General Features

- Best diagnostic clue
  - Diffuse bowel wall thickening with central, smooth (featureless) hyperenhancement
    - Enhancing layer represents vascular granulation tissue replacing destroyed mucosa
- Location
  - Skin, GI tract, liver, lung

Radiographic Findings

- May resemble adynamic ileus
- ± evidence of bowel wall thickening, pneumatosis

Fluoroscopic Findings

- SBFT: Small bowel wall thickening with luminal narrowing & separation of loops; may be featureless & "ribbon-like"

Ultrasonographic Findings

- Fluid-filled loops of thick-walled bowel ± ascites
  - ↑ blood flow due to inflammation
  - Contrast & elastography of bowel may provide additional detail

CT Findings

- CECT
  - Diffuse bowel abnormality
    - Bowel wall thickening/edema ± loss of folds
    - Hyperenhancement of bowel wall, especially centrally
  - ± hepatomegaly, ascites, bilateral ground-glass pulmonary opacities

MR Findings

- Similar to CECT: Bowel wall thickening, hyperenhancement

DIFFERENTIAL DIAGNOSIS

Infectious Colitis

- Nonspecific wall thickening, inflammation

Typhlitis

- Severely immunocompromised patients
- Most commonly right-sided

Radiation Enteritis

- Thickened bowel wall & adhesions

Posttransplant Lymphoproliferative Disease

- Associated with Epstein-Barr virus infection
- Bowel wall thickening ± aneurysmal dilation, solid organ lesions, lymph node enlargement

Shock Bowel (Hypoperfusion Complex)

- Relevant clinical history; bowel wall thickening, hyperenhancement

PATHOLOGY

General Features

- Complication of allogenic transplants
  - Histocompatibility is major predictor of incidence & severity of GVHD
- Development of GVHD requires
  - Immunocompetent cells (T cells) within graft
  - Recipient (host) tissue antigens
    - Donor T cells react to mismatched host antigens & attack host tissues

Microscopic Features

- Extensive crypt cell necrosis
- In severe cases, diffuse large & small bowel ulceration & mucosal destruction
- Mucosal replacement with thin layer of highly vascular granulation tissue

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Skin is most commonly affected; usually 1st site of involvement
    - Typical maculopapular rash, ± pain, pruritus
  - GI tract: Diarrhea, anorexia, vomiting, pain, rarely, GI bleed
  - Liver: Cholestatic hyperbilirubinemia, hepatomegaly
- Other signs/symptoms
  - Chronic GVHD: More diverse manifestations
    - Often affects skin, mucosal surfaces

Demographics

- Age
  - Older children have ↑ likelihood of GVHD
- Epidemiology
  - Affects 30-70% of patients with allogenic transplant of immunocompetent lymphocytes
- Sex: M = F

Natural History & Prognosis

- Overall prognosis is good: 80-85% survival

Treatment

- Typically steroids, ↑ immunosuppression

Chronic Granulomatous Disease

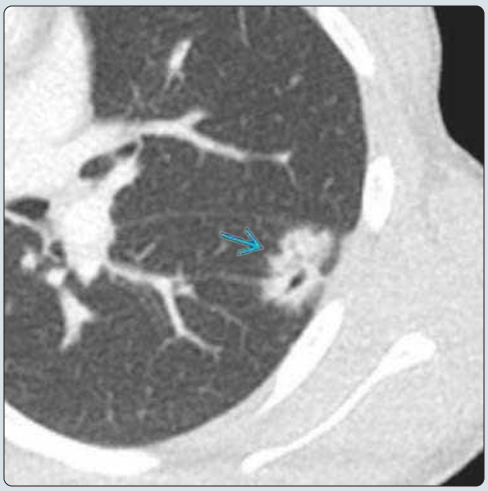
KEY FACTS

TERMINOLOGY

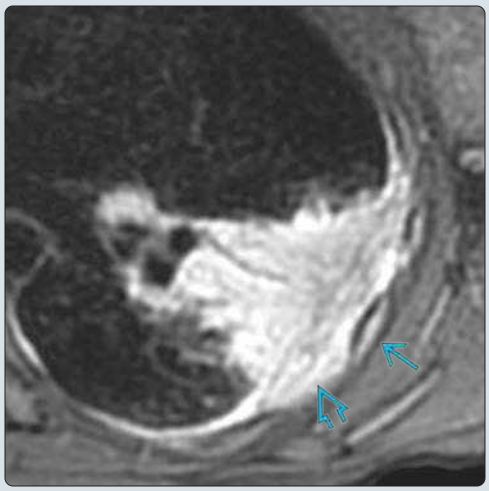
- Primary immunodeficiency characterized by recurrent infections at epithelial surfaces & organs with large numbers of reticuloendothelial cells

IMAGING

- Recurrent infections with catalase-positive organisms such as *Aspergillus* or *Staphylococcus aureus*
- Chronic granulomatous disease (CGD) can affect any organ system
- Pneumonia: Consolidation, nodules, reticulonodular opacities, & scarring
  - Complicated by abscess or empyema in 20%
- Lymph nodes
  - Lymphadenopathy in ~ 100% of patients
  - Suppurative adenitis is most common in neck
  - Calcified lymph nodes as sequelae of prior infection
- Osteomyelitis
  - Common locations: Lower & upper extremities
  - Chest wall & vertebral body involvement in up to 1/3 from contiguous spread of *Aspergillus* pneumonia
- Hepatic abscess(es)
- Gastrointestinal
  - CGD involvement mimics Crohn disease



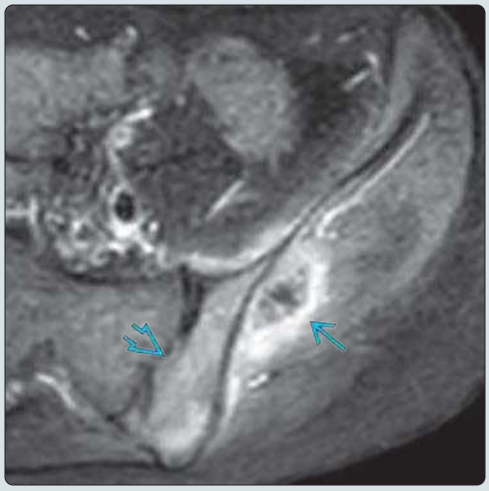
PATHOLOGY



- Defect in 1 of 5 genes encoding for NADPH-oxidase
  - Defect prevents phagocytic cells from producing respiratory burst used to kill pathogens
- 2 types: X-linked > autosomal recessive

CLINICAL ISSUES

- 76% of patients are diagnosed before 5 years of age
- 85% of patients with CGD are male
- Pneumonia is most common infection in CGD (80%)
- Suppurative adenitis is 2nd most common infection (60%)
- Hepatic abscesses occur in 1/3 of patients



(Left) *Axial NECT of the chest in a patient with chronic granulomatous disease (CGD) shows cavitary pneumonia in the left lower lobe. Aspergillus is the most common cause of pneumonia in patients with chronic granulomatous disease.* **(Right)** *Axial T2 FS MR shows focal consolidation in the left lower lobe with edema of the adjacent rib & intervening pleural thickening & fluid. Aspergillus pneumonia can cause osteomyelitis of adjacent ribs.*

(Left) *Axial CECT of the abdomen shows a multiseptated abscess in the left lobe of the liver. Note the surrounding parenchymal edema. Up to 33% of patients with CGD develop a hepatic abscess, & 60% of these patients will have multiple abscesses at diagnosis.* **(Right)** *Axial T1 C+ FS MR in a patient with CGD shows enhancement of the iliac bone consistent with osteomyelitis. There is an intramuscular abscess in the adjacent gluteal musculature.*

TERMINOLOGY

Abbreviations

- Chronic granulomatous disease (CGD)

Definitions

- Primary immunodeficiency characterized by recurrent infections at epithelial surfaces & organs with large numbers of reticuloendothelial cells

IMAGING

General Features

- Best diagnostic clue
  - Recurrent infections with catalase-positive organisms such as *Aspergillus* or *Staphylococcus aureus*
- Location
  - CGD can affect every organ system

Radiographic Findings

- Chest
  - Consolidation, nodules, reticulonodular opacities, & scarring
- Skeletal
  - Osteomyelitis
    - Common locations: Extremities, chest wall
      - Chest wall & vertebral involvement in up to 1/3 from contiguous spread of *Aspergillus* pneumonia

Fluoroscopic Findings

- Upper GI
  - Gastrointestinal
    - Esophagus: Dysmotility & strictures
    - Stomach: Narrowing of gastric antrum
      - Gastric outlet obstruction, delayed gastric emptying, thickened rugae
    - Bowel: Can mimic Crohn disease

CT Findings

- NECT
  - Chest
    - Pneumonia
      - Consolidation, ground-glass opacity, tree-in-bud opacity, centrilobular or random nodules, bronchiectasis, air trapping, septal thickening, or scarring
      - ± cavitation, mycetoma
      - Abscess or empyema in 20%
    - Prolonged course may lead to chronic findings
      - Mediastinal or hilar adenopathy, pulmonary fibrosis, honeycomb lung, pulmonary arterial hypertension, & pleural thickening
      - Adenopathy can be calcified related to granuloma formation
- CECT
  - Lymph nodes
    - Lymphadenopathy in nearly all patients with CGD
    - Suppurative adenitis occurs most commonly in neck
      - Enlarged, enhancing lymph node with central hypodensity ± thick, enhancing septations
    - Calcified lymph nodes as sequelae of prior infection
  - Liver
    - Hepatic abscess occurs in 1/3
      - Multiple in 60% of patients
      - Recurrence in 40% of patients
      - Abscesses < 1 cm in size enhance homogeneously
      - Abscesses between 1-3 cm have incomplete central enhancement
      - Abscesses > 3 cm have heterogeneous enhancement with thick, irregular loculations
      - Ca^{2+} can occur at site of prior infection
    - Hepatomegaly
  - Spleen
    - Splenic abscesses occur in up to 1/3 of patients with hepatic abscess
      - Splenic Ca^{2+} can occur after abscess has healed
    - Splenomegaly
  - Gastrointestinal tract
    - CGD involvement mimics Crohn disease
      - Can affect mouth to anus
      - Stomach: Narrowing of gastric antrum with wall thickening
      - Bowel: Wall thickening, mucosal hyperenhancement, skip lesions, luminal narrowing, fistulas, & perirectal abscess
  - Kidneys
    - Renal findings occur in 3% of patients
    - Pyelonephritis ± renal abscess
      - Ca^{2+} can occur after renal abscess
  - Sinuses
    - Sinusitis has similar appearance to that in immunocompetent patients (i.e., mucosal thickening, air-fluid levels)
      - Fungal sinusitis can appear hyperdense
      - ± bone destruction

MR Findings

- Liver
  - Abscess
    - T1: Hypointense
    - T2: Heterogeneously hyperintense with irregular, hypointense septations/rim ± surrounding edema
    - T1 C+: Thick rim with enhancing septations
    - DWI: Central diffusion restriction
  - Hepatosplenomegaly
- Gastrointestinal
  - Stomach: Wall thickening
  - Bowel: Wall thickening, mucosal hyperenhancement, skip lesions, luminal narrowing, fistulas, & perirectal abscess
- Brain
  - Encephalitis
  - Brain abscess
    - T2-hypointense rim with surrounding vasogenic edema
    - Irregular rim enhancement with central diffusion restriction
    - Typically occur at gray-white matter junctions
  - Meningitis: Thickened, enhancing meninges
- Sinuses
  - Sinusitis

