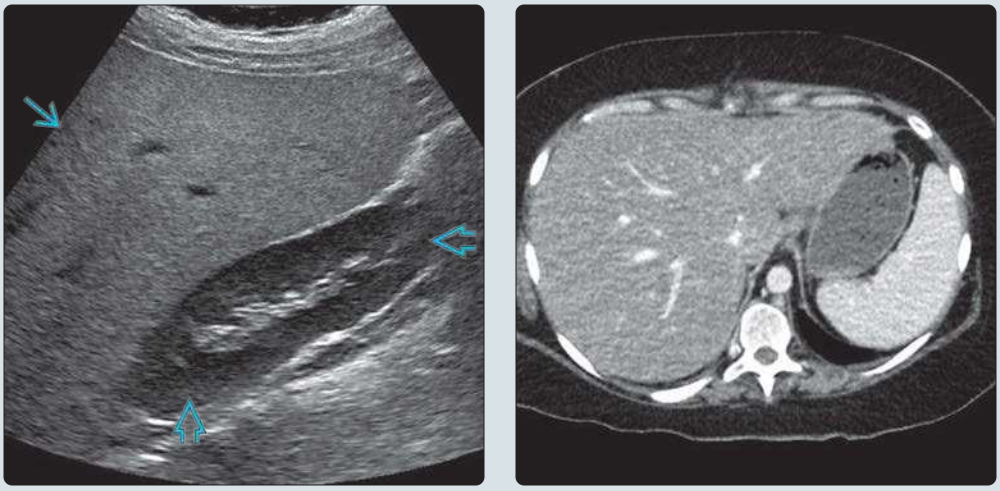
TERMINOLOGY

- Hepatic steatosis: > 5% of hepatocytes with fat infiltration
- Nonalcoholic fatty liver disease (NAFLD): Steatosis with metabolic syndrome &/or abnormal liver function enzymes
- Nonalcoholic steatohepatitis (NASH): Abnormal hepatic fat content with inflammatory activity or fibrosis



IMAGING

- NECT: ↓ liver attenuation relative to spleen
  - Normally 8-10 Hounsfield units (HU) > spleen
- CECT: Difficult to assess steatosis due to variable enhancement of liver & spleen depending on phase
  - Venous/delayed images: Liver HU ≥ 35 lower than spleen
- MR: Only imaging test that can quantify hepatic fat
  - Multiple methods to measure hepatic fat content
    - MR spectroscopy
    - Chemical shift imaging
      - Signal dropout on opposed-phase vs. in-phase T1
  - Steatosis is defined as fat fraction > 5%
- Ultrasound shows diffusely ↑ hepatic echogenicity
  - Liver much more echogenic than right kidney
  - Poor through transmission of sound waves
    - ↓ visualization of echogenic portal triads & right hemidiaphragm



CLINICAL ISSUES

- Most common cause of chronic liver disease in children
  - NAFLD is present in 38-40% of obese patients
  - Most commonly presents between 11-13 years of age
- Risk factors
  - Modifiable: Obesity, sedentary lifestyle, high intake of sugar-sweetened beverages, sleep apnea
  - Nonmodifiable risk factors: Male, Hispanic origin, family history, parental obesity, intestinal microbiome, premature birth, low birth weight
- Thought to represent progression from simple steatosis → NAFLD → NASH → cirrhosis
- Treatment: Weight loss with dietary modification & exercise

(Left) *Axial T1 in-phase MR in an 11-year-old girl with a history of obesity & steatohepatitis (confirmed with biopsy) shows a normal appearance of the liver.* **(Right)** *Axial T1 opposed-phase MR in the same patient shows diffuse signal loss throughout the liver due to steatosis. The fat fraction was measured at 32% in this patient (but is normally < 5%).*

(Left) *Longitudinal ultrasound in the same patient shows diffusely ↑ echogenicity of the liver relative to the kidney with loss of the normally visualized echogenic portal triads, typical of hepatic steatosis.* **(Right)** *Axial CECT in an adolescent status post bone marrow transplant shows diffusely low attenuation of the liver compared to the spleen. The liver measured 63 Hounsfield units (HU), while the spleen measured 119 HU, consistent with hepatic steatosis.*

TERMINOLOGY

Definitions

- Hepatic steatosis: Fatty infiltration of > 5% of hepatocytes
- Nonalcoholic fatty liver disease (NAFLD): Steatosis with metabolic syndrome &/or abnormal liver function tests
- Nonalcoholic steatohepatitis (NASH): Abnormal hepatic fat content with inflammatory activity or fibrosis

IMAGING

General Features

- Best diagnostic clue
  - Fatty infiltration of hepatic parenchyma, demonstrable by variety of modalities/techniques

CT Findings

- CT is not reliable method to identify steatosis

MR Findings

- Steatosis is defined as MR fat fraction > 5%
- Multiple methods to measure hepatic fat content
- MR spectroscopy
  - Considered imaging gold standard for quantification
    - Measures protons in acyl groups of liver tissue triglycerides
    - Able to measure fat content across spectrum of severity & confounding diseases
      - Not susceptible to effects from fibrosis, iron, or glycogen
  - Rarely performed in most clinical practices
- Chemical shift imaging
  - Spin-echo (Dixon) technique
    - By altering echo time, creates in-phase & opposed-phase images based on differing precession frequencies of protons in fat vs. water
      - Signal of fat & water protons are additive for in-phase
      - Signal cancellation for opposed-phase (if both fat & water protons are present in same voxel)
  - Modified Dixon technique: GRE images ↓ scan time
  - Multipoint Dixon technique: Adds more echo series, allowing for better fat quantification
  - Proton density fat fractionation
    - Uses spoiled gradient-recalled echo images
- MR elastography
  - ↓ liver stiffness, ↑ liver volume in hepatic steatosis
  - Liver stiffness > 2.8 kPa suggests significant fibrosis (> stage 2) in children with chronic liver disease

Ultrasonographic Findings

- Diffusely ↑ hepatic echogenicity
  - Liver much more echogenic than right kidney
- Poor through transmission of sound waves
  - Poor visualization of echogenic portal triads
  - Poor visualization of echogenic right hemidiaphragm

Imaging Recommendations

- Best imaging tool
  - MR: Currently only modality that can quantify hepatic fat

DIFFERENTIAL DIAGNOSIS

Cirrhosis

- End result of various chronic liver diseases → shrunken, nodular morphology with bridging fibrosis at histology

Cystic Fibrosis

- Steatosis occurs in 23-75% of patients, potentially due to malnutrition, oxidative stress, insulin resistance

PATHOLOGY

Staging, Grading, & Classification

- Histologic fat content measures % of cells containing fat
- MR fat fraction measures % of liver tissue made up of fat

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Obesity (NAFLD is present in 38-40%)
  - Vague abdominal pain, irritability, fatigue
  - Hepatomegaly

Demographics

- Age
  - Most commonly presents between 11-13 years
  - Onset may be associated with puberty
- Sex
  - More common in males
- Ethnicity
  - Affects Hispanic > White > Black patients
- Epidemiology
  - Most common cause of chronic liver disease in children
  - Affects 7-10% of all pediatric patients, 34-38% of obese children
- Risk factors
  - Modifiable risk factors: Obesity, sedentary lifestyle, ↑ fructose intake, sleep apnea
  - Nonmodifiable risk factors: Male, Hispanic origin, family history, parental obesity, intestinal microbiome, premature birth, low birth weight

Natural History & Prognosis

- Thought to represent progression from simple steatosis → NAFLD → NASH → cirrhosis
  - Unknown why some patients progress & others do not
  - Progression to NAFLD or NASH does not guarantee further progression of disease

Treatment

- Weight loss with dietary modification & exercise

SELECTED REFERENCES

Hepatic Venoocclusive Disease

KEY FACTS

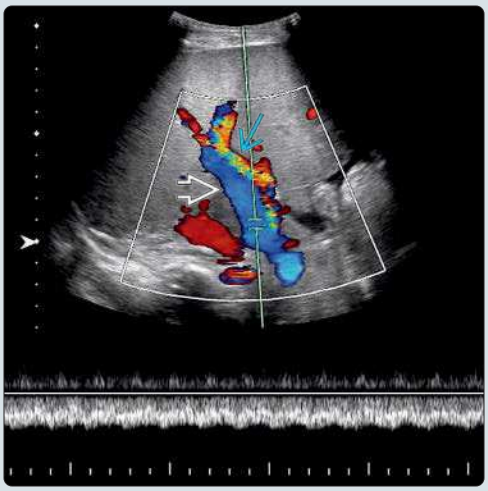
TERMINOLOGY

- Occlusion of hepatic sinusoids → clinical triad of jaundice, ascites, & hepatomegaly
- Occurs after stem cell transplantation or certain tumor chemotherapy regimens
  - Usually within 2-3 weeks after stem cell transplantation
    - Late occurrences are more common in children

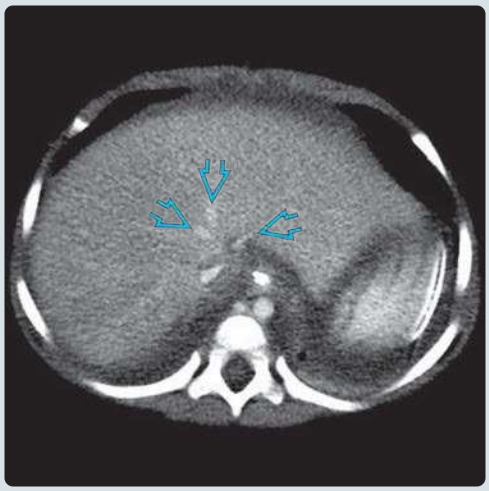
IMAGING

- Ultrasound with Doppler
  - Hepatomegaly, ascites
  - Reversed or to-&-fro flow in portal veins
    - Specific but not sensitive
  - Elevated resistive indices in hepatic arteries (> 0.75)
- CECT or MR
  - Enlarged, heterogeneous liver, ascites, small-caliber hepatic veins
- Newer diagnostic criteria (EBMT) are clinical & do not require imaging

TOP DIFFERENTIAL DIAGNOSES

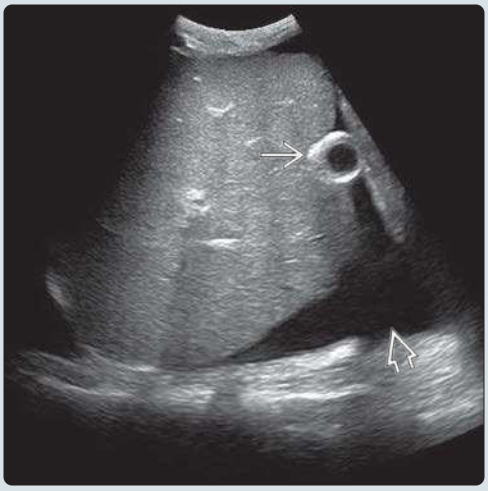


- Graft-vs.-host disease
- Infection

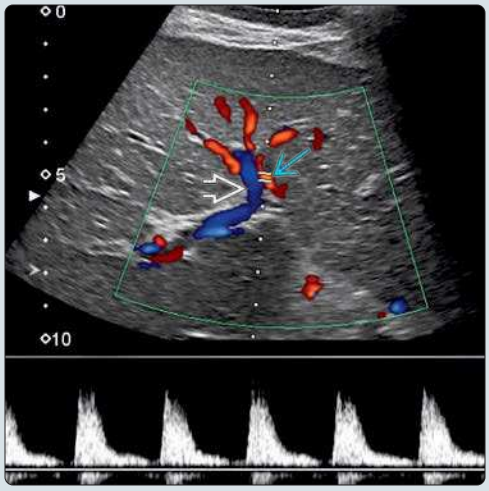


PATHOLOGY

- Toxicity from chemotherapy &/or radiation therapy leads to small-vessel endothelial damage & sinusoidal occlusion



CLINICAL ISSUES



- Presents with jaundice, ascites, hepatomegaly
- May have elevated bilirubin, thrombocytopenia, ± hepatic synthetic dysfunction
- Treatment includes
  - Supportive care, withdrawal of hepatotoxic therapy
  - Defibrotide is approved to treat moderate to severe disease

(Left) *Pulsed Doppler ultrasound in a 2-year-old girl receiving chemotherapy for neuroblastoma, now presenting with new onset of ascites & elevated bilirubin, shows that flow in the main portal vein is reversed (hepatofugal flow), typical of hepatic venoocclusive disease. Note the normal hepatopetal flow in the hepatic artery.* **(Right)** *Axial CECT in the same patient shows small-caliber but patent hepatic veins, typical of hepatic venoocclusive disease.*

(Left) *Longitudinal grayscale ultrasound in a 13-year-old girl on chemotherapy with newly diagnosed hepatic venoocclusive disease shows ascites & marked thickening of the gallbladder wall. The portal venous flow was reversed (not shown).* **(Right)** *Transverse pulsed Doppler ultrasound in a 5-year-old patient status post stem cell transplantation shows reversed portal venous flow with high-resistance waveforms in the adjacent hepatic artery, suggesting hepatic venoocclusive disease.*

TERMINOLOGY

Synonyms

- Sinusoidal obstruction syndrome

Definitions

- Therapy-induced occlusion of hepatic sinusoids → clinical triad of jaundice, ascites, & hepatomegaly
- Onset is typically within weeks of stem cell transplantation (SCT); later onset can occur in children
  - Secondary to myeloablative chemotherapy &/or irradiation preceding SCT
- Risk may be specific to different diseases & treatment regimens

IMAGING

General Features

- Best diagnostic clue
  - Hepatomegaly & ascites status post SCT or chemotherapy
  - Reversed flow in portal veins is specific but not sensitive

Radiographic Findings

- Displaced bowel loops due to hepatomegaly & ascites

Ultrasonographic Findings

- Grayscale ultrasound
  - Nonspecific hepatomegaly
  - Ascites
  - ± splenomegaly
- Pulsed Doppler
  - Reversed or to-&-fro flow in portal vein
  - Elevated resistive indices in hepatic artery (> 0.75)
- Color Doppler
  - Reversed portal vein flow
  - Small but patent hepatic veins
  - ± recanalized paraumbilical vein

CT Findings

- CECT
  - Enlarged, heterogeneous liver
  - ± small-caliber hepatic veins
  - Ascites

MR Findings

- Similar to CECT
  - Hepatomegaly, ascites, small-caliber hepatic veins

Imaging Recommendations

- Best imaging tool
  - Ultrasound with Doppler

DIFFERENTIAL DIAGNOSIS

Graft-vs.-Host Disease

- Affects skin, bowel, liver, lung
- Diffusely thickened, potentially featureless bowel

Infection

- Typical pathogens, particularly cytomegalovirus
- Variable imaging findings

PATHOLOGY

General Features

- Etiology
  - Toxicity from chemotherapy or radiation therapy leads to endothelial cell activation & endothelial damage
    - Sloughed endothelial lining ultimately embolizes & occludes sinusoids
  - Direct toxicity to hepatocytes also contributes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Jaundice, ascites, hepatomegaly
- Other signs/symptoms
  - European Society for Bone Marrow Transplantation (EBMT) Pediatric Criteria
    - Requires 2 or more of
      - Thrombocytopenia
      - ↑ bilirubin
      - ↑ weight
      - Hepatomegaly
      - Ascites
    - Can occur any time after SCT
    - Doppler US is not part of diagnostic criteria
      - Used to evaluate ascites & hepatomegaly
  - Baltimore & Modified Seattle criteria were developed for adults
    - ↑ bilirubin, ↑ weight, ascites, hepatomegaly
      - Within 21 days of SCT

Demographics

- Age
  - Occurs in children & adults
- Epidemiology
  - Affects 8-14% of SCT patients; up to 60% of high risk

Natural History & Prognosis

- Modified EBMT severity grading
  - Mild, moderate, severe, very severe
  - Based on clinical features, lab abnormalities & multiorgan system dysfunction

Treatment

- Supportive care, withdrawal of hepatotoxic therapy
- Defibrotide is approved to treat moderate to severe disease

Abernethy Malformation

KEY FACTS

TERMINOLOGY

- Congenital extrahepatic portosystemic shunt
  - Type 1: Absence of portal vein (PV) with extrahepatic portosystemic shunt
  - Type 2: Intact but hypoplastic PV with extrahepatic portosystemic shunt

IMAGING

- Absent or hypoplastic PV without findings of PV thrombosis or portal hypertension
- Extrahepatic portosystemic shunt, typically draining to IVC
- Small liver with multiple nodules
- Occlusion venogram is required to identify origin of very small PV branches & plan definitive shunt occlusion

TOP DIFFERENTIAL DIAGNOSES

- PV thrombosis
- Intrahepatic portosystemic shunt

PATHOLOGY

- Hepatic lesions in 65-75% of patients; 50-80% have multiple lesions
  - Most common: Focal nodular hyperplasia, nodular regenerative hyperplasia, adenoma, hepatocellular carcinoma
- Congenital heart disease in ~ 15% of patients

CLINICAL ISSUES

- F:M ratio of 3:1 in type 1 Abernethy malformation; no sex predilection in type 2
- May be diagnosed in utero or up to 7th decade of life
  - Type 1 malformations typically present at younger age with hepatic dysfunction, failure to thrive
  - Risks of hepatic encephalopathy & hepatopulmonary syndrome ↑ with age

(Left) *Digital subtraction angiography (DSA) in a 3-month-old boy with an Abernethy type 1A malformation shows the splenic vein & superior mesenteric vein joining to form the portal vein. There is a connection between the portal vein & inferior vena cava.* **(Right)** *Transverse color Doppler ultrasound in a 3-month-old boy with an Abernethy type 1A malformation shows a connection between the portal vein & inferior vena cava.*

(Left) *Sagittal CECT MIP in a 3-month-old boy with an Abernethy type 1A malformation shows a connection between the portal vein & inferior vena cava.* **(Right)** *Oblique noncontrast MR venogram MIP in a 7-month-old boy with Abernethy malformation shows a connection between the portal vein & inferior vena cava.*

TERMINOLOGY

Synonyms

- Congenital extrahepatic portosystemic shunt

Definitions

- Congenital portosystemic shunt characterized by variable absence of intrahepatic portal vein (PV)
  - Type 1: Absence of intrahepatic PV with extrahepatic portosystemic shunt
  - Type 2: Intact but hypoplastic intrahepatic PV with extrahepatic portosystemic shunt

IMAGING

General Features

- Best diagnostic clue
  - Absent or hypoplastic intrahepatic PV without findings of PV thrombosis or portal hypertension (HTN)
    - Type 1: Absent intrahepatic PV with shunt vessel draining into inferior vena cava (IVC)
    - Type 2: Hypoplastic intrahepatic PV with partial extrahepatic drainage into IVC
  - Liver findings: Small liver with multiple nodules

CT Findings

- CECT
  - Venous phase shows portosystemic shunt ± small PV
  - Coronal plane & maximum-intensity projection images are useful to evaluate shunt & portal system

MR Findings

- T1WI C+ FS
  - Hepatocyte-specific contrast agent is helpful to delineate nodules & identify malignant degeneration
- MRV
  - Use techniques to ↑ spatial resolution to best evaluate portosystemic shunt

Ultrasonographic Findings

- Grayscale ultrasound
  - Absent PV with ↑ periportal echogenicity (related to fibrosis) in expected region of PV
  - Small liver with multiple nodules
- Color Doppler
  - Absent or ↓ PV flow without cavernous transformation
  - Enlarged hepatic artery
  - Extrahepatic shunt

Angiographic Findings

- Occlusion venogram may be required to identify origin of very small PV branches & plan definitive shunt occlusion
  - Shunt imaged via transjugular or transfemoral approach
  - Type 1: Uniform size of portal trunk; PV enters left side of IVC
  - Type 2: Dilation of portal trunk before joining IVC; PV enters anterior aspect of IVC
- Occlusion venogram can identify tiny PV branches, changing diagnosis from type 1 to type 2

Imaging Recommendations

- Protocol advice
  - Maximum-intensity projection images are useful to show small vessels or shunt vessels
  - Occlusion venogram may be required to identify origin of small PV branches

DIFFERENTIAL DIAGNOSIS

Portal Vein Thrombosis

- Filling defect with absence of portal venous flow (US) or enhancement (CECT or MR)
- Cavernous transformation with numerous small hilar venous collaterals
- Secondary findings of portal HTN

Intrahepatic Portosystemic Shunt

- Abnormal connection between branches of PV & hepatic veins or IVC
- Can spontaneously close in 1st year of life

PATHOLOGY

General Features

- Associated abnormalities
  - Hepatic lesions in 65-75% of patients; 50-80% of those have multiple lesions
    - Most common: Focal nodular hyperplasia, nodular regenerative hyperplasia, adenoma, hepatocellular carcinoma
  - Congenital heart disease in ~ 15% of patients

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hyperammonemia can lead to neurocognitive deficits
  - Hepatopulmonary syndrome
  - Pulmonary arterial HTN

Demographics

- Age
  - May be diagnosed in utero or up to 7th decade of life
- Sex
  - Type 1: F:M = 3:1
  - Type 2: No sex predilection
- Epidemiology
  - Type 1 accounts for ~ 60% of all diagnoses

Natural History & Prognosis

- Risks for hepatic encephalopathy & hepatopulmonary syndrome ↑ with age
- Liver lesions are at risk for malignant transformation

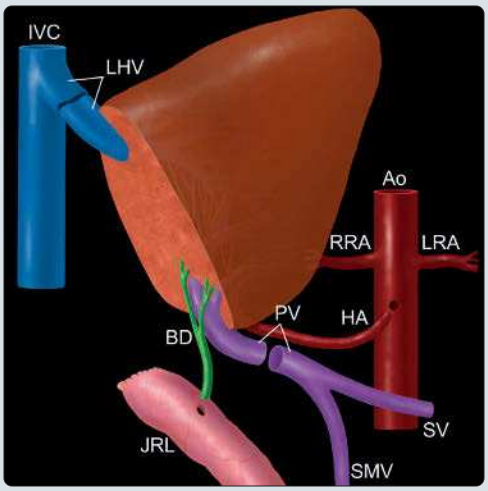
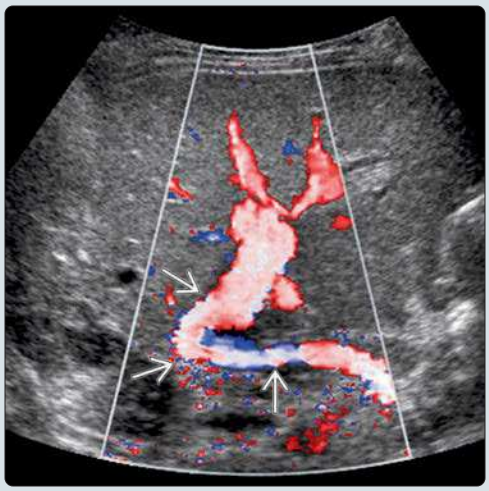
Liver Transplant Complications

KEY FACTS

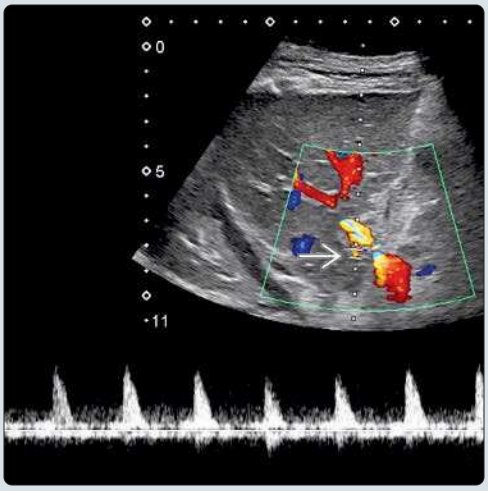


TERMINOLOGY



- Segmental liver transplant
  - In children, left lobe or lateral segment of left lobe of liver is usually transplanted
  - Developed to ↑ supply of liver transplants for children
    - Usually adult donor, cadaveric or living
- Vascular complications
  - Hepatic arterial thrombosis (HAT) or stenosis
  - Hepatic artery pseudoaneurysm at anastomosis
  - Portal vein stenosis or thrombosis
  - Hepatic vein stenosis
  - Anastomotic bleeding
- Biliary complications
  - Biliary stenosis or leak
- Extrahepatic fluid collection
  - Hematoma, seroma, bile leak, abscess
  - Usually found soon after surgery
- Posttransplant lymphoproliferative disorder (PTLD)
- Infection
- Organ rejection

CLINICAL ISSUES



- Treatment options
  - Vascular complications
    - Vasodilator for arterial spasm early
    - Balloon dilation ± stent for narrowing
    - Thrombectomy for early HAT
    - Surgical revision
    - Retransplant
  - Biliary complications
    - Balloon dilation
    - ± placement of percutaneous biliary drain
    - Surgery
  - PTLD
    - Reduce immunosuppression
    - ± chemotherapy

(Left) *Graphic shows segmental left lobe liver transplant anatomy: Bile duct (BD), jejunal Roux loop (JRL), portal vein (PV), superior mesenteric vein (SMV), splenic vein (SV), hepatic artery (HA), aorta (Ao), right & left renal arteries (RRA & LRA), inferior vena cava (IVC), left hepatic vein (LHV).* **(Right)** *Transverse color Doppler US shows the typical curved course of the main PV ➔ & HA following segmental liver transplant. Note how the neoporta is located along the side of the liver rather than in the center.*

(Left) *Pulsed Doppler US of HA edema/vasospasm immediately after transplant shows a small-caliber HA ➔ with a high resistive index (RI). Elevated RIs can be seen with downstream arterial narrowing/thrombus or parenchymal edema. Sampling distal to a focus of narrowing may give a parvus et tardus waveform (not shown).* **(Right)** *Transverse color Doppler US shows acute PV thrombosis with hypoechoic clot ➔ in the main PV & robust HA flow ➔ next to the clot.*

TERMINOLOGY

Synonyms

- Segmental liver transplant = partial liver transplant, split liver transplant, reduced-size liver transplant, living donor liver transplant

Definitions

- Segmental liver transplant
  - In children, left hepatic lobe or lateral segment of left lobe is usually transplanted
    - Technique was developed to ↑ supply of liver transplants for children
  - Usually adult donor, cadaveric or living
- Vascular complications
  - Hepatic artery (HA): Vasospasm (immediate postoperative timeframe), HA thrombosis (HAT) or stenosis, pseudoaneurysm
  - Portal vein stenosis (PVS) & thrombosis
  - Hepatic vein stenosis (HVS)
  - Anastomotic bleeding
- Biliary complications
  - Anastomotic: Biliary stenosis or leak
  - Nonanastomotic: Intrahepatic biliary stenosis → dilation, biloma, intraductal sludge or stone
- Other complications
  - Extrahepatic collections: Hematoma, seroma, abscess
  - Posttransplant lymphoproliferative disorder (PTLD)
  - Infection: Abscess (hematologic spread), cholangitis (ascending route)
  - Organ rejection
  - Acute kidney injury
  - Diaphragmatic hernia post transplant

IMAGING

Ultrasonographic Findings

- Grayscale ultrasound
  - HAT: Echogenic clot within artery
  - HA pseudoaneurysm: Round, anechoic structure near HA anastomosis
  - PVS: Narrowing (usually at anastomosis), poststenotic dilation
  - PV thrombosis: Echogenic clot in PV lumen
  - HVS: Distended HVs
  - Biliary complications: Biliary dilation or collection
  - PTLD: Adenopathy, mass(es) within abdomen
- Color Doppler
  - Doppler values associated with normal graft status
    - Resistive index (RI): 0.5-0.8; some studies observe normal RI up to 0.9 in immediate postoperative period
    - HA peak systolic velocity (PSV): 50-200 cm/s is associated with normal graft status within 1st year post transplant
  - Doppler values associated with vascular complications
    - RI: < 0.5 in immediate postoperative period
    - HA PSV: > 200 cm/s or < 50 cm/s is associated with ↑ vascular & biliary complications
    - PV velocity: < 30 cm/s or HV velocity < 25 cm/s
  - HA spasm/edema/stenosis: Hours to days after transplant
    - High RI proximal to narrowing
      - Graft edema may also cause ↑ RI
    - Elevated PSV at narrowing
    - Tardus parvus waveform distal to narrowing
  - HAT: Absent or reversed flow in HA
    - ↑ RI proximal to clot
    - Distal tardus parvus waveform (if any distal flow)
    - Abundant PV flow
  - HA pseudoaneurysm: Swirling to-&-fro color flow filling hypoechoic focus along artery
  - PVS: Focal narrowing
  - PV thrombosis: ↓, absent, or reversed flow
    - May see abundant HA flow in response
  - HVS: Dampened atrial pulsations
    - May normally be dampened early from edema
  - Arteriovenous fistula: Turbulent flow with spectral broadening, low arterial RI, arterialization of veins
    - Occurs weeks-months after transplant, post biopsy
  - ↑ role for contrast-enhanced ultrasound

CT Findings

- CECT
  - HAT or stenosis
    - Peripheral, wedge-shaped, low-attenuation regions
    - Unopacified HA
    - May lead to biliary necrosis with biloma or biliary dilation due to strictures
  - HA pseudoaneurysm at anastomosis
  - PVS & thrombosis
    - Stenosis: Focal narrowing, ± poststenotic dilation
      - Note that adult donor PV is often larger
    - Thrombosis: Unopacified PV, portosystemic shunts, splenomegaly, ascites
      - Residua of pretransplant portal hypertension
  - HVS
    - Distended HVs
    - Congested liver with delayed enhancement
  - Biliary strictures from necrosis → dilation
  - Extrahepatic fluid collection
    - Hematoma, bile, abscess, or seroma
    - Aspiration is required for determination of contents
  - PTLD: Wide range of appearances; may be adenopathy or masses almost anywhere in body
  - Infection: Fluid collections, solid organ lesions, dilated bile ducts (cholangitis)
  - Organ rejection: Nonspecific, biopsy is required

MR Findings

- T1WI C+ FS
  - Hepatocyte-specific contrast agent can confirm biliary leak on delayed images
- MRA
  - HAT: Signal loss beyond thrombus due to absent flow
  - HA pseudoaneurysm: High-signal focal enlargement of artery near anastomosis
- MRCP
  - Biliary dilation: High-signal dilated bile ducts

Nonvascular Interventions

- Transhepatic cholangiography

- Biliary strictures: Anastomotic or nonanastomotic → biliary dilation proximal to stricture
- Biliary sludge/stones: Intraluminal filling defects → proximal biliary dilation

Imaging Recommendations

- Best imaging tool
  - Vasculature & biliary system
    - 1st-line screening: Ultrasound with Doppler
    - If possible arterial abnormality, may consider CTA
    - HAT: Angiogram with intervention
    - PVS/thrombosis: Percutaneous transhepatic portogram
    - HVS: Venogram with intervention
    - Biliary stenosis: Percutaneous transhepatic cholangiogram (PTC)
  - Biloma or fluid collection: MR vs. CECT
    - MR with hepatobiliary contrast agent can confirm biliary leak on delayed images
  - PTLD or infection: CECT, MR, or PET

PATHOLOGY

General Features

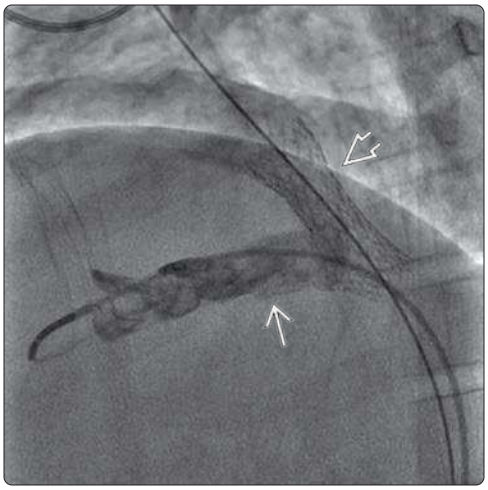
- Etiology
  - Biliary complications: Depends on surgical reconstruction technique, length of cold ischemia time, immunologic reactions, HAT, CMV infection, ABO incompatibility
  - PTLD: EBV related in 90%, usually EBV(-) recipient → EBV infection post transplant

CLINICAL ISSUES

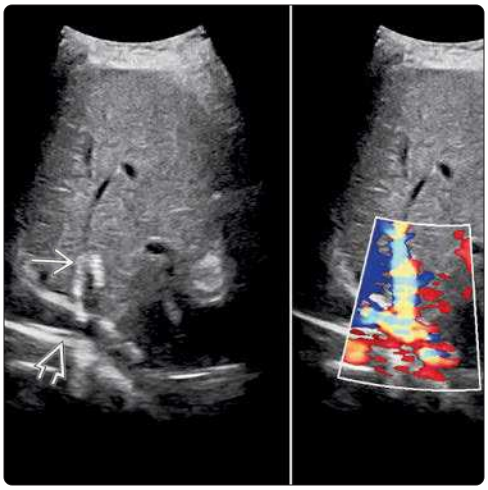
Presentation

- Most common signs/symptoms
  - Depends on complication
    - HAT: Elevated liver function tests (LFTs)
    - PVS: GI bleeding, splenomegaly, ascites
    - Biliary strictures: Jaundice, cholangitis
    - PTLD: Nonspecific & variable, EBV seroconversion
    - Infection: Fever

Demographics



- Epidemiology
  - HAT
    - Most common vascular complication & cause of graft loss/retransplant (6%)
    - ↑ risk in pediatrics due to small arteries
    - Interposition grafts or anastomosis with recipient aorta may ↓ HAT incidence when arteries are < 3 mm
    - Children do better than adults because of higher rate of recruitment of collateral arteries
  - PV thrombosis
    - High risk in segmental liver transplant because of short PV segment from donor (3%)
    - Higher risk in patients with ↓ PV flow because of splenectomy, portosystemic collaterals
    - Higher risk in PV < 4 mm & weight < 7 kg
  - HVS/thrombosis or inferior vena cava (IVC) obstruction
    - Most often at anastomosis with IVC/atrium
    - Can be due to twisting when transplant moves/shifts
  - Anastomotic bleeding
    - Occurs early & usually requires surgical repair
  - Biliary complications
    - Higher incidence in segmental liver transplants
    - May lead to chronic graft failure, biliary cirrhosis
  - PTLD
    - More common in children than adults; 1-20% incidence
  - Rejection
    - Diagnosed by biopsy or acoustic radiation force impulse (ARFI) elastography
    - Acute cellular rejection is seen in up to 35% in 1st year
  - Infection: Leading cause of death (43%)



Treatment

- Vascular complications
  - HA vasospasm: Vasodilators
  - HA stenosis: Balloon dilation ± stent
    - Surgical repair if balloon resistant
  - HAT: Thrombectomy if early, HA revision, thrombolytic therapy; may require retransplantation
  - PVS: Percutaneous transhepatic portogram → balloon dilation ± stent; surgical revision if necessary
  - HVS: Balloon dilation ± stent, or surgery
- Biliary complications
  - Anastomotic biliary stricture
    - Balloon dilation ± placement of percutaneous biliary drain or surgery
    - Stents have variable long-term patency
  - Nonanastomotic biliary stricture
    - Percutaneous biliary drain & balloon dilation
  - Biliary obstruction
    - 20% have no biliary dilation despite obstruction on PTC
    - Thus, if patient is jaundiced with ↑ LFTs → PTC & possible percutaneous drain
  - Biloma: Drain if infected
  - Biliary leak: Surgery if large; heals with drain if small
  - Biliary sludge/stones: Remove percutaneously ± drain
- PTLD: Reduce immunosuppression ± chemotherapy
- Infection: Antibiotics, antifungals, ± drainage
- Rejection: Immune modulation

(Left) *Lateral image during a venogram shows a stent placement to treat combined hepatic vein ➡ & IVC ➡ stenoses several years after a segmental liver transplant.* **(Right)** *Tranverse split screen grayscale & color Doppler US images following venoplasty & stent placement in the same patient show a patent hepatic vein ➡ & IVC ➡. Artifact from the metallic stent walls is minimized on live scans & dynamic clips.*

(Left) *Axial FDG PET/CT through the lung base in a liver transplant patient shows multiple FDG-avid soft tissue lesions along the pleura ➡ in this case of PTLD. Adenopathy & masses from PTLD can occur anywhere in the body.* **(Right)** *Transverse color Doppler US of the left hepatic lobe shows a heterogeneous ovoid lesion ➡ with mild surrounding hyperemia in a patient with fever & abdominal pain. This was confirmed to represent a posttransplant hepatic abscess.*

(Left) *Axial CECT through a liver transplant shows a rounded, low-density collection ➡ along the staple line in addition to abundant ascites ➡ in this case of bile leak/biloma.* **(Right)** *Transverse pulsed Doppler US shows turbulent flow (by both color ➡ & pulsed Doppler waveform ➡) in a tortuous vessel extending to the anterior capsule, consistent with an arteriovenous fistula, likely secondary to a prior percutaneous liver biopsy.*

Wandering Spleen

KEY FACTS

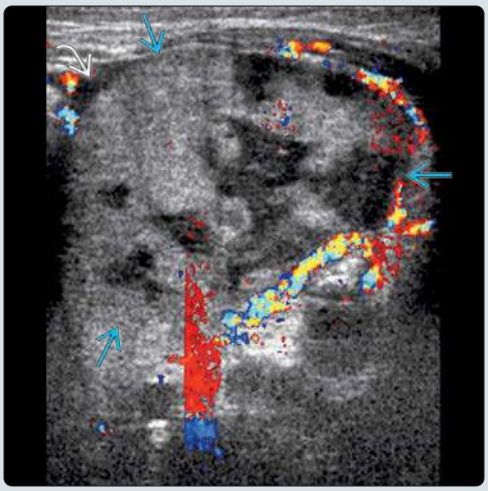
TERMINOLOGY

- ↑ mobility of spleen due to abnormal ligamentous attachments (congenitally absent vs. ↑ laxity)
  - Long, vascular pedicle predisposes to acute or chronic intermittent torsion ± infarction

IMAGING

- Absence of normal spleen in LUQ
- Enlarged spleniform mass in mid lower abdomen
- With torsion: Twisted hilar vessels, fat edema, & ascites
  - CT: Globally ↓ splenic enhancement ± residual capsular/rim enhancement
  - US: Hypovascular, heterogeneous splenic parenchyma

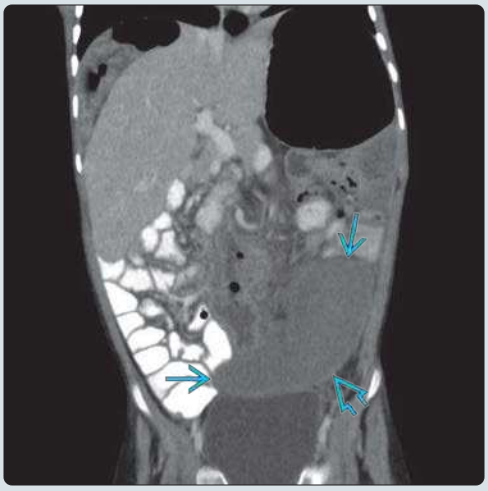
TOP DIFFERENTIAL DIAGNOSES



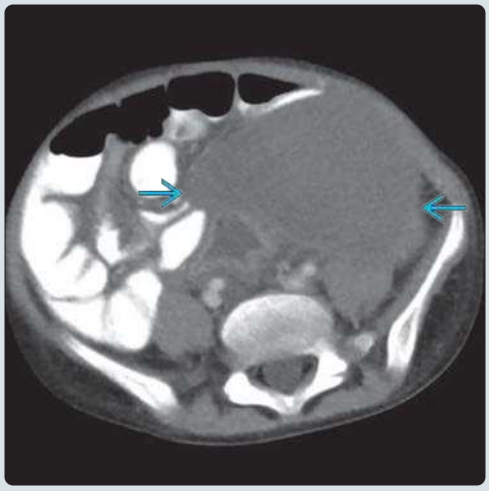
- Sickle cell disease
- Heterotaxy syndromes
- Lymphoma
- Splenic trauma
- Mononucleosis

PATHOLOGY

- Due to abnormal splenic fixation by gastrosplenic, splenophrenic, splenorenal, splenocolic ligaments
  - Congenital absence of ligaments (affects young children)
  - Acquired laxity (affects women of reproductive age)
- Associated abnormalities include gastric volvulus, diaphragmatic hernia, & prune-belly syndrome



CLINICAL ISSUES



- Presentation
  - Pain, vomiting, palpable mobile abdominal mass
  - Asymptomatic (15%)
  - Rarely: Bowel obstruction, pancreatitis, bleeding varices
- Treatment
  - Without infarction: Detorsion + splenopexy
  - With infarction: Splenectomy + vaccinations, antibiotic prophylaxis for asplenia

(Left) *Transverse color Doppler ultrasound in a newborn with a palpable abdominal mass shows a spleniform mass ⇨ in the mid to lower left abdomen with heterogeneous internal echotexture. No internal vascular flow is seen in the mass. Mild ascites ⇨ is noted. A normal spleen was not found in the LUQ.* **(Right)** *Axial CECT of the same patient shows diminished enhancement of the spleniform left abdominal mass ⇨. A torsed & infarcted wandering spleen was surgically removed.*

(Left) *Coronal CECT in a 9-year-old patient with abdominal pain & a history of repaired gastroschisis shows an inferiorly displaced, enlarged, & nonenhancing spleen ⇨ in the mid to lower left abdomen, consistent with splenic torsion. There is a subtle residual rim of capsular enhancement ⇨. No splenic tissue is seen in the LUQ.* **(Right)** *Axial CECT in the same patient shows the torsed nonenhancing spleen ⇨. (Courtesy H. Baskin, MD.)*

TERMINOLOGY

Definitions

- ↑ mobility of spleen due to abnormal ligamentous attachments (absence vs. ↑ laxity)
  - Long, vascular pedicle predisposes to acute or chronic intermittent torsion ± infarction

IMAGING

General Features

- Best diagnostic clue
  - Hypoenhancing/hypovascular spleniform abdominal mass in mid to lower abdomen
  - Absence of normal spleen in high LUQ/hypochondrium

Radiographic Findings

- Splenic shadow may be enlarged or absent from LUQ
- ± mid to lower abdominal mass displacing bowel

CT Findings

- Absence of splenic tissue in normal high posterior LUQ
- Displaced, enlarged spleniform mass
- Elongated vascular pedicle
  - Chronically enlarged splenic vein ± adjacent varices
- With torsion
  - Whirl or corkscrew sign of twisted vascular pedicle
    - Swirling lucent & dense bands at hilum due to vessels surrounded by thickened folds of peritoneum & fat
  - Global nonenhancement of splenic parenchyma is more likely than heterogeneous enhancement from congestion or infarcts
    - May have preserved capsular/rim enhancement
  - Ascites + perisplenic fat edema

Ultrasonographic Findings

- Absence of splenic tissue in normal posterior LUQ
- Displaced spleniform mass with variable echogenicity
  - Heterogeneous from congestion or infarcts
- Internal vascular flow variable
  - Lack of flow confirms torsion + ischemia
- Vascular pedicle
  - Chronically dilated, tortuous vessels
  - Twisting, narrowing ± thrombosis in torsion

Imaging Recommendations

- Best imaging tool
  - Ultrasound is excellent screening modality in children with abdominal pain &/or mass
    - Altering patient position (to right decubitus) during scan can demonstrate mobility of wandering spleen
  - CECT is historically more accurate in setting of torsion

DIFFERENTIAL DIAGNOSIS

Sickle Cell Disease

- Splenic infarction
  - Heterogeneous spleen acutely
  - Calcified, small spleen chronically
- Splenic sequestration
  - Acutely enlarged, heterogeneous spleen in young patients due to blood trapping by vasoocclusion

Heterotaxy Syndromes

- Spleen may be absent (asplenia), malpositioned, or of unusual configuration (polysplenia)

Lymphoma

- Enlarged spleen with round, hypoenhancing masses

Splenic Trauma

- Broad imaging spectrum from isolated laceration to shattered, devascularized spleen

Mononucleosis

- Nonspecific splenomegaly + adenopathy
- Fever, pharyngitis, fatigue

PATHOLOGY

General Features

- Etiology
  - Abnormal splenic fixation by gastrosplenic, splenophrenic, splenorenal, &/or splenocolic ligaments
    - Congenital absence (affects young children)
    - Acquired laxity (affects women of reproductive age)
- Associated abnormalities include gastric volvulus, diaphragmatic hernia, prune-belly syndrome

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Without torsion: Palpable mobile mass or asymptomatic
  - With torsion: Abdominal pain, palpable mass
- Other signs/symptoms
  - Fever, vomiting ± bowel obstruction, pancreatitis (due to pancreatic tail involvement), bleeding varices

Demographics

- Bimodal distribution: < 1 year of age (M > F) or 3rd decade of life (F > > M)

Natural History & Prognosis

- Acute torsion (up to 65%): Splenic infarction, peritonitis; potentially fatal
- Chronic complications
  - Intermittent torsion: Recurrent pain, splenomegaly (rupture risk from trauma), varices
  - Functional or iatrogenic asplenia: Infections, sepsis

Treatment

- Without infarction: Detorsion + splenopexy
- With infarction: Splenectomy + vaccinations, antibiotic prophylaxis for asplenia

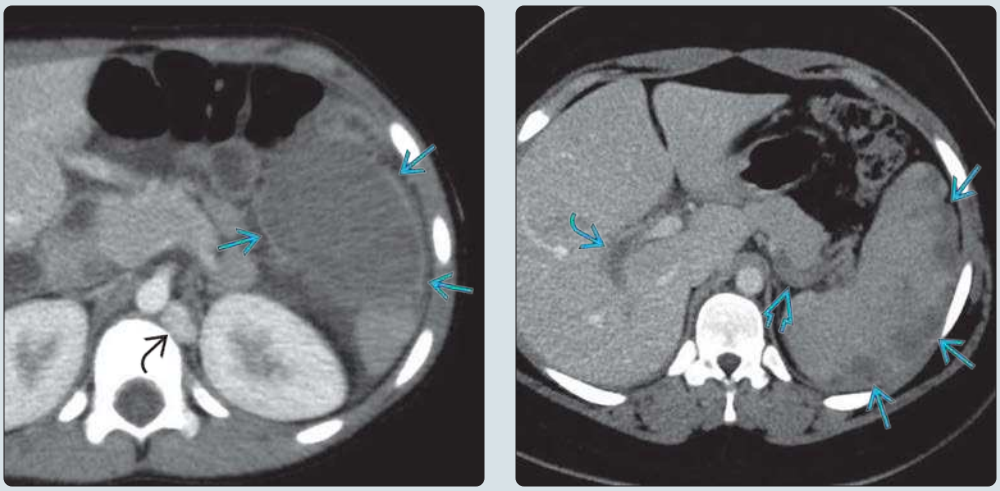
Splenic Infarct

KEY FACTS

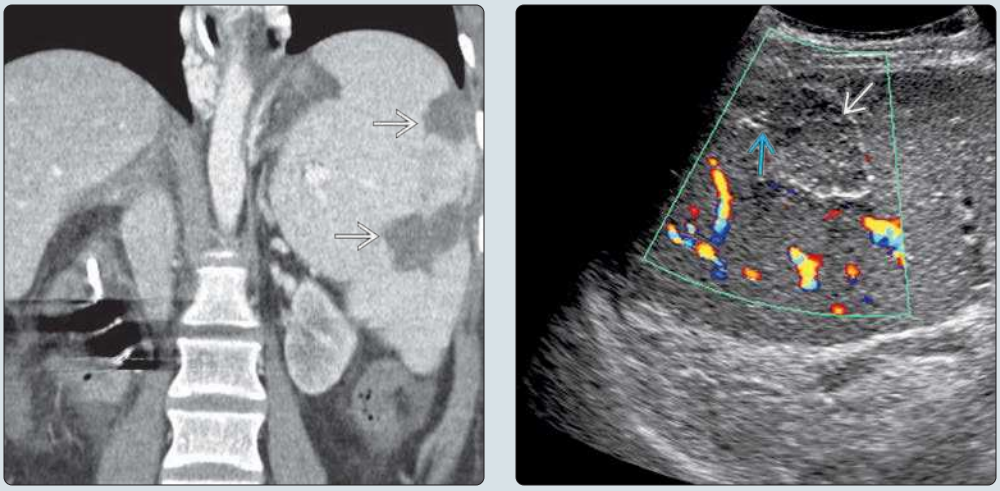
IMAGING

- CECT/MR
  - Early: Ill-defined, mottled area(s) of ↓ enhancement relative to normal spleen
  - Late: Wedge-shaped, peripheral area(s) of ↓ enhancement
  - Diffuse infarction: Global nonenhancement ± preserved cortical rim of enhancement from capsular arteries
  - ± perisplenic fluid & inflammatory changes
- Ultrasound with Doppler
  - Peripheral, wedge-shaped, hypoechoic foci ± internal, parallel echogenic lines (bright band sign)
  - Absent flow in infarcted parenchyma



PATHOLOGY

- Segmental vs. diffuse infarction
  - Segmental: Occlusion of segmental arteries, emboli, or venous occlusion
  - Diffuse: Twisting or occlusion of splenic artery
- Etiologies include
  - Hematologic: Sickle cell disease, myeloproliferative disorders, leukemia/lymphoma, hypercoagulable conditions
  - Embolic: Atrial fibrillation, endocarditis
  - Torsion: Wandering spleen, polysplenia
  - Vasculitis
  - Splenomegaly: Portal hypertension, Gaucher disease, mononucleosis



CLINICAL ISSUES

- Presents with left upper quadrant pain ± fever
- May resolve with focus of scar ± Ca^{2+} or cyst
- Acute complications: Rupture, hemorrhage, abscess formation
  - Long term: ↑ risk of infection due to asplenia
- Typically managed conservatively unless complications

(Left) *Axial CECT in a 5-year-old girl with situs ambiguous & polysplenia who presented with abdominal pain shows a nonenhancing spleen with a rim of capsular enhancement, typical of a splenic infarction. Note the left-sided inferior vena cava.* **(Right)** *Axial CECT in a 17-year-old girl with a history of smoking & obesity now presenting with left upper quadrant pain shows peripheral, wedge-shaped splenic infarcts, a thrombosed splenic vein, & right portal vein thrombosis.*

(Left) *Coronal CECT in a liver transplant patient shows splenomegaly & 2 peripheral, relatively well-demarcated areas of hypoattenuation in an enlarged spleen, consistent with splenic infarcts.* **(Right)** *Longitudinal oblique color Doppler ultrasound in a 17-year-old bone marrow transplant patient shows a well-demarcated, wedge-shaped, peripheral focus of avascular ↓ echogenicity within the spleen, consistent with infarct. Note the echogenic, parallel lines (bright band sign) in this infarct.*

TERMINOLOGY

Definitions

- Segmental or diffuse ischemia &/or necrosis caused by loss of blood supply

IMAGING

General Features

- Best diagnostic clue
  - Peripheral, wedge-shaped, hypoenhancing foci on CECT/MR
  - Heterogeneous, hypoechoic, peripheral avascular foci on ultrasound with Doppler
    - ± bright band sign: Thin, linear, echogenic foci within hypoechoic infarct
- Location
  - Peripheral, segmental, or diffuse type
- Size
  - Variable, can involve entire spleen
- Morphology
  - Typically wedge-shaped
    - Can be spherical/round or peripheral band

Ultrasonographic Findings

- Grayscale ultrasound
  - Peripheral, well-demarcated region of ↓ echogenicity
    - May see small linear parallel echogenic foci: Bright band sign
  - ± splenomegaly
  - May see islands of normal parenchyma within otherwise infarcted spleen
  - Diffuse infarction gradually results in small, calcified spleen
- Color Doppler
  - Absent flow in infarcted areas

CT Findings

- Variable appearance depending on stage
  - Early: Ill-defined, mottled area(s) of ↓ enhancement relative to normal spleen
  - Late: Wedge-shaped, peripheral area(s) of ↓ enhancement
  - Diffuse infarction: Global nonenhancement ± rim of cortical enhancement from capsular arteries
- ± associated vascular filling defects
- ± perisplenic fluid & inflammatory change

MR Findings

- Wedge-shaped, peripheral focus of nonenhancement
  - ↓ T1, ↑ T2 signal due to edema
- ↑ poorly defined edema/fluid in surrounding tissues

DIFFERENTIAL DIAGNOSIS

Laceration

- Irregular linear foci of hypoenhancement + surrounding fluid in trauma setting

Transient Heterogeneous Enhancement Pattern

- Alternating bands of ↑ & ↓ enhancement during arterial phase on postcontrast CT/MR

Lymphoma

- Focal masses throughout spleen ± splenomegaly, adjacent adenopathy

Preserved Splenic Tissue in Chronic Infarction

- Round, hypoechoic mass(es) of residual functioning splenic tissue in otherwise echogenic, chronically infarcted spleen
- Normal internal vascularity on ultrasound
- + uptake on nuclear medicine sulfur colloid scan
- Associated with sickle cell disease

PATHOLOGY

General Features

- Etiology
  - Hematologic: Sickle cell disease, myeloproliferative disorders, leukemia/lymphoma, hypercoagulable conditions
  - Embolic: Atrial fibrillation, endocarditis
  - Torsion: Wandering spleen, polysplenia
  - Vasculitis
  - Splenomegaly: Portal hypertension, infection, Gaucher disease

Staging, Grading, & Classification

- Segmental infarction
  - Occurs due to end-artery configuration of splenic arteries with ↓ collateral circulation
- Diffuse infarction
  - Due to occlusion or twisting of main splenic vessels

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Left upper quadrant pain
  - ± fever & constitutional symptoms
- Clinical profile
  - ↑ association with sickle cell disease & mononucleosis

Natural History & Prognosis

- Variable; often requires no treatment
- May resolve completely, leaving focus of scar ± Ca^{2+}
- May resolve & leave acquired cyst
- Complications: Rupture, abscess, intraperitoneal hemorrhage
- Functional asplenia may result from extensive infarctions
  - Predisposed to overwhelming postsplenectomy infection with encapsulated organisms

Treatment

- Typically none unless complications develop

Splenic Cysts

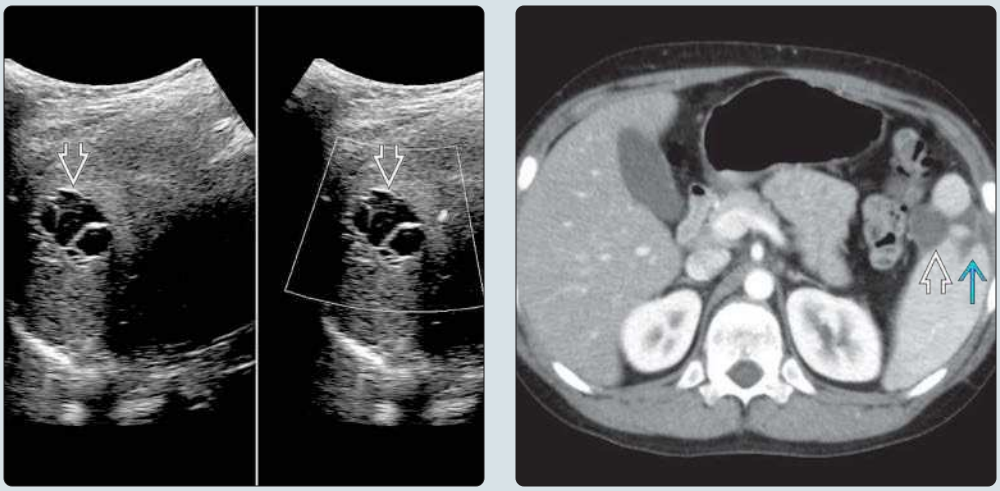
KEY FACTS

IMAGING

- Best clue: Well-circumscribed, round splenic mass
  - Follows fluid characteristics on all modalities
  - "Claw" of splayed splenic tissue along margin of larger cysts (confirming spleen as organ of origin)
- Typically solitary & unilocular
- Can occasionally have thin rim of Ca^{2+}
- US: Typically suffices to demonstrate cystic nature
  - Anechoic/hypoechoic with ↑ through transmission
  - Can have low-level internal echoes
  - No internal flow on color/power Doppler US
- No enhancement on CECT, MR C+, or CEUS
  - Typically hypointense on precontrast T1 MR unless proteinaceous or hemorrhagic contents

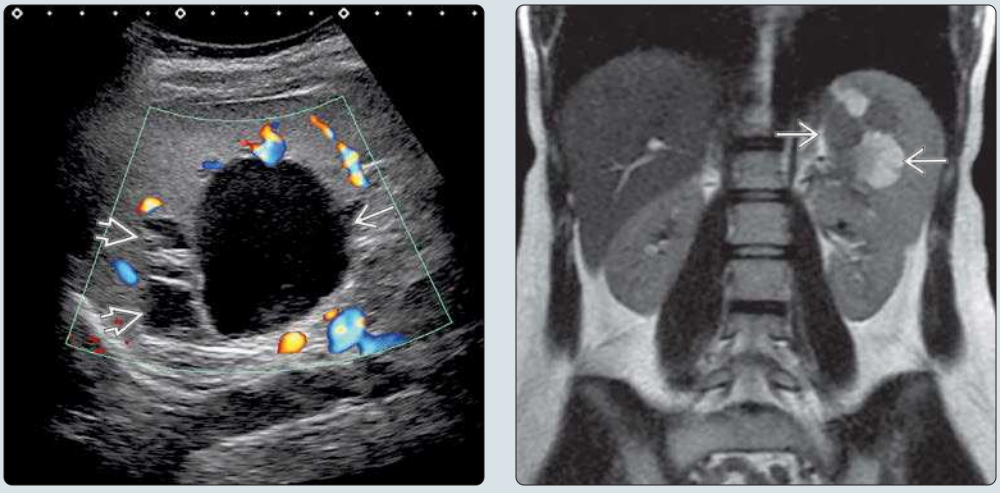
TOP DIFFERENTIAL DIAGNOSES

- Splenic lymphoma
- Splenic infection
- Splenic infarct
- Splenic perfusion artifact
- Intrasplenic pancreatic pseudocyst



PATHOLOGY

- Congenital (true) cysts: Either epidermoid or mesothelial
  - ± elevation of serum CEA, CA 125, & CA 19-9
- Acquired cysts (comprise 80% of splenic cysts)
  - Post traumatic
  - Post infarction
  - Infectious/inflammatory (pyogenic, parasitic, fungal)
  - Vascular malformation (venolymphatic)
    - Congenital but not visible early



CLINICAL ISSUES

- Most commonly incidental
- Complications may include hemorrhage, rupture, infection
- Distinction between congenital (true) & acquired cysts is not possible by imaging

(Left) *Longitudinal grayscale & color Doppler ultrasound images show an incidentally detected, mildly complex splenic cyst with thin septations in a 10-year-old girl. Pathology confirmed a benign epidermoid cyst.* **(Right)** *Axial CECT in a teenager who was involved in a motor vehicle accident several weeks prior shows a hypoattenuating, rounded mass adjacent to a prior laceration, consistent with a posttraumatic cyst.*

(Left) *Longitudinal color Doppler ultrasound in a 16-year-old with a posttraumatic splenic cyst shows a dominant cyst with smaller adjacent cysts in an area of ↓ perfusion related to ischemic injury.* **(Right)** *Coronal SSFSE T2 MR in a 17-year-old patient with a posttraumatic splenic cyst shows heterogeneous signal intensity in the lesion due to aging blood products.*

IMAGING

General Features

- Best diagnostic clue
  - Well-circumscribed, round mass with simple fluid characteristics
  - Distinction between congenital (true) & acquired cysts is not possible by imaging
- Size
  - Variable

Ultrasonographic Findings

- Grayscale ultrasound
  - Well-circumscribed, rounded mass
  - Typically anechoic but can have low-level internal echoes
  - ↑ posterior acoustic transmission
  - Thin wall
  - No contrast enhancement
- Color Doppler
  - No internal color flow

CT Findings

- Well-circumscribed, water attenuation mass
- Typically solitary & unilocular
- No enhancement
- Can occasionally have thin rim of Ca^{2+}

MR Findings

- Well-circumscribed, rounded mass
- Typically hypointense on T1 unless proteinaceous or hemorrhagic material is present internally
- Hyperintense on T2
- No enhancement
- No restricted diffusion (unless prior hemorrhage)

Imaging Recommendations

- Best imaging tool
  - US typically suffices to demonstrate cystic nature of splenic mass
  - Further characterization with any imaging modality is not typically possible

DIFFERENTIAL DIAGNOSIS

Splenic Lymphoma

- Can be solitary, multifocal, or diffuse
- Typically higher density/echogenicity than cysts
- Look for associated lymphadenopathy

Splenic Infection

- Numerous tiny lesions are typical for fungal microabscesses
- Look for lesions in liver, kidneys, & lungs

Splenic Infarct

- Typically well-demarcated, peripheral, wedge-shaped foci of ↓ attenuation/echogenicity/enhancement
- Higher attenuation/density than cysts
- Lacks internal blood flow
- May resolve completely or evolve into acquired cyst

Splenic Perfusion Artifact

- Focal areas of ↓ attenuation on early arterial phase of CECT or T1 C+ MR
  - Classically archiform waves of ↑ & ↓ enhancement
- Resolves on delayed phase (typically not necessary)
- US is usually normal

Intrasplenic Pancreatic Pseudocyst

- May result from tail pancreatitis
- Patient typically has clinical &/or imaging evidence of recent pancreatitis

PATHOLOGY

General Features

- Congenital (true) cysts = epidermoid or mesothelial cysts
  - Differentiated by type of epithelial lining
  - Thought to arise from defect in mesothelial migration
- Acquired cysts (comprising 80% of splenic cysts)
  - Post traumatic
  - Post infarction
  - Inflammatory/infectious (pyogenic, parasitic, fungal)
  - Vascular (venolymphatic)
    - Congenital but not visible early

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Typically asymptomatic & incidentally identified
- Other signs/symptoms
  - Left upper quadrant pain
  - Palpable mass
  - Splenomegaly
  - ± elevated serum CEA, CA 125, or CA 19-9
  - Large cysts predispose to splenic torsion &/or ptosis

Natural History & Prognosis

- Complications may include hemorrhage, rupture, infection

Treatment

- Small & asymptomatic masses typically require no treatment
- Larger or symptomatic masses may undergo surgical excision or splenectomy

DIAGNOSTIC CHECKLIST

Consider

- Infectious & neoplastic processes should be excluded
  - Splenic neoplasms are uncommon in children (outside of lymphoma)

Cat-Scratch Disease

KEY FACTS

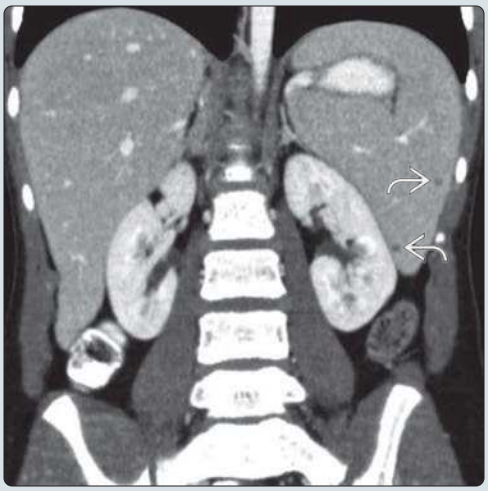
TERMINOLOGY

- Spectrum of clinical manifestations resulting from *Bartonella henselae* inoculation of skin by cat scratch
  - Typical cat-scratch disease (CSD) includes tender regional adenopathy + fever 1-3 weeks after inoculation
    - Papule at scratch site may be 1st clue
  - Self-limited in most patients; dissemination in 5-14%

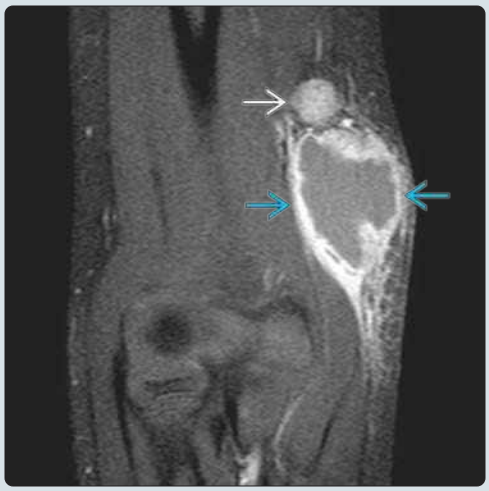
IMAGING

- Numerous small, hypoechoic (US), hypodense (CT) splenic &/or hepatic lesions of variable size
- ± splenomegaly, rarely complicated by rupture
- Residual granulomas may calcify

TOP DIFFERENTIAL DIAGNOSES

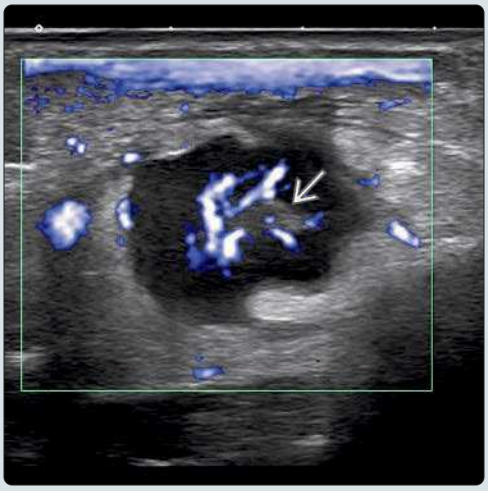


- Lymphoma
- Microabscesses
- Lymphatic anomalies
- Other granulomatous diseases

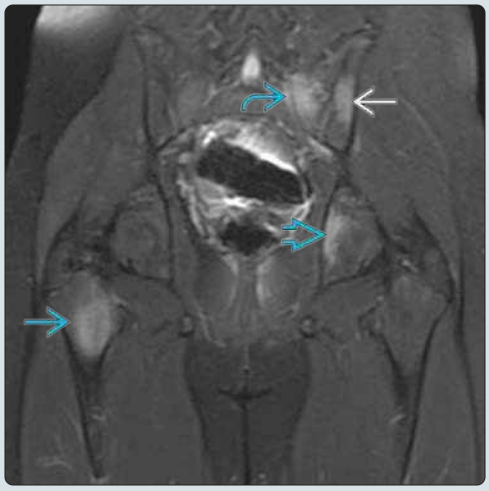


CLINICAL ISSUES

- Typical CSD: Single lymph node involved in up to 85%
  - Axillary, epitrochlear > head/neck > groin, other nodes
- Disseminated disease manifestations include hepatic &/or splenic involvement, conjunctivitis, retinitis, encephalopathy, osteomyelitis, endocarditis, pneumonia
  - Adenopathy occurs in only 55% of splenic cases
- Diagnosis made by combination of cat exposure history, positive serum antibody titers or DNA PCR, hepatic/splenic lesions, positive biopsy
- Treatment
  - Most typical CSD cases in immunocompetent hosts resolve within months without antibiotics
  - Antibiotic therapy for systemic disease &/or immunocompromised states



DIAGNOSTIC CHECKLIST



- Multifocal splenic lesions → nonspecific; recent cat exposure ± focal adenopathy should raise suspicion for CSD

(Left) *Abdominal coronal CECT in an 11-year-old patient with 1 month of fevers + back & neck pain shows numerous tiny, hypodense lesions in the spleen. Excisional biopsy of enlarged inguinal lymph nodes showed cat-scratch disease (CSD).* **(Right)** *Coronal T1 C+ FS MR in an 8-year-old patient with arm swelling shows a suppurative medial epitrochlear lymph node with thick, irregular wall & central necrosis/fluid. Additional adjacent adenopathy is noted. The patient had a history of kitten exposure & showed positive Bartonella titers.*

(Left) *Transverse Doppler US in a 7-year-old patient with an epitrochlear mass for weeks shows an enlarged lymph node with classic fatty hilum, radiating vasculature, & surrounding subcutaneous edema. The patient had a history of kitten exposure & showed positive Bartonella titers.* **(Right)** *Coronal T2 FS MR in a 10-year-old with fever of unknown origin & leg pain shows multiple poorly defined, hyperintense lesions scattered throughout the marrow of the sacrum, iliac wing, ischium, & right femur. Biopsy & titers revealed CSD.*

TERMINOLOGY

Definitions

- Cat-scratch disease (CSD): Spectrum of clinical manifestations resulting from *Bartonella henselae* inoculation of skin by cat scratch
- "Typical CSD" (most common clinical presentation): Tender regional adenopathy + fever 1-3 weeks after inoculation
  - Papule at scratch site may be 1st clue
  - Self-limited in most patients
  - Disseminated disease in 5-14%

IMAGING

General Features

- Best diagnostic clue
  - Splenic ± hepatic lesions in setting of focal extremity adenopathy & recent cat exposure
- Morphology
  - Numerous small, hypoechoic (US), hypodense (CT) splenic lesions of variable size
  - Lesions show ↑ metabolic activity on FDG PET
  - ± splenomegaly, rarely complicated by rupture
  - Residual granulomas may calcify

Imaging Recommendations

- Best imaging tool
  - US
- Protocol advice
  - Clinical history is important as many pathologies involving spleen have similar imaging appearances

DIFFERENTIAL DIAGNOSIS

Splenic Lymphoma

- Hypoechoic/hypodense, round masses of variable size
- Multifocal/confluent adenopathy ± other visceral lesions

Splenic Microabscesses

- Fungal infection (most commonly *Candida*) with numerous tiny, hypoechoic lesions
  - ± central echogenic foci (target or bull's-eye sign)

Lymphatic Anomalies

- Numerous small, hypoechoic/hypodense splenic lesions in setting of cystic soft tissue &/or bony lymphatic malformations

Other Granulomatous Diseases

- Hypoechoic splenic lesions from tuberculosis, sarcoid, histoplasmosis, Wegener granulomatosis

PATHOLOGY

General Features

- Etiology
  - Inoculation of skin by scratch (or possibly bite) of cat/kitten (less commonly guinea pig, rabbit, or dog)
    - Specific cat flea typically serves as vector with bacteria carried in flea excrement
    - Certain ticks rarely serve as vector
- Associated abnormalities
  - Lymphadenopathy (only in 55% of splenic cases), conjunctivitis, retinitis, encephalopathy, osteomyelitis, endocarditis, pneumonia

Microscopic Features

- Necrotizing granulomas + microabscesses

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Erythematous papule at inoculation site, regional adenopathy, fever ("typical CSD"): Up to 95% of cases
    - Adenopathy 1-3 weeks post inoculation
      - Axillary, epitrochlear > head/neck > groin, other
      - Single node involved in up to 85% of patients
- Other signs/symptoms
  - Aches, malaise, abdominal pain, fever of unknown origin (FUO), neurologic & ocular involvement
    - 3rd leading infectious cause of pediatric FUO (after Epstein-Barr virus & osteomyelitis)
- Clinical profile
  - Elevated erythrocyte sedimentation rate
  - Confirmation by serology (IgM & IgG antibodies) or tissue PCR

Demographics

- Age
  - Up to 87% of cases < 18 years old
- Epidemiology
  - 22,000 cases of CSD per year in United States
  - 50-87% report scratch by cat

Natural History & Prognosis

- Diagnosis made by combination of clinical, laboratory, &/or imaging criteria
  - Hepatosplenic lesions by imaging, cat or flea contact, positive antibody serology, positive biopsy, sterile pus aspiration

Treatment

- Most typical CSD cases in immunocompetent hosts resolve within months without antibiotics
  - Suppurative nodes require drainage in 10% of cases
- Antibiotic therapy for systemic disease &/or immunocompromised state