- Similar appearance to sinusitis in immunocompetent patients
- Fungal sinusitis: Hypointense on T1/T2

Ultrasonographic Findings

- Grayscale ultrasound
  - Lymph nodes
    - Suppurative adenitis: Hypoechoic internal contents ± swirling internal debris, thickened septa; absent central vascularity, ↑ peripheral vascularity
    - Late: Hyperechoic foci with posterior shadowing (Ca^{2+}) after prior infection
  - Liver
    - Hepatic abscess: Solid or complex-appearing, hypo- to isoechoic mass
    - Absent or only septal central vascularity, ↑ peripheral vascularity
  - Bladder
    - Urinary tract infection with wall thickening
    - Inflammatory pseudotumors: Focal bladder wall thickening
      - Can mimic rhabdomyosarcoma

Imaging Recommendations

- Best imaging tool
  - Depends on site of infection: US or MR are preferred modalities due to frequent imaging in affected patients
    - Patients often receive multiple CECT scans over course of life due to rapid scan time & ease of scheduling
  - PET/CT (or potentially whole-body MR + DWIBS) can be used if site of infection cannot be identified

DIFFERENTIAL DIAGNOSIS

Recurrent Bacterial Pneumonia

- May be indistinguishable from pneumonia in CGD
- Look for underlying congenital lung lesion

Severe Combined Immunodeficiency

- Primary immunodeficiency with severe T- & B-cell dysfunction
- Infants present with infections due to lack of T cells

Crohn Disease

- Chronic, recurrent, segmental, granulomatous inflammatory bowel disease
- Differentiated from CGD by absence of pigmented histiocytes
- CGD should be considered in all patients with early-onset inflammatory bowel disease

PATHOLOGY

General Features

- Etiology
  - Defect in 1 of 5 genes encoding for NADPH-oxidase
    - Defect prevents phagocytic cells from producing respiratory burst used to kill pathogens
    - Neutrophils are able to phagocytose catalase-positive organisms but not kill them
    - Organism lives inside neutrophil causing chronic inflammatory response & granuloma formation
- Genetics
  - Transmitted in X-linked or autosomal recessive patterns
    - X-linked transmission in 65-70% of cases
    - Incidence of autosomal recessive transmission is higher in countries with higher rates of consanguinity

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pneumonia is most common infection in CGD, occurring in 80% of patients
    - Most commonly caused by *Aspergillus*
  - Suppurative adenitis is 2nd most common infection in CGD, occurring in 60% of patients
    - Most commonly caused by *S. aureus*
  - Hepatic abscesses occur in 1/3 of patients with CGD
    - Most commonly caused by *S. aureus*
  - Osteomyelitis occurs in up to 25% of patients with CGD
    - Most commonly caused by *Serratia marcescens*

Demographics

- Age
  - 76% are diagnosed before 5 years of age
  - 15% diagnosed in 2nd decade
- Sex
  - 85% of patients with CGD are male
- Epidemiology
  - Occurs in 1 in 200,000-250,000 live births

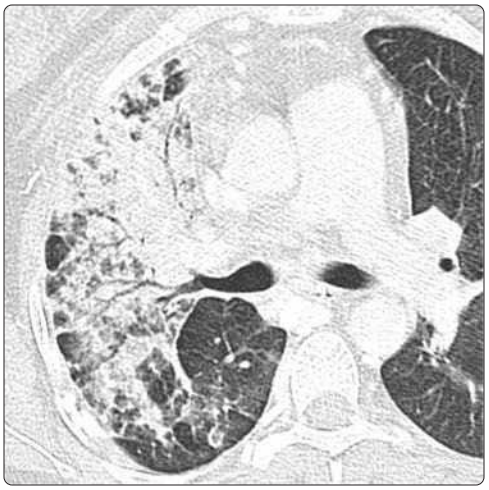
Natural History & Prognosis

- X-linked disease typically presents at younger age with more severe manifestations
- Recurrent infections are typical
  - CGD has highest prevalence of invasive fungal infections among primary immunodeficiencies (20-40%)
- Historically high mortality rate: In 1967, only 21% of patients survived beyond 5 years of age
  - Currently 90% survive to 10 years of age
  - Median age of death: 30-40 years of age
  - Pneumonia or sepsis is most common cause of death

Treatment

- Stem cell transplant is only known cure for CGD
  - CGD is 3rd most common indication for stem cell transplant in patients with primary immunodeficiency

DIAGNOSTIC CHECKLIST



Consider

- Consider CGD in patients with hepatic abscess, recurrent pneumonia, or other unusual infections

SELECTED REFERENCES

(Left) *Transverse ultrasound of the liver shows a heterogeneous, multiseptated abscess. No significant internal vascularity was identified on color Doppler imaging (not shown) to suggest a solid mass.* **(Right)** *Axial CECT of the chest in a patient with CGD shows pneumonia throughout the right lung. Pneumonia is the most common type of infection & the most common cause of death in patients with CGD.*

(Left) *Axial T2 FS MR of the pelvis shows diffuse wall thickening & ↑ signal intensity of the sigmoid colon with associated engorgement of the vasa recta. Inflammatory bowel disease in patients with CGD can mimic Crohn disease.* **(Right)** *Axial CECT of the stomach shows thickening of the gastric antrum, a typical location of inflammation in chronic granulomatous disease.*

(Left) *Axial CECT of the neck shows a suppurative lymph node in the right cervical chain. All patients with CGD have lymphadenopathy, & up to 60% of patients develop suppurative adenitis.* **(Right)** *Coronal T1 C+ FS MR shows a targetoid focus of abnormal enhancement of the calcaneus. The center of this lesion does not enhance, typical of pus. There is a moderately thick rim of enhancing granulation tissue + marked surrounding marrow edema.*

Pneumatosis in Older Children

KEY FACTS

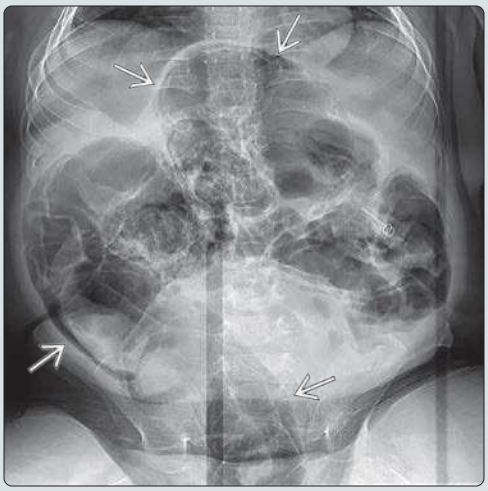
TERMINOLOGY

- Presence of gas within walls of gastrointestinal tract
- In older children, more frequently benign & associated with variety of underlying conditions & medications

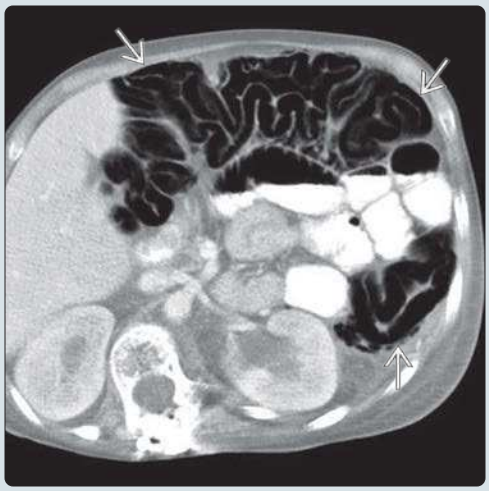
IMAGING

- Radiography is 1st-line imaging modality
  - CT is more sensitive but often not needed
- Curvilinear or round gas collections within bowel wall
  - Colon > small bowel > > stomach
  - Benign pneumatosis can be extensive
- ± free intraperitoneal air
  - Not necessarily due to intestinal perforation
- CT findings concerning for clinically significant causes: Bowel wall thickening or ↓ enhancement, adjacent inflammatory stranding, free fluid

TOP DIFFERENTIAL DIAGNOSES

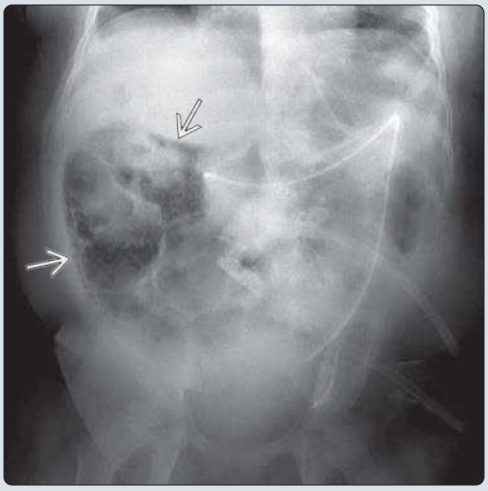


- Benign causes: Medications (corticosteroids), systemic or pulmonary diseases, solid organ or bone marrow transplant
- Significant causes: Ischemia, bowel obstruction, severe infection, trauma

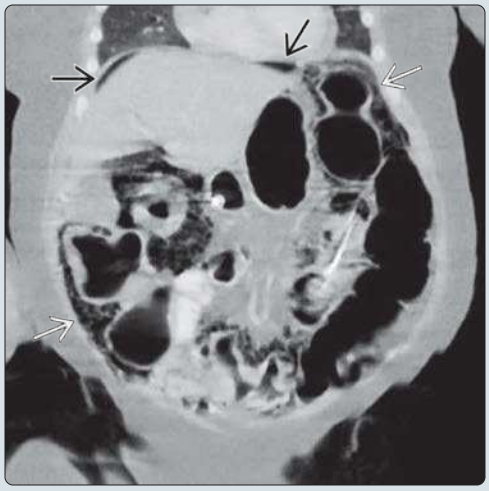


PATHOLOGY

- Multiple proposed mechanisms for gas dissecting into bowel wall; likely multifactorial
  - Mucosal damage &/or ↑ intraluminal pressure allows gas to dissect into wall



CLINICAL ISSUES



- Without worrisome clinical features → managed conservatively
  - Observation, bowel rest, alter medications, treat underlying conditions
- Worrisome clinical features → frequently require surgical management

(Left) *AP radiograph in a 3-year-old boy with multiple medical problems shows extensive curvilinear lucencies separating layers of the colonic wall. This pneumatosis extends all the way to the rectum. The patient was clinically stable, & the pneumatosis was thought to be benign & due to corticosteroid use.* **(Right)** *Axial CECT in a different child shows diffuse pneumatosis throughout the visualized colonic wall.*

(Left) *AP radiograph in a 2-year-old boy with a seizure disorder & multiple medical problems shows colonic pneumatosis, mostly in the ascending colon & proximal transverse colon.* **(Right)** *Coronal CECT in the same 2-year-old boy shows extensive pneumatosis throughout the colon. There is also a small amount of free intraperitoneal gas. Despite the presence of free air, the patient was treated conservatively due to his clinical status & lack of other imaging features to suggest ischemia or obstruction.*

TERMINOLOGY

Synonyms

- Pneumatosis intestinalis; pneumatosis coli (confined to colon); pneumatosis cystoides intestinalis