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Multifocal splenic lesions → nonspecific: Clinical history of recent cat exposure ± focal adenopathy should raise suspicion for CSD

Pancreatoblastoma

KEY FACTS

TERMINOLOGY

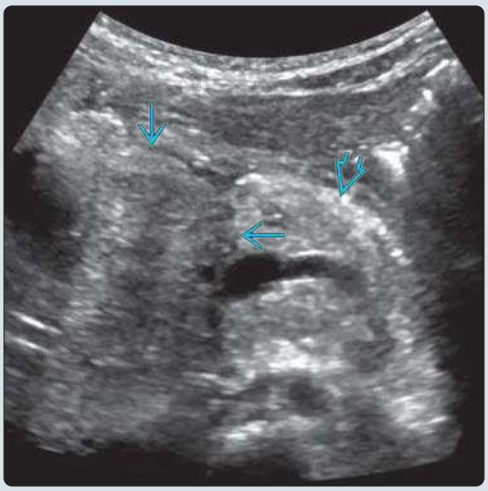
- Primary exocrine epithelial malignancy of pancreas occurring in young children

IMAGING

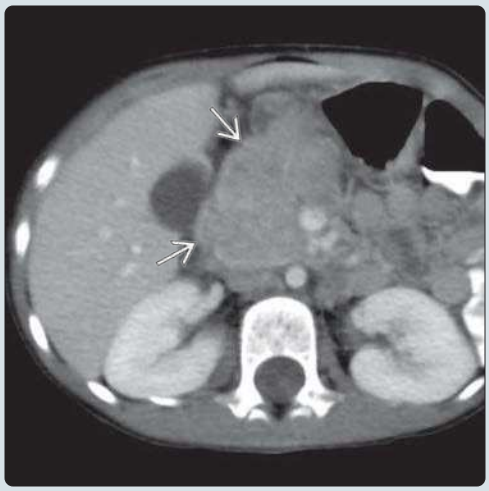
- Most commonly arises in pancreatic head
- Mean size: 7-18 cm
  - May be difficult to determine organ of origin due to size
- Well-circumscribed mass with smooth border
- Heterogeneous appearance due to mixed cystic & solid foci
  - Predominantly hypoechoic (US), hypoenhancing (CECT)
- Speckled Ca^{2+} is common

TOP DIFFERENTIAL DIAGNOSES

- Pancreatic pseudocyst
- Solid pseudopapillary neoplasm
- Pancreatic neuroendocrine tumor
- Non-Hodgkin lymphoma

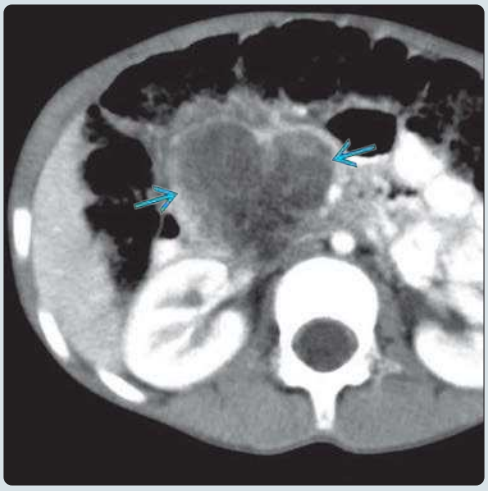


PATHOLOGY

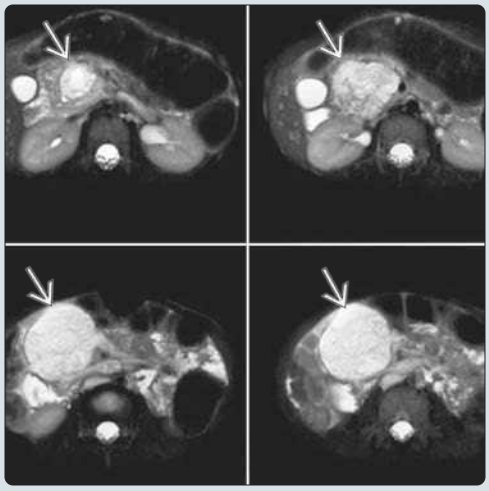


- ↑ incidence in patients with Beckwith-Wiedemann syndrome & familial adenomatous polyposis

CLINICAL ISSUES



- Most common malignant pancreatic tumor of young children
- Mean age at presentation: 5 years
- 1.3-2.7x more common in male patients
- More common in Asian population
- Most commonly presents as asymptomatic abdominal mass
- Elevated α-fetoprotein in 33-70% of patients
- Metastases are present in 1/3 at diagnosis
  - Liver > lungs, lymph nodes
- Best treated with surgical resection ± chemotherapy
  - Recurrence is common



(Left) *Transverse ultrasound of the pancreas ⇨ in a young child with pain & a palpable mass shows a large, lobulated hypoechoic mass ⇨ arising from the pancreatic head.* **(Right)** *Axial CECT in the same patient shows a lobulated, nearly homogeneously enhancing mass ➡ arising from the head of the pancreas, which is the most common site of origin. Pancreatoblastoma usually presents in the 1st decade of life as an asymptomatic abdominal mass.*

(Left) *Axial CECT in a child with pancreatoblastoma shows a heterogeneously enhancing but predominantly hypodense mass ⇨ arising from the head of the pancreas.* **(Right)** *Axial T2 FS MR images in the same child show a lobulated, hyperintense, cystic-appearing mass ➡ arising from the head of the pancreas. The internal signal intensity suggests septations.*

TERMINOLOGY

Definitions

- Primary exocrine epithelial malignancy of pancreas occurring in young children

IMAGING

General Features

- Best diagnostic clue
  - Large, heterogeneous mass of pancreas in child
- Location
  - 33-50% arise in pancreatic head
  - 13-37% arise in pancreatic tail
  - 10-25% arise in pancreatic body
- Size
  - Large tumors; average: 7-18 cm in diameter
- Morphology
  - Well-circumscribed vs. poorly defined margins; may have local/regional vascular invasion
    - May be difficult to determine organ of origin

Ultrasonographic Findings

- Well-circumscribed mass with heterogeneous echogenicity
  - Cystic & solid components
    - Cystic foci are hypoechoic with hyperechoic septa

CT Findings

- CECT
  - Well-circumscribed vs. poorly defined margins
  - Heterogeneous attenuation of mixed cystic & solid foci
    - Cystic areas represent necrosis
    - Overall hypodense vs. normally enhancing pancreas
  - Multiloculated with enhancing septa
  - Small punctate Ca^{2+} are common

MR Findings

- T1: Well-circumscribed, iso- to hypointense mass
  - Areas of lower signal correspond to necrosis
  - Areas of higher signal correspond to hemorrhage
- T2 FS: Heterogeneously hyperintense mass
- T1 C+ FS: Enhances < adjacent pancreas
  - Rim may enhance to greater degree than remainder of pancreas
- DWI: Lower ADC values than solid pseudopapillary neoplasm

DIFFERENTIAL DIAGNOSIS

Pancreatic Pseudocyst

- Collection of fluid, tissue, debris, pancreatic enzymes, & blood surrounded by fibrous capsule
- Gradually develops 4 weeks after onset of acute pancreatitis

Solid Pseudopapillary Neoplasm

- Most common pancreatic neoplasm in pediatric population
- Occurs in adolescent to young adult female patients
- Large, well-defined, solid mass of pancreas with variable cystic components
- Usually benign

Pancreatic Neuroendocrine Tumor

- Rare tumor in children, may be nonfunctioning
  - Insulinoma is most common in children
- Usually hypervascular
- Associated with von Hippel-Lindau, multiple endocrine neoplasia type 1

Non-Hodgkin Lymphoma

- Typically smaller & uniformly hypodense solid lesion
- Pancreatic involvement typically occurs in setting of other nodal &/or visceral involvement
  - Adjacent adenopathy is common

PATHOLOGY

General Features

- Associated abnormalities
  - Beckwith-Wiedemann syndrome in ~ 10%
    - Patients present earlier in life
    - More likely to have cystic tumor
  - Familial adenomatous polyposis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic, large abdominal mass
- Other signs/symptoms
  - Abdominal pain, fatigue, lethargy, weight loss, anorexia, diarrhea, & vomiting
  - Elevated α-fetoprotein in majority of patients

Demographics

- Age: Typically occurs in 1st decade of life
  - Mean age at presentation: 5 years
- Sex: 1.3-2.7x more common in males
- Ethnicity: More common in Asian population
- Epidemiology: Most common malignant pancreatic tumor of young children

Natural History & Prognosis

- Metastases in 1/3 of patients at presentation
  - Liver > lungs, lymph nodes, brain

Treatment

- Best treated with surgical resection
- Adjuvant/neoadjuvant chemotherapy is often used

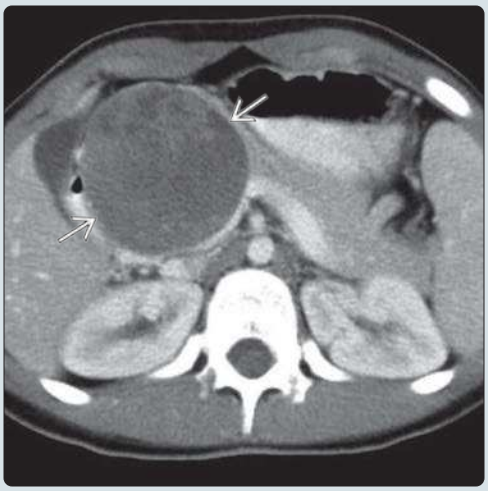
Solid Pseudopapillary Neoplasm

KEY FACTS

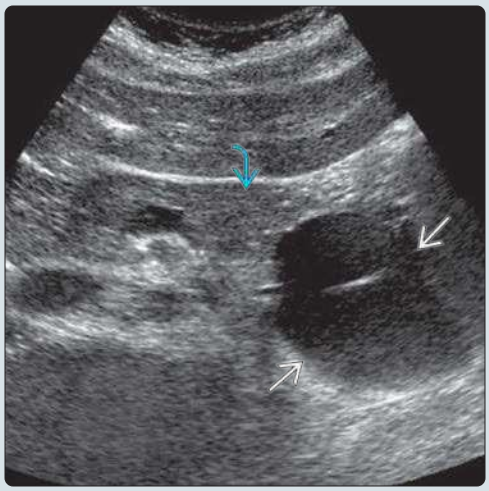
TERMINOLOGY

- Synonyms: Solid-cystic pancreatic tumor, Frantz tumor, papillary cystic tumor, solid & papillary neoplasm, solid & cystic acinar cell tumor, papillary epithelial neoplasm

IMAGING

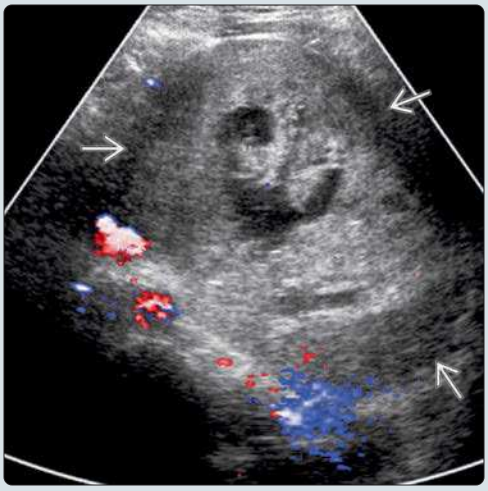


- Large, well-defined, solid mass of pancreas with variable cystic components
  - Mean size: 6-10 cm
- Central areas of ↑ T1 & heterogeneous T2 MR signal due to hemorrhage or necrosis
- Peripheral low signal due to fibrous capsule or compressed pancreatic tissue
- Higher ADC values than pancreatoblastoma
- Ca^{2+} may be present in 30-65%
- Most common site of origin in pancreas = body & tail

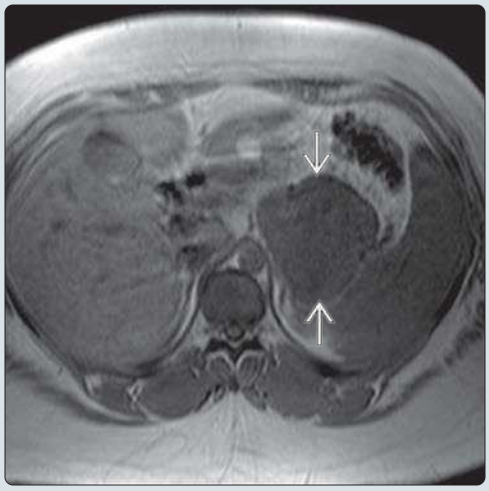


TOP DIFFERENTIAL DIAGNOSES

- Pancreatic pseudocyst
- Pancreatoblastoma
- Pancreatic adenocarcinoma



CLINICAL ISSUES



- Mean age of affected pediatric patients: 17 years
- 9x more common in female patients
- Accounts for 1-3% of all pancreatic tumors but 61% of pediatric pancreatic tumors
  - Most common primary pancreatic neoplasm in pediatric population
- Patients most commonly present with large epigastric mass
  - Can present with chronic abdominal pain or acute abdominal pain after cyst rupture
- Usually benign tumor
  - > 95% overall survival
  - Local spread & metastases to liver reported in 10-20%
- Treatment: Surgical resection
  - Can rarely have local recurrence after resection

(Left) *Axial CECT in an adolescent girl with a solid pseudopapillary neoplasm (SPN) shows a well-defined, hypodense, round mass arising from the pancreatic head. SPNs occur almost exclusively in women in their 2nd or 3rd decade of life.* **(Right)** *Transverse abdominal ultrasound in a young girl with an SPN shows a cystic mass arising from the tail of the pancreas. SPNs are variable in their appearance with differing solid & cystic components.*

(Left) *Longitudinal ultrasound of an adolescent girl with an SPN shows a large, heterogeneous mass of the tail of the pancreas. The mass is mostly solid with a small central cystic component. There is no appreciable internal blood flow. SPNs often present as a large mass with a mean size at presentation of 6-10 cm.* **(Right)** *Axial T1 MR in a young adult woman with an SPN shows a hypointense mass arising from the tail of the pancreas. On MR, SPNs can show mildly ↑ T1 signal related to hemorrhage.*

TERMINOLOGY

Definitions

- Exocrine tumor of pancreas

IMAGING

General Features

- Best diagnostic clue
  - Solid & cystic pancreatic mass in young woman
- Location
  - Most common site of origin in pancreas = body & tail
- Size
  - Mean: 6-10 cm
- Morphology
  - Well-defined pancreatic mass with variable cystic components

Radiographic Findings

- Soft tissue mass in upper abdomen displacing bowel

Ultrasonographic Findings

- Large pancreatic mass with thick capsule
- Mixed cystic & solid components
- Echogenic Ca^{2+}
- CEUS shows ↓ enhancement of tumor compared to pancreas with enhancement of fibrous capsule & intratumoral vessels

CT Findings

- Large, well-defined, solid mass of pancreas with variable cystic components
- Ca^{2+} may be present in 30-65%
  - Pattern of Ca^{2+} is variable & includes eggshell, dystrophic, or stippled
- Tumor does not enhance as much as background pancreas

MR Findings

- T1WI
  - Large, hypointense mass of pancreas
  - Central areas of ↑ signal due to hemorrhage or necrosis
  - Peripheral ↓ signal due to fibrous capsule or compressed pancreatic tissue
- T2WI
  - Heterogeneous signal due to hemorrhage & necrosis
- DWI
  - Higher ADC values than pancreatoblastoma
- T1WI C+
  - Vast majority show enhancing components

Nuclear Medicine Findings

- PET/CT: Various patterns of FDG uptake (depending on degree of cystic change)

DIFFERENTIAL DIAGNOSIS

Pancreatic Pseudocyst

- Collection of fluid, tissue, debris, pancreatic enzymes, & blood surrounded by fibrous capsule
- Gradually develops 4 weeks after onset of acute pancreatitis

Pancreatoblastoma

- Most common pancreatic malignancy in young children (mean age = 5 years)
- ~ 2x more common in male patients
- Relative to solid pseudopapillary neoplasm (SPN): Lower ADC values; higher rate of Ca^{2+}, vessel invasion, & metastases

Pancreatic Adenocarcinoma

- Extremely rare in pediatric population
- Usually originates from pancreatic duct
- Most common in head of pancreas → double duct sign of dilated biliary & pancreatic ducts

PATHOLOGY

Gross Pathologic & Surgical Features

- Pancreatic tumor with solid outer capsule
- Has solid & pseudopapillary structures, ↑ vascularization, & cellular degeneration

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Large epigastric mass
- Other signs/symptoms
  - Chronic abdominal pain & distention, back pain, vomiting
  - Acute abdominal pain after cyst rupture

Demographics

- Age
  - Mean age of affected pediatric patients: 17 years
- Sex
  - 9x more common in female patients
- Epidemiology
  - Accounts for 1-3% of all pancreatic tumors
  - Most common primary pediatric pancreatic neoplasm

Natural History & Prognosis

- Usually benign tumor
  - > 95% overall survival
  - Local spread & metastases to liver in 10-20%

Treatment

- Surgical resection can be curative
  - 97% 5-year survival
  - Can rarely have local recurrence after resection

Pancreas Divisum

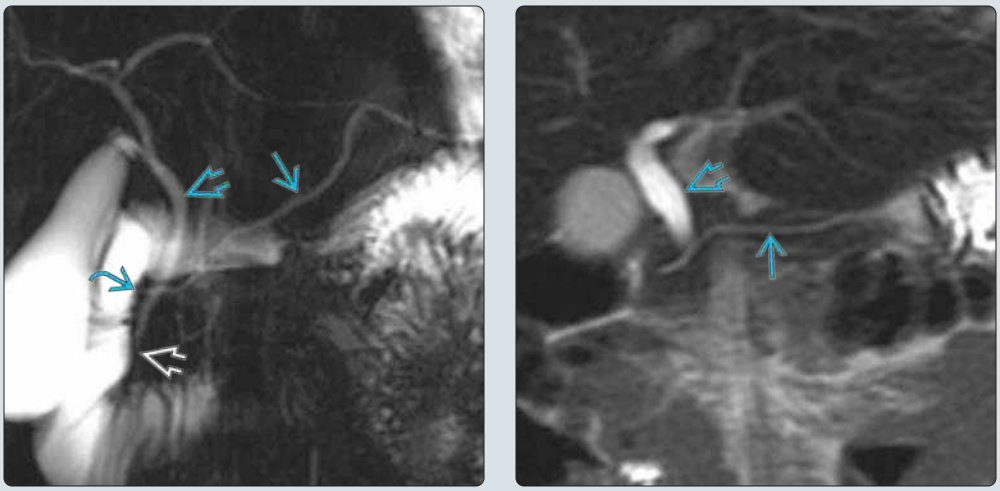
KEY FACTS

TERMINOLOGY

- Incomplete fusion of dorsal & ventral pancreatic ducts with persistence of 2 separate ductal systems
- 2 main types
  - Complete divisum: No connection between dorsal & ventral pancreatic ducts
  - Incomplete divisum: Rudimentary connection between dorsal & ventral pancreatic ducts

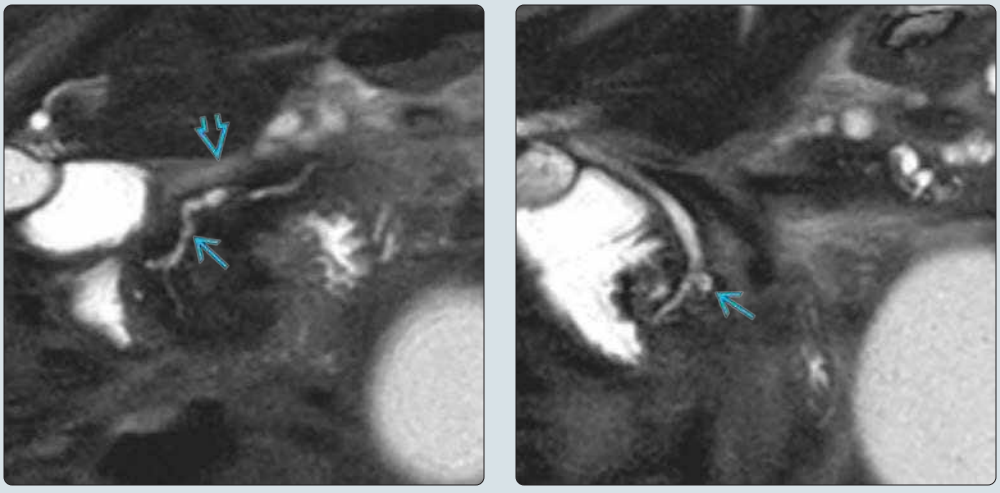
IMAGING

- Separate pancreatic ducts are seen draining dorsal & ventral pancreas on CECT, MRCP, or ERCP
  - Dorsal duct drains majority of pancreas through minor papilla
  - Short ventral duct of Wirsung drains to major papilla
    - Ventral duct does not cross midline
- Secretin may be used to ↑ diameter of pancreatic ducts



PATHOLOGY

- Dorsal anlage forms pancreatic body & tail
- Ventral anlage forms head of pancreas & uncinate process
- When dorsal & ventral ducts fail to fuse, dorsal duct drains majority of pancreas through minor papilla
  - Superior & anterior to major papilla, which drains duct of Wirsung & common bile duct
- Proposed etiology for pancreatitis: Small diameter of minor papilla causes relative obstruction to drainage of large volume from pancreatic body & tail



CLINICAL ISSUES

- Most common congenital variant of pancreatic ductal development (5-10% of general population)
- Most patients are asymptomatic
  - Children uncommonly present with pancreatitis
  - Pancreatitis is more common from 30-50 years of age
- Most symptomatic patients respond to sphincterotomy of minor papilla

(Left) *Coronal MIP MRCP shows pancreas divisum. The pancreatic duct drains via the minor papilla, while the common bile duct drains via the major papilla at the sphincter of Oddi.* **(Right)** *Coronal T2 MRCP shows pancreas divisum. The common bile duct is dilated throughout its course. Its insertion at the sphincter of Oddi is not shown. The pancreatic duct crosses the common bile duct & inserts at the minor papilla, superior to the common duct insertion.*

(Left) *Coronal T2 MRCP in a patient with acute-on-chronic pancreatitis & pancreas divisum shows an irregular pancreatic duct (with areas of dilation & narrowing) that is draining to the minor papilla. There is mild peripancreatic edema.* **(Right)** *Coronal T2 MRCP in the same patient shows a focal outpouching at the distal common bile duct. The pancreatic duct & common bile duct drain separately at the minor & major papilla, respectively, consistent with pancreas divisum.*

TERMINOLOGY

Definitions

- Failed fusion of dorsal & ventral pancreatic ducts with persistence of 2 separate ductal systems
- 2 main types
  - Complete divisum: No connection between dorsal & ventral pancreatic ducts
  - Incomplete divisum: Rudimentary connection between dorsal & ventral pancreatic ducts

IMAGING

General Features

- Best diagnostic clue
  - Separate pancreatic ducts draining dorsal & ventral pancreas
- Location
  - Duct of Santorini (dorsal duct) drains to minor papilla, superior & anterior to major papilla
  - Duct of Wirsung (ventral duct) joins common bile duct & drains at major papilla

CT Findings

- CECT
  - Pancreatic ducts are usually not dilated & not visible
  - May see 2 discrete pancreatic moieties separated by fatty cleft

MR Findings

- MRCP
  - Separate T2-hyperintense pancreatic ducts draining dorsal & ventral pancreas
    - Secretin may be used to ↑ diameter & visibility of pancreatic ducts

Ultrasonographic Findings

- Grayscale ultrasound
  - 2 separate pancreatic ducts do not communicate
- Endoscopic ultrasound
  - No continuity of pancreatic duct in uncinate process with duct in body & tail

Nonvascular Interventions

- ERCP
  - Cannulation of major papilla reveals short ventral duct of Wirsung
    - Ventral duct ranges from 1-4 cm in length
    - Ventral duct does not cross midline
  - Cannulation of minor papilla can be difficult
    - Located superior & anterior to major papilla

Imaging Recommendations

- Best imaging tool
  - ERCP or MRCP: Defines pancreatic ductal anatomy

DIFFERENTIAL DIAGNOSIS

Annular Pancreas

- Result of incomplete separation of dorsal & ventral pancreatic anlage
- Pancreatic tissue & duct encircle 2nd portion of duodenum
- Can cause neonatal bowel obstruction

Dorsal Agenesis of Pancreas

- Absence of pancreatic body or tail
- ERCP appearance of pancreatic duct is identical to pancreas divisum
- Associated with polysplenia

PATHOLOGY

General Features

- Etiology
  - Dorsal & ventral pancreatic anlagen normally rotate & fuse during 6th-8th weeks of fetal development
    - Ventral anlage forms head of pancreas & uncinate process
    - Dorsal anlage forms pancreatic body & tail
  - When 2 ducts fail to fuse, dorsal duct remains & drains majority of pancreas through minor papilla
  - Proposed etiology for pancreatitis
    - Small diameter of minor papilla causes relative obstruction to drainage of large volume from pancreatic body & tail
    - Thought to require 2nd hit, ↑ likelihood that pancreas divisum leads to pancreatitis
      - Most common association: Mutation in cystic fibrosis transmembrane conductance regulator (CFTR)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Most patients are asymptomatic
  - Associated with acute recurrent pancreatitis &/or chronic pancreatitis

Demographics

- Age
  - Congenital anomaly that can present at any age
    - If symptomatic, patients may have recurrent abdominal pain & vomiting
    - Mean age of initial presentation in children: 6 years
- Epidemiology
  - Most common congenital variant of pancreatic ductal development
  - Occurs in 5-14% of general population

Treatment

- Most symptomatic patients respond to sphincterotomy of minor papilla

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Short ventral pancreatic duct does not communicate with long dorsal duct

Pancreaticobiliary Maljunction

KEY FACTS

TERMINOLOGY

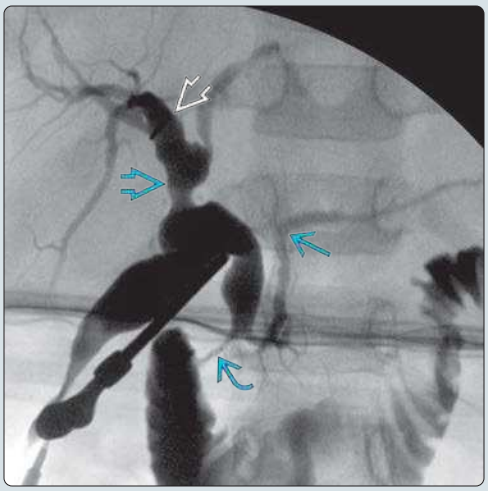
- Pancreaticobiliary maljunction (PBM): Congenital malformation in which pancreatic duct & common bile duct (CBD) join outside of duodenal wall
- 2 types of PBM
  - PBM with congenital biliary dilation (choledochal cyst)
    - More likely to present with symptoms in childhood
  - PBM without biliary dilation
    - Often asymptomatic until cancer develops in adulthood

IMAGING

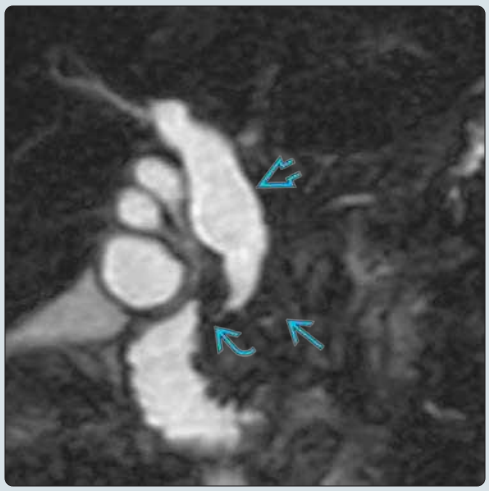
- Modalities
  - Ultrasound screening of patients with clinical/laboratory manifestations of hepatobiliary &/or pancreatic disease
  - MRCP for detailed ductal evaluation
  - ERCP to confirm diagnosis, particularly in equivocal cases
- Findings
  - Abnormal union of pancreatic duct & CBD outside of duodenal wall
  - ± visualization of fluid-filled long common channel extending from high confluence to duodenum
  - ± type I or type IV choledochal cyst
  - Associated abnormalities: Gallstones, gallbladder wall thickening, sequelae of pancreatitis

TOP DIFFERENTIAL DIAGNOSES

- Pancreas divisum
- Choledochal cyst

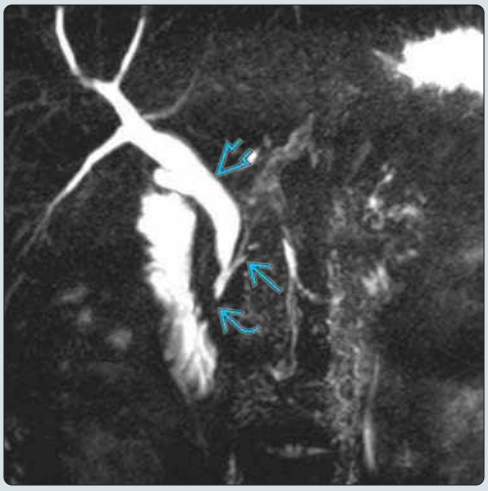


PATHOLOGY

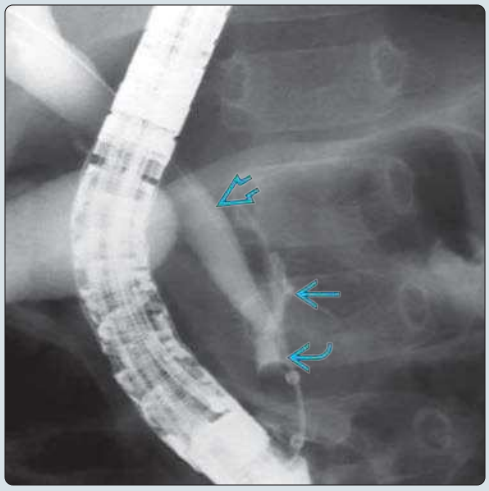


- 200x ↑ risk of biliary cancer (usually in later adulthood)
  - Gallbladder is most common site

CLINICAL ISSUES



- Treated with cholecystectomy & resection of extrahepatic bile duct due to high risk of malignancy



(Left) *Direct cholangiogram shows dilation & irregularity of the common bile duct & central intrahepatic bile ducts, consistent with a type IV choledochal cyst. The pancreatic duct joins the common bile duct in an anomalous position, creating a long common channel.* **(Right)** *Coronal MRCP in the same patient shows dilation of the common bile duct. The pancreatic duct is small & joins the common bile duct in an anomalous location, creating a long common channel.*

(Left) *Coronal MRCP in a patient with a choledochal cyst shows fusiform dilation of the common bile duct. The pancreatic duct joins the common bile duct in an anomalous location, creating a long common channel that measured 1.8 cm in length.* **(Right)** *ERCP in the same patient shows fusiform dilation of the common bile duct + an abnormal junction with the pancreatic duct, creating a long common channel.*

TERMINOLOGY

Synonyms

- Long common channel

Definitions

- Pancreaticobiliary maljunction (PBM): Congenital malformation where pancreatic duct & common bile duct (CBD) join outside of duodenal wall
  - Long common channel allows pancreatobiliary & biliopancreatic reflux
  - Chronic pancreatobiliary reflux leads to high risk of gallbladder & biliary cancer
  - Biliopancreatic reflux causes acute pancreatitis
- 2 types of PBM
  - PBM with congenital biliary dilation
  - PBM without congenital biliary dilation
- Congenital biliary dilation
  - Previously referred to as type I or IVa choledochal cyst
  - Requires enlarged diameter of CBD + PBM
  - Definition for enlarged CBD depends on age

IMAGING

General Features

- Best diagnostic clue
  - Long common channel extending from abnormally high confluence of pancreatic duct & CBD to duodenum
    - Duct union lies outside of duodenal wall

Ultrasonographic Findings

- Transabdominal ultrasound may identify nonspecific gallbladder wall thickening, cholelithiasis, dilated CBD
- Endoscopic ultrasound can confirm extraduodenal union of pancreaticobiliary junction

MR Findings

- MRCP
  - Long, fluid-filled channel distal to high confluence of pancreatic duct & CBD
  - Type I or type IVa choledochal cyst may be present
  - Secretin can help to improve visualization of pancreatic duct & pancreatobiliary reflux
  - Associated findings: Gallstones, sequelae of pancreatitis

Other Modality Findings

- Endoscopic retrograde cholangiopancreatography (ERCP)
  - Only method able to evaluate location & effect of sphincter of Oddi

Imaging Recommendations

- Best imaging tool
  - Ultrasound screening of patients with clinical/laboratory manifestations of hepatobiliary &/or pancreatic disease
  - MRCP for detailed ductal evaluation
  - ERCP to confirm diagnosis, particularly in equivocal cases

DIFFERENTIAL DIAGNOSIS

Pancreas Divisum

- Incomplete fusion of dorsal & ventral pancreatic ducts with persistence of 2 separate draining ductal systems

Choledochal Cyst

- Spectrum of malformations of extrahepatic & intrahepatic bile ducts
  - Classified via system developed by Todani
  - Types I & IVa are termed congenital biliary dilation
- Associated with PBM

PATHOLOGY

Staging, Grading, & Classification

- 2 types of PBM
  - PBM with congenital biliary dilation
  - PBM without biliary dilation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - PBM with congenital biliary dilation
    - Presents in childhood
    - Symptoms: Pain, vomiting, jaundice, & fever
  - PBM without biliary dilation
    - Presents in adulthood
    - Most patients are asymptomatic until cancer develops
    - Up to 10% of patients present with cholangitis
- Other signs/symptoms
  - Manifestations of pancreatitis or cholelithiasis

Demographics

- More common in patients from Japan
- Congenital biliary dilation is 3x more common in female patients

Natural History & Prognosis

- Pancreatic enzymes induce chronic inflammation of biliary tree → proliferation of biliary epithelium → induction of carcinogenesis
  - 200x ↑ risk of biliary cancer
    - Gallbladder cancer is most common
  - Cancer is more common in PBM patients without biliary dilation compared to those with dilation (42.4% vs. 21.6%)
  - Cancers typically occur in 6th or 7th decade of life, 15-20 years younger than those without PBM
  - Cancer type in PBM with congenital biliary dilation: Gallbladder (62%) & bile duct (32%)
  - Cancer type in PBM without congenital biliary dilation: Gallbladder (88%) & bile duct (7%)

Treatment

- Cholecystectomy & resection of extrahepatic bile duct is recommended due to high risk of malignancy

Annular Pancreas

KEY FACTS

TERMINOLOGY

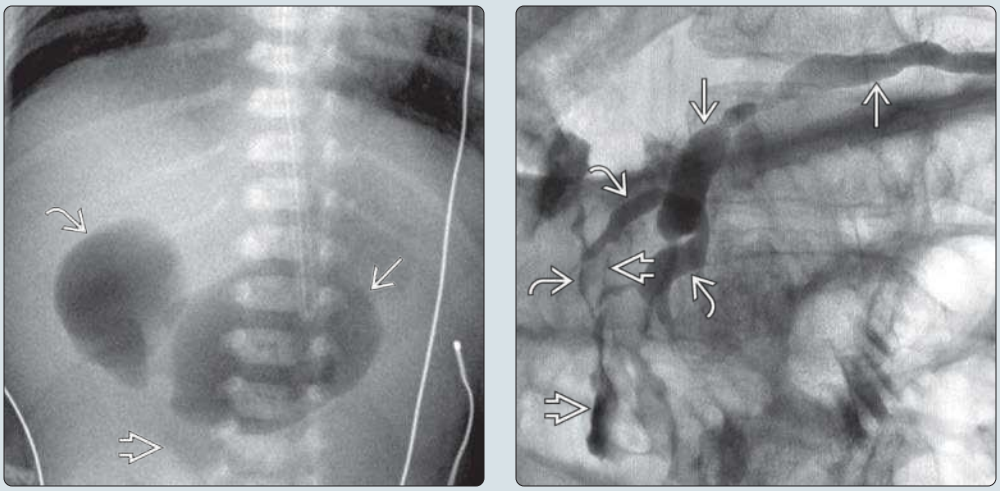
- Congenital anomaly with ring of pancreatic tissue surrounding 2nd portion of duodenum (D2); results in variable degrees of duodenal obstruction

IMAGING

- Radiograph: ± newborn "double bubble" of dilated stomach & 1st portion of duodenum (D1)
  - Distal bowel gas is present
- Upper GI: Circumferential narrowing of D2
- MRCP or ERCP: Split pancreatic duct encircling D2
- MR, CT, or ultrasound: Pancreatic tissue surrounding D2
  - Water is useful as oral contrast for MR, CT, & ultrasound
- Diagnosis may be suggested on prenatal imaging

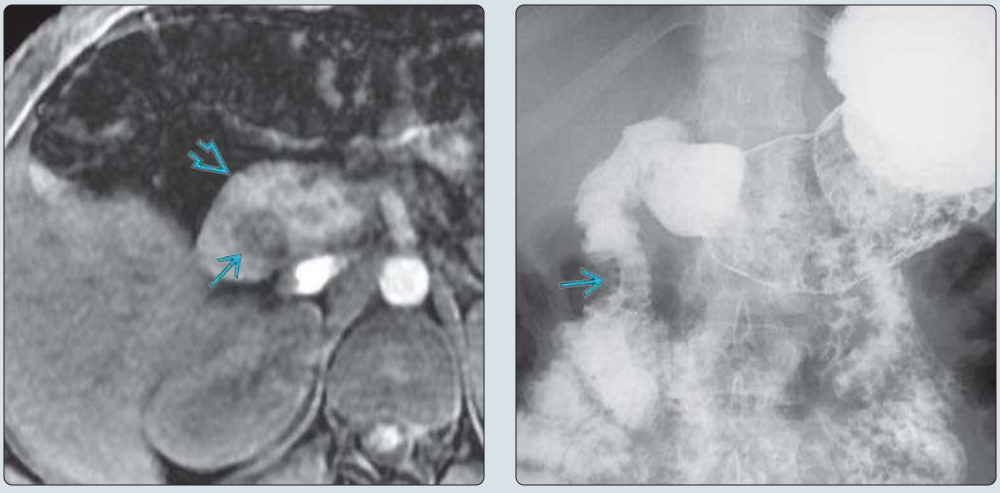
TOP DIFFERENTIAL DIAGNOSES

- Duodenal atresia
- Duodenal web
- Malrotation with midgut volvulus



PATHOLOGY

- Associations include
  - Congenital heart disease, malrotation, Meckel diverticulum, pancreas divisum, duodenal web, intestinal atresia, duplicated renal collecting system
  - Down syndrome



CLINICAL ISSUES

- 3 main presentations
  - Newborns: Signs of proximal duodenal obstruction either on prenatal ultrasound or after birth
    - Postnatal manifestations include vomiting (may be bilious), feeding intolerance, abdominal distention
  - Adults: Abdominal pain, ulcers, pancreatitis
  - Incidental imaging finding
- 51.5% diagnosed in childhood (77% of those are diagnosed by 2 days of life)
- Treatment of duodenal obstruction: Surgical duodenal bypass

(Left) *AP radiograph in a newborn with annular pancreas shows a "double bubble" appearance with a dilated air-filled stomach & a bulbous proximal duodenum. However, small amounts of distal bowel gas are present, suggesting a partial obstruction rather than duodenal atresia.* **(Right)** *ERCP in a teenager shows a dilated & irregular main pancreatic duct secondary to recurrent pancreatitis. There are 2 ducts in the pancreatic head encircling the contrast in the 2nd duodenum.*

(Left) *Axial T1 FS MR shows the hypointense 2nd duodenum encircled by the hyperintense pancreatic head, consistent with annular pancreas.* **(Right)** *Frontal image from an upper GI performed in the same patient shows focal moderate narrowing of the 2nd duodenum at the site of the annular pancreas. There is no significant dilation of the proximal duodenum in this case.*

TERMINOLOGY

Definitions

- Ring of pancreatic tissue encircling 2nd portion of duodenum (D2)

IMAGING

General Features

- Best diagnostic clue
  - "Double bubble" dilation of stomach & 1st portion of duodenum (D1) on early postnatal imaging in presence of distal bowel gas
    - D1 is enlarged due to longstanding obstruction
  - Ring of pancreatic tissue encircling & narrowing D2 on cross-sectional imaging at any age

Radiographic Findings

- Newborn with partial duodenal obstruction
  - Dilated stomach & D1
  - Distal bowel gas is present (but may be diminished)

Fluoroscopic Findings

- Upper GI
  - Incomplete proximal duodenal obstruction
    - Dilation & delayed emptying of stomach + D1
  - Circumferential narrowing of D2
  - Relatively small-caliber duodenum beyond constriction
- ERCP
  - Split distal pancreatic duct encircling D2

CT Findings

- CECT
  - Pancreatic head tissue encircles D2
    - Remainder of pancreas is normal in appearance (unless patient has acute or chronic pancreatitis)

MR Findings

- Pancreatic head tissue encircles D2
  - T1 ± FS: Hypointense bowel contents pass through relatively hyperintense pancreas
  - T2 ± FS: Hyperintense bowel contents pass through relatively hypointense pancreas
- MRCP: Split distal pancreatic duct encircles D2

Ultrasonographic Findings

- Postnatal ultrasound
  - Fluid-filled proximal duodenum up to pancreatic head
  - Hyperechoic band of pancreatic tissue encircling or partially encircling duodenum at site of obstruction

Imaging Recommendations

- Protocol advice
  - Water is useful as oral contrast for MR, CT, & ultrasound
  - T1 FS MR increases conspicuity of pancreatic tissue

DIFFERENTIAL DIAGNOSIS

Duodenal Atresia

- Congenital duodenal obstruction at D2
- Radiograph (in absence of gastric decompression) shows classic large "double bubble" without distal bowel gas
- Upper GI is not necessary

Duodenal Web

- Cause of partial duodenal obstruction
- Symptoms depend on aperture of web
- ± "double bubble" appearance; distal bowel gas is present
- ± visualization of thin membrane in duodenal lumen
  - May have "windsock" configuration with distal stretching of web beyond origin at proximal duodenal wall

Malrotation With Midgut Volvulus

- Typically presents with bilious emesis in neonates/infants
- Radiograph may show distended stomach & proximal duodenum with normal to ↓ distal bowel gas
  - In acute midgut volvulus, proximal duodenum is not as bulbous as with longstanding in utero obstructions
- Upper GI shows abnormal abrupt tapering/"beaking" of distal D2/D3 with corkscrew configuration of bowel beyond taper
- Ultrasound shows abnormal anterior position of D3 with clockwise "whirlpool" twisting of bowel & mesentery
- Requires emergent surgery to prevent bowel infarction

PATHOLOGY

Associated Anomalies

- Congenital heart disease, malrotation, Meckel diverticulum, pancreas divisum, duodenal web, intestinal atresia, duplicated renal collecting system

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 3 main presentations
    - Newborn: High-grade duodenal obstruction either on prenatal ultrasound or after birth
      - Signs after birth include emesis (may be bilious), feeding intolerance, abdominal distention
    - Older child/adult: Abdominal pain, pancreatitis, ulcers
    - Incidental imaging finding

Demographics

- Age
  - 51.5% are diagnosed in childhood
    - 77% of children are diagnosed by 2 days of life
  - 48.5% are diagnosed in adults
- Epidemiology
  - Present in 3 of 20,000 autopsies
  - 140 cases per 100,000 patients with Down syndrome

Treatment

- Surgical duodenal bypass

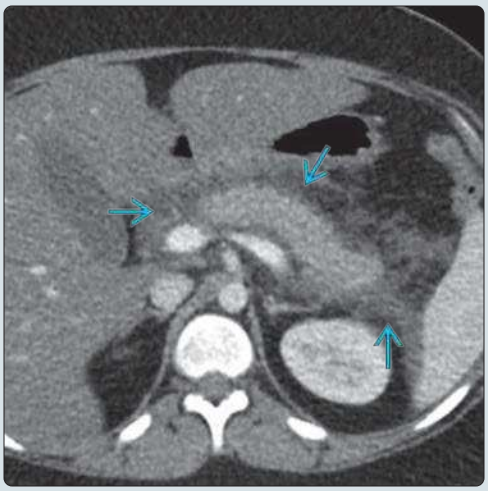
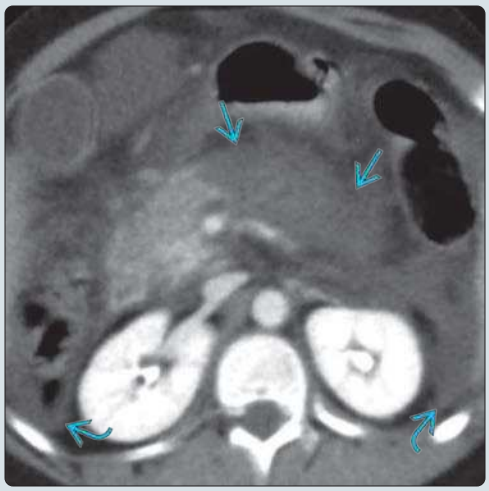
Pancreatitis

KEY FACTS

TERMINOLOGY

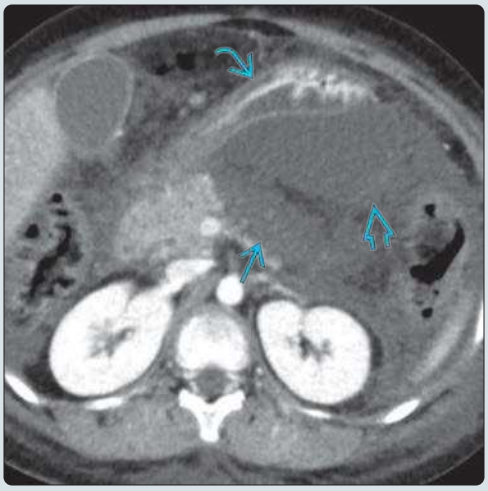


- Acute pancreatitis (AP): Acute inflammation of pancreas with variable involvement of local tissues/remote organs
- 2 of 3 features required for diagnosis: Abdominal pain consistent with disease, 3x rise in serum amylase or lipase, or imaging findings consistent with AP
- 2 types of AP: Interstitial edematous vs. necrotizing
- Fluid collections
  - Acute peripancreatic fluid collection: Fluid collection associated with interstitial edematous pancreatitis during first 4 weeks
  - Pancreatic pseudocyst: Fluid collection associated with interstitial edematous pancreatitis after first 4 weeks
  - Acute necrotic collection: Collection containing fluid & necrotic material during first 4 weeks
  - Walled-off necrosis: Collection containing fluid & necrotic material after first 4 weeks
- Chronic pancreatitis (CP): Relapsing or continuing inflammation with destruction of parenchyma & ducts

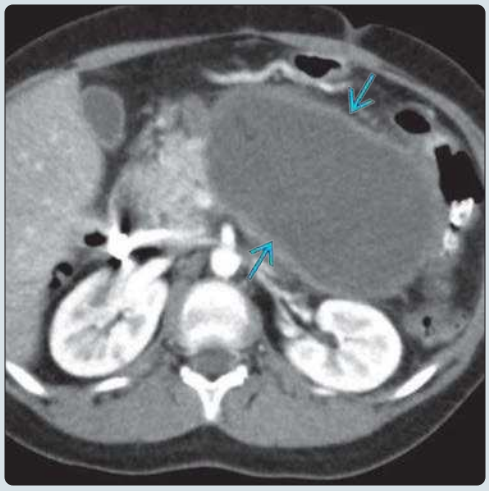


IMAGING

- Interstitial edematous pancreatitis: Gland enlargement with edema & homogeneous (± mildly ↓) enhancement
  - Acute peripancreatic fluid collection: Nonencapsulated collections of variable size & shape
  - Pancreatic pseudocyst: Encapsulated cystic lesion with no internal solid component, > 4 weeks from onset
- Necrotizing pancreatitis: Heterogeneous enhancement (moderately to severely ↓)
  - Acute necrotic collection: Nonencapsulated collection with heterogeneous contents
  - Walled-off necrosis: Well-circumscribed cavity containing necrotic tissue, > 4 weeks from onset
- CP: Atrophic pancreas with dilated duct & pancreatic Ca^{2+}



CLINICAL ISSUES



- Epigastric abdominal pain; ↑ amylase & lipase > 3x normal
- Therapy: Fluid resuscitation, early enteral nutrition, pain management

(Left) *Axial CECT in an adolescent with abdominal pain demonstrates acute interstitial edematous pancreatitis. Note the normal enhancement of the pancreatic parenchyma despite mild enlargement, unsharp margins, & surrounding edema.* **(Right)** *Axial CECT in an adolescent with acute necrotizing pancreatitis shows a lack of enhancement of the pancreatic body & tail. There is free fluid throughout the abdomen with small amounts collecting in the parabolic gutters.*

(Left) *Axial CECT in the same patient obtained 2 weeks after the prior image shows a continued lack of enhancement of the pancreatic body & tail. There is an acute necrotic collection in the lesser sac posterior to the stomach.* **(Right)** *Axial CECT obtained 6 weeks after the initial imaging study in the same patient shows a conglomerate collection of walled-off necrosis in the pancreatic body & tail.*

TERMINOLOGY

Definitions

- Acute pancreatitis (AP): Acute inflammation of pancreas with variable involvement of local/regional tissues
  - 2 of 3 features are required for diagnosis
    - Abdominal pain consistent with disease
    - Rise in serum amylase or lipase ≥ 3x normal
    - Imaging findings consistent with AP
  - 2 types of AP
    - Interstitial edematous pancreatitis
    - Necrotizing pancreatitis
- Acute recurrent pancreatitis (ARP): ≥ 2 distinct episodes of AP with complete resolution of pain for ≥ 1 month or normalization of enzyme levels
- Chronic pancreatitis (CP): Requires 1 or more of following clinical features or imaging findings of chronic pancreas damage
  - Abdominal pain consistent with pancreatic origin
  - Exocrine pancreatic insufficiency
  - Endocrine pancreatic insufficiency
- Fluid collections
  - Acute peripancreatic fluid collection: Fluid collection associated with interstitial edematous pancreatitis during first 4 weeks
  - Pancreatic pseudocyst: Fluid collection associated with interstitial edematous pancreatitis after first 4 weeks
  - Acute necrotic collection: Collection containing fluid & necrotic material during first 4 weeks
  - Walled-off necrosis: Collection containing fluid & necrotic material after first 4 weeks

IMAGING

General Features

- Best diagnostic clue
  - AP: Edematous pancreas & peripancreatic inflammation
    - Interstitial edematous pancreatitis: Gland enlargement, homogeneous enhancement (which may be mildly ↓ diffusely), & edema
      - Acute peripancreatic fluid collection: Nonencapsulated collections of variable size & shape
      - Pancreatic pseudocyst: Encapsulated cystic lesion with no internal solid component > 4 weeks from onset
    - Necrotizing pancreatitis: Gland enlargement, heterogeneous enhancement (with foci of moderately to severely ↓ enhancement), & edema
      - Acute necrotic collection: Nonencapsulated collection, may be single or multiple, with heterogeneous contents
      - Walled-off necrosis: Well-circumscribed cavity containing necrotic tissue, often involving pancreatic parenchyma, > 4 weeks from onset
    - Complications: Fluid collections, infection, disconnected duct, pseudoaneurysm of splenic artery, splenic vein thrombosis
  - CP: Pancreatic Ca^{2+}, glandular atrophy, duct irregularity or enlargement
- Location
  - Acute peripancreatic fluid collection/pseudocyst: Adjacent to pancreas in lesser sac or anterior pararenal space
  - Acute necrotic collection/walled-off necrosis: Peripancreatic, pancreatic, or both
- Size
  - AP: Focal or diffuse enlargement of pancreas
  - CP: Atrophy of pancreas, enlargement of pancreatic duct

Ultrasonographic Findings

- AP: Enlarged, hypoechoic, heterogeneous pancreas
  - Look for gallstones, biliary dilation, fluid collection
- CP: Atrophic pancreas with echogenic areas of Ca^{2+} & dilated pancreatic duct

CT Findings

- Interstitial edematous pancreatitis
  - Focal or diffuse pancreatic enlargement
  - Homogeneous enhancement, often mildly ↓, of edematous pancreatic parenchyma
  - ± surrounding fat inflammation
  - Acute peripancreatic fluid collection: Homogeneous fluid collection without defined capsule
  - Pancreatic pseudocyst: Fluid density cyst with well-defined capsule > 4 weeks from onset
- Necrotizing pancreatitis
  - Can affect pancreas, peripancreatic tissue, or both
  - Area of moderately to severely ↓ enhancement within pancreas or peripancreatic mesentery
  - Acute necrotic collection: Irregular hyperdense material within hypodense fluid collection
  - Walled-off necrosis: Fluid density collection in area of prior necrosis > 4 weeks from onset
    - Other findings: Paracolic or retrocolic extension, irregular border, fat attenuation debris, thick septations, pancreatic deformity
- CP
  - Atrophic pancreas
  - Dilation of pancreatic duct
  - Coarse Ca^{2+} in pancreas

MR Findings

- Interstitial edematous pancreatitis
  - T1 or T2 FS: Peripancreatic fat stranding
  - T2: Enlarged, hyperintense pancreas
    - Autoimmune pancreatitis may show striking thickening & hypointense "capsule" or rim
      - Diffuse sausage-like thickening vs. focal & mass-like
  - Diffuse enhancement
  - Acute peripancreatic fluid collection: Fluid signal on T1 & T2
  - Pancreatic pseudocyst: Fluid signal intensity on T1 or T2 with dependent debris
- Necrotizing pancreatitis
  - Portions of pancreas are hyperintense on T1, hypointense on T2, & do not enhance after contrast
  - Acute necrotic collection
    - Nonencapsulated
    - T2 hypointense material layering within hyperintense fluid
  - Walled-off necrosis: Collection with visible capsule in area of prior necrosis, disconnected duct

- MRCP
  - ARP: Look for congenital anomalies
    - Pancreas divisum
    - Pancreatobiliary maljunction
  - CP: Look for sequelae of pancreatitis
    - Pancreatic duct strictures
    - Dilated pancreatic duct
    - ↓ exocrine response to secretin administration

DIFFERENTIAL DIAGNOSIS

Pancreatic Trauma

- Can cause pancreatitis
- More common in children due to relative size of pancreas in abdomen
- Classic mechanisms include handlebar injury & nonaccidental trauma
- May cause pancreatic transection ± duct injury

Pancreatic Lymphoma

- Uncommon site of involvement
- Enlargement of pancreas can be focal or diffuse
- Hypoechoic/hypoenhancing masses + adjacent adenopathy

Shock Pancreas

- Enlarged, hyperenhancing pancreas with hypoenhancing septa in setting of hypovolemic shock
- Associated with other findings of shock
- Resolves following fluid resuscitation

Cystic Fibrosis

- Cause of CP
- Usually associated with diffuse fatty infiltration of pancreas
  - ± atrophy with speckled Ca^{2+}

PATHOLOGY

General Features

- Etiology
  - AP: Caused by acinar cell injury & premature activation of trypsinogen to trypsin in pancreas
    - Biliary obstruction: Gallstones
    - Anatomic: Pancreas divisum, pancreatobiliary maljunction, choledochal cyst, annular pancreas
    - Systemic illness: Sepsis, shock, hemolytic uremic syndrome, systemic lupus erythematosus
    - Drugs: L-asparaginase, valproic acid, azathioprine, mercaptopurine, mesalamine
    - Trauma: Motor vehicle accident, handlebar injury, nonaccidental trauma
    - Metabolic disorders: Cystic fibrosis, hyperlipidemia, hyperparathyroidism
    - Genetic/hereditary
    - Autoimmune
    - Idiopathic (up to 20%)
  - CP: Pancreatic injury followed by sustained immune activation where fibrosis dominates
    - Cystic fibrosis: Most common cause of CP
    - Hereditary pancreatitis: Autosomal dominant disorder associated with recurrent bouts of pancreatitis
    - Anatomic causes: Pancreas divisum, annular pancreas, choledochal cyst
- Genetics
  - Multiple genetic mutations are associated with ARP/CP
    - *SPINK1*, *CFTR*, *CTRC*, *PRSS1*, & *PRSS2*

CLINICAL ISSUES

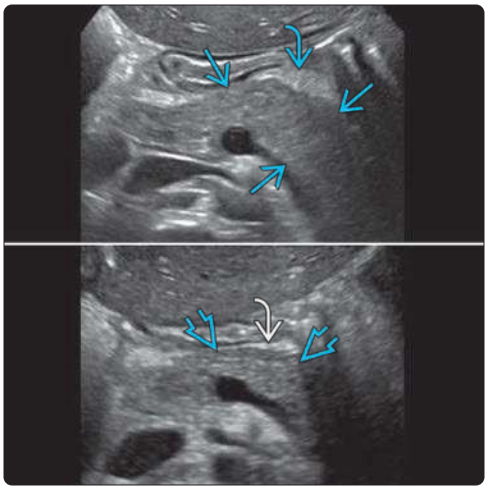
Presentation

- Most common signs/symptoms
  - Epigastric abdominal pain
  - Elevated amylase & lipase to level > 3x normal
- Other signs/symptoms
  - Vomiting, anorexia, & nausea
  - Patient appears ill, irritable, & quiet
  - Physical exam findings: Tachycardia, fever, hypotension, abdominal signs

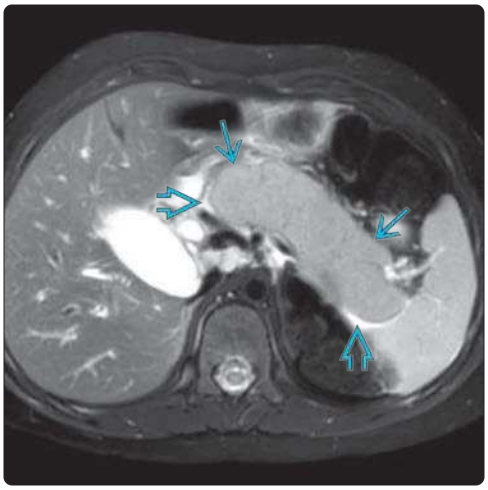
Demographics

- Epidemiology
  - Increasing in incidence over last decade
    - AP: 1 in 10:1000; CP: 2 in 100,000
  - ~ 50% of patients with hereditary pancreatitis develop CP
  - Mortality rate from AP: 2-10%

Natural History & Prognosis



- Pseudocyst is most common complication of AP
- With CP, pain may be transient & not severe
  - End-stage disease leads to endocrine & exocrine dysfunction



Treatment

- Treatment has evolved over past decade
- Current mainstays of therapy: Fluid resuscitation, early enteral nutrition, & pain management
- Fluid collections may require drainage
- Various surgical procedures in setting of chronic pain, including total pancreatectomy with islet autotransplantation (TPIAT)

(Left) *Transverse US in a 13-year-old with abdominal pain shows that the pancreas is enlarged & heterogeneous compared to its appearance 1 year prior. Also note the induration of adjacent fat compared to the prior exam. The current findings are consistent with acute pancreatitis.* **(Right)** *Axial T2 FS MR in a 6-year-old with pain shows diffuse, sausage-like thickening of the pancreas with ↑ signal of the parenchyma + surrounding edema, a typical appearance for autoimmune pancreatitis.*

(Left) *Axial T2 FS MR in an adolescent with acute interstitial edematous pancreatitis shows enlargement & edema of the pancreatic body & tail. The pancreatic duct is mildly enlarged.* **(Right)** *Axial oblique T1 FS MR in a patient with acute interstitial edematous pancreatitis shows relatively normal ↑ T1 signal in the pancreatic head while the pancreatic body & tail have ↓ signal due to interstitial edema.*

(Left) *Axial CECT in a young child with nonaccidental trauma shows a transection in the body of the pancreas. There is mild peripancreatic edema near the transection.* **(Right)** *Axial CECT in the same patient obtained 5 days later shows a large peripancreatic collection in the lesser sac arising from the transection, strongly suggesting a pancreatic duct injury.*

Primary Mesenteric Adenitis

KEY FACTS

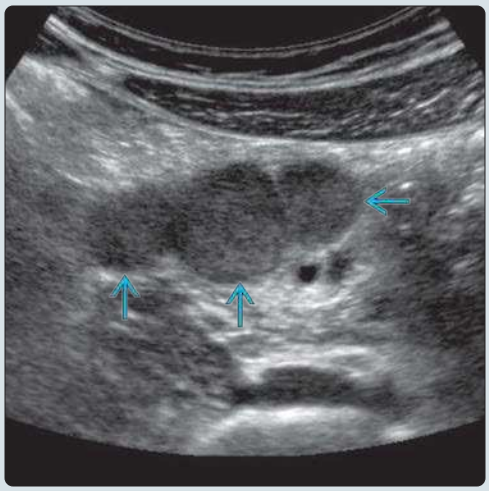
TERMINOLOGY

- Self-limited, benign inflammation of lymph nodes in bowel mesentery; diagnosis of exclusion

IMAGING

- Best diagnostic clue
  - Cluster of ≥ 3 enlarged right lower quadrant or mesenteric lymph nodes
  - Literature on size for diagnosis varies: ≥ 5 mm in short axis vs. >10 mm in short axis vs. >10 mm in long axis
- Ultrasound
  - Enlarged hyperemic lymph nodes often retain normal nodal architecture with fatty hilum
  - Pain with compression over nodes
  - ± fat induration; no abscess or phlegmon
  - Normal appendix (< 6 mm & compressible)
- CECT findings
  - Mildly enlarged lymph nodes, most commonly anterior to right psoas muscle
  - Ileal or colonic wall thickening in < 1/3
    - More common < 5 years of age
  - Normal appendix without surrounding inflammation

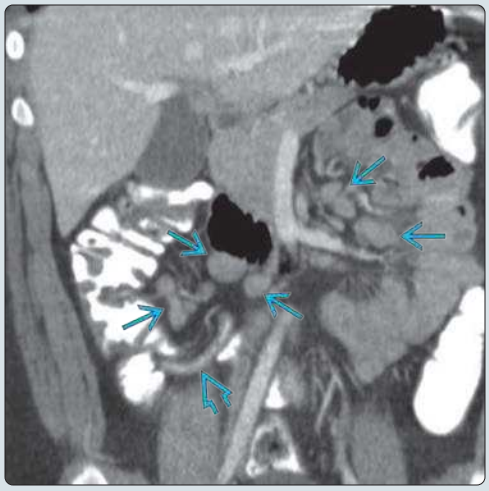
TOP DIFFERENTIAL DIAGNOSES



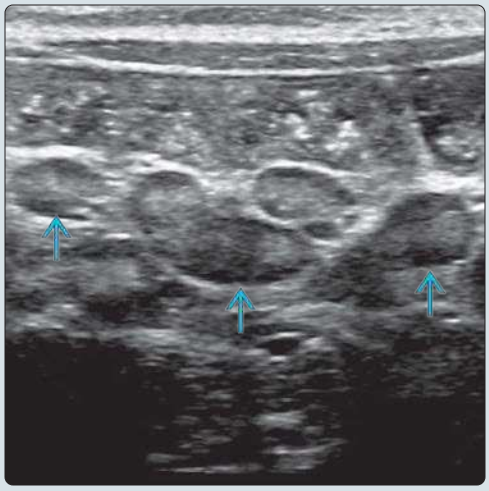
- Appendicitis
- Omental infarction
- Crohn disease
- MIS-C
- Burkitt lymphoma

PATHOLOGY

- Majority are likely secondary to viral or bacterial infection
- Recent upper respiratory infection in up to 25%



CLINICAL ISSUES



- Most commonly occurs < 15 years of age
- Mimics appendicitis: Similar clinical presentation
  - Most frequent alternative diagnosis to appendicitis
- Conservative treatment for primary mesenteric adenitis

(Left) *Transverse ultrasound of the right lower quadrant in a 10-year-old with abdominal pain & fever shows a cluster of 3 lymph nodes, each measuring > 5 mm in short axis, at the site of tenderness. Additional enlarged lymph nodes were also present. The appendix was not visualized.* **(Right)** *Coronal CECT in the same patient shows a cluster of 3 lymph nodes, each measuring > 5 mm in size. The appendix was normal (not shown). The patient was diagnosed with mesenteric lymphadenitis & treated conservatively.*

(Left) *Coronal CECT in a 9-year-old with abdominal pain depicts multiple lymph nodes that measure >5 mm & a normal contrast opacified appendix. The patient was diagnosed with mesenteric adenitis.* **(Right)** *Longitudinal ultrasound in a 2-year-old with abdominal pain shows mildly enlarged but otherwise normal-appearing lymph nodes in the right abdomen. No other pathology was identified. The patient's symptoms resolved with conservative therapy, typical of mesenteric adenitis.*

TERMINOLOGY

Definitions

- Self-limited, benign inflammation of lymph nodes in bowel mesentery; diagnosis of exclusion
- Secondary mesenteric adenitis refers to lymphadenopathy associated with detectable intraabdominal inflammatory process, commonly Crohn disease or infectious ileitis
- Most frequent alternative diagnosis to appendicitis

IMAGING

General Features

- Best diagnostic clue
  - ≥ 3 clustered, enlarged right lower quadrant (RLQ) or mesenteric lymph nodes
  - Literature varies on size for diagnosis; recommendations include
    - ≥ 5 mm in short axis
    - > 10 mm in short axis
    - > 10 mm in long axis
  - Normal appendix

Ultrasonographic Findings

- Cluster of enlarged RLQ or mesenteric lymph nodes
- Nodes may be hyperemic but often retain normal sonographic architecture with echogenic fatty hilum
- May have pain with compression at nodes
- ± ↑ echogenicity of RLQ fat
- ± ileal or colonic wall thickening (especially < 5-years-old)
- Normal appendix (< 6 mm & compressible)

CT Findings

- Cluster of enlarged RLQ or mesenteric lymph nodes
  - Most commonly anterior to right psoas muscle
  - Often track along superior mesenteric artery branches
- Normal appendix
- Ileal (up to 33%) or colonic (up to 18%) wall thickening
  - More common < 5 years of age

Imaging Recommendations

- Best imaging tool
  - Graded compression ultrasound
    - No ionizing radiation
    - Confirms tenderness at lymph nodes
    - Normal appendix visualized

DIFFERENTIAL DIAGNOSIS

Appendicitis

- Noncompressible appendix ≥ 6 mm in diameter with surrounding fat induration
- Lumen is typically distended by fluid ± calcified appendicolith
- Enlarged lymph nodes in 40-82%, mean of 9 mm
  - Typically less numerous than primary adenitis
- Ileal or colonic wall thickening, particularly with appendix perforation

Omental Infarction

- Poorly defined focus of echogenic/hyperattenuating fat immediately deep to anterior right abdominal wall

Crohn Disease

- Abnormal thickening, hyperenhancement/hyperemia, & diffusion restriction of terminal ileum & cecum
- ± mesenteric fat proliferation, vasa recta engorgement, enlarged lymph nodes, fistula, abscess, small bowel feces sign (due to distal stricture)

MIS-C

- COVID-19-related pediatric inflammatory syndrome with numerous neurologic, cardiopulmonary, & abdominal manifestations
  - Gallbladder wall thickening, hepatomegaly, ascites, bowel wall thickening, mesenteric adenopathy, echogenic kidneys

Burkitt Lymphoma

- Larger conglomerate nodal masses, potentially inseparable from thickened bowel wall
- Loss of normal nodal architecture
- Rapid doubling time of tumor

PATHOLOGY

General Features

- Majority of primary mesenteric adenitis is likely infectious
  - Viral: Coxsackievirus & adenovirus
  - *Yersinia enterocolitica* is classic
  - Also *Yersinia pseudotuberculosis*, *Helicobacter jejuni*, *Salmonella*, *Shigella*, *Campylobacter*, *Staphylococcus*
- Recent streptococcal upper respiratory infection in up to 25% (may be reactive)

CLINICAL ISSUES

Presentation

- Diffuse or focal RLQ abdominal pain is most common
- ± nausea, vomiting, diarrhea, recent upper respiratory infection, leukocytosis

Demographics

- Most commonly < 15-years-old

Treatment

- Primary mesenteric adenitis: Conservative
- Secondary mesenteric adenitis: Treat underlying cause

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Bowel findings are uncommon overall in primary mesenteric adenitis & necessitate further investigation
- Appendix must be normal

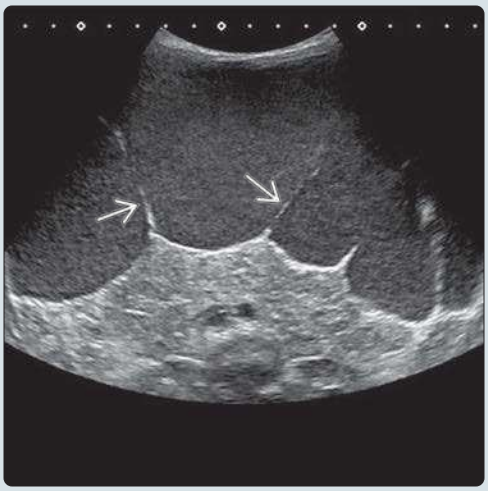
Mesenteric Lymphatic Malformation

KEY FACTS

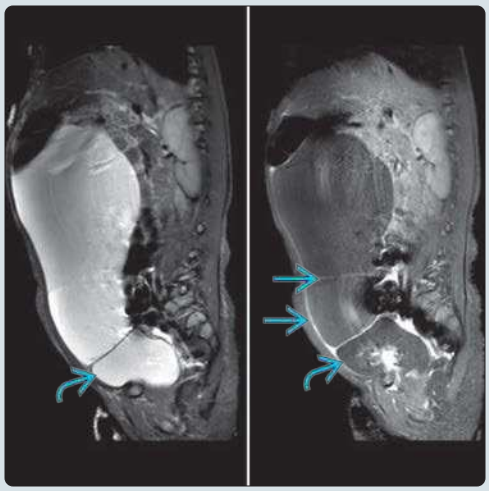
TERMINOLOGY

- Subtype of congenital slow-flow vascular malformation due to error of lymphatic vessel formation
- Results in well-defined, cyst-like (macrocystic) &/or infiltrative, solid-appearing (microcystic) mass of abnormal lymphatic channels focally or diffusely within mesentery
  - Individual cyst size: Macrocyst > 1 cm, microcyst < 1 cm

IMAGING



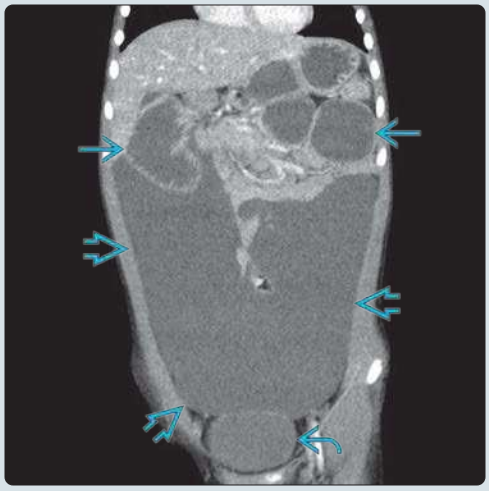
- Macrocystic: Well-defined, lobulated, unilocular or multilocular, fluid-filled mass in mesentery
  - Thin septations with minimal enhancement (unless complicated by hemorrhage or infection)
  - Simple vs. complex fluid varies between cystic components
    - ± layering fluid-fluid levels (due to blood products) & fat/chylous fluid; Ca^{2+} is uncommon
- Microcystic: More solid-appearing, infiltrative
- Best imaging tool: Ultrasound or MR
  - More sensitive than CT for characteristic thin septations & fluid-debris/fluid-fluid levels