Definitions

- Presence of gas within walls of gastrointestinal tract
  - Associated with necrotizing enterocolitis in
    - Premature infants
    - Term newborns with congenital heart disease & other cardiovascular abnormalities
  - In older children, more frequently benign & associated with variety of underlying conditions & medications

IMAGING

General Features

- Best diagnostic clue
  - Curvilinear or rounded gas collections within bowel wall
    - Colon > small bowel > > stomach
  - Extensive colonic pneumatosis is most frequently due to benign causes

Radiographic Findings

- Curvilinear or rounded foci of gas outlining bowel wall
  - Can have mottled appearance
- ± dilated bowel or evidence of bowel wall thickening
- ± free intraperitoneal air

CT Findings

- CECT
  - Gas collections within wall of bowel
    - Foci of gas in posterior bowel wall may help differentiate from intraluminal gas or gas-containing fecal debris
  - CT findings helpful in differentiating benign from clinically significant causes
    - Extensive pneumatosis: More commonly benign
    - Bowel wall thickening: Usually significant
    - ↓ bowel wall enhancement: Typically significant
    - Adjacent inflammatory stranding: Typically significant
    - Moderate to large free fluid: Typically significant
  - Some CT findings **not** helpful in differentiating benign from clinically significant causes
    - Curvilinear vs. cystic pattern
    - Distribution in small vs. large bowel
    - Portal venous gas
    - Free intraperitoneal air

Ultrasonographic Findings

- Look for echogenic gas tracking within bowel wall, particularly lateral & posterior aspects
  - Posterior acoustic shadowing & ring-down artifact
  - ± twinkling artifact with color Doppler

DIFFERENTIAL DIAGNOSIS

Benign Causes of Pneumatosis Intestinalis

- Medications
  - Corticosteroids, certain chemotherapy agents
- Transplant patients
  - Bone marrow/stem cell transplants
    - May be associated with graft-vs.-host disease
  - Solid organ transplants
- Pulmonary disease
  - Mechanical barotrauma
- Autoimmune/rheumatologic diseases
  - ↑ in conditions associated with vasculitis

Clinically Worrisome Causes of Pneumatosis Intestinalis

- Intestinal ischemia
- Severe enterocolitis
- Bowel obstruction
- Trauma

PATHOLOGY

General Features

- Etiology
  - Multiple proposed mechanisms; may be multifactorial
    - Mucosal injury ± limited ability to repair mucosa due to medications (e.g., corticosteroids) or vascular abnormalities (e.g., vasculitis)
    - Abnormal bowel wall lymphatics from medications (chemotherapy, corticosteroids), allowing gas to dissect into wall
    - ↑ intraluminal pressure pushing gas or gas-forming bacteria into bowel wall
    - Dissection of gas from mediastinum → mesentery → bowel wall

Gross Pathologic & Surgical Features

- Gas within submucosal & subserosal spaces
  - May represent gas within dilated intramural lymphatics

CLINICAL ISSUES

Treatment

- Managed conservatively if clinically stable
  - Bowel rest, removal of offending medications, treatment of underlying conditions
- If worrisome by clinical or laboratory features → surgical or more aggressive medical management

Crohn Disease

KEY FACTS

TERMINOLOGY

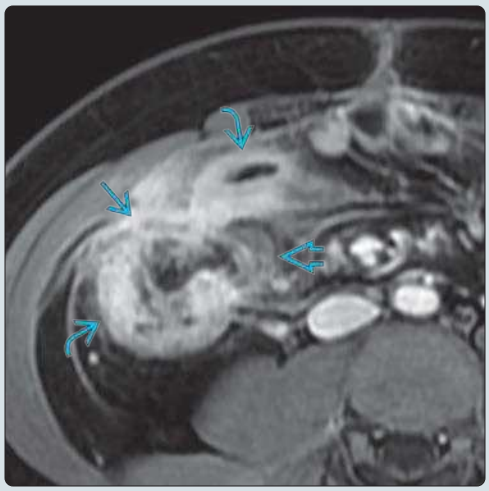
- Chronic, recurrent, segmental, granulomatous inflammatory bowel disease; etiology is unknown

IMAGING

- CD occurs anywhere in GI tract from mouth to anus
  - Disease distribution in children varies with age & differs from adults
- US: Thickened bowel wall with loss of gut signature, ↑ perienteric fat echogenicity, ± bowel wall & perienteric hyperemia
- CT/MR enterography
  - Bowel findings
    - Mural hyperenhancement & thickening: Most sensitive findings
    - Mural stratification of bowel wall enhancement
    - Strictures showing upstream effects (dilation & small bowel feces sign)
    - Ulcers/fistulas/sinus tracts
  - Mesenteric findings
    - Engorged vasa recta (comb sign & dot sign)
    - Fat stranding, fibrofatty proliferation
    - Inflammatory mass/abscesses
    - ↑ size & number of lymph nodes
  - Perianal disease
    - Tract/collection extending from anus/skin

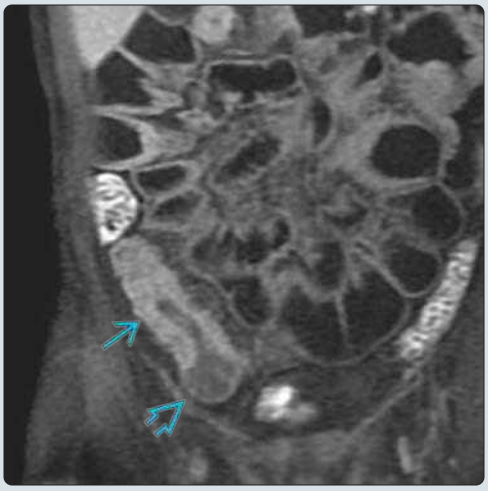
PATHOLOGY

- Skip lesions of transmural inflammation occur anywhere from mouth to anus: Ileocolic is most common

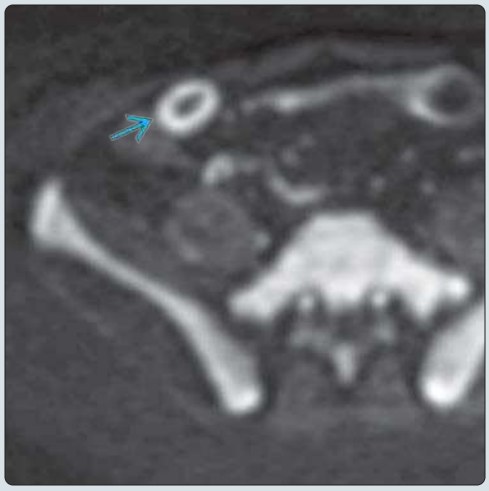


CLINICAL ISSUES

- Prevalence: 58 cases/100,000 children
- 25-30% of patients are diagnosed in 1st 2 decades of life
- Extraintestinal manifestations in 17-28% at diagnosis



DIAGNOSTIC CHECKLIST



- Penetrating &/or stricturing disease alters management

(Left) *Delayed image from a small bowel follow-through in a patient with CD shows isolation, narrowing, & irregularity of the terminal ileum & cecum. It is inferred that the separated loops are caused by bowel wall thickening & "creeping fat."* **(Right)** *Axial T1 C+ FS MR in an adolescent shows multiple findings of Crohn disease. The affected bowel is thickened with diffuse wall enhancement. There is stranding of the adjacent mesenteric fat. The loops of bowel are clumped together at the site of a fistula.*

(Left) *Coronal T1 FS MR shows inflammation & wall thickening of the terminal ileum. The affected bowel has a bulging nonthickened focus along the antimesenteric border, typical of a pseudosacculation.* **(Right)** *Axial DWI MR of the pelvis shows a segment of bowel with restricted diffusion, which is a sign of active inflammation in patients with Crohn disease.*

TERMINOLOGY

Abbreviations

- Crohn disease (CD)

Definitions

- Chronic, recurrent, segmental, granulomatous inflammatory bowel disease (IBD)

IMAGING

General Features

- Best diagnostic clue
  - CT/MR enterography
    - Bowel wall thickening & mucosal hyperenhancement with associated perienteric inflammatory changes
- Location
  - Anywhere in gastrointestinal (GI) tract from mouth to anus
  - Disease distribution in children varies with age & differs from adults
    - Very early onset IBD (age < 6 years)
      - More likely to present with isolated colonic disease
    - Older children/adolescents
      - Most common location: Ileocolonic region
      - Isolated terminal Ileum (TI) disease is uncommon, occurring in < 10%
      - Small bowel involvement proximal to TI in > 50%
      - Upper GI involvement occurs in 1/3-1/2 of patients
      - Gastric involvement is more common than in adults
      - Appendix may be involved, even in isolation

Fluoroscopic Findings

- Upper GI with SBFT
  - Separation of bowel loops due to wall thickening & "creeping" proliferative fat
  - Irregular appearance of bowel mucosa
    - Cobblestone pattern: Longitudinal + transverse ulcers
    - Thickened mucosal folds & featureless mucosa
  - String sign of narrowed bowel lumen
    - Up to 20%, most commonly in TI
  - Skip lesions (90%)
  - Sacculations at antimesenteric border

CT Findings

- CT enterography
  - Technique
    - Low-density oral contrast material maximizes bowel luminal distention
    - IV contrast with imaging in enteric phase (~ 45 s) or portal venous phase (~ 70 s)
  - Bowel findings
    - Mural hyperenhancement
    - Bowel wall thickening (lower attenuation edema)
    - Mural stratification: Layers of bowel wall show differential enhancement
    - Luminal narrowing or stricture
    - Sacculations
  - Mesenteric findings
    - Engorged vasa recta (comb sign if tangential or dot sign in cross section)
    - Fat stranding ± fibrofatty proliferation
    - Prominent lymph nodes (↑ in size & number, often not > 1 cm in short axis)
  - Penetrating disease
    - Ulceration/fistula/sinus tract
    - Inflammatory mass/abscess
    - Perianal disease
  - Stricturing disease
    - Luminal narrowing with proximal dilation ± proximal small bowel feces sign or stuck pill/enterolith

MR Findings

- MR enterography
  - Technique
    - Biphasic enteric contrast agent to maximize bowel luminal distention
      - Bright on T2, dark on T1
    - Glucagon may be used to slow/stop bowel peristalsis
    - SSFSE T2 ± FS
    - DWI (particularly helpful if IV contrast is not possible)
    - Rapid 3D GRE T1 C+ FS sequences
    - Targeted axial & coronal oblique images of anus for suspicion of perianal disease
  - Findings are similar to those seen with CT enterography
    - Additional findings
      - Restricted diffusion of inflamed segment
      - Focally ↓ peristalsis
  - Benefits of MR enterography over CT enterography
    - Improved visualization of penetrating/fistulizing disease, particularly in perianal region
    - Visualization of bowel at multiple timepoints
    - Lack of ionizing radiation
    - Improved visualization of extraintestinal manifestations of CD

Ultrasonographic Findings

- Grayscale ultrasound
  - High-resolution, high-frequency linear transducer with graded compression
  - Findings are similar to those seen on CT/MR
    - Thickened bowel with loss of normal gut signature
    - ↓ or absent peristalsis
    - ↑ perienteric fat echogenicity & volume
    - Lymphadenopathy
    - Fluid collections
- Color Doppler
  - Bowel wall & perienteric hyperemia