CLINICAL ISSUES

- Generally grow commensurate with patient
  - May rapidly enlarge due to hemorrhage/trauma, infection, or hormonal stimulation (puberty, pregnancy)
- Complications include bowel obstruction, volvulus, infection, hemorrhage, rupture, compartment syndrome
- Age of presentation varies widely
  - Abdominal pain, distention, vomiting, palpable mass
- Treatments include
  - Simple excision, partial bowel resection, sclerotherapy
  - Sirolimus (mTOR inhibitor) medical therapy

DIAGNOSTIC CHECKLIST



- Verify cystic mass is not actually due to distended hollow organ (such as urinary bladder)
- Look for true solid components suggesting neoplasm

(Left) *Transverse ultrasound through the abdomen in a 2-year-old patient with abdominal distention shows a large, hypoechoic mass occupying the anterior peritoneal cavity & displacing bowel posteriorly. Thin septations & swirling granular debris were seen in the mass.* **(Right)** *Sagittal STIR (left) & T1 C+ FS (right) MR images in the same patient show only mild rim & septal enhancement of this massive mesenteric lymphatic malformation (LM). Note the distortion of the urinary bladder by the mass.*

(Left) *AP radiograph in a 5-year-old with vomiting & abdominal distention shows a few dilated small bowel loops in the upper abdomen with a paucity of bowel gas in the lower abdomen.* **(Right)** *Coronal CECT in the same patient shows a large, fluid-attenuation mass filling the peritoneal cavity, extending from the urinary bladder to the liver. This LM of the jejunal mesentery was found to be causing a segmental volvulus with proximal bowel dilation, requiring resection.*

TERMINOLOGY

Synonyms

- Mesenteric or omental cyst; lymphangioma (antiquated)

Definitions

- Subtype of congenital slow-flow vascular malformation due to error of lymphatic vessel formation
- Results in well-defined, cyst-like (macrocystic) &/or infiltrative, solid-appearing (microcystic) mass of abnormal lymphatic channels focally or diffusely within mesentery
  - Individual cyst size: Macrocyst > 1 cm, microcyst < 1 cm
- Often lacks communication with normal lymphatics

IMAGING

General Features

- Best diagnostic clue
  - Multicystic mass in small bowel mesentery

Ultrasonographic Findings

- Grayscale ultrasound
  - Mostly anechoic mass with numerous thin septations
  - Can be complex with varying degrees of debris or hemorrhage within different components
    - Debris may be uniform or layer dependently
    - Contents swirl with intermittent compression
- Color Doppler
  - No significant internal vascularity, though LMs frequently encase normal vessels

MR Findings

- Unilocular or multiseptated cystic mass
  - Largely of fluid signal intensity
    - Layering fluid-fluid levels are often present (due to blood products, typical of slow-flow vascular malformations)
  - Components of T1 shortening may be due to hemorrhage or fat
  - Minimal rim/septal enhancement (unless complicated)
  - ± foci of restricted diffusion due to blood products

Imaging Recommendations

- Best imaging tool
  - Ultrasound or MR
    - More sensitive than CT for characteristic thin septations & fluid-debris/fluid-fluid levels
- Protocol advice
  - Subtracted (pre- from postcontrast) FS T1 MR images provide clearest assessment of enhancing components

DIFFERENTIAL DIAGNOSIS

Gastrointestinal Duplication Cyst

- Unilocular cyst with sonographic gut signature sign
- ± peristalsis (pathognomonic if seen)

Ovarian Cystic Mass

- Simple or complicated cyst vs. cystic neoplasm

Distended/Obstructed Viscus

- Large urinary bladder, chronically obstructed vagina (hydrocolpos), chronic focal dilation of bowel

Mesothelial Cyst

- Due to incomplete fusion of peritoneal surfaces
- Typically unilocular

Cystic Malignancy

- Infantile fibrosarcoma, primitive neuroectodermal tumor
- Typically have intermixed solid/nodular components with restricted diffusion & vascularity/enhancement

Mesenteric Lymphangiectasia

- Diffusely dilated mesenteric lymphatics/mesenteric lymphedema; difficult to discern from microcystic LM
- Due to mesenteric lymphatic flow disorder
- Protein-losing enteropathy & chylous ascites are typical
- Abnormal flow can be demonstrated on MR lymphangiography

Other Cysts/Pseudocysts

- Ventriculoperitoneal shunt pseudocyst, hepatic cyst, choledochal cyst, meconium pseudocyst, loculated ascites, peritoneal inclusion cyst, abscess, hematoma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Abdominal pain, distention, vomiting, palpable mass
  - Commonly asymptomatic

Demographics

- Age of presentation varies widely

Natural History & Prognosis

- Generally grow commensurate with patient
  - May rapidly enlarge due to hemorrhage/trauma, infection, or hormonal stimulation (puberty, pregnancy)
- Complications
  - Bowel obstruction, volvulus, ischemia, infection, hemorrhage, compartment syndrome, rupture

Treatment

- Simple excision, partial bowel resection
  - Relationship to intestinal walls, mesenteric vessels, & other vital structures determines resectability
  - Recurrence: Up to 100% with incomplete resection
- Sclerotherapy (commonly used in other sites of macrocystic LM) is gaining popularity for abdominal LM
- Sirolimus (mTOR inhibitor) is now often used as medical therapy for LM

Omental Infarction

KEY FACTS

TERMINOLOGY

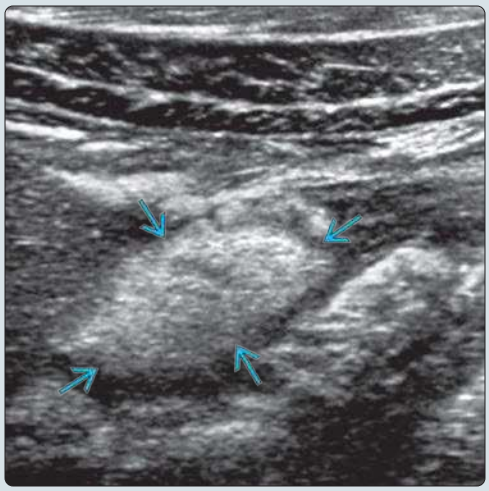
- Benign, self-limited cause of acute abdominal pain due to segmental vascular occlusion of omentum

IMAGING

- General features
  - Well-demarcated, triangular/wedge-shaped or oval focus of ↑ attenuation/echogenicity within omental fat
  - Right mid to upper abdomen, deep to anterior wall
  - ± thickening of overlying peritoneal membrane
  - ± free intraperitoneal fluid &/or pleural effusion
  - No adjacent inflammatory etiologies (e.g., appendicitis)
- US: Echogenic focus with no internal color Doppler flow + tethered fat sign; painful to direct sonographic palpation
- CT: Focal fat stranding ± hyperattenuating, streaky densities due to fibrous bands or thrombosed vessels
  - ± peripheral enhancement
  - ± whirl or vascular pedicle sign with torsion
- Recommendations
  - Ultrasound: Acceptable 1st-line modality despite lower sensitivity for this diagnosis compared to CECT
    - Sensitivity is higher for surgical diagnoses (e.g., appendicitis)

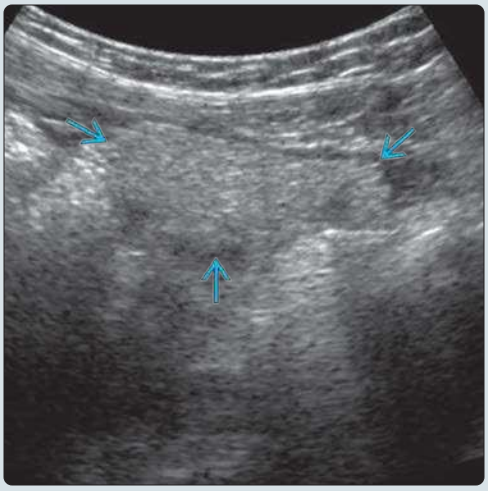
TOP DIFFERENTIAL DIAGNOSES

- Epiploic appendagitis, appendicitis, slow-flow vascular malformation, mesenteric contusion, fat-containing masses



PATHOLOGY

- Etiologies: Anatomic vascular variation, hypercoagulability, torsion, systemic states prone to vascular congestion
- Majority of patients are obese



CLINICAL ISSUES

- Abdominal pain & tenderness, nausea, vomiting, fever
- Conservative treatment is typically adequate
- Occasional surgical excision if pain is intractable, symptoms worsen, or imaging is equivocal

(Left) *Axial CECT in an 11-year-old with right abdominal pain depicts a focus of inflammatory stranding immediately deep to the abdominal wall & anterior to the ascending colon, typical of an omental infarct.* **(Right)** *Transverse ultrasound in a 7-year-old with abdominal pain shows a well-demarcated, ovoid, hyperechoic focus deep to the right anterior abdominal wall. A normal appendix was not visualized. Omental infarct was confirmed at surgery.*

(Left) *Transverse ultrasound in an 8-year-old with right lower quadrant abdominal pain secondary to omental infarct demonstrates a triangular focus of ↑ echogenicity deep to the anterior abdominal wall at the site of palpable pain.* **(Right)** *Coronal CECT from an 8-year-old with abdominal pain shows a focal area of ↑ omental attenuation at the right upper quadrant, compatible with an omental infarction. Note the internal linear densities. The appendix was normal (not shown).*

TERMINOLOGY

Definitions

- Benign, self-limited cause of acute abdominal pain due to segmental vascular occlusion of omentum

IMAGING

General Features

- Best diagnostic clue
  - Well-demarcated, triangular/wedge-shaped or oval focus of omental fat stranding (CT) or hyperechogenicity (US) without other source of inflammation
    - Typically in right upper quadrant (RUQ)

Ultrasonographic Findings

- Relatively hyperechoic noncompressible, wedge-shaped, or oval focus with no color Doppler flow
- Typically in RUQ immediately deep to anterior abdominal wall
  - Tethered fat sign: Adherent to abdominal wall, no motion with respiration
- Painful to direct sonographic palpation
- ± free intraperitoneal fluid &/or pleural effusion

CT Findings

- Well-defined focus of hazy ↑ attenuation of omental fat
- Triangular/wedge-shaped or oval
- Typically in RUQ between anterior abdominal wall & transverse or ascending colon
- ± streaky/linear densities representing fibrous bands or thrombosed vessels
- ± peripheral enhancement
- ± whirl or vascular pedicle sign: Torsion of omental fat & vessels around engorged vascular pedicle
- ± thickening of overlying peritoneum
- ± free intraperitoneal fluid &/or pleural effusion
- No other source for inflammation (e.g., appendicitis, colitis, etc.)

Imaging Recommendations

- Ultrasound is typically 1st-line modality
  - Low sensitivity (60-80%) for omental infarction but higher for other diagnoses with similar presentations
- CECT has greater sensitivity (90%) for omental infarction

DIFFERENTIAL DIAGNOSIS

Epiploic Appendagitis

- Torsion & resultant inflammation of epiploic appendage along colon, typically in lower quadrants
- Oval focus of pericolonic fat inflammation
- Hyperdense central dot sign (thrombosed vessel) is classic

Appendicitis

- Enlarged, noncompressible appendix with adjacent inflammatory change

Mesenteric Lymphadenitis

- Cluster of ≥ 3 lymph nodes ≥ 5 mm each (in short axis)
- ± adjacent fat stranding

Mesenteric Contusion

- Typically preceded by clear history of trauma
- ± overlying contusion of subcutaneous fat

Slow-Flow Vascular Malformation

- ± poorly defined infiltrative components of venous or lymphatic malformations, typically in conjunction with mass-like abnormal vascular channels or cysts

Meckel Diverticulitis

- Noncompressible, blind-ending tubular structure arising from distal ileum with adjacent inflammatory change

Fat-Containing Masses

- Teratoma & lipoblastoma are uncommon in anterior abdomen in children
- More solid & heterogeneous in appearance

PATHOLOGY

General Features

- Due to anatomic vascular variation, hypercoagulability, torsion (due to scars, hernias, omental cysts), systemic states prone to vascular congestion (right heart failure)

Gross Pathologic & Surgical Features

- Venous stasis &/or thrombosis → venous congestion → omental edema & congestion (early infarct) → hemorrhagic necrosis/infarction → granulomatous infiltrate (6-7 days) → fibrosis & scar

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Abdominal pain & tenderness, typically right-sided
- Other signs/symptoms
  - Nausea, vomiting, mild fever, mild ↑ CRP & WBC

Demographics

- Epidemiology
  - 15% of all cases occur in children
  - M:F = ~ 2-4:1
  - Risk factors: Obesity, omental anatomic abnormalities

Treatment

- Conservative treatment, including analgesia & antibiotics
  - Complete resolution in < 2 weeks
- Occasional surgical excision if pain is intractable, symptoms worsen, &/or imaging is equivocal

Hypoperfusion Complex

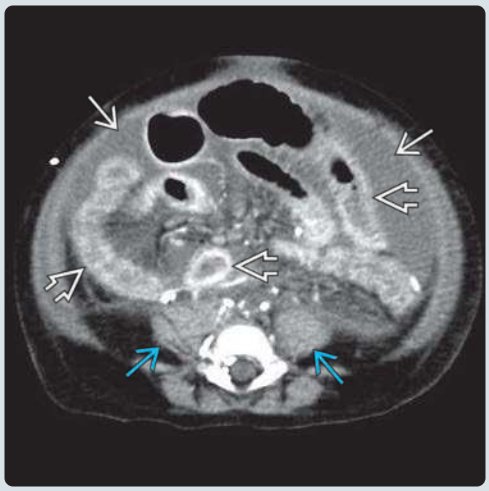
KEY FACTS

TERMINOLOGY

- Synonyms: Shock bowel, hypotension complex

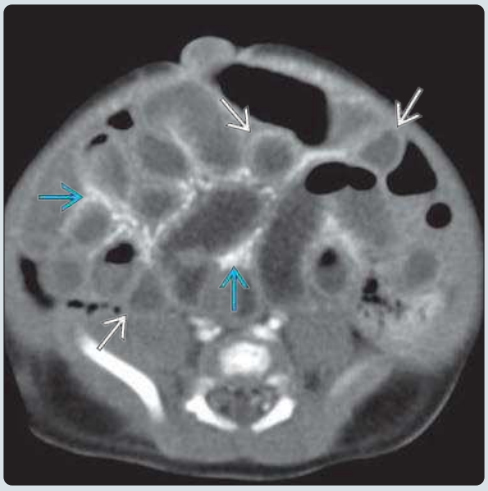
IMAGING

- Bowel: Diffuse wall thickening, ↑ enhancement (mucosal vs. full thickness), ± fluid distention
- Vessels: ↑ enhancement but ↓ caliber
- Abnormal solid organ appearances may include
  - Adrenal glands: Prolonged enhancement > IVC
  - Kidneys: Prolonged cortical enhancement > aorta; rarely ↓ enhancement < 10 HU (poor prognosis)
  - Pancreas: Enlarged, feathery appearance due to septal edema; altered enhancement at least 20 HU > or < liver
  - Liver: Heterogeneous enhancement with ≥ 30 HU difference between highest & lowest measurements at level of portal vein
  - Gallbladder mucosal enhancement (50 HU > psoas)
  - Spleen: ↓ enhancement (20 HU < liver); ≥ 30% ↓ in volume

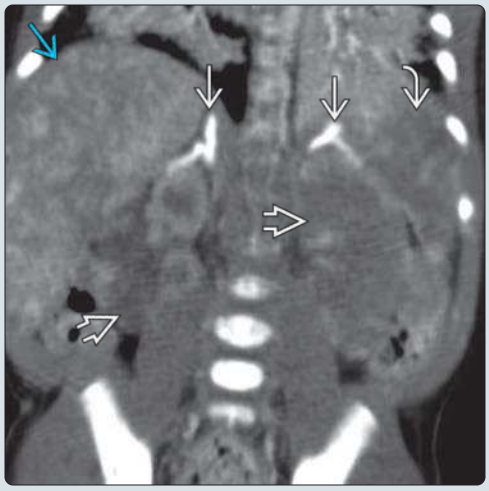


PATHOLOGY

- Shock: Compensated → decompensated → irreversible
- Sympathetic nervous, cardiovascular, & neuroendocrine systems help maintain arterial pressure & cardiac output in compensated state
- Pediatric patients can maintain normal/near-normal blood pressure longer than cardiac output → rapid, abrupt progression to decompensated state



CLINICAL ISSUES



- CT findings often precede clinical recognition of shock
  - In one series, hypotension developed within 10 minutes of CT in 19% of children
  - In same series, 85% mortality rate with presence of hypoperfusion complex (compared with 2% of all children who suffered blunt trauma)
- Requires prompt notification & transfer to clinical service for intense monitoring, volume replacement, supportive measures, & surgery if needed

(Left) *Coronal CECT in a 5-month-old patient in septic shock demonstrates a large volume of ascites, diffuse bowel wall hyperenhancement & thickening, & heterogeneity of the liver parenchyma.* **(Right)** *Axial CECT in the same patient illustrates the diffuse bowel wall thickening & hyperenhancement relative to the psoas muscles. A large volume of ascites is again seen. The constellation of findings in this patient is compatible with hypoperfusion complex.*

(Left) *Axial CECT in a 2-month-old boy with cardiogenic shock shows diffusely dilated & fluid-filled small bowel with mild wall thickening. There is intense enhancement of the mesenteric vessels.* **(Right)** *Coronal CECT in the same patient demonstrates intensely enhancing adrenal glands, a characteristic finding in hypoperfusion complex. There is heterogeneous liver parenchyma & ↓ enhancement of the kidneys & spleen.*

TERMINOLOGY

Synonyms

- Shock bowel, shock abdomen, hypovolemic shock complex, hypotension complex

Definitions

- Hypoperfusion complex (HC): Constellation of CT findings indicative of compensated shock

IMAGING

CT Findings

- Best imaging clues (on CECT)
  - Diffuse small bowel wall thickening with ↑ enhancement
  - Abnormal solid organ enhancement
  - ↑ enhancement of small-caliber vessels
- Bowel (predominantly small intestine)
  - Diffuse, mild dilation of fluid-filled loops
  - Diffuse mural or mucosal hyperenhancement (> psoas muscle)
  - Diffuse wall thickening > 3 mm
- Vasculature
  - Flat "pancake" inferior vena cava (IVC)
    - ± intense enhancement
    - May show normal caliber & shape with aggressive fluid resuscitation
    - Circumferential ↓ attenuation (< 20 HU) fluid halo around IVC
  - ↓ caliber of intensely enhancing aorta & mesenteric arteries
- Solid viscera
  - Adrenal glands
    - Symmetric & prolonged hyperenhancement (> IVC)
  - Kidneys
    - Symmetric hyperenhancement (> aorta), prolonged in cortex
    - May see ↓ enhancement of medulla on delayed phase
    - ↓ enhancement (< 10 HU) is rarely seen; may represent poor prognosis (black kidney sign)
  - Pancreas
    - Diffusely enlarged, feathery appearance due to edematous intervening septa
    - Altered enhancement (at least 20 HU > or < than liver)
    - Peripancreatic fluid
  - Spleen
    - ↓ enhancement (20 HU < liver)
    - Enhancement > liver is also reported in children
    - Splenic contraction: ≥ 30% ↓ in volume compared to prior study or height- & sex-corrected normal values
      - Due to adrenergic stimulation; persists after fluid resuscitation
  - Liver
    - Parenchymal heterogeneity: ≥ 30 HU difference between highest & lowest measurements at level of portal vein
  - Gallbladder
    - Wall enhancement 50 HU > psoas muscle
    - Wall thickening & surrounding edema
- Mesentery/peritoneum: Generalized edema & unexplained ascites
- Thoracic structures
  - ↓ caliber of intensely enhancing aorta & great vessels
  - ↓ caliber of superior vena cava & IVC
  - ↓ cardiac chamber volume
  - Thyroidal & perithyroidal edema (shock thyroid)
    - Enlargement with intervening septal edema

Ultrasonographic Findings

- FAST scanning of abdomen for potential injury screening
  - May show peritoneal fluid
  - Diffusely fluid-filled & dilated bowel with wall thickening
  - ↓ caliber of IVC, aorta

Imaging Recommendations

- Best imaging tool
  - CECT

DIFFERENTIAL DIAGNOSIS

Bowel Trauma

- Focal (rather than diffuse) bowel wall thickening, dilation, & enhancement abnormalities (↑ or ↓)
- Adjacent vessel extravasation, mesenteric fluid, extraluminal gas
- Extensive extraintestinal findings favor shock bowel over focal bowel injury (though these entities may coexist)

Transient Small Bowel Intussusception

- Short segment(s) of small bowel showing alternating rings of high & low attenuation (in cross section)
- Typically incidental & self-limited
- Seen with higher frequency in trauma patients

Henoch-Schönlein Purpura

- Small vessel vasculitis of unknown etiology
  - Purpuric rash, abdominal pain, arthritis, nephritis, intussusceptions
  - Typical ages of 3-7 years; boys > girls
- Bowel wall thickening with abnormal attenuation/enhancement due to intramural edema &/or hemorrhage

Graft-vs.-Host Disease

- Bone marrow transplant patient with new skin, liver, & gut abnormalities
- Diffusely hyperenhancing but featureless small bowel lumen (ribbon-like)

Other Bowel Inflammatory Processes

- Preexisting bowel conditions may rarely cause hypovolemic shock or occur coincidental with trauma
  - Pseudomembranous colitis: Pancolitis with severe bowel wall thickening but disproportionately minor pericolonic inflammatory change; related to antibiotic use
  - Crohn disease: Marked thickening & abnormal enhancement of terminal ileum & cecum with surrounding inflammation
  - Infectious enterocolitis: *Shigella*, *Escherichia coli*, etc., show abnormal bowel wall thickening & enhancement; colonic lumen is often narrowed with small bowel often being fluid filled & hyperperistaltic

Bowel Ischemia Due to Vascular Occlusion

- Iatrogenic (i.e., neonatal vascular catheter), coagulopathy, cardiovascular disease, midgut volvulus
- May present with bowel wall thickening, diffuse dilation
- Abnormal enhancement of bowel: ↓ with arterial occlusion, ↑ with venous occlusion
- Extensive extraintestinal findings favor shock bowel over primary bowel pathology

PATHOLOGY

General Features

- Shock: Clinical expression of limited oxygen supply/utilization
  - Can result from hypovolemia, head/spine injury, cardiac arrest, septicemia, diabetic ketoacidosis
- Stages of shock
  - Compensated
    - Perfusion to vital organs is maintained by response of sympathetic nervous, cardiovascular, & neuroendocrine systems
    - Children may maintain arterial pressure longer than cardiac output, thus appearing stable enough for CT
    - May abruptly transition to decompensated stage
  - Decompensated
    - Response of sympathetic nervous, cardiovascular, & neuroendocrine systems is insufficient to maintain perfusion
  - Irreversible
    - Volume replacement is unable to reverse depressed cardiac output & hypoperfusion
- Variable organ enhancement results from selective vasoconstriction mediated by ↑ sympathetic tone & renin-angiotensin axis
  - Small-caliber aorta & IVC are due to vasospasm, hypovolemia
  - Relatively intense & prolonged enhancement of adrenal glands is related to central role of adrenal in generating sympathetic response to hypovolemic shock
  - Hyperintense, prolonged enhancement of kidneys is related to vasoconstriction of renal efferent arterioles
  - Splenic arterial flow is without autoregulatory mechanism → vasoconstriction & ↓ perfusion
  - Splanchnic vasoconstriction → ↓ bowel perfusion
    - Altered, ↑ permeability of intestinal mucosa → interstitial leak of fluid & contrast → mucosal enhancement, submucosal edematous wall thickening
    - ↓ fluid reabsorption & ileus may result in fluid-distended lumen
- Associated abnormalities
  - Findings of solid organ injury: Liver, spleen, kidney
  - HC is more frequent with ↑ grades of injury, active extravasation
  - Focal bowel injury may also be present
  - In 1 review, 48% had abdominal organ injury

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pediatric patients in tenuous hemodynamic state
    - Significant hemorrhage after blunt trauma
    - Less common: Neurogenic shock, septic shock, & cardiac arrest
  - Tachycardic
  - Normotensive before decompensation
  - Signs/symptoms of concomitant/causative intracranial & intraabdominal injuries
    - Low Glasgow Coma Scale: < 6 in 20%

Demographics

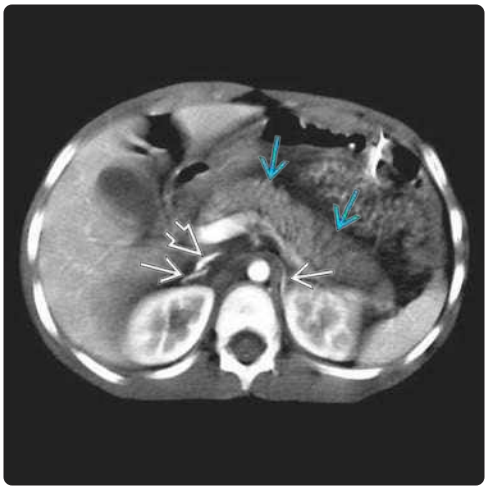
- Age
  - CT findings of shock are more common & more striking in young children (but can be seen at any age)

Natural History & Prognosis

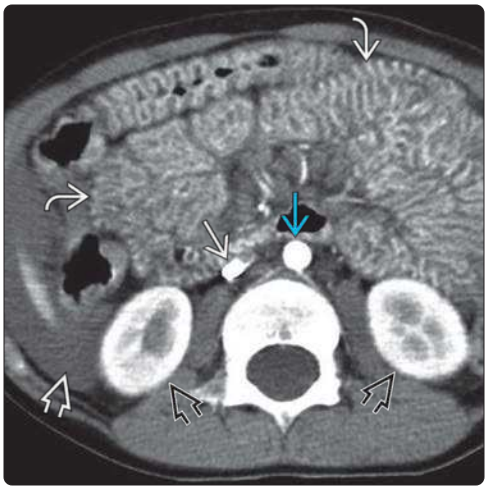
- Poor prognosis in trauma patient
  - CT findings often precede clinical recognition of shock
  - Pediatric patients are able to maintain arterial pressure at or near normal levels longer than cardiac output after severe hemorrhage → stable-appearing patients can rapidly decompensate
    - In one series, progressive hypotension developed within 10 minutes of CT in 19% of children
    - In same series, 85% mortality rate occurred with presence of HC (compared with 2% of all children who suffered blunt trauma)

Treatment

- Fluid/blood volume replacement
- Intense monitoring
- Surgery when necessary for underlying injuries



DIAGNOSTIC CHECKLIST



Consider

- Diffuse small bowel wall thickening with ↑ enhancement & luminal dilation: Suspect HC & look for supporting signs
- Requires prompt notification of clinical team & transfer of patient from CT to ICU or operating room

Bowel Injury

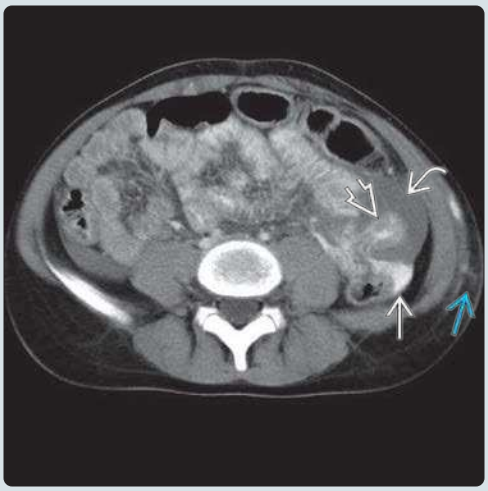
KEY FACTS

IMAGING

- Best clue: Bowel wall discontinuity + extraluminal enteric contents + free intraperitoneal air
- Nonspecific signs: Focal bowel wall thickening, abnormal bowel wall enhancement, mesenteric fluid/stranding
- Sentinel clot sign: Localized mesenteric hematoma adjacent to bowel (40-80 HU)
- In acute blunt trauma setting, oral contrast does not significantly improve sensitivity & may result in inappropriate delay of diagnosis & treatment

TOP DIFFERENTIAL DIAGNOSES

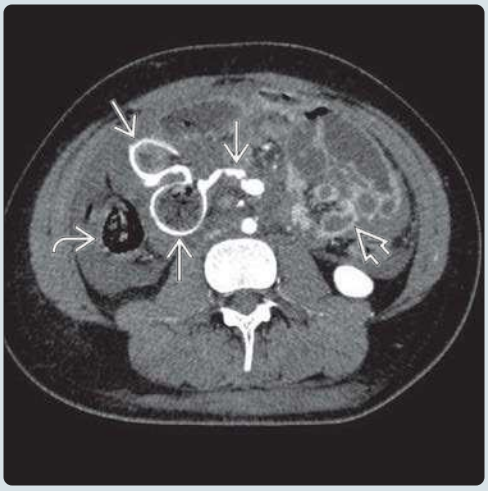
- Hypoperfusion complex (shock bowel)
- Henoch-Schönlein purpura (HSP)
- Inflammatory bowel disease
- Air introduced by iatrogenic procedure, penetrating trauma, or from other sites (chest, genitourinary system)
- Air from extraperitoneal rectal or bladder perforation



PATHOLOGY

- 77% from blunt trauma: Motor vehicle related, nonaccidental trauma, & bicycle related are most common; mechanisms include
  - Sudden ↑ in intraluminal pressure → perforation
  - Crush injury between abdominal wall & spine
  - Shear force between fixed & mobile bowel
- 23% from penetrating trauma
  - With rectal involvement, consider sexual assault

CLINICAL ISSUES



- Signs & symptoms
  - Abdominal pain, peritoneal signs, tachycardia, ↑ WBC
  - Bowel injury in 11% of patients with seat belt sign: Relative risk of 9.4%
- Treatment
  - Perforations: Surgical management
  - Contusion/hematoma: Typically nonoperative
    - Clinical deterioration is main indicator for surgery

(Left) *Axial CECT shows extraluminal oral contrast leaking from a thickened bowel loop in a pediatric car accident victim. Ascites & soft tissue stranding are also seen. Note that oral contrast generally does not improve sensitivity for bowel perforation & delays diagnosis.* **(Right)** *Coronal CECT in a 2-year-old victim of nonaccidental trauma shows thickened bowel loops, regions of ↑ & ↓ bowel wall enhancement, & extensive free fluid. Devascularized jejunum was found at surgery.*

(Left) *Axial CECT in a 13-year-old after a car accident shows IV contrast extravasation from a superior mesenteric artery branch. Hyper- & hypo- enhancing segments of bowel are concerning for hypoperfusion & ischemia.* **(Right)** *Axial CECT in a 12-year-old motor vehicle accident victim shows thick-walled small bowel in the left abdomen. There is edema of the overlying subcutaneous fat with skin thickening, typical of a seat belt sign. Jejunal perforations were found at surgery.*

TERMINOLOGY

Synonyms

- Contusion or hematoma vs. perforation, laceration, tear, enterotomy, transection

IMAGING

General Features

- Best diagnostic clue
  - CECT: Focal bowel wall thickening with discontinuous bowel wall enhancement, extraluminal gas, & surrounding mesenteric fluid/stranding in trauma setting
- Location
  - Retroperitoneal bowel: 2nd, 3rd, & 4th duodenal segments (D2-D4) + ascending & descending colon
  - Intraperitoneal bowel: Stomach, 1st duodenal segment (D1), ileum, jejunum, cecum, transverse & sigmoid colon, upper 2/3 of rectum
  - Extraperitoneal bowel: Lower 1/3 of rectum

Radiographic Findings

- Dilated bowel loops, focal or generalized
  - Inflammation & ischemia may → ileus or obstruction
- Pneumoperitoneum (sensitivity < 30% in cases of bowel perforation due to blunt trauma)
  - Air under diaphragm: Best visualized on upright or left lateral decubitus views
  - ↑ volume of air is required for visualization on supine views
    - Rigler sign: Air outlining both sides of bowel wall
    - Falciform ligament sign: Vertically oriented linear density in medial right upper quadrant outlined by air
    - Football sign: Ovoid lucency filling abdominal cavity
    - Inverted V sign: Air outlining medial umbilical folds
- Retroperitoneal air
  - Perforation of retroperitoneal bowel segments
  - Outlines psoas, kidney, &/or hemidiaphragm crus
- Flank stripe sign: Peritoneal fluid separating ascending or descending colon from peritoneal reflection or properitoneal fat
- Dog ear sign: Pelvic fluid separating bowel from bladder
- Splinting: Scoliotic curvature concave toward injury

CT Findings

- CECT
  - Peritoneal fluid
    - Nonspecific but must consider bowel injury if > trace fluid volume is seen in absence of solid organ injury or pelvic fracture
    - Specificity 15-26%, sensitivity 90-100%
  - Bowel wall thickening of 1 or several loops
    - ≥ 3 mm or disproportionate to normal bowel wall
    - Seen in 75% of full-thickness lacerations
    - Intramural hematoma may show focal, mass-like eccentric thickening
  - Abnormal bowel wall enhancement
    - Psoas muscle is used as reference
    - ↑ enhancement
      - Patchy & irregular with full-thickness laceration
      - Seen paradoxically with hypoperfusion due to damaged vascular endothelium
    - ↓ enhancement
      - Focal contusion/hematoma, traumatic ischemia, &/or mesenteric vascular injury
  - Discontinuity of bowel wall from laceration/perforation
    - Specificity 100%, sensitivity 5-34%
  - Extraluminal enteric contents
    - Specificity ~ 100%, sensitivity 6-15% for perforation
    - Oral contrast does not ↑ sensitivity in blunt trauma; may result in unnecessary delay & aspiration
    - Oral & rectal contrast may help in stable patients with penetrating injury
  - Pneumoperitoneum
    - Angular/curvilinear gas in antidependent abdomen between anterior abdominal wall & liver surface
    - Small, round foci of gas may be confined within mesenteric sheets adjacent to disrupted bowel wall
    - Lung windows are helpful for detection
    - Specificity 95-99%, sensitivity 20-30% for surgically significant injury
    - Sensitivity for bowel perforation ~ 74%
  - Mesenteric fluid, hematoma, &/or stranding
    - Often at mesenteric root; polygonal or V-shaped
    - Sentinel clot (40-80 HU) suggests adjacent bowel injury
  - Mesenteric vessel thrombosis with partial or complete lack of vessel opacification
  - Beaded appearance of mesenteric vessels
  - Active vascular extravasation
    - Irregular, nonanatomic focus of ↑ attenuation (isodense to aorta with arterial injury) near vessel
  - Retroperitoneal gas
    - Perforation of retroperitoneal bowel segments
  - Extraperitoneal gas
    - Perforation of lower 1/3 of rectum

Ultrasonographic Findings

- FAST scan for free fluid in Morison pouch, splenorenal recess, pouch of Douglas, & paracolic gutters
  - Poor sensitivity of 35-44%; not specific for bowel injury
- Bowel wall thickening
- Intramural hematoma: Focal bowel wall thickening of varying echogenicity depending on age
- Pneumoperitoneum: Linear echogenic foci with "dirty" shadowing immediately deep to peritoneal lining

Imaging Recommendations

- Best imaging tool
  - CECT with multiplanar reformats

DIFFERENTIAL DIAGNOSIS

Hypoperfusion Complex (Shock Bowel)

- Diffuse fluid-distended bowel with wall thickening & ↑ enhancement
- ↑ enhancement of adrenals, pancreas, & mesenteric vessels
- ↓ size of aorta & inferior vena cava

Henoch-Schönlein Purpura

- Focal or multifocal bowel wall thickening from hemorrhage of vasculitis
- Purpuric rash on legs & upper extremity extensor surfaces

Inflammatory Bowel Disease

- Colicky abdominal pain, recurrent diarrhea ± blood, weight loss, perianal disease, malabsorption
- Terminal ileal & cecal involvement is most common
- Wall thickening, enhancement ± adjacent mesenteric stranding, vascular engorgement, fat proliferation

Coagulopathy

- Bleeding into bowel wall

Other Causes of Free Intraperitoneal Air

- Iatrogenic introduction of air: Diagnostic peritoneal lavage, peritoneal dialysis catheter, recent surgery
- Air extending from pneumomediastinum, pneumothorax, female genital injury, intraperitoneal bladder perforation
- Air introduced by penetrating injury
- Air from extraperitoneal rectal or bladder perforation
- Serosal rupture of benign colonic pneumatosis beyond infancy

PATHOLOGY

General Features

- Etiology
  - Blunt trauma (77%)
    - Commonly: Motor vehicle related, nonaccidental trauma, bicycle related
    - Intestinal injury in 1-15% of blunt trauma cases
  - Penetrating trauma (23%)
    - Commonly: Gunshot wound, stabbing, impalement
    - Consider sexual assault with rectal trauma
  - Incidence of iatrogenic bowel injury
    - 0.1-7.0% of esophagogastroduodenoscopies, 0.09-3.0% of colonoscopies
- Associated abnormalities
  - Spine injury (including Chance fracture) (9%)
  - Traumatic brain injury (22%)
  - Liver (16%), spleen (11%), pancreas (10%), kidney (6%)
- Injury associated with rectal impalement
  - Anterior: Bladder, uterus, bowel
  - Posterior: Retroperitoneal & vascular structures
  - Perianal: Anus, vagina, urethra

Staging, Grading, & Classification

- American Association for the Surgery of Trauma injury scale
- Grades for stomach injury
  - I: Contusion/hematoma, partial-thickness laceration
  - II: Laceration < 2 cm in gastroesophageal (GE) junction/pylorus, < 5 cm in proximal 1/3 stomach, < 10 cm in distal 2/3 stomach
  - III: Laceration > 2 cm in GE junction/pylorus, > 5 cm in proximal 1/3 stomach, > 10 cm in distal 2/3 stomach
  - IV: Tissue loss/devascularization < 2/3 stomach
  - V: Tissue loss/devascularization > 2/3 stomach
- Grades for jejunum, ileum, colon, & rectum injury
  - I: Contusion or hematoma without devascularization; partial-thickness laceration without perforation
  - II: Laceration < 50% circumference
  - III: Laceration ≥ 50% circumference without transection
  - IV: Transection (small bowel/colon) or full-thickness laceration with extension into perineum (rectum)
  - V: Transection + segmental tissue loss, devascularization

Gross Pathologic & Surgical Features

- Compression of intestinal loops at impact → sudden ↑ in intraluminal pressure → perforation
- Crush injury between anterior abdominal wall & spine
- Rapid deceleration → shear force between fixed & mobile segments of bowel
- Poor fit of seat belt contributes to injury mechanisms
  - "Submarining" under lap belt or lap belt too high on abdomen ± hyperflexion → compression + crush injuries
  - Higher center of gravity in children → shearing force

CLINICAL ISSUES

Presentation

- Abdominal pain, guarding, rigidity, absent bowel sounds, hypotension, tachycardia, elevated WBC
- Seat belt sign in 11%
- Delayed presentation of symptoms > 24 hours: 6.5%

Natural History & Prognosis

- Overall mortality of 5%, usually related to associated injuries
- In contrast to adults, delay in diagnosis & intervention by up to 24 hours does not significantly affect prognosis
- Mesenteric & vascular injury may → delayed bowel injury → ischemia, necrosis, perforation, &/or stenosis
- Can be complicated by sepsis, peritonitis, abscess, postoperative stenosis/obstruction, hernia, leak

Treatment

- Observation + serial examination if diagnosis is in question
  - Clinical deterioration is main indicator for intervention
- Contusion or hematoma typically receives nonoperative management; bowel perforations are managed surgically

DIAGNOSTIC CHECKLIST

Consider

- Unexplained free fluid with focally thickened bowel & surrounding mesenteric edema/hemorrhage is bowel injury until proven otherwise
- Relative risk of bowel injury of 9.4 with lap belt ecchymosis
- Closely analyze bowel in Chance fracture patients

(Left) *Axial CECT in a 7-year-old with a seat belt sign shows high-attenuation fluid at the mesenteric root ➡ with foci of small bowel wall thickening ➡. A mesenteric root hematoma & jejunal contusions were found at surgery.* **(Right)** *Sagittal CECT (with rectal contrast) in a 2-year-old who was rectally impaled by a pencil shows extraluminal gas ➡ & high-attenuation fluid ➡ anterior to the rectum in the rectovesical pouch. An intraperitoneal rectal perforation was found at surgery.*

(Left) *Axial CECT in a 15-year-old after a jet ski accident shows discontinuity of the bowel wall at the rectosigmoid junction ➡. There is peritonitis with extraluminal air ➡, peritoneal enhancement ➡, & fluid ⇨.* **(Right)** *Axial CECT in a 10-year-old boy shot with a pellet gun shows foci of free intraperitoneal air ➡ & small bowel wall thickening ➡. Subcutaneous gas ➡ was also seen in the abdominal wall near the site of penetration. Multiple jejunal perforations were discovered at surgery.*

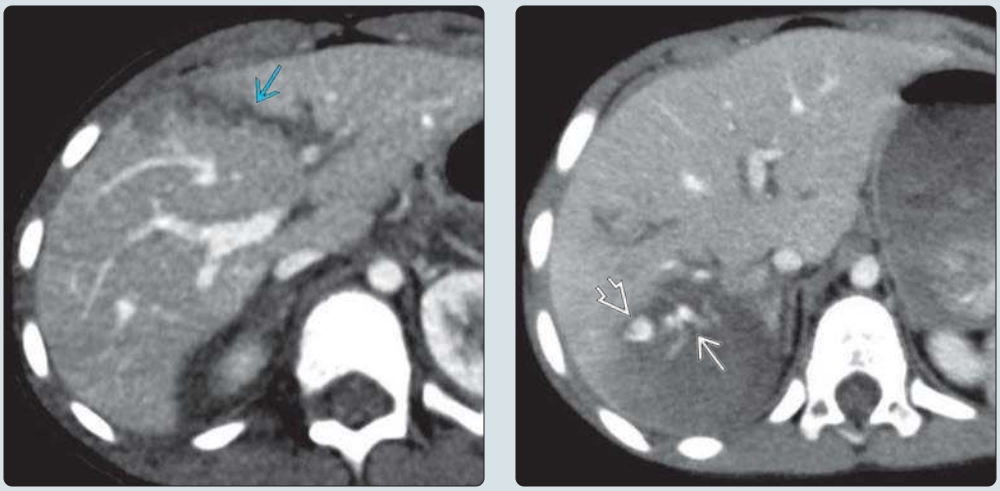
(Left) *Axial CECT in a 4-year-old boy after a motor vehicle accident demonstrates anterior gastric wall disruption ➡ with extrusion of contents ➡. There is a large volume of pneumoperitoneum ➡.* **(Right)** *Axial CECT in a 12-year-old with a bicycle handlebar injury shows ↓ & discontinuous enhancement of the posterior wall of a fluid-filled jejunal loop ⇨ with mild adjacent mesenteric fluid. A jejunal perforation was found intraoperatively.*

Hepatic Trauma

KEY FACTS

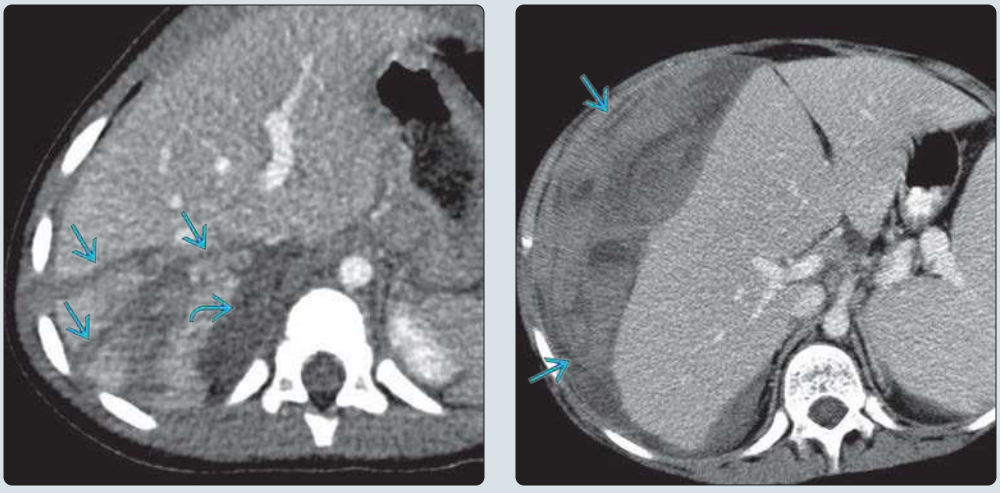
IMAGING

- Gold standard exam for blunt abdominal trauma: CECT
- Parenchymal laceration
  - Irregular, linear, branching foci of fluid attenuation
  - Posterior right hepatic lobe is most commonly involved
  - Extension to bare area (segment VII) is associated with retroperitoneal hematoma
  - Risk of bile duct injury with extension to porta hepatis
- Hematoma may be intraperitoneal, retroperitoneal, subcapsular, or intraparenchymal
  - Fluid attenuation if hematoma is fresh & unclotted
  - Focal ↑ attenuation may represent clot at site of injury
  - ± hematocrit level of settling peritoneal blood in pelvis
    - ↑ density of dependent-most fluid component is due to layering cellular blood elements
- Active hemorrhage or extravasation
  - Irregular high attenuation near vessel (isodense to aorta with arterial injury); accumulates with delay
  - Majority of patients with contrast extravasation are successfully managed nonoperatively
- Generalized periportal edema
  - Frequent finding of resuscitation due to distended intrahepatic lymphatics from vigorous hydration



TOP DIFFERENTIAL DIAGNOSES

- Normal fissures
- Artifacts: Beam hardening or motion
- Hepatic abscess



CLINICAL ISSUES

- Nonoperative management of hemodynamically stable patients: > 90% successful
- Complications: Biliary injury, pseudoaneurysm, arteriovenous fistula, delayed hemorrhage, abscess
- Routine follow-up imaging is not indicated for asymptomatic patients with low-grade injury
- ↑ liver enzymes in infant warrant CECT in presence of other clinical/radiological signs of nonaccidental trauma

(Left) *Axial CECT in a 6-year-old girl after a motor vehicle accident depicts a laceration ⇨ of the medial left hepatic lobe > 4 cm in depth, consistent with a grade III injury.* **(Right)** *Axial CECT in a 6-year-old car accident victim shows irregular areas of contrast extravasation contained within the parenchyma, compatible with a grade III injury ➡. The more rounded focus of contrast is suspicious for a pseudoaneurysm ➡.*

(Left) *Axial CECT in a 2-year-old boy hit by a car shows branching hypodense lacerations ⇨ extending from the superior posterior aspect of the right hepatic lobe (bare area). This disrupted > 25% of the right lobe, consistent with a grade IV injury. There is associated retroperitoneal hemorrhage ⇨.* **(Right)** *Axial CECT in a 12-year-old boy 1 day after liver biopsy shows a mixed attenuation, > 50% surface area subcapsular hematoma ⇨, consistent with a grade III injury. Higher density in the hematoma represents clot.*

TERMINOLOGY

Synonyms

- Liver or hepatic laceration, fracture, or injury

IMAGING

CT Findings

- CECT
  - Laceration
    - Irregular, linear, branching foci of nonenhancement in liver parenchyma
    - May parallel hepatic or portal veins
  - Hematoma
    - Round, crescentic, or poorly defined fluid collection
    - Focal ↑ attenuation (40-70 HU) may represent clot & implicate site of injury
    - Subcapsular
      - Lentiform or crescentic peripheral collection
      - Compresses convex margin of parenchyma
    - Intraparenchymal
      - Round or irregular
    - Intraperitoneal
      - Poorly defined, tracking dependently in abdomen/pelvis vs. focal collections
      - ± hematocrit level of dependently settling peritoneal blood components in pelvis
    - Retroperitoneal
      - Surrounds inferior vena cava, right adrenal gland
      - Often occurs with lacerations of bare area (segment VII)
  - Active hemorrhage or extravasation
    - Irregular collection of high attenuation near vessel (isodense to aorta with arterial injury); accumulates on delayed images
  - Pseudoaneurysm
    - Round focus of high attenuation (isodense to aorta)
    - Will have diminished attenuation on delayed images
    - Decompression into biliary system → hemobilia, melena
  - Arteriovenous fistula (AVF)
    - Early enhancement of involved hepatic/portal vein, simultaneous with artery
  - Biliary injury (biloma, leak): Delayed, simple-appearing fluid accumulations without clinical hematocrit drop
    - Often with lacerations extending to porta hepatis + contracted gallbladder
  - Periportal edema: Generalized ↓ attenuation surrounding portal veins
    - Most commonly due to lymphatic engorgement from aggressive hydration rather than periportal blood

Ultrasonographic Findings

- Grayscale ultrasound
  - Limited for detecting hepatic injury in acute setting
    - Abdominal US: 51% sensitivity, 95% specificity
    - Abdominal CEUS: 84% sensitivity, 99% specificity
    - FAST exam: 55% sensitivity, 83% specificity for intraabdominal injury
  - Echogenicity of hematoma/laceration varies with age
    - Anechoic (initially unclotted) → hyperechoic (24 hours with fibrin & clot) → hypoechoic (2-3 days with liquefaction of blood)
  - Pseudoaneurysm
    - Anechoic, cyst-like structure near vessel
    - Yin-yang sign on color Doppler
  - AVF
    - Dilated hepatic artery with very low resistance
    - Arterialized portal/hepatic venous waveform
    - Surrounding tissue vibration
  - Biliary injury (biloma, leak)
    - Delayed appearance of intrahepatic/intraperitoneal anechoic collection ± septations
    - Continued accumulation without hematocrit drop
- CEUS
  - Laceration/contusions: Linear, round, or irregular areas of nonenhancement
  - Active bleeding: Intra- or extraparenchymal contrast pooling that ↑ in size

MR Findings

- T1 & T2 signal intensity varies with hematoma age
- MRCP can be useful in evaluation of biliary tree

Nuclear Medicine Findings

- Hepatobiliary scintigraphy
  - Bile leak: Accumulating extrabiliary collection of radiotracer around liver in peritoneal cavity
  - Biloma: Focal, contained extrabiliary radiotracer

Imaging Recommendations

- Best imaging tool: CECT

DIFFERENTIAL DIAGNOSIS

Normal Fissures

- Isolated thin, smooth, linear hypodense foci in characteristic locations for ligamentum venosum or falciform ligament

Artifacts

- Beam hardening: ↓ density streaks extending from ribs
- Excessive patient motion: Random throughout whole image ± adjacent images
- Both artifacts extend beyond liver

Hepatic Abscess

- Round or irregular discrete lesion(s) in ill patient
- Central fluid attenuation with thick, irregular rim & septal enhancement ± surrounding edema

Primary Tumor or Metastatic Disease

- Neoplasm may rupture or bleed, ± trauma

Liver Infarction

- Peripheral, wedge-shaped focus of nonenhancement
- Uncommon in children, occasionally results from trauma

PATHOLOGY

General Features

- Etiology
  - Blunt vs. penetrating trauma: 90% vs. 10%
    - Blunt trauma causes deceleration or shearing injury
      - Motor vehicle-related injuries are most common

- Falls & recreational accidents
- Hepatic injury is seen in 25% of blunt trauma cases & 3% of nonaccidental trauma (NAT) cases overall
- Associated abnormalities
  - Concomitant splenic injury: 45%

Staging, Grading, & Classification

- American Association for the Surgery of Trauma (AAST)
  - Grade I
    - Hematoma: Subcapsular, < 10% surface area
    - Laceration: < 1-cm parenchymal depth
  - Grade II
    - Hematoma: Subcapsular, 10-50% surface area; intraparenchymal, < 10 cm in diameter
    - Laceration: 1- to 3-cm parenchymal depth & ≤ 10 cm in length
  - Grade III
    - Hematoma: Subcapsular, > 50% surface area or ruptured subcapsular or parenchymal hematoma; intraparenchymal, > 10 cm
    - Laceration: > 3-cm parenchymal depth
    - Vascular injury (defined as pseudoaneurysm or AVF) or active bleeding contained within parenchyma
  - Grade IV
    - Laceration: Parenchymal disruption involving 25-75% of 1 hepatic lobe
    - Active bleeding extending beyond liver parenchyma into peritoneum
  - Grade V
    - Laceration: Parenchymal disruption involving > 75% of hepatic lobe
    - Vascular: Juxtahepatic venous injuries (i.e., retrohepatic vena cava/central major hepatic veins)
  - ↑ 1 grade for multiple injuries up to grade III

Gross Pathologic & Surgical Features

- Pattern of injury
  - Posterior segment of right lobe is most common
    - Greatest volume of liver & surrounded by ribs, spine
    - Fixation by coronary ligaments enhances effect of acceleration-deceleration injury
  - Left lobe is most commonly injured in NAT

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Right upper quadrant pain, guarding, rebound tenderness, hypotension, lap belt ecchymosis (seat belt sign); elevated LFTs

Natural History & Prognosis

- Hemodynamic stability is primary determinant of nonoperative success
  - > 90% are successfully managed nonoperatively
- Contrast extravasation
  - Associated with more severe overall injury & transfusion
  - Association with delayed hemorrhage is debated
  - Nonoperative management is successful in 83% of patients with contrast extravasation
- Complications
  - Typically occur with higher grade injuries (> grade III)
  - Biliary: Biloma (most common), bile leak, hemobilia
  - Vascular: Pseudoaneurysm, AVF, delayed hemorrhage
  - Abscess

Treatment

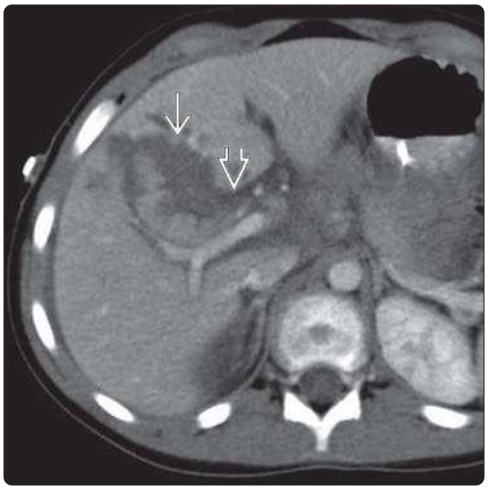
- Nonoperative management if hemodynamically stable
- 2019 updated American Pediatric Surgical Association guidelines for hemodynamically stable isolated liver injury
  - Length of stay is based on clinical presentation
  - Activity restriction = injury grade + 2 weeks
    - Imaging may not correlate with organ integrity
    - Return to full-contact sports at discretion of surgeon
  - Arterial embolization
    - May be useful in patients with arterial contrast extravasation + hemodynamic compromise from ongoing bleeding
    - Prophylactic embolization is not indicated if hemodynamically stable
  - Follow-up imaging
    - Routine reimaging of asymptomatic, uncomplicated, low-grade injuries is not indicated
    - Limited data support reimaging of high-grade injuries
    - Symptomatic patients may benefit from reimaging
- ATOMAC+ guidelines outline clinical parameters to define end point for nonoperative management
- Laparotomy & surgical hemostasis in unstable patients
- Consider ERCP + sphincterotomy &/or stent for bile leak

DIAGNOSTIC CHECKLIST

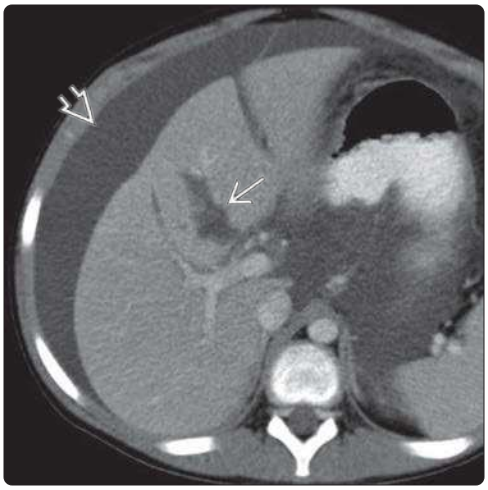
Consider

- In infants, CECT is warranted with ↑ liver enzymes + clinical/radiological signs of NAT

Image Interpretation Pearls



- Describe hepatic injuries & seek out additional injuries that may be less obvious but of greater clinical significance



Reporting Tips

- AAST grade guides management

(Left) *Axial CECT in an 11-year-old with right upper quadrant pain after a roller skating accident shows a grade IV liver laceration that extends to the porta hepatis.* **(Right)** *Axial CECT in the same patient was performed 9 days later for increasing jaundice & distention. While the laceration is again seen, there is new moderate to large volume of free fluid.*

(Left) *ERCP in the same patient demonstrates irregular pools of contrast collecting along the biliary system during injection, compatible with biliary injury.* **(Right)** *Coronal CECT in a 14-year-old girl after an all-terrain vehicle accident shows a laceration extending to the right hepatic vein with devascularization of the inferior right hepatic lobe. Injuries to the retrohepatic inferior vena cava or central major hepatic veins are grade V injuries. Hemoperitoneum is also shown.*

(Left) *Axial CECT images obtained in an 11-year-old that was hit by a bus demonstrate a laceration with ill-defined vascular contrast extravasation that extends inferior to the liver parenchyma, compatible with a grade IV injury.* **(Right)** *Right parasagittal CECT in a 3-year-old trauma patient with a laceration that extends to the inferior vena cava demonstrates contrast extravasation & retrohepatic hematoma, compatible with a grade V injury.*

Splenic Trauma

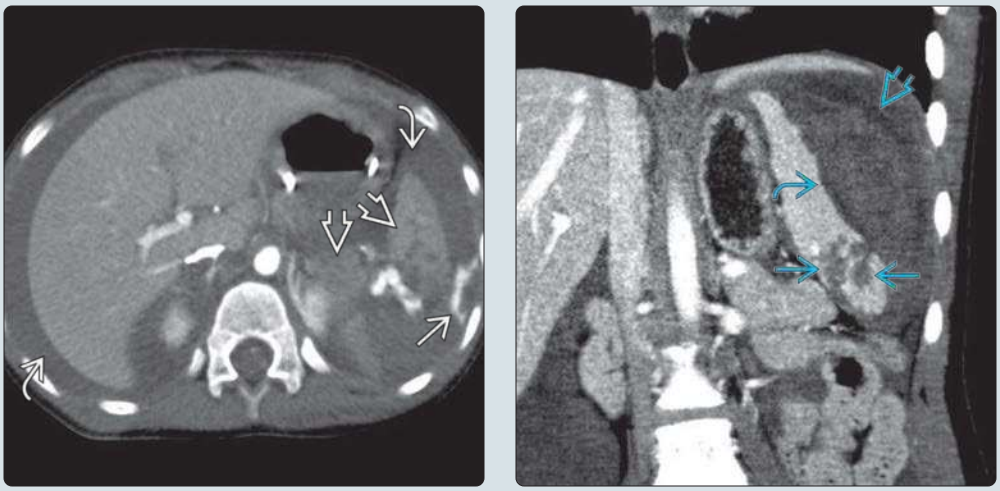
KEY FACTS

IMAGING

- CECT: Gold standard for blunt abdominal trauma
- Laceration: Irregular, linear, branching foci of fluid density
- Hematoma: Intraperitoneal, retroperitoneal, subcapsular, &/or intraparenchymal collection(s)
  - Fluid attenuation (0-30 HU) if fresh, unclotted blood; ↑ attenuation (40-80 HU) suggests clotted blood, may implicate site of injury by proximity (sentinel clot)
- Active extravasation: Irregular, nonanatomic focus of ↑ density (isodense to adjacent artery); accumulates on delayed images
- Pseudoaneurysm: ↑ density outpouching of arterial lumen (isodense to adjacent artery); washes out with delay
- Complications: Pseudocyst, pseudoaneurysm, arteriovenous fistula, delayed rupture (hemorrhage > 48 hours after trauma), venous thrombosis, abscess

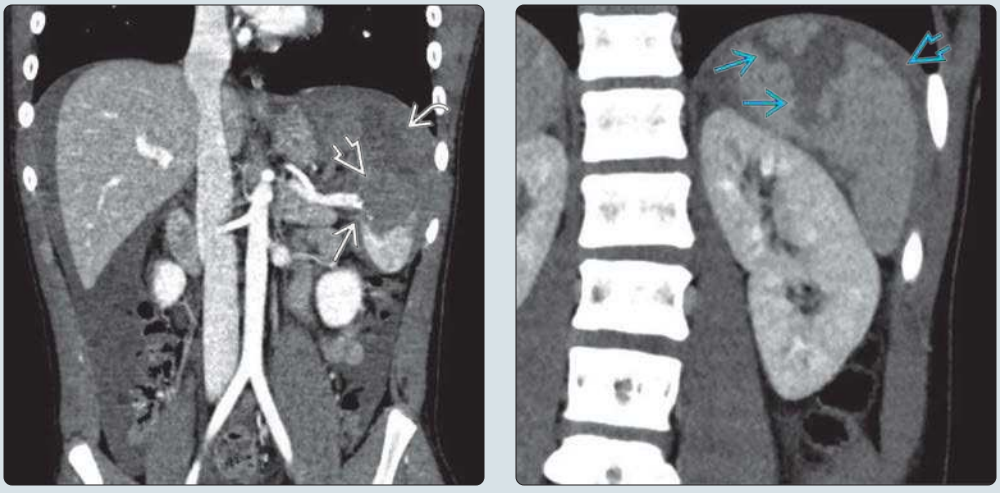
TOP DIFFERENTIAL DIAGNOSES

- Splenic cleft
- Artifacts: Beam hardening, early bolus, patient motion
- Hypoperfusion complex
- Splenic infarct
- Splenic abscess



PATHOLOGY

- Typical etiologies: Blunt trauma, motor vehicle accident
- ± additional injuries: Left lower rib fractures, other viscera



CLINICAL ISSUES

- Presentations: LUQ pain & tenderness, hypotension
- Treatment
  - Nonoperative management of isolated blunt splenic injury in stable patients: > 95% success rate
  - Routine follow-up is not indicated in asymptomatic patients with low-grade injury
  - Prophylactic arterial embolization is not indicated in hemodynamically stable patients with contrast extravasation

(Left) *Axial CECT in an 8-year-old after a motor vehicle accident shows a grade V splenic injury. There is contrast extravasation ➡ that extends outside the fractured spleen ➡ with high-density fluid ➡ (i.e., blood) throughout the abdomen.* **(Right)** *Coronal CECT in a patient injured while playing basketball shows a grade III splenic injury with lacerations > 3 cm in depth ⇨. A subcapsular hematoma > 50% of the splenic surface area ⇨ scallops the splenic margin ⇨.*

(Left) *Coronal CECT in a 14-year-old after a fall from a bike shows a grade IV splenic injury involving hilar vessels ➡ with major devascularization of the spleen (> 25%) as represented by the hypoattenuating parenchyma ➡. A perisplenic hematoma ➡ is also noted.* **(Right)** *Coronal CECT in a 14-year-old injured while skiing shows a grade III splenic injury. Branching linear & jagged hypodensities > 3 cm in depth ⇨ & extending to the splenic capsule are consistent with lacerations. A small perisplenic hematoma ⇨ is also seen.*

TERMINOLOGY

Synonyms

- Splenic laceration, fracture, or injury; blunt injury to spleen

Definitions

- Parenchymal injury to spleen ± capsular disruption

IMAGING

General Features

- Best diagnostic clue
  - Jagged, linear, fluid-density foci in splenic parenchyma ± intraparenchymal or subcapsular fluid collection
  - Perisplenic hematoma > 40 Hounsfield units (HU)

Radiographic Findings

- Triad: Elevated left hemidiaphragm, left lower lobe atelectasis/collapse, left pleural effusion
- Left lower rib fractures are common (44% of patients)
- Medial displacement of gastric bubble
- Inferior displacement of splenic flexure, bowel gas
- Hemorrhage may obscure contours of intraperitoneal/retroperitoneal structures: Psoas margin, flank stripe, renal contour, splenic margin

CT Findings

- CECT
  - Accuracy 98%, sensitivity 95%
  - Laceration: Irregular, fluid-attenuation, linear/branching foci within parenchyma; may extend to capsule
  - Fracture: Laceration extending from one capsular surface to another
  - Rupture: Multiple fractures with discontinuous splenic fragments
  - Hematoma: Fluid-attenuation (0-30 HU) collection; ↑ attenuation (40-80 HU) may represent clotted blood
    - Parenchymal: Round or irregular collection in spleen
    - Subcapsular: Peripheral crescentic or lenticular collection compressing parenchymal margin
    - Perisplenic: Collection in adjacent peritoneal spaces
      - Sentinel dense clot adjacent to spleen: Sensitive predictor for splenic injury
    - Hemoperitoneum: Layering, dense hematocrit level in dependent pelvis (may be subtle)
    - Retroperitoneal: Typically if splenic hilum is injured
      - Involves splenorenal ligament, anterior pararenal space, pancreas
  - Active arterial hemorrhage (extravasation)
    - Irregular, nonanatomic contrast collection; isodense to aorta; accumulates on delayed images
  - Pseudoaneurysm
    - ↑ attenuation outpouching of arterial lumen; isodense to aorta
    - ↓ attenuation on delayed images without ↑ size
    - Almost 75% are not seen on initial CECT
  - Arteriovenous fistula (AVF)
    - Early enhancement of involved vein, simultaneous with artery
  - Venous thrombosis: Focal or diffuse lack of splenic vein enhancement despite visualization of other veins

Ultrasonographic Findings

- Grayscale ultrasound
  - Linear or branching hypoechoic foci
  - Subcapsular or perisplenic collection with variable echogenicity
  - Free intraperitoneal fluid (absent in 25% of splenic injury)
- Color Doppler
  - Splaying or compression of vessels by hematoma
  - Yin-yang appearance of pseudoaneurysm
  - Lack of splenic vein flow with venous thrombus
  - Lack of parenchymal flow with devascularizing injury
- CEUS: 93% sensitivity, 99% specificity
  - Laceration/contusions: Linear, round, or irregular areas of nonenhancement
  - Active bleeding: Intra- or extraparenchymal contrast pooling that ↑ in size
- FAST exam: 37-85% sensitivity, 99-100% specificity

Angiographic Findings

- Blush from active arterial extravasation of contrast
- Distortion of vessels & enhancing parenchyma by hematoma
- Pseudoaneurysm: Arterial outpouching
- Venous thrombosis: Filling defect

Imaging Recommendations

- Best imaging tool
  - CECT rapidly covers entire abdomen & pelvis

DIFFERENTIAL DIAGNOSIS

Splenic Cleft

- Congenital variant in contour of spleen
- Smooth, thin, curvilinear ↓ attenuation focus without other evidence of hemorrhage

Artifacts

- Beam hardening: Linear hypodense streaks from ribs/arms
- Motion: Blurring or discontinuity of structures across image
- Early bolus: Specific pattern of enhancement
  - Parallel, archiform, "corrugated" waves of ↓ splenic enhancement on early arterial-phase CECT
    - 95% resolve by 70 seconds
    - Due to enhancement differences of red & white pulp

Hypoperfusion Complex

- ↓ splenic enhancement; fluid-filled bowel with ↑ wall enhancement diffusely
- ± flattened inferior vena cava, intensely enhancing small-caliber aorta

Splenic Infarct

- Wedge-shaped focus of ↓ density with apex towards hilum
- Associated with splenomegaly & systemic disorders

Splenic Abscess

- Fluid attenuation with enhancing rim, surrounding edema
- Clinical history/findings of infection, immunodeficiency, trauma, emboli, travel, or cat-scratch disease

PATHOLOGY

General Features

- Etiology
  - Blunt trauma
    - Motor vehicle accident is most common
    - Bicycle-related, falls, sports-related injuries
    - Iatrogenic injury is rare (thoracentesis, biopsy, intraoperative)
    - Nonaccidental trauma (NAT) is rare cause (1%)
      - Seen in up to 26% of NAT patients
  - Preexisting splenic enlargement (EBV, hematologic disorders) predisposes to injury

Staging, Grading, & Classification

- American Association for the Surgery of Trauma (AAST)
  - Grade I
    - Hematoma: Subcapsular, < 10% surface area
    - Laceration: Capsular tear, < 1-cm parenchymal depth
  - Grade II
    - Hematoma: Subcapsular, 10-50% surface area; intraparenchymal, < 5 cm in diameter
    - Laceration: 1- to 3-cm parenchymal depth
  - Grade III
    - Hematoma: Subcapsular, > 50% surface area; ruptured subcapsular or parenchymal hematoma; intraparenchymal hematoma ≥ 5 cm or expanding
    - Laceration: > 3-cm parenchymal depth
  - Grade IV
    - Laceration: Involving segmental or hilar vessels producing > 25% devascularization
    - Vascular injury (defined as pseudoaneurysm or AVF) or active bleeding confined within capsule
  - Grade V
    - Laceration: Completely shattered
    - Active bleeding extending beyond spleen into peritoneum
  - Advance 1 grade for multiple injuries up to grade III

Gross Pathologic & Surgical Features

- Forceful flexion of spleen along axis
- Laceration is typically intersegmental, extending towards hilum

CLINICAL ISSUES

Presentation

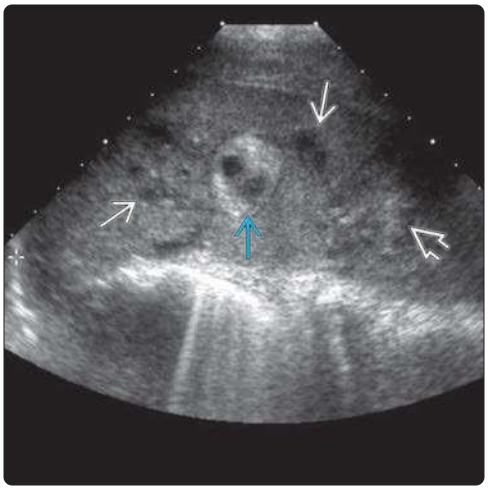
- Most common signs/symptoms
  - Left upper quadrant (LUQ) tenderness, pain
  - Hypotension (25-30%); lap belt ecchymosis, seat belt sign
- Other signs/symptoms
  - Rib pain: Left lower posterior rib fractures
  - Kehr sign: Pain radiating to left shoulder by phrenic nerve; abdominal rigidity, shock in neonates
  - Not clinically apparent (10-20%)

Natural History & Prognosis

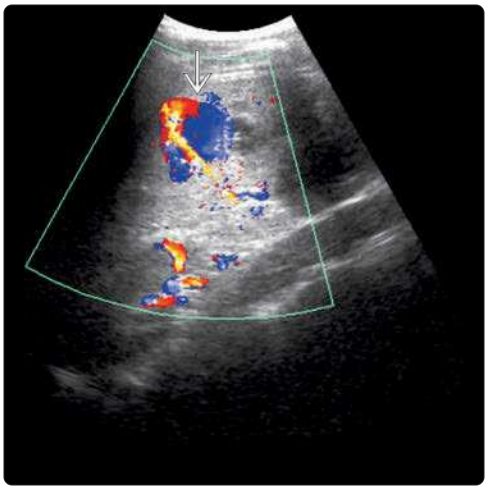
- Nonoperative management of isolated blunt splenic injuries in stable patients: > 95% success rate
  - Hemodynamic stability is important for nonoperative success
- Contrast extravasation
  - Associated with more severe overall injury & transfusion
  - Pseudoaneurysm may result in delayed hemorrhage; many spontaneously resolve
    - Some data suggest association with contrast extravasation on initial CT
  - Nonoperative management is successful in 83% of patients with contrast extravasation
- Complications: Pseudocyst, pseudoaneurysm, AVF, delayed rupture (hemorrhage > 48 hours after trauma), venous thrombosis, abscess