Other Modality Findings

- Direct visualization with upper & lower endoscopy
  - Allows contemporaneous biopsy
  - Cannot view jejunum & ileum
  - Cannot visualize extraintestinal manifestations
- Capsule endoscopy
  - 11- x 27-mm capsule camera
  - Direct visualization of mucosal lesions
  - Risk of capsule not passing beyond area of stricture
  - Retained capsule camera is not MR compatible

Imaging Recommendations

- Protocol advice

- CT & MR enterography: High accuracy for detection of active IBD & associated complications
  - MR enterography lacks ionizing radiation exposure
  - CT enterography may be more sensitive in detecting early/mucosal disease & has less interrater variation
- Ultrasound is less sensitive but may be useful in initially suggesting CD or following diseased segment

DIFFERENTIAL DIAGNOSIS

Ulcerative Colitis

- Contiguous colitis extending proximally from anus
  - No skip lesions
- Most common cause of IBD in children < 6 years of age
- ± backwash ileitis
- Not transmural: No strictures, sinuses, or fistulas
- Pseudopolyps, ↑ risk of colon cancer

Indeterminate Colitis

- Term used when there are histologic features of CD & ulcerative colitis (UC)
- Accounts for 5-33% of IBD in pediatric population
- Up to 30% are later reclassified as CD or UC

Appendicitis

- Dilated, thick-walled, noncompressible appendix with induration of surrounding fat
  - ± hyperemia, appendicolith, abscess
- Adjacent bowel is typically normal in absence of appendiceal perforation

Infectious Enterocolitis

- Nonspecific imaging findings of ileocecal infection; resolves with appropriate treatment

Chronic Granulomatous Disease

- Primary immunodeficiency characterized by recurrent infection with catalase-positive organisms
- Bowel is affected in 30-50% of patients
  - Mimics CD with involvement from mouth to anus

PATHOLOGY

General Features

- Etiology
  - Idiopathic IBD with prolonged & unpredictable course

Gross Pathologic & Surgical Features

- Skip lesions, edema, inflammation, fibrosis, & strictures

Microscopic Features

- Transmural inflammation, lymphoid aggregates, & noncaseating granulomas
- Dilation & sclerosis of lymphatic channels

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, diarrhea, & weight loss
    - Weight loss is presenting feature in 85% of children
- Laboratory findings
  - Anemia, leukocytosis, ↑ C-reactive protein, & ↑ erythrocyte sedimentation rate
  - ↑ fecal calprotectin
  - p-ANCA(-), ASCA(+): Favors CD over UC
    - UC is suggested when p-ANCA(+) & ASCA(-)

Demographics

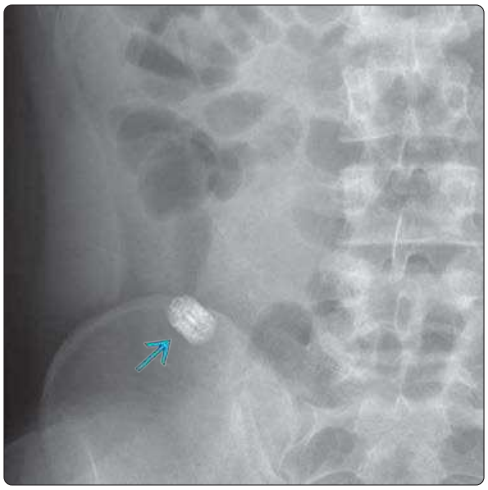
- Age
  - Bimodal age distribution with main peak at 18-25 years, smaller peak at 60-80 years
  - 25-30% of patients are diagnosed in 1st 2 decades of life
- Sex
  - 1.5:1 male predominance in prepubertal patients
- Epidemiology
  - ↑ incidence in developing world
  - Prevalence: 58 cases/100,000 children

Natural History & Prognosis

- Recurrence: 30-53% after resection; only 10-20% lead symptom-free lives
- Complications
  - Stricturing/penetrating
    - Penetrating complications almost always occur in setting of stricture
    - Potential complications: Ulceration, sinus tracts, fistulas, & abscesses
  - Extraintestinal manifestations in 17-28% at diagnosis
    - Stones: Cholelithiasis, urolithiasis (oxalate)
    - Arthropathy: Enthesis-related arthritis
    - Hepatobiliary: Autoimmune hepatitis, primary sclerosing cholangitis
    - Skin: Erythema nodosum, pyoderma gangrenosum
    - Other: Thromboembolism, pancreatitis, episcleritis, uveitis
  - Malignancy
    - Adenocarcinoma: Latency of 25-30 years
    - Lymphoma

Treatment

- Medical
  - Bowel rest, steroids, azathioprine, mesalamine, metronidazole
  - Biologic agents: Infliximab
- Surgical
  - Resection of diseased bowel, strictureplasty, & primary fistulotomy



DIAGNOSTIC CHECKLIST

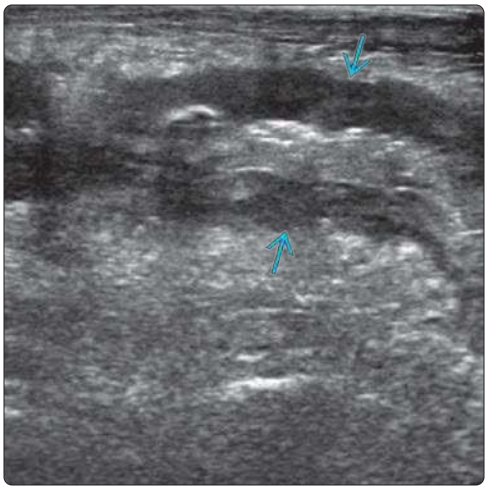


Image Interpretation Pearls

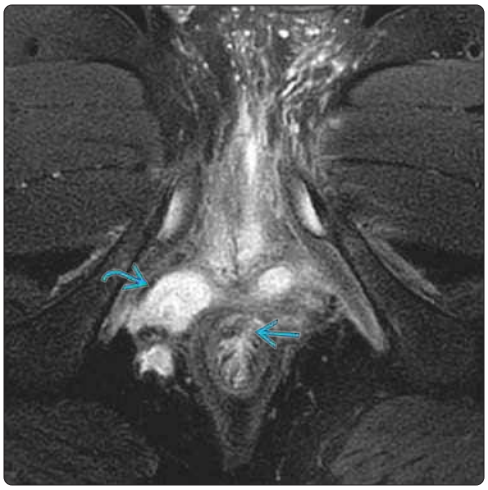
- Penetrating/stricturing disease: Alters clinical management



SELECTED REFERENCES

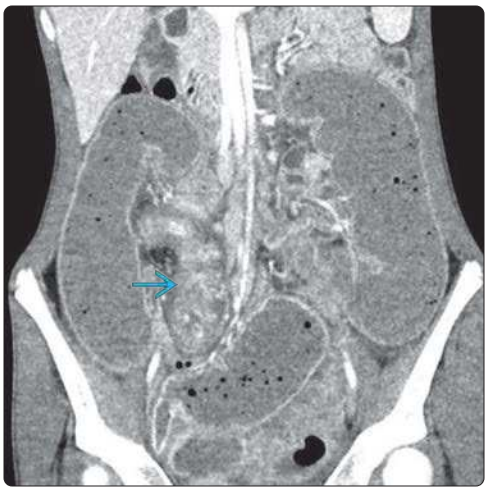
5. Towbin AJ et al: CT and MR enterography in children and adolescents with inflammatory bowel disease. Radiographics. 33(7):1843-60, 2013



(Left) *AP abdominal radiograph shows a patency capsule in the right lower quadrant. Patency capsules are used to identify a bowel stricture prior to capsule endoscopy as a stricture is a contraindication to this procedure.* **(Right)** *Transverse ultrasound of bowel in the right lower quadrant shows diffuse wall thickening of the imaged segment. There is proliferation of echogenic fat deep to this loop of bowel.*

(Left) *Axial T2 FS MR shows a fistula arising from the 12:00-1:00 position of the rectum. There is a large abscess in the ischiorectal fossa.* **(Right)** *Axial T1 C+ FS MR in the same patient shows a fistula arising from the 12:00-1:00 position of the anus. There is a large abscess in the ischiorectal fossa. An abscess can be differentiated from an inflammatory mass by the lack of central enhancement in the collection.*

(Left) *Coronal T1 C+ FS MR shows the terminal ileum to be inflamed with wall thickening, enhancement, & sinus tracts extending perpendicular to the bowel. The bowel lumen is severely narrowed, causing a stricture. Upstream small bowel loops are dilated.* **(Right)** *Coronal CECT shows severe inflammation with stricture of the terminal ileum. Upstream loops of small bowel are markedly dilated with their luminal contents appearing as feces, a sign that the stricture has been longstanding.*

Ulcerative Colitis

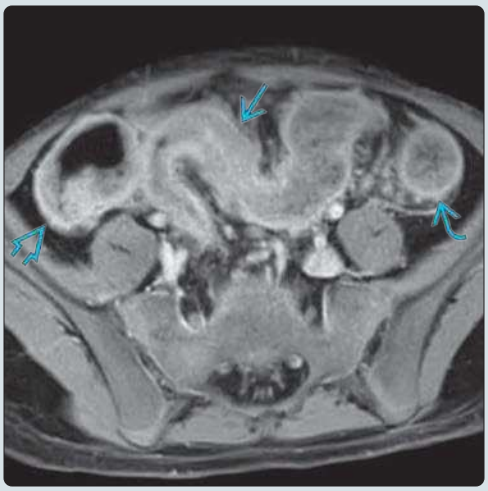
KEY FACTS

TERMINOLOGY

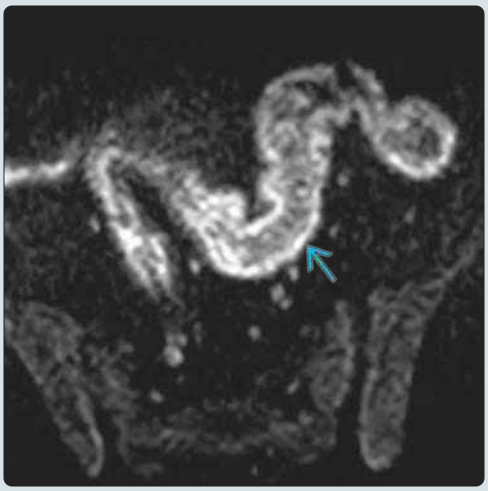
- Chronic, idiopathic inflammatory disease that primarily involves colorectal mucosa & submucosa
  - Extends retrograde from rectum
  - No skip lesions or transmural involvement

IMAGING

- CT/MR enterography findings
  - Continuous colonic inflammation extending proximally from rectum for variable distance
  - Mucosal hyperenhancement & wall thickening
  - Thickened, edematous haustra (thumbprinting)
  - Luminal narrowing
  - Mural stratification: More common in ulcerative colitis than Crohn disease
  - DWI MR can aid in detecting inflammation, particularly if IV contrast is not available
  - In later disease, dilation or narrowing of colon with loss of haustra

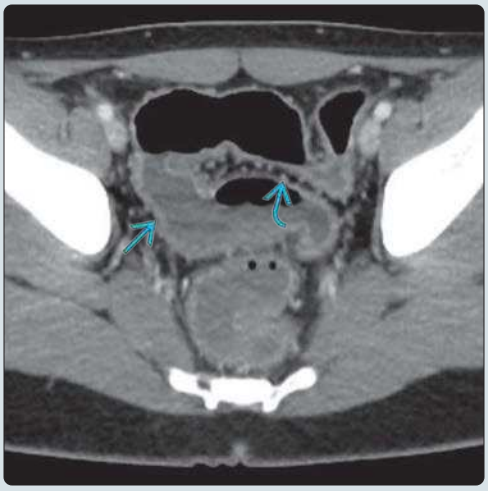


TOP DIFFERENTIAL DIAGNOSES



- Crohn disease
- Pseudomembranous colitis
- Infectious colitis

CLINICAL ISSUES



- Majority of patients are diagnosed in 4th-5th decades
- Annual incidence: 5-10 cases/100,000 population
  - More common than Crohn disease in preschool age
- Most common presenting symptom: Bloody diarrhea
- Complications
  - Toxic megacolon: 5-10%
  - Stricture: 10%
  - Colorectal cancer risk: ↑ 30x
- Common extraintestinal manifestations: Arthralgias, primary sclerosing cholangitis, uveitis

(Left) *Axial T1 C+ FS MR enterography in an adolescent with ulcerative colitis shows inflammation of the ascending, descending, & sigmoid colon with wall thickening & hyperenhancement. There is mild stranding of the adjacent fat & engorgement of vasa recta at several levels.* **(Right)** *Axial DWI MR in the same patient shows restricted diffusion of the sigmoid colon, consistent with active inflammation.*

(Left) *Axial CECT in an adolescent with ulcerative colitis shows inflammation of the sigmoid colon, demonstrating mild wall thickening & enhancement. The vasa recta are engorged.* **(Right)** *Coronal T2 FS MR in a patient with ulcerative colitis shows an abnormal, featureless appearance of the descending colon with associated wall thickening. The featureless or lead pipe appearance of the colon is a classic description in the setting of ulcerative colitis.*

TERMINOLOGY

Abbreviations

- Ulcerative colitis (UC)

Definitions

- Chronic, idiopathic diffuse inflammatory disease that primarily involves colorectal mucosa & submucosa

IMAGING

General Features

- Best diagnostic clue
  - CT/MR enterography: Mucosal hyperenhancement & wall thickening of colon/rectum
- Location
  - Continuous colonic inflammation extending proximally from rectum for variable distance
  - Pancolonic disease is present in 60-90% of children at diagnosis

Radiographic Findings

- Thickened, edematous haustra (thumbprinting) with narrowing of gas-filled lumen
- In later disease, dilation of colon with loss of haustra

Fluoroscopic Findings

- Contrast enema is not routinely used for UC evaluation in current practice
- Classic findings on contrast enema: Mucosal irregularity, ulceration, thickened haustra, luminal narrowing
  - Chronic phase: Featureless, foreshortened colon ("lead pipe" colon)

CT Findings

- CECT
  - Continuous, symmetric wall thickening of colon
  - Luminal narrowing
  - Mucosal islands or inflammatory pseudopolyps
  - Mural stratification: More common in UC than Crohn disease
  - Inflammatory pericolonic stranding
  - No penetrating disease (fistula, abscess) due to lack of transmural inflammation

MR Findings

- Findings similar to those seen with CT
- DWI can aid in detecting inflammation

Ultrasonographic Findings

- Degree of colonic wall thickening & loss of colonic wall stratification may predict failure of steroids

Other Modality Findings

- Ileocolonoscopy
  - Allows contemporaneous biopsy
  - Cannot visualize extraintestinal manifestations

Imaging Recommendations

- Relatively low sensitivity for detecting colonic inflammation with CT/MR enterography due to colonic nondistention

DIFFERENTIAL DIAGNOSIS

Crohn Disease

- Anywhere from mouth to anus may be involved
- Noncontiguous skip lesions are characteristic
- Transmural eccentric sinuses, fissures, fistulas

Pseudomembranous Colitis

- Pancolitis related to antibiotic use & overgrowth of *Clostridium difficile*

Infectious Colitis

- Nonspecific wall thickening & hyperenhancement
- Distribution varies depending on organism

CLINICAL ISSUES

Presentation

- Most common presentation: Bloody diarrhea
- Less common presenting symptoms: Anemia, poor growth, perianal symptoms
- Complications
  - Toxic megacolon: 5-10%
  - Stricture: 10%
  - Colorectal cancer risk: ↑ 30x
- Extraintestinal manifestations
  - Occur in 16-30% of patients
  - Common: Arthralgias, primary sclerosing cholangitis, uveitis
  - ↑ likelihood of colectomy
- Laboratory finding
  - p-ANCA(+) & ASCA(-) favors UC over Crohn disease

Demographics

- Age
  - Majority of patients are diagnosed in 4th-5th decades
  - More common than Crohn disease in preschool age
  - UC accounts for 25-30% of pediatric inflammatory bowel disease (IBD)

Treatment

- Medical: Sulfasalazine, steroids, azathioprine, methotrexate, LTB4 inhibitors
- Surgical: Total colectomy

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Continuous involvement of colon extending proximally from rectum for variable length
- UC is more common than Crohn disease in patients with sclerosing cholangitis

SELECTED REFERENCES

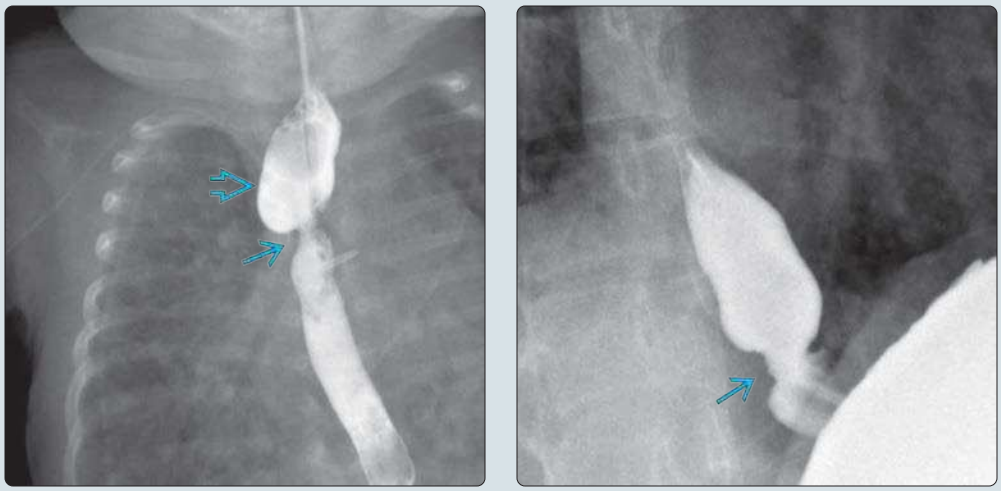
Esophageal Strictures

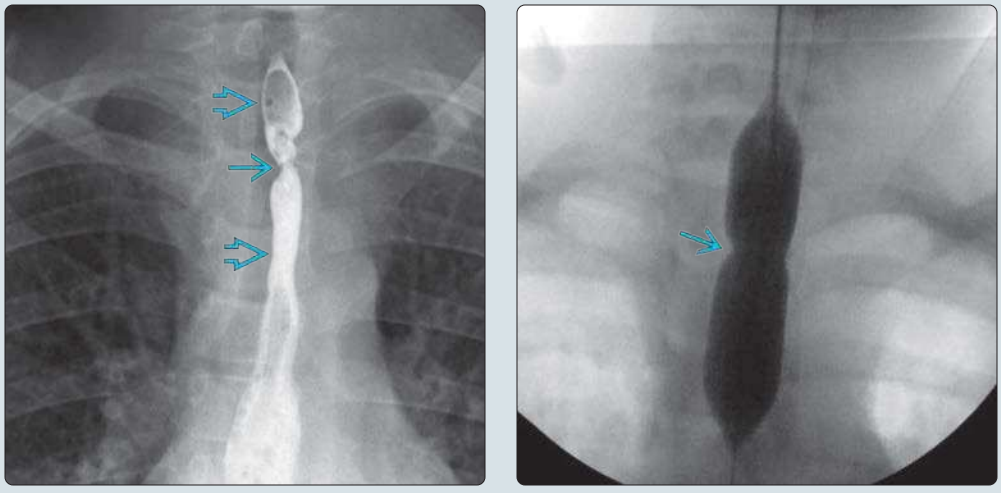
KEY FACTS

TERMINOLOGY



- Acquired narrowing of esophagus, caused by variety of entities; congenital stenosis is considered here as well

IMAGING



- Focal or diffuse narrowing of esophagus, associated with proximal dilation & altered peristalsis
- Particular segment affected as well as length & degree of narrowing depend on etiology & severity of initial esophageal injury
- Different causes of stricture have different imaging characteristics
- Esophagram findings
  - Esophageal atresia repair: Focal stricture at junction of upper & middle 1/3
  - Peptic stricture: Stricture in distal esophagus
  - Eosinophilic esophagitis: Most commonly normal; may be diffusely narrow
  - Caustic strictures: Most common in proximal & mid esophagus
    - Multiple strictures can occur
  - Epidermolysis bullosa: Stricture is most common in cervical esophagus
  - Infective esophagitis: May progress to strictures
  - Congenital stenosis
    - Membranous web: Upper or middle 1/3
    - Fibromuscular thickening: Middle or distal 1/3
    - Tracheobronchial cartilage remnant/foregut malformation: Distal 1/3

CLINICAL ISSUES

- Infants present with feeding difficulties; food bolus impaction occurs in older children with drooling, vomiting, pain, sensation of food getting stuck
  - ± airway symptoms (e.g., wheezing, recurrent coughing)
- Balloon dilation is used for many conditions; stricture resection or esophageal replacement for refractory cases

(Left) *Frontal image from an esophagram in an infant status post esophageal atresia repair shows a focal stricture ⇨ at the esophageal anastomosis. The proximal esophagus ⇨ remains dilated due to longstanding obstruction prior to repair.* **(Right)** *Frontal image from an esophagram in an adolescent with a history of food getting stuck & eosinophilic esophagitis shows a stricture ⇨ in the distal esophagus, confirmed at endoscopy.*

(Left) *AP image from an esophagram in a child with epidermolysis bullosa shows a focal stricture ⇨ at the thoracic inlet, which is superimposed on more generalized narrowing ⇨.* **(Right)** *Frontal fluoroscopic image in the same patient shows balloon dilation of the proximal esophageal stricture. The waist ⇨ in the mid balloon corresponds to the site of stricture.*

TERMINOLOGY

Definitions

- Acquired narrowing of esophagus from variety of entities
- Congenital causes of stenosis considered here as well

IMAGING

General Features

- Best diagnostic clue
  - Narrowing of esophagus, associated with proximal dilation & altered peristalsis
  - Particular segment affected as well as length & degree of narrowing depend on etiology & severity of esophageal injury

Radiographic Findings

- Search for radiopaque foreign body
- Search for acute or chronic complications of foreign body or caustic ingestion
  - Perforation of esophagus with pneumomediastinum or pleural effusion
  - Chronically dilated esophagus with air-fluid level on upright view