Treatment

- 2019 updated American Pediatric Surgical Association (APSA) guidelines for hemodynamically stable patient with isolated splenic injury
  - Length of stay is based on clinical presentation
  - Activity restriction = injury grade + 2 weeks
    - Imaging may not correlate with organ integrity
    - Return to full-contact sports at discretion of surgeon
  - Arterial embolization
    - May be useful in patients with arterial contrast extravasation + hemodynamic compromise from ongoing bleeding
    - Prophylactic embolization is not indicated if hemodynamically stable
  - Follow-up imaging: Routine reimaging of asymptomatic, uncomplicated, low-grade injuries is not indicated
    - Limited data support reimaging of high-grade injuries
    - Symptomatic patients may benefit from reimaging
- ATOMAC+ guidelines outline clinical parameters to define end point for nonoperative management
- Splenectomy or splenorrhaphy when surgery is required
  - ↑ hospital stay, ↑ transfusions, ↑ infections
- Vaccination (pneumococcal, *Haemophilus influenzae* type b, meningococcal, influenza) if no functional spleen
- Daily prophylactic antibiotics in patients < 5 years old without functional spleen



DIAGNOSTIC CHECKLIST



Reporting Tips

- Injury grade assists with management decisions

(Left) *Longitudinal ultrasound of the spleen in a pediatric trauma patient shows multiple irregular, hypoechoic lacerations & an ill-defined heterogeneous region of hematoma. A rounded, heterogeneously hyper- & hypoechoic focus centrally is suspicious for pseudoaneurysm.* **(Right)** *Color Doppler ultrasound in the same patient shows the characteristic yin-yang sign of bidirectional flow in the round, heterogeneous lesion, consistent with a traumatic pseudoaneurysm.*

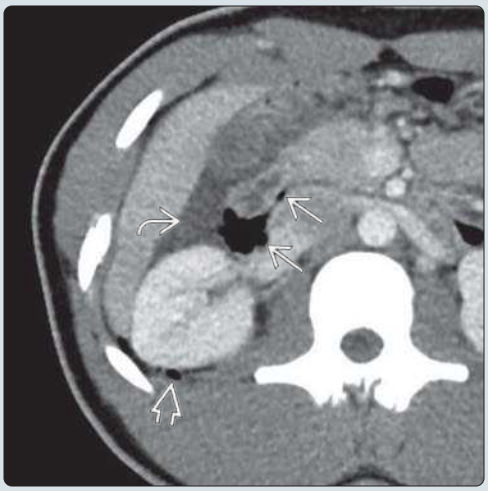
(Left) *Axial CECT obtained in a 14-year-old after a skiing accident shows an irregular parenchymal hypodensity < 1 cm in depth, compatible with a grade I injury. Trace perisplenic fluid is also seen.* **(Right)** *Axial CECT shows a small, irregular, linear, hypodense band within the spleen. This was categorized as a grade II splenic injury given that it was between 1-3 cm in length.*

(Left) *Coronal CECT in a patient hit by a train shows a grade V splenic injury. The spleen is shattered & devascularized due to hilar avulsion. There is contrast extravasation from active arterial hemorrhage extending beyond the spleen. Note the large perisplenic hematoma & hemoperitoneum.* **(Right)** *Coronal CECT in a 15-year-old trauma patient depicts a jagged, stellate hypodensity representing a branching laceration, consistent with a grade III splenic injury.*

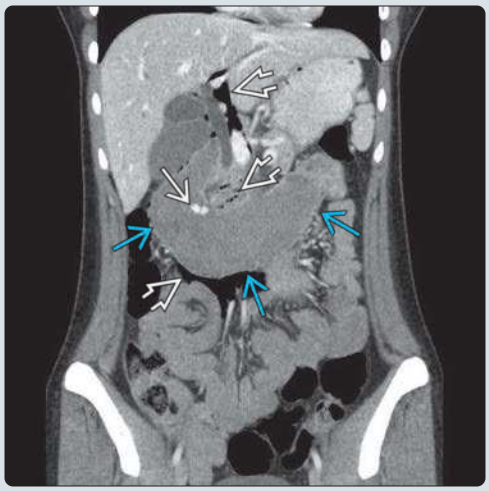
Duodenal Trauma

KEY FACTS

IMAGING

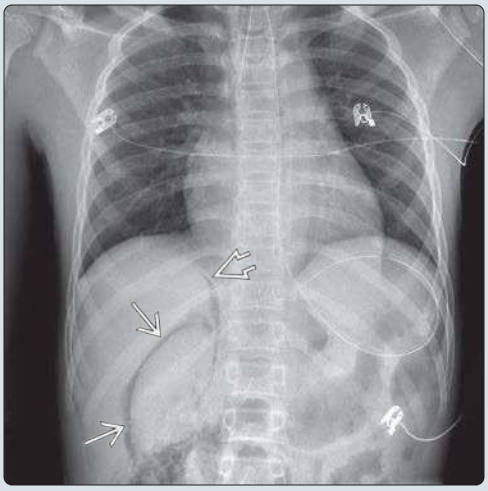


- CECT is best imaging tool in acute trauma setting
- Injuries classified as hematoma vs. laceration
  - Hematoma: Nonenhancing intraluminal, intramural, &/or paraduodenal collection of ↑ attenuation
    - Intraluminal: Expansile ovoid or tubular filling defect
      - Coiled-spring appearance on upper GI series
    - Intramural: Mass-like focal wall thickening ± intramural gas; eccentric narrowing of displaced lumen
  - Duodenal laceration/perforation
    - Interruption of bowel wall, extravasation of intraluminal contents, & free retroperitoneal air: Specific but not sensitive
    - Duodenal wall thickening > 3 mm & ↑ attenuation fluid + stranding in retroperitoneum: Sensitive but not specific
- Associated pancreatic trauma in up to 42% of cases

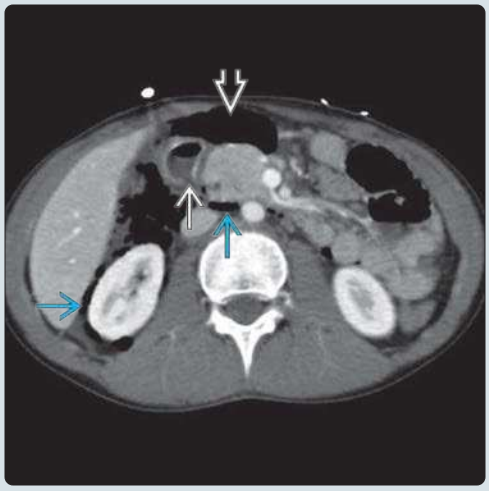


PATHOLOGY

- Blunt trauma in > 70%, penetrating trauma in > 20%
  - Motor vehicle accident, fall, bicycle handlebar injury, assault
  - Consider nonaccidental trauma in young patients (particularly < 2 years old with delayed presentation)
- Also consider with bleeding disorders, anticoagulation, Henoch-Schönlein purpura, recent endoscopic procedures



CLINICAL ISSUES



- Common symptoms: Abdominal pain, nausea, vomiting
- Delay in diagnosis & treatment: ↑ morbidity & mortality
- Treatment
  - Intramural/intraluminal hematoma: Initial management is nonoperative (bowel rest, TPN, nasogastric decompression); drainage in refractory cases
  - Perforation: Primary surgical repair & drainage vs. more complex procedures in severe cases

(Left) *Axial CECT in a 17-year-old boy with abdominal pain after being kicked shows retroperitoneal air posterior to the 2nd & 3rd portions of the duodenum (D2 & D3) & posterior to the right kidney. Adjacent fluid is also noted. A duodenal laceration was found at surgery.* **(Right)** *Coronal CECT in a 16-year-old with perforation from an ERCP shows active contrast extravasation into a large hematoma that distends the duodenum. Note the adjacent pneumoperitoneum.*

(Left) *Supine AP radiograph shows gas outlining the right kidney & underlying the medial right diaphragm in this 11-year-old nonaccidental trauma victim.* **(Right)** *Axial CECT in the same patient demonstrates discontinuity of the hyperenhancing duodenal wall at D2, compatible with perforation. There is free retroperitoneal & intraperitoneal air. A laceration involving intra- & retroperitoneal portions of the duodenum was discovered at surgery.*

TERMINOLOGY

Abbreviations

- D[x] = segment of duodenum (e.g., D1 = 1st segment of duodenum)

IMAGING

General Features

- Location
  - Most commonly involves D2 (46%) or D3 (63%)

Radiographic Findings

- Mass effect of hematoma may lead to
  - Dilated stomach &/or duodenal bulb
  - Displaced bowel gas in right upper quadrant (RUQ)
- Laceration may lead to
  - Retroperitoneal air (from D2-D4 injury)
    - Outlines kidneys, psoas muscles
  - Intraperitoneal air (from D1 injury)
    - Upright or left-side down (i.e., left lateral decubitus) view: Air under diaphragm overlying liver
    - Supine
      - Rigler sign: Air on both sides of bowel wall
      - Falciform ligament sign: Vertical linear density in RUQ outlined by air lucency
      - Football sign: Ovoid lucency of whole abdomen

Fluoroscopic Findings

- Upper GI
  - Typically not performed in acute trauma setting
  - Intramural hematoma
    - Displaced lumen with eccentric or circumferential narrowing/obstruction
    - Wall/fold thickening
  - Intraluminal hematoma
    - Ovoid clot expands duodenal lumen
    - Coiled-spring appearance due to contrast tracking between mucosal folds & intraluminal clot

CT Findings

- CECT
  - Hematoma: Well-circumscribed, ovoid, heterogeneous, or homogeneous mass with ↑ attenuation of 40-80 HU
    - Occurs in lumen, bowel wall, or paraduodenal tissues
      - Dense sentinel clot may localize injury site
  - Contusion: Focal duodenal wall thickening/edema
    - > 3 mm or disproportionate to normal bowel wall
  - Vascular insult vs. response to wall injury: Abnormal bowel wall enhancement
    - Judged relative to psoas muscle
    - ↑ enhancement: Paradoxically found with hypoperfusion due to damaged vascular endothelium
    - ↓ enhancement: Suggests traumatic ischemia, vascular compromise
  - Specific signs of duodenal laceration/perforation
    - Interruption of enhancing bowel wall
    - Extraluminal contrast &/or air
      - Retroperitoneal (if D2-D4) or intraperitoneal (if D1)
      - Sensitivity of free air for traumatic bowel injury: 30-60%
      - Lung windows ↑ sensitivity for free air

MR Findings

- Not generally performed in acute trauma setting
- T1, T2: Hematoma signal varies with age
- T1 C+: Nonenhancing mass; may have enhancing rim

Ultrasonographic Findings

- Grayscale ultrasound
  - Hematoma
    - Focal intramural/intraluminal/paraduodenal mass, wall thickening, or collection
    - Variable echogenicity based on age; ↓ with time
  - Retroperitoneal air: May see linear hyperechogenicity with "dirty" posterior acoustic shadowing
- Color Doppler
  - No vascularity within hematoma

Imaging Recommendations

- Best imaging tool: CECT
  - In blunt trauma setting, oral contrast does not significantly improve sensitivity for duodenal injury → delay in imaging & treatment
  - In cases with persistent clinical symptoms, consider follow-up with ultrasound or upper GI every 7 days

DIFFERENTIAL DIAGNOSIS

Enteric Duplication Cyst

- 12% occur in gastroduodenal location
- Well-circumscribed, cystic mass
- US: Cyst wall frequently has trilaminar gut signature; may demonstrate peristalsis

Duodenal Ulcer/Duodenitis

- Uncommon in young patients
- Poorly defined proximal duodenal wall edema with interruption of enhancing mucosa
- May perforate → extraluminal gas
- May cause duodenal stricture & gastric outlet obstruction

Crohn Disease

- Involves duodenum in 5-20% of patients
- Wall thickening, hyperenhancement, or stricture
- May form fistula with adjacent bowel

Small Bowel Neoplasm

- Rare in children; Burkitt lymphoma is most common
- Typically enhances & demonstrates internal vascularity, unlike hematoma
- May cause duodenal luminal narrowing or (rarely) paradoxical dilation

Pancreatitis

- Enlarged, edematous pancreas with peripancreatic stranding & fluid
- Duodenum may have secondary inflammatory change

Pancreatic Trauma

- Concomitant pancreatic & duodenal injuries are common
- Enlarged, edematous pancreas with peripancreatic stranding & fluid
- Linear transversely oriented focus of ↓ attenuation due to parenchymal laceration

Annular Pancreas

- Commonly presents in neonatal period
- Ring of pancreatic tissue surrounding D2 results in duodenal stenosis, obstruction

PATHOLOGY

General Features

- Etiology
  - Blunt trauma accounts for > 70% of duodenal injuries
    - Duodenal injury in 2-10% of children with blunt abdominal trauma
    - Common causes: Motor vehicle accidents, falls, bicycle-related accidents, nonaccidental trauma (NAT)
      - Consider NAT in younger patients (particularly < 2 years of age) with delayed presentation to emergency department
  - Penetrating trauma in > 20%
  - Iatrogenic
    - Upper endoscopy with biopsy: Hematoma in 0.1-7.0%
      - ↑ risk in bone marrow transplant patients
    - ERCP: Hematoma in 1.3%, perforation in 0.1-0.6%
  - Spontaneous intramural hematomas occur with bleeding disorders, anticoagulation therapy, vasculitis, Henoch-Schönlein purpura
- Associated abnormalities
  - Abdominal injuries: Pancreas 42%, liver 29%, spleen 17%
  - Duodenal hematoma may obstruct papilla of Vater → cholestasis & pancreatitis

Staging, Grading, & Classification

- American Association for the Surgery of Trauma Organ Injury Scale
  - I: Hematoma involving single portion of duodenum; partial-thickness laceration without perforation
  - II: Hematoma involving > 1 portion of duodenum; laceration disrupting < 50% of circumference
  - III: Laceration disrupting 50-75% of circumference of D2 or 50-100% D1/D3/D4
  - IV: Laceration disrupting > 75% of circumference of D2 or involving ampulla or distal common bile duct
  - V: Laceration with massive disruption of duodenopancreatic complex; duodenum devascularized
  - Advance 1 grade for multiple injuries up to grade III

Gross Pathologic & Surgical Features

- 3 mechanisms act in isolation or in combination
  - Compression of intestinal loops at impact
    - Sudden ↑ in intraluminal pressure → perforation
  - Direct force crush-injury between anterior abdominal wall & spine
  - Rapid deceleration → tear at junction of mobile intraperitoneal & fixed retroperitoneal segments

Microscopic Features

- Duodenal hematoma typically develops in submucosal &/or subserosal layers

CLINICAL ISSUES

Presentation

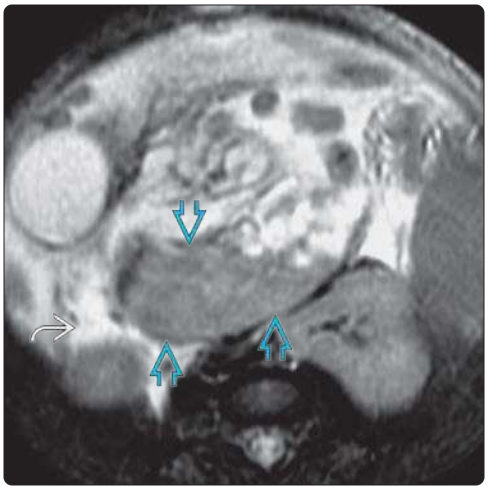
- Most common signs/symptoms
  - Nausea, vomiting, abdominal pain

Natural History & Prognosis

- Overall morbidity 48%, mortality 19%
- Delay in diagnosis & treatment → ↑ length of hospitalization, ICU time, need for TPN, complication rates
- Mortality is usually secondary to associated injuries, most commonly traumatic brain injuries
- Stricture may rarely occur as long-term complication
- Postoperative complications: Postoperative ileus 19%, wound infection 9%, traumatic pancreatitis 5%, abscess 3%, pancreatic fistula 2%, enterocutaneous fistula 2%

Treatment

- Nonoperative
  - Hemodynamically stable patients
  - Bowel rest, nasogastric decompression, TPN
  - Progressive symptoms, worsening imaging findings, or unresolved obstruction due to hematoma after 14 days may indicate nonoperative management failure
    - Consider operative management or percutaneous drainage of hematoma
    - Nonoperative failure rate for hematoma: 5-10%
- Operative
  - Hemodynamically unstable & patients with definite evidence of perforation
  - Duodenal primary repair/resection, nasogastric decompression, drain
  - Ancillary pyloric exclusion ± gastrojejunostomy & biliary diversion considered for grades III, IV, & V
- Disruption of duodenopancreatic complex
  - May require antrectomy & gastrojejunostomy or other Roux-en-Y reconstructions depending on level of injury
  - Staged pancreaticoduodenectomy for extensive duodenopancreatic complex injury



DIAGNOSTIC CHECKLIST

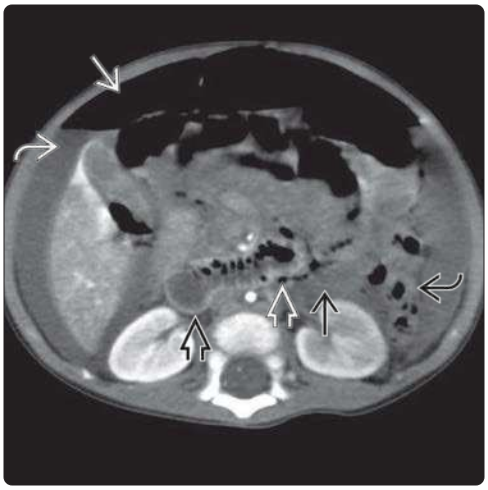


Image Interpretation Pearls

- Duodenal injury is suggested by wall thickening &/or intraluminal mass + air, fluid, or stranding in retroperitoneum
  - Bowel wall interruption & extravasation are rarely seen
- Evaluate pancreas closely for concomitant injury
- Consider NAT in younger patients (especially patients < 2 years old with delayed presentation)

(Left) *Axial T2 FS MR shows an intermediate signal intensity hematoma filling D3 in this patient with liver disease & a preceding endoscopic biopsy. Note the adjacent fluid .* **(Right)** *Axial CECT in a 9-year-old with nonaccidental trauma shows free intra- & retroperitoneal air as well as intra- & retroperitoneal fluid. Mucosal hyperenhancement & small bowel wall thickening are also noted. Perforations of the duodenum & jejunum were repaired surgically.*

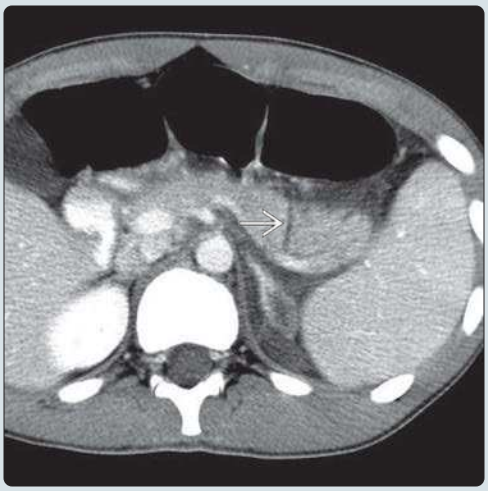
(Left) *Axial CECT in an 8-year-old with a handlebar injury shows hyperenhancement of the D3 wall with retroperitoneal air & fluid . There is poor definition of the bowel wall at the junction of D2 & D3 with perforations confirmed at this level at surgery.* **(Right)** *Axial CECT in a 16-year-old girl after a motor vehicle accident shows free air & fluid in the anterior pararenal space near D3 & D4. A perforation was found at this site during surgery.*

(Left) *Transverse ultrasound in a 2-year-old girl with pancytopenia & hematemesis after endoscopy with biopsy shows a bulky, C-shaped, heterogeneous mass of D1-D3 , consistent with an intraluminal duodenal hematoma.* **(Right)** *Lateral view from an upper GI series in the same patient demonstrates a large, obstructive filling defect expanding D1, consistent with an intraluminal duodenal hematoma.*

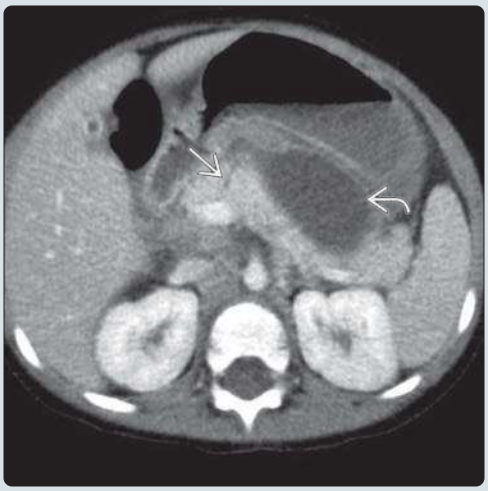
Pancreatic Trauma

KEY FACTS

IMAGING



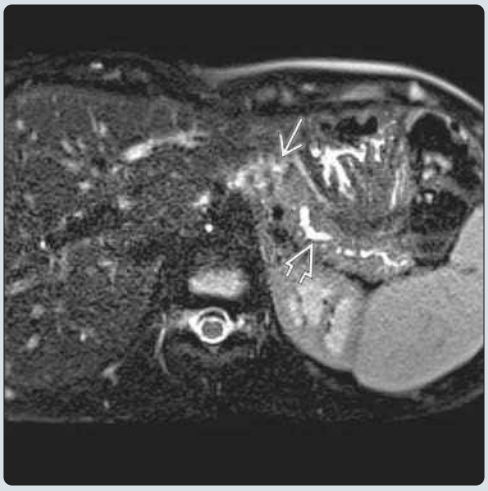
- Modality of choice: CECT
  - Caveat: 20-40% false-negative rate in first 12 hours
- Classic imaging findings
  - Contusion/inflammation: Focal or diffuse ↓ enhancement & ↑ size relative to normal parenchyma
  - Laceration: Linear fluid-attenuation parenchymal defect
    - Usually of short axis; most common at junctions of pancreatic head-neck or body-tail
    - Depth > 50% suggests pancreatic duct disruption
  - Hematoma: Irregular or round fluid collection in/around pancreas; ↑ attenuation (40-80 HU) if clotted
  - Varying degrees of peripancreatic fluid tracking along/within fascial planes & adjacent compartments
- MRCP or ERCP to assess main pancreatic duct injury



PATHOLOGY

- Blunt trauma in 93%, penetrating trauma in 7% of cases
- Pancreatic injury in 17% of nonaccidental trauma patients

CLINICAL ISSUES



- Epigastric pain out of proportion to physical findings
- ↑ serum amylase (may be normal initially)
- Management of American Association for the Surgery of Trauma grades
  - I & II: Typically nonoperative
    - TPN, serial abdominal exams, bowel rest, nasogastric tube, ± percutaneous/endoscopic collection drainage, ± endoscopic duct stenting
    - Failure is more likely with pancreatic duct injury
  - III-V: No consensus on management strategy
    - Hemodynamic stability is important determinant
    - Nonoperative management is successful in 89% of those attempted; risk of pseudocyst formation
    - Operative management: Pancreaticojejunostomy, operative drainage, spleen-sparing partial/distal pancreatectomy

(Left) *Axial CECT in a 14-year-old patient who sustained an elbow injury to the abdomen shows a linear, fluid-density laceration ➡ through the pancreatic body near the tail. A left adrenal injury was also noted on contiguous images.* **(Right)** *Axial CECT in a 2-year-old nonaccidental trauma victim with elevated serum amylase shows a laceration at the pancreatic neck-body junction ➡. The > 50% depth of the laceration is concerning for duct injury, & a large pancreatic bed fluid collection is noted anteriorly ➡.*

(Left) *Axial CECT in a 12-year-old patient after a motor vehicle accident shows a fluid-attenuation laceration ➡ through the body of the pancreas with depth > 50% of the parenchyma.* **(Right)** *Axial STIR MR in the same patient from a follow-up study performed 6 months later shows high signal at the site of the laceration ➡ as well as dilation & irregularity of the upstream pancreatic duct ➡, suggesting a duct stricture.*

IMAGING

General Features

- Best diagnostic clue
  - Linear, fluid-attenuation cleft through short axis of enhancing pancreas + peripancreatic fluid

CT Findings

- CECT
  - Contusion/inflammation
    - Focal or diffuse ↓ attenuation relative to normally enhancing parenchyma
    - Focal or diffuse enlargement of pancreas
  - Laceration
    - Linear fluid-attenuation cleft; ↑ attenuation with clotted blood (40-80 HU)
    - Usually involves short axis of organ
      - Most common at junctions of pancreatic head-neck or body-tail
    - Depth > 50% suggests pancreatic duct disruption
  - Hematoma
    - Irregular or round parenchymal/peripancreatic fluid-attenuation collection; ↑ attenuation with clotted blood (40-80 HU)
  - Fluid collections adjacent to & tracking away from pancreas
    - Separating splenic vein & pancreas
    - Surrounding superior mesenteric & portal veins
    - Separating pancreas & duodenum
    - Intraperitoneal: Lesser sac, paracolic gutters
    - Retroperitoneal: Anterior & posterior pararenal spaces
      - Thickening of fascial planes
  - Pseudocyst
    - Well-circumscribed peripancreatic fluid collection (in absence of pancreatic necrosis)
      - < 4 weeks = acute peripancreatic fluid collection
      - ≥ 4 weeks + enhancing rim = pseudocyst
    - Components are essentially all liquefied

MR Findings

- T2WI
  - ↑ signal intensity in & around pancreas: Edema, hemorrhage, pancreatic enzymes, inflammation
  - Focal or diffuse pancreatic enlargement
  - Linear discontinuity of parenchyma in short axis: ↑ intensity fluid within defect or separating 2 fragments of fractured parenchyma
- T1WI C+
  - Heterogeneous enhancement of pancreas
  - Nonenhancing fluid collections
  - Pseudocyst (≥ 4 weeks post trauma)
    - Nonenhancing, low signal intensity fluid collection
      - Hyperintense signal may indicate hemorrhage (with precontrast T1 shortening)
    - May have enhancing capsule
- MRCP
  - Allows better visualization of duct vs. CT
  - Signs of pancreatic duct injury
    - Disruption of duct continuity ± dilation
    - Signal intensity difference proximal vs. distal to injury
    - Continuity of pseudocyst with pancreatic duct
  - May be difficult to distinguish disruption vs. compression by extrinsic collection

Ultrasonographic Findings

- Grayscale ultrasound
  - Hematoma
    - Poorly marginated fluid collection in/around pancreas; variable echogenicity
  - Laceration
    - Linear hypoechoic defect in parenchyma; hyperechoic with clot
  - Contusion
    - Focal/diffuse enlargement of hypoechoic gland ± peripancreatic fluid
  - Pseudocyst (≥ 4 weeks post trauma)
    - Anechoic collection ± septations, thick rim
    - Internal echoes may indicate infection or hemorrhage
- For acute pancreatic injury, abdominal US sensitivity is 44-71%, specificity 100%

Fluoroscopic Findings

- ERCP
  - Definitive pancreatic duct evaluation
    - Duct may be normal, deviated, or narrowed with contusion or laceration
    - Duct obstruction: Disruption vs. compression
    - Duct laceration is confirmed with irregular pooling of contrast adjacent to main/branch duct (extravasation)
      - ± continuity of duct with fluid collection, pseudocyst
      - ± extension of contrast into retroperitoneal spaces
  - At risk for post-ERCP pancreatitis, infection, stricture
  - Not always readily available

Imaging Recommendations

- Best imaging tool
  - CECT
    - Caveat: 20-40% false-negative rate in first 12 hours
  - MRCP or ERCP if main pancreatic duct injury is suspected

DIFFERENTIAL DIAGNOSIS

Shock Pancreas

- Diffusely enlarged & heterogeneous pancreas
  - Low-attenuation septa throughout enhancing parenchyma
- Typical constellation of findings in hypoperfusion complex
  - Diffuse fluid distention of small bowel with thickened, hyperenhancing walls
  - Intense enhancement of adrenal glands
  - ↓ caliber of hyperenhancing aorta; collapsed inferior vena cava
  - Free fluid & mesenteric stranding

Duodenal Trauma

- Hematoma/contusion
  - Wall thickening, ↓ enhancement, &/or ovoid intramural/intraluminal mass
- Duodenal perforation
  - Retroperitoneal contrast, extraluminal gas, discontinuity of enhancing duodenal wall
- Luminal narrowing, edema/fluid in retroperitoneum

- High association with pancreatic injuries

Pancreatitis

- Focal/diffuse pancreatic enlargement with mildly ↓ enhancement
- Peripancreatic fluid & fat stranding
- Fluid in lesser sac &/or anterior pararenal space
- Areas of nonenhancement represent necrosis

PATHOLOGY

General Features

- Etiology
  - Blunt trauma: 93% of pancreatic injuries
    - Motor vehicle related 36%, bicycle injury 24%, nonaccidental trauma 10%, other assault 8%, fall 7%, other blunt injury 15%
  - Penetrating trauma: 7% of pancreatic injuries
    - Gunshot wound: 88% of penetrating injuries
- Pancreatic injury found in
  - 0.4% of abdominal trauma patients; 0.3% of blunt & 0.1% of penetrating trauma patients
    - 15% involve pancreatic duct
  - 17% of patients admitted for nonaccidental trauma
- Mechanism of injury
  - AP force compresses pancreas against spine
  - Children at greater risk than adults

Staging, Grading, & Classification

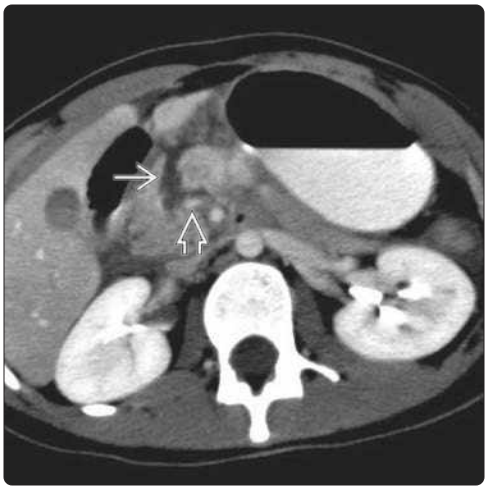
- American Association for the Surgery of Trauma (AAST)
  - Grade I: Minor contusion without duct injury; superficial laceration without duct injury
  - Grade II: Major contusion, no duct injury or tissue loss; major laceration, no duct injury or tissue loss
  - Grade III: Distal transection or parenchymal injury with duct injury
  - Grade IV: Proximal (right of superior mesenteric vein) transection or parenchymal injury involving ampulla
  - Grade V: Massive disruption of pancreatic head
  - Advance 1 grade for multiple injuries up to grade III

CLINICAL ISSUES

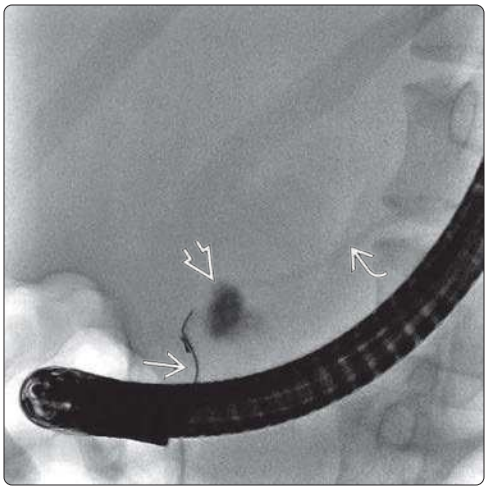
Presentation

- Clinical triad
  - Epigastric pain out of proportion to physical findings
  - Leukocytosis
  - ↑ serum amylase
    - May be normal initially
    - Trend may help identify injury or complications
    - Magnitude is not predictive of injury severity
    - Not specific to pancreatic injury
- Isolated injuries are rare (< 30%); average of 3-4 coexisting injuries per patient
  - Hepatic: 46.8%; major vascular: 41.3%; splenic: 28%; renal: 23.4%; duodenal: 19.3%
- Subtle imaging findings may lead to delay in diagnosis & treatment with ↑ morbidity & mortality

Natural History & Prognosis



- Pancreatic duct injury: Critical prognostic factor
  - ↑ morbidity, more likely to fail nonoperative management
- Complications
  - Pancreatitis: 3-26%; pseudocyst: 15-35%; fistula: 2-15%; abscess 10-25%



Treatment

- Grades I & II
  - Nonoperative management if hemodynamically stable
    - Successful in 96% of cases
    - TPN ± percutaneous or endoscopic fluid drainage
    - Serial abdominal exams, bowel rest, nasogastric tube
- Grades III-V
  - No consensus regarding nonoperative vs. early operative management; hemodynamic stability is important determinant
  - Nonoperative management
    - Attempted in 46% of patients; successful in 89%
    - ↑ rates of pseudocyst formation & repeat IR or endoscopic drainage procedures
    - At risk for post-ERCP pancreatitis, infection, stricture
    - US if symptoms progress/persist or if patient is unable to tolerate oral diet after 7 days
  - Operative management
    - Options include: Pancreaticojejunostomy, operative drainage (open cystogastrostomy, Roux-en-Y), spleen-sparing partial/distal pancreatectomy
    - Complications include: Bowel obstruction, fistula, leak/dehiscence, pancreatitis, infection
- With penetrating trauma, operative exploration is often necessary to manage associated injuries
- US, CEUS, or MR is recommended for follow-up of fluid collections, pseudocysts, pancreatic disruption

(Left) *Axial CECT in a 14-year-old girl with a soccer injury shows a deep grade IV proximal transection of the pancreas to the right of the superior mesenteric vein, raising concern for an associated main duct disruption.* **(Right)** *Oblique frontal view from an ERCP in the same patient shows cannulation of the major papilla. There is irregular pooling of contrast at the site of pancreatic neck injury, consistent with main duct disruption. The distal duct is opacified, & a stent was subsequently placed.*

(Left) *Axial CECT in a 15-year-old patient after blunt abdominal trauma during a baseball game shows a fluid-attenuation focus interrupting the pancreatic parenchyma, consistent with laceration.* **(Right)** *Axial oblique US through the pancreatic body & tail in the same patient shows the fluid-filled cleft separating the pancreatic parenchyma.*

(Left) *Axial 3D T1 GRE FS (top) & T2 FS (bottom) MR images in the same patient show the site of parenchymal transection with surrounding intraperitoneal & retroperitoneal fluid.* **(Right)** *ERCP in the same patient shows retrograde opacification of the main pancreatic duct with a contrast leak occurring at the site of parenchymal transection, consistent with ductal disruption. This patient ultimately required a spleen-preserving distal pancreatectomy.*

Posttransplant Lymphoproliferative Disease

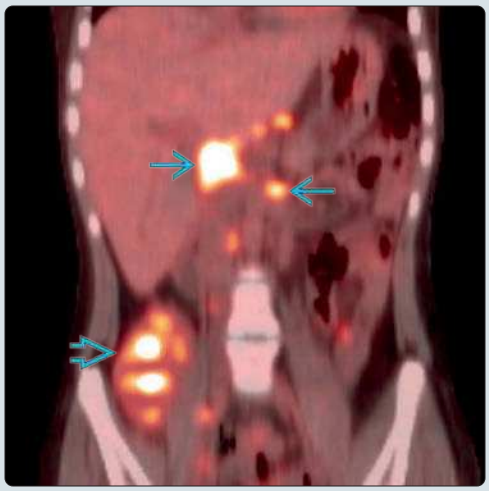
KEY FACTS

TERMINOLOGY

- Posttransplant lymphoproliferative disease (PTLD): Spectrum of abnormal lymphoid proliferation in transplant patients