Fluoroscopic Findings

- Esophagram
  - Focal or diffuse narrowing of esophagus; dysmotility is common
  - Different causes of stricture have different imaging characteristics
    - Congenital stenosis
      - Membranous web: Upper or middle 1/3
      - Fibromuscular thickening: Middle or distal 1/3
      - Tracheobronchial cartilage remnant/foregut malformation: Distal 1/3
    - Prior esophageal atresia repair
      - Focal stricture at site of prior anastomosis between dilated proximal esophageal pouch & remaining mid to distal esophagus
    - Peptic stricture
      - Stricture in distal esophagus from chronic gastroesophageal reflux (GER)
    - Caustic strictures
      - Esophagram may not be helpful in acute phase as it delays endoscopy & may not reveal mucosal injury
      - Subsequent strictures can be focal, multifocal, or long segment, depending on ingested substance
      - Most common in proximal & mid esophagus
    - Eosinophilic esophagitis
      - Most common finding: Normal esophagus
      - ± GER, irregular contractions, esophageal strictures or rings, generally small-caliber esophagus, & food bolus impaction
    - Epidermolysis bullosa
      - Stricture is most common in cervical esophagus
    - Infective esophagitis
      - Severe esophageal infections may progress to strictures
  - Useful to identify complications (e.g., food impaction, leak after dilation or repair)

CT Findings

- CECT may be used in concert with esophagram to identify complications
  - Esophageal injury ± perforation → mediastinitis, abscess
    - Look for extraluminal oral contrast or gas
  - Enhancement pattern of esophagus may be able to predict future stricture in setting of caustic ingestion
- Esophageal thickening & periesophageal stranding during acute inflammation
- CECT is important to evaluate for aortic injury in setting of button battery ingestion

Ultrasonographic Findings

- Endoscopic US may visualize congenital cartilage rings

Imaging Recommendations

- Best imaging tool
  - Esophagram
- Protocol advice
  - Barium is used for chronic strictures
  - Water-soluble contrast is used for initial imaging if leak is suspected
    - Iso-osmolar contrast if concerned for aspiration
  - Double contrast technique is not commonly used in children

DIFFERENTIAL DIAGNOSIS

Achalasia

- Failure of relaxation of lower esophageal sphincter
- Neuromuscular abnormality with thickening of circular & longitudinal muscles
- Dilated esophagus + air-fluid levels in upright position

Vascular Ring/Sling

- Smooth, round impression on esophagus
  - Pulmonary sling: Impression on anterior wall
  - Double aortic arch: Impression on posterior wall with reverse S appearance of esophagus on AP view
  - Right arch with aberrant left subclavian artery: Oblique impression upon posterior esophagus

Extrinsic Compression by Mass

- Neoplastic: Neuroblastoma, plexiform neurofibromas
- Congenital: Foregut duplication cyst, thymic cyst, lymphatic malformation

PATHOLOGY

General Features

- Etiology
  - Postoperative esophageal atresia anastomotic stricture
    - Probably most frequent cause in children; occurs in up to 80% of esophageal atresia repairs
    - May present with retained foreign bodies in proximal pouch
  - Esophageal foreign body
    - Button batteries cause caustic burn injuries in esophagus within hours of ingestion, may lead to perforation or subsequent stricture
    - Chronic foreign bodies in esophagus can cause esophageal edema
  - Peptic strictures

- Caused by acidic injury due to GER
- Eosinophilic esophagitis
  - Allergic response to food
- Postoperative Nissen fundoplication
  - Complication of procedure occurs when wrap is too tight
  - Proximal esophagus dilates secondary to stricture or tight wrap
- Caustic esophagitis & strictures
  - Ingestion of household cleaners, lye, or acid cleaning substance
    - Ingestion is usually accidental in younger children, purposeful in teens
  - Type of ingested material affects depth of injury
    - Alkali ingestion causes liquefactive necrosis, destroying cell architecture, & leading to deeper tissue injuries
    - Acid ingestion causes coagulation necrosis leading to eschar of burnt tissue
  - Type of ingested material can affect appearance of stricture
    - Alkali ingestion typically causes long-segment stricture, more commonly injures esophagus
    - Acid ingestion typically causes short-segment stricture, more commonly injures stomach
  - Strictures can occur as early as 3 weeks after ingestion
- Infective esophagitis
  - Higher risk in immunocompromised
  - *Candida albicans* is most common
- Epidermolysis bullosa
  - Hereditary disorder with > 100 distinct genotypes
    - Mutations in genes expressed at dermal-epidermal junction
  - Numerous bullous lesions, sloughing, then healing/scarring
  - Patients develop blisters & erosions after minor mechanical trauma
    - Repeated blistering → scar formation

- Associated abnormalities
  - Peptic strictures are more common in patients with associated comorbidity
    - 25% of patients have neurologic impairment

Microscopic Features

- Eosinophilic esophagitis is characterized by esophageal mucosal biopsy with > 15 eosinophils per HPF
- Specific diagnosis of infectious esophagitis is made by biopsy or culture

CLINICAL ISSUES

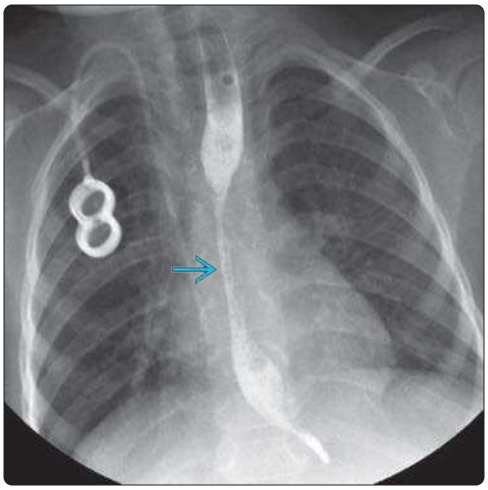
Presentation

- Most common signs/symptoms
  - Difficulty swallowing, pain, drooling, vomiting, or sensation of food stuck due to bolus impaction
    - Common symptoms in eosinophilic esophagitis, esophageal atresia repair, & tight Nissen fundoplication
  - Airway symptoms, such as wheezing, recurrent coughing episodes
    - Postoperative esophageal atresia patients have tracheomalacia
    - As esophagus dilates, it imprints posterior wall of trachea
  - Systemic diseases (such as scleroderma, dermatomyositis, epidermolysis bullosa) have multiorgan involvement
    - Many systemic diseases have skin findings
  - Feeding difficulties &/or choking in infants

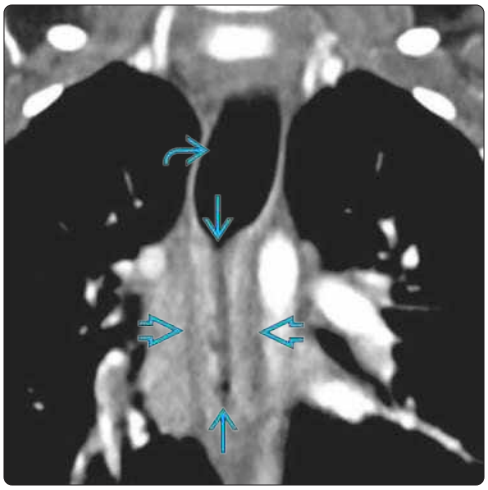
Demographics

- Ethnicity
  - Eosinophilic esophagitis is more common in White population
- Age: Depends on disease process
- Sex: Eosinophilic esophagitis is 4x more common in male patients

Natural History & Prognosis



- Strictures may occur at site of prior injury or surgery
- Can progress to obliteration of esophageal lumen
- Recurrent strictures may occur in similar site
- Patients with caustic ingestion are at risk of developing esophageal squamous cell carcinoma
- Patients with GER & Barrett esophagitis have higher risk of developing esophageal adenocarcinoma



Treatment

- Balloon dilation is used for many conditions
  - Preferred over dilation using bougie as balloons dilate strictures in radial direction rather than longitudinal direction
  - Children often require multiple dilations depending on symptoms
  - Complications of balloon dilation
    - Perforation, mediastinitis
  - Endoscopic US can be used to triage congenital strictures
- Stricture resection or esophageal replacement is reserved for cases where dilation fails
  - Tracheobronchial cartilage remnant classically fails dilation

(Left) *Frontal image from an esophagram in a child who has received radiation therapy for thoracic neuroblastoma shows a long-segment stricture in the mid esophagus.* **(Right)** *Coronal CECT in the same patient shows the long segment esophageal stricture with associated wall thickening. Note the gaseous esophageal distention above the level of the stricture.*

(Left) *Frontal image from an esophagram in a child with a recent caustic ingestion shows a long segment of narrowing of the esophagus, starting in its mid portion. The most severe narrowing is at the gastroesophageal junction. Contrast also extends through a false tract into a collection in the upper abdomen.* **(Right)** *Frontal image from an esophagram in an adolescent with achalasia shows diffuse dilation of the esophagus, which extends to a stricture at the gastroesophageal junction.*

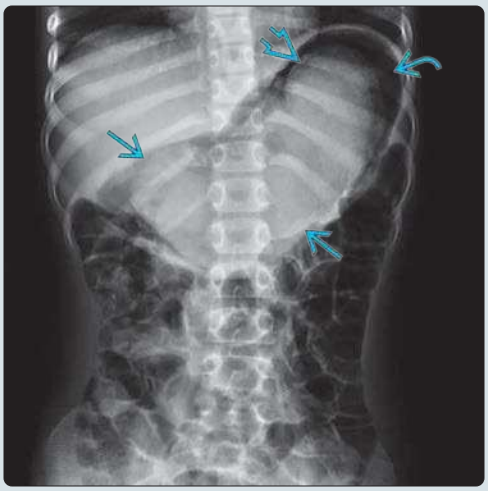
(Left) *PA radiograph of the chest in an adolescent with achalasia shows dilation of the air-filled esophagus. The esophageal wall is visible as an undulating interface along the right mediastinal border.* **(Right)** *Frontal esophagram in the same patient shows a dilated esophagus with flocculation of the barium, suggesting that it has mixed with other ingested material. There is a focal narrowing at the distal esophagus near the gastroesophageal junction.*

Bezoars

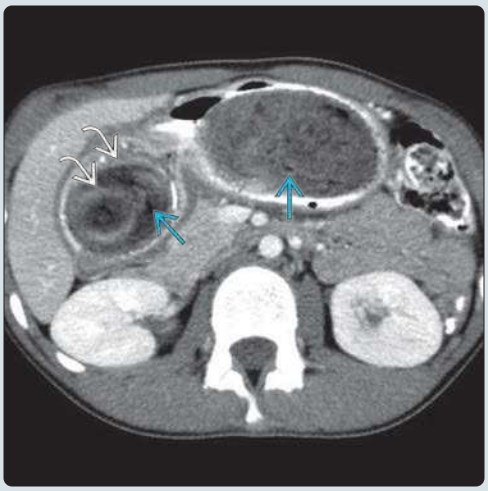
KEY FACTS

TERMINOLOGY

- Specific ingested materials accumulate to form indigestible & potentially obstructive mass in GI tract
- Classified based on ingested material, including
  - Trichobezoar: Hair
  - Phytobezoar: Indigestible food components
  - Lactobezoar: Concretion of milk & mucous proteins



IMAGING



- Radiographs: Round/ovoid/tubular mass with mottled appearance due to air in interstices
  - Distention of affected lumen ± frank obstruction
- Fluoroscopy: Filling defect with contrast in interstices
- US: Echogenic, arc-like surface & posterior shadowing
- CT: Concentric architecture & air/contrast in mass
  - ↑ sensitivity for gastric bezoars with window level setting of -100 HU
  - Small bowel bezoars are located at transition point in cases presenting with obstruction
  - Floating fat density debris sign & relatively short length help distinguish from small bowel feces sign

CLINICAL ISSUES

- Presentation: Palpable abdominal mass, abdominal pain, vomiting, distention, dysphagia, bowel obstruction
- Trichobezoar
  - Most common in young female patients with alopecia, trichotillomania, trichophagia
  - Treatment: Surgical removal by laparotomy
- Lactobezoar
  - Most common in premature neonates
  - Treatment: NPO, IV fluids, ↓ caloric intake ± gastric lavage & saline dissolution; surgery if necessary
- Phytobezoar
  - Most common in adults
  - Treatment: Endoscopic fragmentation ± suction; gastric lavage with enzymatic dissolution; surgery if necessary

(Left) *Abdominal frontal radiograph in an 8-year-old girl with trichotillomania shows a circumscribed mass in the stomach that is outlined by a crescent of air, compatible with a trichobezoar. Note the mottled appearance due to entrapped air.* **(Right)** *Axial CECT in a 13-year-old girl with abdominal pain & a palpable mass shows concentric rings & trapped air in the interstices of the mass. The mass conforms to the stomach & is surrounded by contrast. A trichobezoar was removed surgically.*

(Left) *Longitudinal US in a 12-year-old with pain & vomiting demonstrates a mass with a broad, echogenic, arc-like surface & posterior acoustic shadowing. Proximal small bowel loops are fluid filled & dilated.* **(Right)** *Sagittal CECT in the same patient shows a small bowel obstruction with dilated, fluid-filled bowel. An obstructing mass with an appearance similar to feces is seen distally & was confirmed to be a bezoar at surgery. Another bezoar is seen in the stomach.*

TERMINOLOGY

Definitions

- Specific ingested materials accumulate to form indigestible & potentially obstructive mass in GI tract
- Classified based on ingested material, including
  - Trichobezoar: Hair
  - Phytobezoar: Indigestible food components, typically vegetable or fruit fibers
  - Lactobezoar: Concretion of coagulated milk & mucous proteins
- Rapunzel syndrome: Gastric trichobezoar that extends distally through pylorus

IMAGING

Radiographic Findings

- Mottled appearance of solid matter in (typically proximal) GI tract due to lucencies of gas in interstices of accumulated ingested material
  - Nonspecific appearance: Abscess, stool, or recently ingested food can have similar appearance
- Bezoars are rarely identified on radiographs alone
- ± evidence of small bowel obstruction: Dilated proximal bowel with air-fluid levels

Fluoroscopic Findings

- Upper GI
  - Round, ovoid, or tubular filling defects
  - May have mottled appearance due to contrast within interstices of accumulated ingested material
  - Gastric bezoars
    - Majority are freely mobile
    - Gastric dilation with ↓ or absent peristalsis
  - Small bowel bezoars commonly present with obstruction
    - Impacted filling defect
    - Dilated, air-/fluid-filled loops of proximal bowel

Ultrasonographic Findings

- Intraluminal mass with broad, hyperechoic, arc-like surface & posterior acoustic shadowing
  - "Dirty" shadowing due to intermixed air
  - Lactobezoar lacks posterior acoustic shadowing
- Dilated, fluid-filled bowel in cases of obstruction
  - Compression of bowel loops may show fluid shifting around intraluminal mass
- Color Doppler twinkling artifact at hyperechoic surface
  - No true internal vascularity in mass
- Low sensitivity to detect multiple bezoars & gastric bezoars
  - Only 2/5 cases with multiple intestinal bezoars were identified as such in 1 study
  - Same study identified only 2/8 gastric bezoars associated with intestinal bezoars

CT Findings

- Circumscribed intraluminal mass with interstitial air
- Mass may have concentric ring architecture
- Persimmon fruit seeds appear as hyperdense foci in mass
- Gastric bezoars
  - May float or fill lumen
  - May not be identified on soft tissue windows: Window level setting of -100 HU may improve sensitivity
- Small bowel bezoars are located at bowel transition point in cases presenting with obstruction
  - Appearance strongly mimics small bowel feces sign
    - Bezoars may extend distally into nondilated bowel
    - Floating fat densities in dilated bowel loops proximal to obstruction help distinguish from small bowel feces
      - Floating fat density debris sign reported using window level of -50 HU & width of 500 HU
    - Mean attenuation < -11.75 HU & length < 9.5 cm have also been reported to help differentiate from small bowel feces
- Up to 97% sensitivity for GI bezoars

Imaging Recommendations

- Abdominal radiographs are typically obtained due to presenting symptoms
- CECT
  - Advantages
    - High sensitivity
    - Can identify multiple bezoars
    - Allows evaluation of entire abdomen
  - No consensus on use of oral contrast
  - Often ordered in setting of suspected small bowel obstruction
- Upper GI
  - Dynamic study allows evaluation of intraluminal mass mobility
  - Can identify mucosal injuries to gastric & bowel wall
  - Ideally performed after fasting

DIFFERENTIAL DIAGNOSIS

Small Bowel Feces

- Classically seen in dilated bowel just proximal to transition point of obstruction
- Longer length, greater density, & lack of encapsulated appearance is more likely than bezoars

Ingested Material

- Recently ingested food in stomach can simulate bezoar on radiographs
- Food & gas in stomach show "dirty" shadowing on US
  - Gastric food should be minimal with adequate NPO ("nothing by mouth") status for exam

Neoplasm

- Intraluminal & adjacent extraluminal masses: Juvenile polyp, lymphoma, neuroblastoma, etc.
- Solid mass with visible internal vascularity by color Doppler
- Calcified masses may simulate US features of bezoars
  - True Ca^{2+} is not typical of bezoars
- Intraluminal neoplasm has connection to gastric/bowel wall

Duodenal Hematoma

- ↑ attenuation nonenhancing mass in duodenal wall or lumen
- History of trauma, endoscopy/biopsy, bleeding disorder, Henoch-Schönlein purpura

Gallstone Ileus

- Gallstone may have similar appearance to bezoar on US
- Pneumobilia is classic feature in gallstone ileus
- Extremely uncommon in children

PATHOLOGY

General Features

- Trichobezoar
  - Hair is resistant to digestion & peristalsis
  - Forms concretion with mucus + food
- Lactobezoar
  - GI tract capacity becomes overwhelmed
    - Caloric & protein intake > age-related dietary reference (erroneous preparation of formula, low-birth-weight formula)
    - Medication-induced antagonization of gastric secretion & motility
    - Likely multifactorial as also seen with breast milk & cow's milk
  - GI tract capacity overload → vomiting & diarrhea → dehydration → excessive water reabsorption → lactobezoar
- Phytobezoar
  - Indigestible fruit & vegetable fibers: Cellulose, tannin, lignin
    - Persimmon is common culprit
  - Gastroparesis/↓ gastric peristalsis: Major risk factor; may be due to
    - Gastric surgery
    - Medical conditions: Hypothyroidism, diabetes, cystic fibrosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Palpable abdominal mass, abdominal pain, vomiting, distention, dysphagia, small bowel obstruction
- Other signs/symptoms
  - Trichobezoar: Alopecia, psychiatric conditions (anxiety, trichotillomania, trichophagia, depression)
  - Lactobezoar: Dehydration, diarrhea, respiratory distress, weight loss/failure to thrive, feeding intolerance
  - Phytobezoar: Small bowel obstruction is most common presentation
  - Lamerton sign: Mobile, palpable, & indentable mass in upper abdomen

Demographics

- Trichobezoar
  - Most common bezoar in pediatric population
  - Almost all documented cases are in female patients
- Lactobezoar
  - > 70% of documented cases: Patient ≤ 30 days old
  - > 75% of documented cases: Patient born prematurely
- Phytobezoar
  - Most common in adult population
  - Prevalence varies among ethnic groups & geographic locations relating to food preferences

Natural History & Prognosis

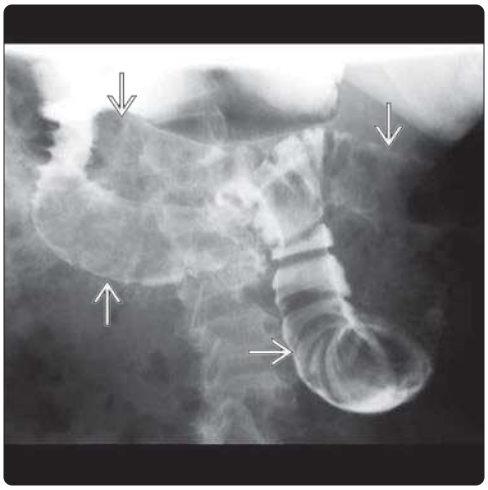
- Complications
  - Obstruction, mucosal erosion/ulceration, GI bleeding, perforation
  - Less common: Intussusception, jaundice, protein-losing enteropathy, pancreatitis

Treatment

- Trichobezoar
  - Laparotomy is typically required due to bezoar size; allows evaluation of GI tract
    - Laparoscopy has been reported
  - Endoscopy is valuable for diagnosis
    - Poor therapeutic option: No success in series of 40 reported cases due to obstruction
      - Large size of bezoars
      - Bezoars resistant to fragmentation
      - With fragmentation, components may impact distally
  - Psychiatric referral is critical to prevent recurrence
- Lactobezoar
  - Conservative management: NPO, IV fluids, ↓ caloric density
  - Gastric lavage with saline + N-acetylcysteine if conservative management fails
  - Surgery for perforation or failure of conservative management & gastric lavage
- Gastric phytobezoar
  - Endoscopic fragmentation ± suction retrieval
  - Gastric lavage with enzymatic or biochemical dissolution
    - N-acetylcysteine, papain, metoclopramide, cellulase, Coca-Cola

DIAGNOSTIC CHECKLIST

Consider



- Trichobezoar in patients with psychiatric conditions, alopecia
- Phytobezoar in patients with prior gastric surgery, ↓ or absent gastric peristalsis, or ↓ gastric acid secretion/acidity
- Lactobezoar in premature infants

Image Interpretation Pearls

- Adjust CT window level & width: ↑ sensitivity to bezoars

(Left) *Supine frontal upper GI series shows an elongated filling defect ➡ in the duodenum & proximal jejunum that is surrounded by contrast & conforms to the bowel contour.* **(Right)** *Surgical photograph of the specimen removed from the proximal small bowel in the same patient shows an elongated trichobezoar.*

(Left) *Supine frontal upper GI in a 14-year-old girl with vomiting & abdominal pain shows a large filling defect ⇨ in the stomach. Contrast surrounds the mass ⇨ & fills the interstices ⇨, giving it a mottled appearance compatible with a known trichobezoar.* **(Right)** *Coronal CECT demonstrates bezoars in the stomach ⇨ & small bowel ⇨ of a 10-year-old girl with abdominal pain. The bezoars appear as mottled masses with areas of rim-like calcification ⇨.*

(Left) *Axial CECT in an 8-year-old girl with a history of trichotillomania, trichophagia, & episodes of epigastric pain shows an intraluminal mass with concentric architecture ➡. Air is trapped within the peripheral interstices ⇨ of the mass, consistent with a bezoar.* **(Right)** *Lateral view from an upper GI series in a 3-month-old boy with failure to thrive & emesis shows fragmented filling defects ➡ in the stomach. A lactobezoar was confirmed at endoscopy.*