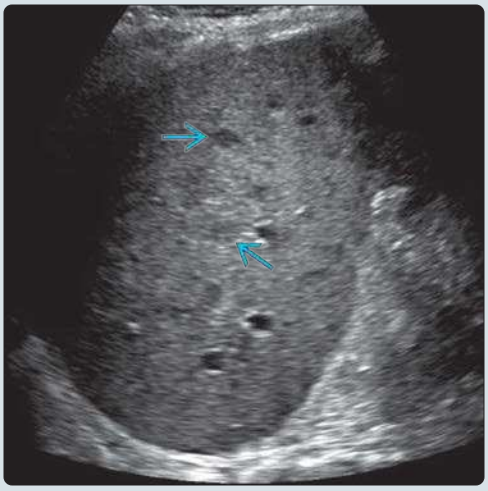
IMAGING

- Any organ system can be affected
- Abdominal region is most commonly involved by PTLD, including
  - Gastrointestinal: Bowel wall thickening & dilation, eccentric mass, luminal ulceration, mesenteric stranding, & intussusception
  - Liver: Low-attenuation nodules, periportal infiltration, heterogeneous porta hepatis mass
  - Spleen: Splenomegaly, multiple low-attenuation lesions
  - Kidney: Nephromegaly, multifocal parenchymal masses, heterogeneous renal or pararenal mass
  - Chest: Pulmonary mass, parenchymal nodules, pleural effusion, adenopathy
- Imaging: Lesions are often detected by US, CT, or MR
  - DWI MR ↑ conspicuity of nodes against soft tissues
  - PET/CT is useful for staging & therapy response

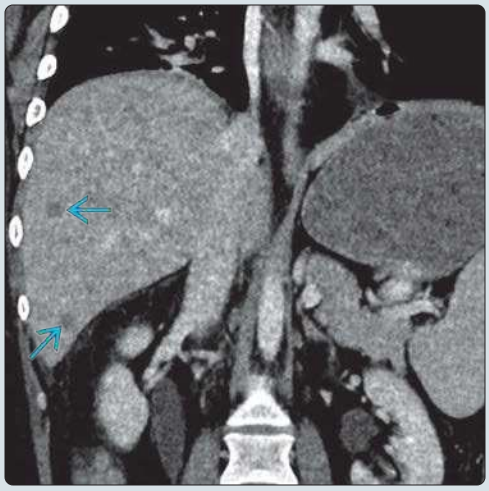


PATHOLOGY

- Risk factors for PTLD: EBV status, young age, type of transplanted organ (& degree of immunosuppression)
  - Greatest risk: Donor EBV positive, recipient EBV negative
  - 50-80% of PTLD biopsies are positive for EBV
  - Small bowel transplant is at highest risk (20%)
  - Kidney transplant is at lowest risk (2%)
- WHO classification: Early lesions, polymorphic, monomorphic, classic Hodgkin lymphoma-like



CLINICAL ISSUES



- Most common malignancy in pediatric transplant patients
- Universally fatal if not treated
- Treatment: Reduce immunosuppression, add chemotherapy for lymphoma

(Left) *Coronal CECT in an adolescent with a history of renal transplant & a new diagnosis of posttransplant lymphoproliferative disorder (PTLD) shows abnormal thickening of the bowel wall ⇨ centered near the ileocecal valve & cecum. The right lower quadrant transplanted kidney ⇨ is also visible.* **(Right)** *Coronal F-18 FDG PET/CT in the same adolescent shows FDG uptake within periportal & mesenteric lymph nodes ⇨. The right lower quadrant renal transplant ⇨ is partially included in this image.*

(Left) *Transverse ultrasound in an adolescent with a history of small bowel transplant shows multiple small, hypoechoic nodules ⇨ scattered throughout the liver. These nodules were later confirmed to represent PTLD.* **(Right)** *Coronal CECT in the same patient shows multiple hypodense PTLD nodules ⇨ in the liver.*

TERMINOLOGY

Abbreviations

- Posttransplant lymphoproliferative disease (PTLD)

Definitions

- Spectrum of abnormal lymphoid proliferation in transplant patients

IMAGING

General Features

- Best diagnostic clue
  - Lymphadenopathy or solid mass occurring virtually anywhere in organ transplant patient
- Location
  - Any organ system can be affected
  - Abdomen is most commonly involved by PTLD
    - Transplanted organ, gastrointestinal (GI) tract, & liver are most commonly affected
  - Other sites: Tonsils, lungs, kidneys, brain, muscle

Radiographic Findings

- Airway: Enlargement of adenoids & palatine tonsils
- Chest: Pulmonary nodule(s), adenopathy, consolidation, pleural effusion

CT Findings

- CECT
  - Abdomen
    - GI tract
      - Focal or uniform bowel wall thickening, bowel dilation, eccentric bowel wall mass, luminal ulceration, mesenteric stranding, & intussusception
      - More common in distal small bowel & proximal colon
    - Liver
      - Hepatomegaly, low-attenuation nodules, infiltrative pattern along portal vessels, heterogeneous porta hepatis mass
    - Spleen
      - Splenomegaly, multiple low-attenuation lesions
    - Kidney
      - Nephromegaly, multifocal parenchymal masses, heterogeneous renal or pararenal mass
  - Lymph nodes
    - Discrete, homogeneous, enlarged lymph node or conglomeration of enlarged lymph nodes
  - Chest
    - Pulmonary mass, parenchymal nodules, pleural effusion, adenopathy
    - Parenchymal nodules usually have homogeneous density but can have halo of ground-glass opacity
  - Neck
    - Nonspecific adenopathy & enlarged tonsils
  - Brain
    - High-attenuation, ring-enhancing parenchymal lesions surrounded by vasogenic edema

MR Findings

- Abdomen
  - Liver
    - Multiple lesions are hypointense on T1 & slightly hyperintense on T2 with mild peripheral enhancement
  - Spleen
    - Splenomegaly, lesions hypointense to spleen on T1 & iso- to hypointense on T2
  - Kidney
    - Discrete renal mass or diffuse, infiltrative lesion causing renal enlargement
      - T1: Isointense to kidney
      - T2: Slightly hypointense
      - T1 C+: Hypoenhancing relative to kidney
    - Unilateral or bilateral
    - Hydronephrosis if mass is obstructive
  - Discrete or conglomerate nodal masses, often isointense to bowel wall
    - Hyperintense on DWI → stand out against bowel
- Brain
  - Solitary or multiple periventricular mass(es) with vasogenic edema
    - T1: Heterogeneously hypo- to isointense with foci of hyperintense hemorrhage
    - T2: Mostly hyperintense
    - T1 C+: Peripheral enhancement

Ultrasonographic Findings

- Solid masses with variable echogenicity & internal vascularity

Nuclear Medicine Findings

- PET
  - ↑ FDG uptake in lesions
  - PET/CT is useful for staging & to determine response to therapy

Imaging Recommendations

- Best imaging tool
  - Body: Disease is often detected on US, CT, or MR; PET/CT to stage & follow-up disease
  - Brain & spine: MR ± contrast
  - Airway: Radiograph to assess tonsils; CECT is more sensitive
- Protocol advice
  - DWI is helpful in identifying body lesions on MR

DIFFERENTIAL DIAGNOSIS

Graft-vs.-Host Disease

- Allogenic bone marrow transplant patients
- Lymphocytes from donor attack recipient tissues
- Often involves bowel, liver, & skin
  - May have similar symptoms, including abdominal pain & diarrhea
  - CECT classically shows featureless, ribbon-like hyperenhancing bowel
- Treatment: ↑ immunosuppression

Colitis

- Types: Inflammatory, pseudomembranous, neutropenic, infectious
- Symptoms: Fever, diarrhea, abdominal pain

- CECT: Circumferential colonic wall thickening (accordion sign)
- Abdominal radiograph: Thumbprinting of colonic wall

Fungal Infection

- *Candida* is most common type to infect GI tract, liver, & spleen
- Microabscess in liver, spleen, or kidneys
  - US: Multiple small, hypoechoic lesions, some with hyperechoic centers → target or bull's-eye appearance
  - CT: Numerous low-attenuation lesions
  - MR: Hypointense on T1 & hyperintense on T2

Abscess/Septic Emboli

- Visceral &/or soft tissue lesion(s) with irregular, thick rim enhancement, surrounding edema

PATHOLOGY

General Features

- Risk factors for PTLD
  - Ebstein-Barr virus (EBV) status at time of transplant
    - Greatest risk: Donor is EBV positive, recipient is EBV negative
    - 50-80% of PTLD biopsies are positive for EBV in tumors cells
      - In immunocompromised host, EBV can lead to uncontrolled B-cell expansion
  - Young age
    - Patients is more likely to be EBV negative
    - Patients will have longer exposure to immunosuppression
  - Type of transplanted organ
    - Small bowel transplant at highest risk (14-19%)
    - Kidney transplant at lowest risk (0.005-9%)
  - Extent of immunosuppression
  - Time from transplantation < 1 year
  - Previous history of PTLD

Staging, Grading, & Classification

- WHO classification
  - Early lesions
    - Includes 3 subtypes: Plasmacytic hyperplasia, florid follicular hyperplasia, & infectious mononucleosis
    - Similar to infectious mononucleosis
    - Reactive plasmacytic hyperplasia without destruction of normal lymph node or tissue architecture
  - Polymorphic
    - Mixture of monoclonal B-cell lymphocytes & polyclonal T-cell lymphocytes
    - B-lymphocytes are EBV positive
  - Monomorphic
    - Exclusively monoclonal
    - Divided into diffuse large B-cell lymphoma, Burkitt lymphoma, & plasma cell myeloma
    - Usually EBV positive
  - Classic Hodgkin lymphoma-like
    - Rare in childhood

CLINICAL ISSUES

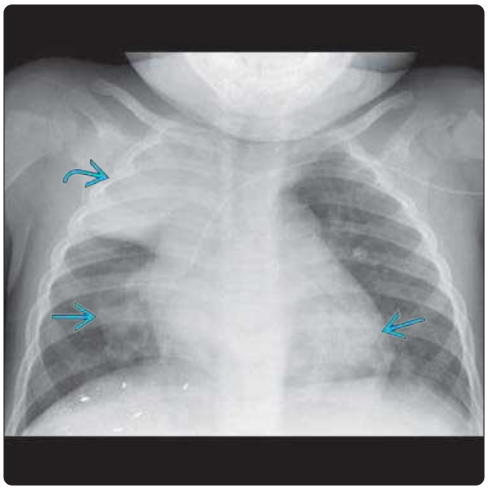
Presentation

- Most common signs/symptoms
  - Lymphadenopathy, fever, weight loss, tonsillitis, transplant dysfunction
- Other signs/symptoms
  - Depends on location of mass
    - Airway: Noisy breathing, snoring, changes in voice
    - Gastrointestinal: Secretory diarrhea, hematemesis, hematochezia, intussusception
    - General abdominal: Abdominal pain, distention, multisystem organ failure
    - Chest: May be asymptomatic with incidental opacity on chest radiograph, fever, ↓ pulmonary function tests
    - Head & neck: Mononucleosis-like symptoms, including fever, malaise, adenopathy, & pharyngitis
    - Neurologic: Seizure, focal neurological deficit

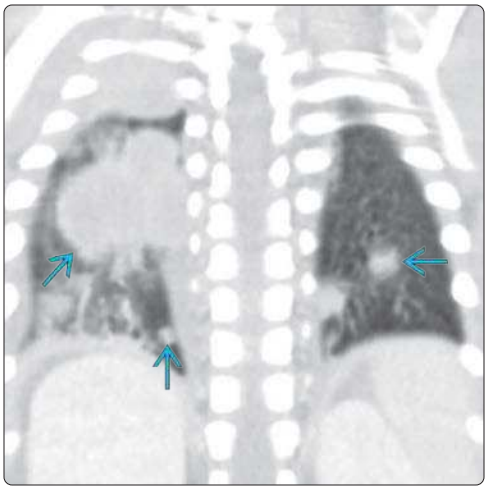
Demographics

- Age
  - Children > adults
- Epidemiology
  - Most common malignancy in pediatric transplant patients (52%)
  - Incidence of PTLD in children is 4x higher than adults
  - Incidence ↑ with ↑ immunosuppression
  - Incidence ↑ in transplants that require more immunosuppression
    - Highest in small bowel transplant & heart-lung transplant; lowest in kidney & liver transplants

Natural History & Prognosis



- Early-onset is more likely to be due to EBV infection
- Universally fatal if not treated
- Prognosis depends on degree of immunosuppression
  - More immunosuppressed = poorer prognosis



Treatment

- Reduced immunosuppression
  - Upon EBV seroconversion or ↑ EBV viral load
  - Works best in early lesions & polymorphic PTLD
  - Must balance with risk of transplant rejection
- Chemotherapy
  - For overt malignancy (Burkitt lymphoma)
  - If inadequate response to reduced immunosuppression

(Left) *Frontal chest radiograph in a young child with liver transplant shows multiple rounded pulmonary opacities bilaterally as well as consolidation in the right upper lobe.* **(Right)** *Coronal CECT in the same patient shows multiple rounded opacities in both lungs. This was confirmed to represent pulmonary PTLD at biopsy.*

(Left) *Axial CECT in the same patient shows multiple well-defined, rounded opacities in both lungs. These nodules were confirmed to represent pulmonary PTLD at biopsy. A small pleural effusion is also present.* **(Right)** *Axial CECT in an adolescent with a palpable cervical mass status post small bowel transplant shows an enlarged cervical lymph node posterior to the right jugular vein. This was confirmed to represent PTLD at biopsy.*

(Left) *Axial CECT in a young adult with a prior history of renal transplant shows a large soft tissue mass arising from bowel in the right lower quadrant.* **(Right)** *Axial F-18 FDG PET/CT in the same patient shows marked FDG uptake in the right lower quadrant mass, confirmed to represent PTLD.*

Pseudomembranous Colitis

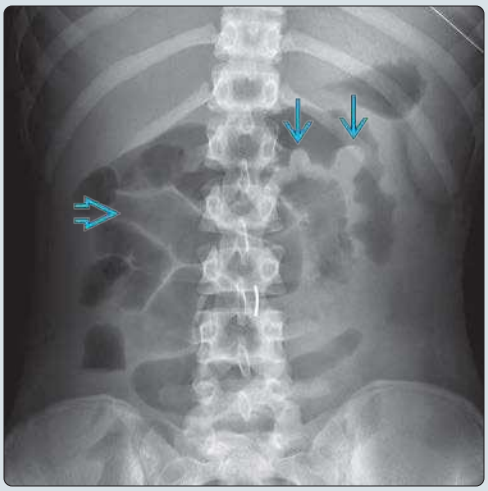
KEY FACTS

TERMINOLOGY

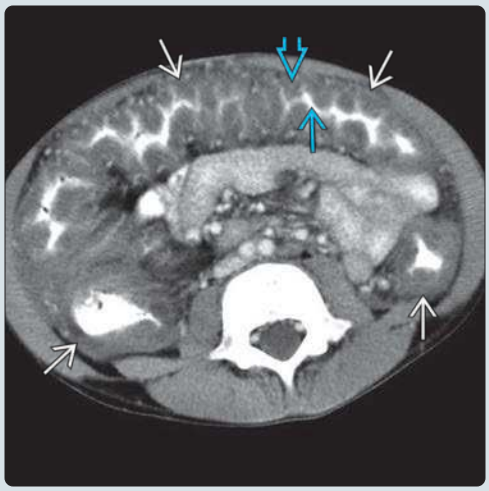
- Colonic inflammation due to *Clostridium difficile* & its toxins A & B → epithelial necrosis & pseudomembranes

IMAGING

- Classic appearance: Pancolitis with marked wall thickening
- Radiographs
  - Thumbprinting ± colonic or small bowel ileus
- CECT
  - Accordion sign: Alternating bands of ↑ & ↓ attenuation of colon due to oral contrast interdigitating between edematous haustra
    - Lumen appears stellate in cross section
  - Target sign: Rings of hyperenhancing mucosa & lower attenuation submucosal/muscular edema
  - Pericolonic stranding is usually very mild, ± ascites
- Ultrasound
  - Accordion sign: Echogenic bowel contents between hypoechoic, thickened wall
  - Pseudomembranes: Linear hyperechogenicity
  - ± ascites
- Paucity of colonic gas with luminal narrowing

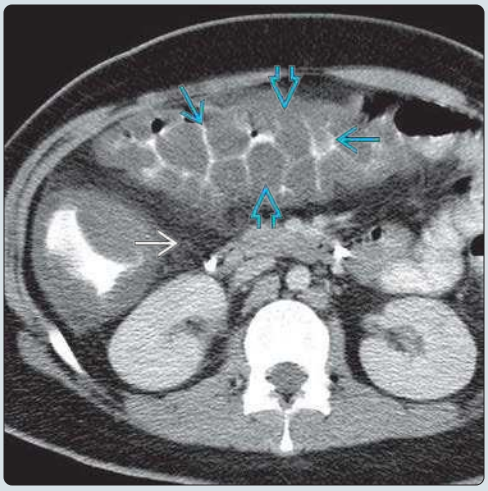


PATHOLOGY

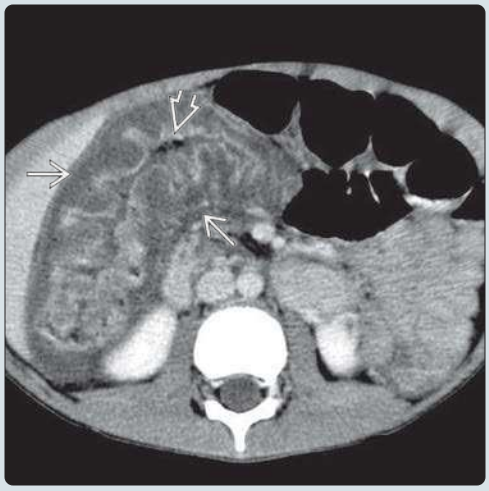


- *C. difficile* overgrowth (usually due to antibiotic therapy) → toxin A & B release
- Inflamed colon with discrete or confluent, raised, yellow-white plaque pseudomembranes on endoscopy

CLINICAL ISSUES



- Most common presentations: Watery or bloody diarrhea, dehydration, abdominal pain, leukocytosis, fever
- Primary treatments include cessation of inciting antibiotic with addition of metronidazole or vancomycin
- Severe *C. difficile* infections are less common in children compared to adults
- If treated early, full recovery is expected
  - Up to 25% recurrence rate



(Left) *Supine abdominal radiograph in a 15-year-old with known pseudomembranous colitis (PMC) demonstrates thumbprinting along the colon due to haustral thickening. A small bowel ileus is also present.* **(Right)** *Axial CECT in a 10-year-old child with fever, abdominal pain, & diarrhea demonstrates findings of PMC with pancolonic marked wall thickening. The alternating bands of hyperdense contrast between the thickened, fluid-density haustra create the accordion sign.*

(Left) *Axial CECT shows marked pancolitis with enteric contrast trapped between thickened haustral folds (the accordion sign). Note the minimal pericolonic fat infiltration, which is typical with PMC.* **(Right)** *Axial CECT demonstrates asymmetric pancolitis with the greatest colonic wall thickening & mucosal enhancement seen in the right & transverse colon. Involvement limited to the proximal colon can be seen in 10-20% of PMC cases.*

TERMINOLOGY

Definitions

- Inflammation of colon by *Clostridium difficile* toxins A & B

IMAGING

General Features

- Location
  - Pancolitis is typical
  - Rectum & sigmoid colon: Up to 90% of cases
  - Proximal colon only: 10-20%

Radiographic Findings

- Low sensitivity: Up to 68% can be normal
- Paucity of colonic gas with luminal narrowing
  - Small amounts of gas in lumen outline thickened haustra (thumbprinting)
    - En face view of affected loop may show stellate lucency of gas in narrowed lumen outlining haustra
  - Haustral thickening may be nodular
- ± colonic & small bowel ileus
- ± separation & centralization of bowel loops by ascites
- Toxic megacolon in fulminant cases
  - Colonic dilation, R > L, usually > 6 cm
  - Loss of haustral pattern
  - Pneumoperitoneum if perforation occurs

Ultrasonographic Findings

- Marked colonic wall thickening effacing lumen
  - Hypoechoic mural edema
  - ± loss of wall stratification (gut signature)
  - Ultrasound accordion sign: Echogenic bowel contents between less echogenic but thickened walls
- Pseudomembranes may appear as linear hyperechogenicity
- ± ascites

CT Findings

- CECT
  - Colonic wall thickening
    - Usually marked; average > 10 mm
    - Smooth, plaque-like, nodular or polypoid
  - Accordion sign: Small amounts of oral contrast (or hyperenhancing mucosa) interdigitate between very thick/edematous haustra → alternating bands of ↓ & ↑ attenuation when viewed in long axis
    - Narrowed lumen may appear stellate in cross section
  - Target sign: In cross section/short axis, thickened colonic wall shows rings of hyperenhancing mucosa, lower attenuation submucosal/mural edema, & possible outer layer of serosal enhancement
  - Pericolonic stranding is usually mild due to mucosal & submucosal nature of disease; ± ascites
  - ± pneumatosis &/or pneumoperitoneum if severe

Imaging Recommendations

- CECT with IV & oral contrast

DIFFERENTIAL DIAGNOSIS

Infectious Colitis

- May be indistinguishable from pseudomembranous colitis

Crohn Disease

- Skip lesions; ileocolic involvement is typical
- Strictures, fistulas, abscesses, "creeping fat"

Ulcerative Colitis

- Contiguous colitis extending variable distances retrograde from rectum
- Symmetric wall thickening < 10 mm

Typhlitis (Neutropenic Colitis)

- History of neutropenia & immunosuppression
- Usually isolated to right colon

Benign Pneumatosis in Older Children

- History of steroids or bone marrow transplant is typical
- Often lacks wall thickening or free fluid

PATHOLOGY

General Features

- *C. difficile* colonization, overgrowth, & toxin production
  - Overgrowth is usually due to antibiotic therapy but can be due to chemotherapy, abdominal surgery, obstruction, uremia, hypotension, bowel hypoperfusion
  - Toxins A & B (enterotoxin & cytotoxin) mediate disease

Gross Pathologic & Surgical Features

- Inflamed colon with discrete or confluent, raised, yellow-white plaques (pseudomembranes) on endoscopy

CLINICAL ISSUES

Presentation

- Most common: Watery or bloody diarrhea, dehydration, abdominal pain, leukocytosis, fever

Natural History & Prognosis

- If treated early, full recovery is expected
- All-cause mortality in children with *C. difficile* infection: 4%
- Severe forms of *C. difficile* infection (pseudomembranous colitis, toxic megacolon, death) are less common in children
  - 8% in recent population surveillance study, with 0 deaths
- 12-25% recurrence rate in pediatric population

Treatment

- Cessation of inciting antibiotic & starting replacement if needed
- 1st-line therapy with metronidazole or vancomycin
- Fecal microbiota transplantation may be considered for refractory/recurrent cases
- Surgery for severe disease resulting in toxic megacolon or perforation, or if rapidly progressing or refractory

Neutropenic Colitis

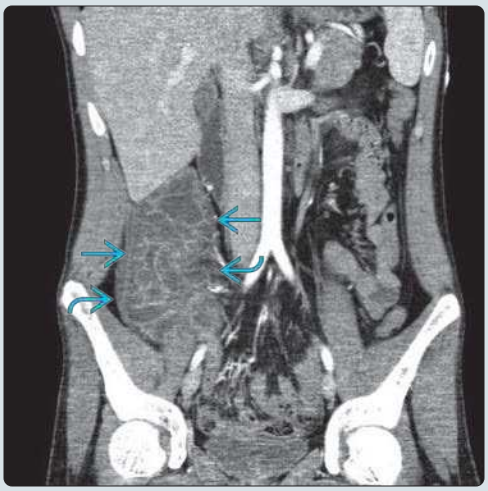
KEY FACTS

TERMINOLOGY

- Necrotizing inflammatory process of bowel most commonly affecting right colon of neutropenic patients (with absolute neutrophil count < 500 cells/μL)

IMAGING

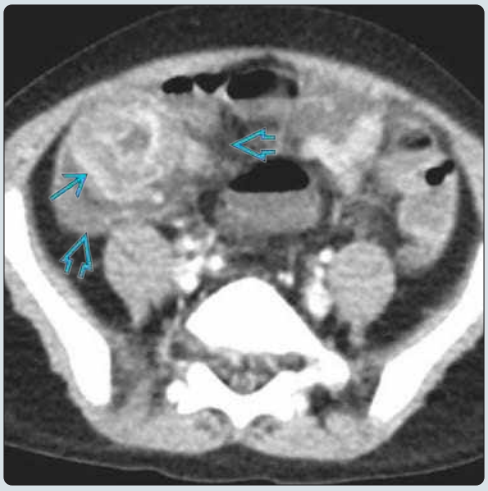
- Right colon is most commonly affected, but distal colon, appendix, & small bowel can be involved
- Bowel wall thickening: Circumferential & symmetric, typically low attenuation on CECT
  - Radiographs may show thumbprinting of thickened haustra &/or paucity of right lower quadrant bowel gas
    - ± stellate appearance of narrowed, gas-containing bowel lumen
- Mucosal hyperenhancement is less common than in graft-vs.-host disease (GVHD)
- Pericolic fluid & fat stranding/hyperechogenicity
- Pneumatosis is more common than other colitides & GVHD
- ± small bowel ileus; ± pneumoperitoneum with perforation
- Modality of choice: US vs. CECT
  - US is more accurate for measurement of bowel wall thickness & uses no ionizing radiation
    - Sufficient for diagnosis & follow-up in most cases
  - CECT may be more sensitive for early changes & complications (necrosis, perforation, abscess)



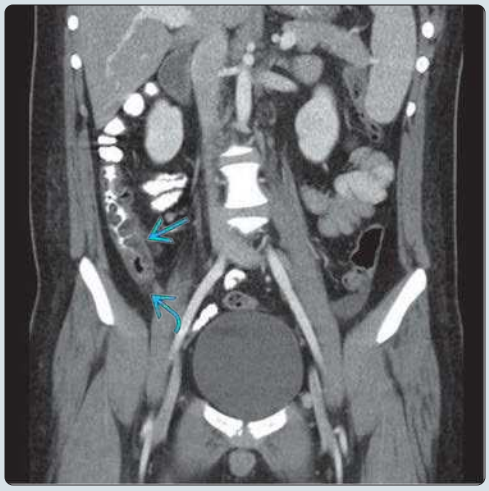
TOP DIFFERENTIAL DIAGNOSES

- Other colitides: Infectious, pseudomembranous, ischemic
- Acute graft-vs.-host disease
- Appendicitis
- Benign pneumatosis of older children

CLINICAL ISSUES



- Clinical triad: Neutropenia, abdominal pain, fever
- Uncomplicated cases: Bowel rest, broad spectrum IV antibiotics (including antifungal), ± granulocyte colony-stimulating factor
- Surgery for perforation, peritonitis, GI bleeding, obstruction



(Left) *Coronal CECT shows marked wall thickening of the cecum & ascending colon in a patient with a history of osteosarcoma status post chemotherapy. Mild surrounding fluid/edema is also noted. The patient presented with neutropenia, vomiting, nausea, & abdominal pain.* **(Right)** *Axial CECT in a 7-year-old neutropenic patient demonstrates marked thickening & edema of the cecal wall & mild adjacent fat stranding, compatible with neutropenic colitis.*

(Left) *Axial CECT in a 3-year-old with acute lymphocytic leukemia presenting with fever, abdominal pain, & neutropenia shows findings typical of neutropenic colitis, including wall thickening in the cecum & ascending colon + moderate associated pericolonic stranding. Note mucosal & serosal hyperenhancement.* **(Right)** *Coronal CECT in an 18-year-old with acute lymphocytic leukemia, neutropenia, & abdominal pain shows edematous wall thickening at the cecum with pericolonic inflammatory change.*

TERMINOLOGY

Definitions

- Necrotizing inflammatory process of bowel most commonly affecting right colon of neutropenic patients (with absolute neutrophil count < 500 cells/μL)

IMAGING

General Features

- Best diagnostic clue
  - Wall thickening of right colon + pericolic stranding & fluid in neutropenic patient with abdominal pain &/or fever without other etiology identified
  - Pneumatosis > compared to other colitides & graft-vs.-host disease (GVHD)
- Location
  - Most common: Cecum & ascending colon
  - ± other colonic segments, appendix, & small bowel

Radiographic Findings

- Paucity of bowel gas in right lower quadrant
- "Soft tissue mass" in right lower quadrant
- Thumbprinting (thickened haustra)
  - May create stellate appearance of narrowed, gas-containing bowel lumen
- ± pneumatosis; ± small bowel ileus

CT Findings

- Circumferential & symmetric bowel wall thickening > 3 mm, predominantly of ↓ attenuation due to muscularis edema
- ± mucosal & serosal hyperenhancement
- Cecal luminal distention or narrowing
- Pericolic fluid & fat stranding
- ± pneumatosis
- ± dilated adjacent small bowel loops (ileus)
- Pneumoperitoneum if perforation occurs

Ultrasonographic Findings

- Bowel wall thickening > 3 mm
  - Hypoechoic muscularis layer & echogenic mucosal layer
- Pericolic fluid & echogenic fat
- ± echogenic pneumatosis tracking circumferentially in wall

DIFFERENTIAL DIAGNOSIS

Crohn Disease

- Mouth to anus may be affected but ileocolic region is most common
- Skip lesions (up to 90%) with transmural inflammation
- Strictures, sinus tracts, fistulas, perianal disease

Appendicitis

- Dilated, noncompressible appendix
- Inflammatory changes are centered at appendix

Infectious Colitis

- Nonspecific imaging findings; many possible organisms

Pseudomembranous Colitis

- Clinical history of recent antibiotic therapy
- Typically pancolitis; isolated to right colon in 10-20%
- Marked wall thickening (mean > 10 mm) & nodularity

Acute Graft-vs.-Host Disease

- Classic triad of dermatitis, hepatitis, & enteritis
- Typically < 100 days from bone marrow transplant
- Mucosal hyperenhancement & fluid-filled bowel are common
  - Small bowel is classically featureless & ribbon-like

Benign Pneumatosis of Older Children

- Patients on steroids or after bone marrow transplant
- Extensive colonic involvement is common
- Bowel wall thickening & free fluid are uncommon

Ischemic Colitis

- Uncommon in children but must be considered in ill, complex patients with pneumatosis
- Bowel wall thickening with ↓ enhancement + free fluid

PATHOLOGY

General Features

- Multifactorial etiology: Immunocompromise, therapy toxicity, bowel ischemia, intramural hemorrhage, neoplastic cell infiltration of bowel wall
- Mechanism: Chemotherapy-related mucositis & mucosal injury → bacterial/fungal invasion of bowel wall → inflammation, hemorrhage, edema → ulceration, transmural necrosis, & perforation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms: Neutropenia, abdominal pain, fever, diarrhea
- Risk factors: Leukemia, hematologic & solid malignancies, solid organ & bone marrow transplant, immunocompromised state, recent chemotherapy
- Incidence: 0.4-6% in pediatric oncology patients

Natural History & Prognosis

- Early diagnosis & treatment are essential to reduce risk of transmural necrosis & perforation
- Mortality ↓ over last 3 decades, recently 0-2.5%

Treatment

- Medical management for uncomplicated cases
  - Bowel rest & decompression
  - Broad spectrum IV antibiotics (including antifungal)
  - ± granulocyte colony-stimulating factor
- Surgery for perforation, peritonitis, active GI bleeding, obstruction

Graft-vs.-Host Disease

KEY FACTS

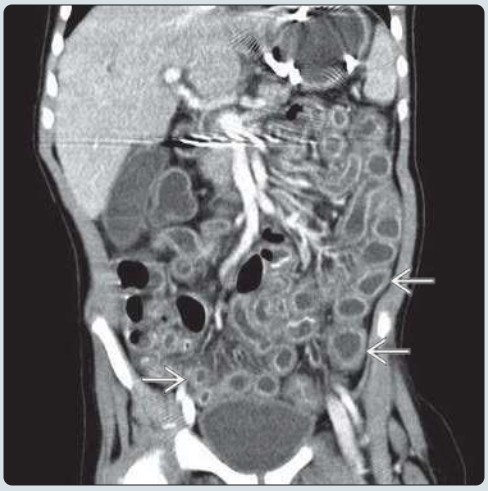
TERMINOLOGY

- Disease of allogenic bone marrow transplant (BMT) or stem cell transplant (SCT) recipients
- Donor T lymphocytes cause damage to epithelial cells lining recipient target organs
  - Can involve skin, GI tract, liver, lung

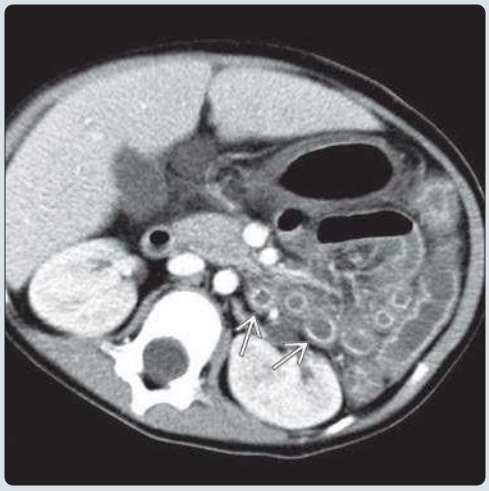
IMAGING

- Diffuse bowel wall thickening, hyperenhancement & featureless bowel (↓ folds)
- Radiography
  - May see findings of ileus
  - ± evidence of bowel wall thickening, pneumatosis
- Fluoroscopy/SBFT
  - Separation of bowel loops & luminal narrowing due to bowel wall thickening, featureless bowel wall
- CECT
  - Diffusely abnormal bowel with wall thickening & hyperenhancement; featureless bowel
  - ± hepatomegaly, ascites
  - Lungs: Typically bilateral ground-glass opacities

CLINICAL ISSUES



- Affects 30-70% of patients with allogenic BMTs or SCTs
- Older children have ↑ likelihood of graft-vs.-host disease (GVHD)
- Acute GVHD (< 100 days post transplant)
  - Most commonly involves skin
    - Maculopapular rash, itching, ± pain
  - GI tract & liver are also commonly involved
  - Differentiate from infection, drug toxicity, hepatic venoocclusive disease
- Chronic GVHD (> 100 days post transplant)
  - Can affect muscles/joints, lungs, eyes, kidneys
- Treatment: ↑ immunosuppression, steroids
- Overall prognosis is good: 80-85% survival



(Left) *Low-power H&E stain of the intestine shows an ulcerated mucosal surface. Note the underlying blood vessels, which may predispose to bleeding.* **(Right)** *Axial CECT shows fluid-filled loops of bowel with central hyperenhancement & infiltration of the mesentery. The mucosal surface is relatively smooth & featureless without typical folds (as this layer actually represents vascular granulation tissue replacing destroyed mucosa), a classic appearance of graft-vs.-host disease (GVHD).*

(Left) *Coronal CECT shows multiple fluid-filled loops of abnormal small bowel throughout the abdomen. Note the mildly thickened bowel walls with smooth central hyperenhancement that is typical of GVHD.* **(Right)** *Axial CECT in the same child shows multiple loops of fluid-filled small bowel with mild wall thickening & smooth, central hyperenhancement, which is due to granulation tissue replacing destroyed mucosa.*

TERMINOLOGY

Abbreviations

- Graft-vs.-host disease (GVHD)

Definitions

- Disease of allogenic bone marrow transplant (BMT) or stem cell transplant (SCT) recipients
- Donor T lymphocytes cause damage to epithelial cells lining recipient target organs

IMAGING