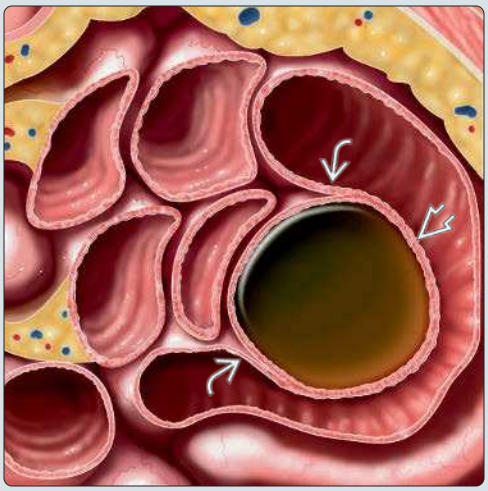
Gastrointestinal Duplication Cysts

KEY FACTS

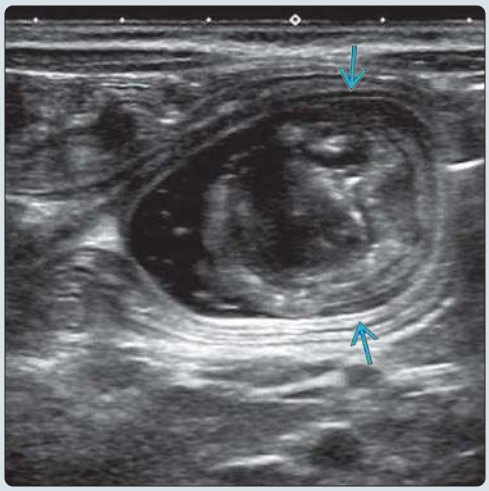
TERMINOLOGY

- GI duplication cysts have 3 defining characteristics
  - Well-developed coat of smooth muscle
  - Epithelial lining representing some part of GI tract
  - Attachment to (± communication with) GI tract
    - Rarely: Isolated cyst with no persistent attachment

IMAGING

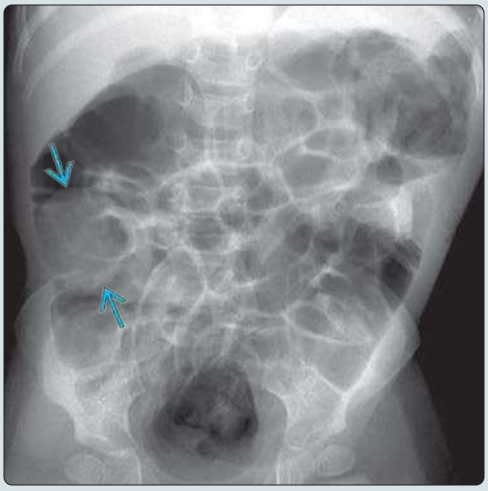


- Cystic (80-90%) vs. tubular (10-20%) lesions with well-defined wall
  - Can occur anywhere along GI tract; most frequently associated with ileum (>30%) & esophagus (18-20%)
- Contiguous (but not necessarily communicating) with adjacent GI tract
- Ultrasound is best modality to visualize key features, though findings with highest specificity have lowest sensitivity
  - Gut signature sign: Trilaminar appearance of wall is less specific than 5-layered wall
  - Y sign: Hypoechoic muscularis propria divides at point of attachment between cyst & adjacent bowel
  - Peristalsis of cyst wall is pathognomonic (if visualized)

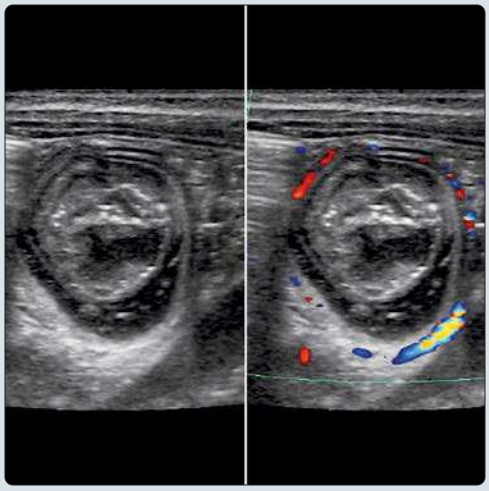


TOP DIFFERENTIAL DIAGNOSES

- Mesenteric lymphatic malformation
- Ovarian cyst
- Meconium pseudocyst
- Urachal cyst
- Hydrometrocolpos
- Choledochal cyst
- Aneurysm



CLINICAL ISSUES



- Congenital lesions, most often presenting < 2 years of age
  - Pain, mass, rectal bleeding; may be incidental
  - Small bowel obstruction is most frequent presentation for ileal duplications
- Complete surgical resection is ideal

(Left) *Axial graphic shows an enteric duplication cyst between sectioned bowel loops. Note that the muscular layer of the bowel is continuous with that of the duplication cyst, creating a Y as the muscle splits.* **(Right)** *Transverse ultrasound of the upper abdomen in a 15-month-old with intermittent pain & vomiting shows an ileocolic intussusception extending to the transverse colon & terminating in a complex cystic mass with a trilaminar wall. The mass was initially mistaken for fluid trapped around the intussusceptum.*

(Left) *Frontal radiograph in the same patient after successful air-enema reduction (confirmed by free reflux of air into the small bowel) shows a persistent, round mass outlined by air in the midright abdomen, concerning for a lead point.* **(Right)** *Transverse grayscale (left) & color Doppler (right) ultrasound images in the same patient after the air-enema reduction show the residual complex cystic mass with no internal vascularity. This mass was found to be an ileocecal duplication cyst with internal debris upon resection.*

TERMINOLOGY

Synonyms

- Foregut/midgut/hindgut malformation or duplication, enteric cyst, enterocyst, enterocystoma, enterogenous cyst, dorsal enteric cyst, alimentary tract duplication (ATD)

Definitions

- GI duplication cysts have 3 defining characteristics
  - Well-developed coat of smooth muscle
  - Epithelial lining representing some part of GI tract
  - Attachment to (± communication with) GI tract
    - Isolated cysts: No longer attached (extremely rare)
  - Neurenteric cysts often have associated vertebral & intraspinal anomalies
    - Most frequent with esophageal duplications

IMAGING

General Features

- Best diagnostic clue
  - Cystic lesion with well-defined wall; contiguous (but not necessarily communicating) with adjacent GI tract
  - Cyst wall has similar appearance to bowel (gut signature sign) on ultrasound
  - Peristalsis is pathognomonic (but often not visualized)
- Location
  - Can occur anywhere along alimentary tract
    - 75% abdominal, 20% thoracic
  - Most frequently associated with ileum (> 30%) & esophagus (18-20%)
  - Less common: Colon (13%), jejunum (10%), stomach (7%), duodenum (6%), retrorectal (4%), floor of mouth (1%), retroperitoneal (< 1%), intrapancreatic (< 1%)
  - Esophageal duplications
    - R > L; inferior > superior
  - Gastric duplications
    - Typically occur at greater curvature or posterior wall
  - Duodenal duplications
    - 2nd or 3rd portions are most common
  - Tubular duplications
    - Can be short or very long
      - Rarely, complete duplication of GI tract segment
    - Tubular form is more likely to extend above & below diaphragm
  - Multiple cysts: 1-20%
    - Single GI segment is affected more frequently than different segments
  - Isolated cyst (separated from GI tract): Extremely rare
- Morphology
  - Cyst (80-90% of duplications)
    - Spherical, ovoid, or dumbbell in shape
    - Sharing bowel wall > > isolated cyst in peritoneum with mesenteric stalk
  - Tubular duplication (10-20%)
    - Perpendicular branch of bowel with solitary communication vs. parallel tube (double-barrel configuration) communicating at both ends

Radiographic Findings

- Abdomen
  - Displacement of bowel gas (depending on size of cyst)
  - ± bowel obstruction
- Chest: Middle or posterior mediastinal/paraspinal mass

Fluoroscopic Findings

- Contrast by mouth or rectum may demonstrate continuity of duplication with normal GI tract

CT Findings

- CECT
  - Ovoid, round, or tubular lesion
  - ± thick, enhancing wall, especially if inflamed
  - ± fluid-debris levels
  - Duplication may be difficult to separate from adjacent normal bowel, especially if no oral contrast has been given

MR Findings

- Best for intraspinal extension of neurenteric cysts
- MR enterography may have increasing role

Ultrasonographic Findings

- Grayscale ultrasound
  - Gut signature sign of cyst wall
    - Trilaminar appearance is classically described but not specific
      - Deep → superficial layers: Hyperechoic mucosa, hypoechoic muscle, hyperechoic serosa
    - Described 5-layered wall is difficult to visualize but more specific
      - Deep → superficial layers: Hyperechoic mucosa, hypoechoic muscularis mucosa, hyperechoic submucosa, hypoechoic muscularis propria, hyperechoic serosa
    - Wall signature may be disrupted by inflammation, ulceration, or perforation
  - Y sign (specific): Split hypoechoic muscularis propria at point of attachment between cyst & adjacent bowel
  - Peristalsis is uncommon but specific
  - Variable cystic contents
  - Wall Ca^{2+} is rare
  - May shift locations slightly in abdomen between exams
- Color Doppler
  - ± vascularity in wall

Nuclear Medicine Findings

- Tc-99m pertechnetate uptake in duplications containing ectopic gastric mucosa

Imaging Recommendations

- Best imaging tool
  - Ultrasound for pediatric abdominal cyst
  - CT or MR for intrathoracic lesions

DIFFERENTIAL DIAGNOSIS

Mesenteric Lymphatic Malformation

- Cystic, often with fluid-fluid levels from hemorrhage
- Unilocular vs. multiseptated
- Round, well-defined vs. irregular, infiltrating
- Microcystic components may appear solid

Ovarian Cyst

- Simple vs. hemorrhagic vs. mixed cystic & solid
- Follicles may be visible in distorted ovary

Meconium Pseudocyst

- Localized complex collection (debris, Ca^{2+}) secondary to in utero bowel perforation
- Bowel obstruction is usually present

Urachal Cyst

- Lies along midline tract from bladder dome to umbilicus

Hydrometrocolpos

- Moderate to marked vaginal distention in neonate or teenager
- Relatively small uterus projects off superior aspect of obstructed vagina

Choledochal Cyst

- Right upper quadrant cyst, often elongated, communicating with biliary system

Aneurysm

- Uncommon in children but may appear as cystic mass
- Fills with color flow on Doppler

PATHOLOGY

General Features

- Etiology
  - Pathogenesis remains unclear; theories include
    - Split notochord theory
    - Possible early embryologic error in branching/diverticularization
    - Error in epithelial recanalization
    - Fusion of longitudinal folds along bowel
    - Result of vascular compromise

Gross Pathologic & Surgical Features

- Attachment ± communication with parent bowel is much more common than complete isolation

Microscopic Features

- GI duplication cysts are lined with either stratified squamous or columnar epithelium
- Supported by muscular & serosal layers
- 50-60% contain gastric mucosa or pancreatic tissue
- Duplications secreting alimentary tract substances (gastric acid, pancreatic enzymes, mucus) are predisposed to rupture & hemorrhage

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, palpable mass, rectal bleeding
  - Intussusception or volvulus causing small bowel obstruction (most frequent presentation for ileal duplications)
  - May be incidental
- Other signs/symptoms
  - Ulceration, perforation, hemorrhage
  - Vascular compromise & urinary retention have been reported from mass effect
  - Respiratory symptoms in thoracic & oral cavity lesions
  - May be detected on prenatal sonography

Demographics

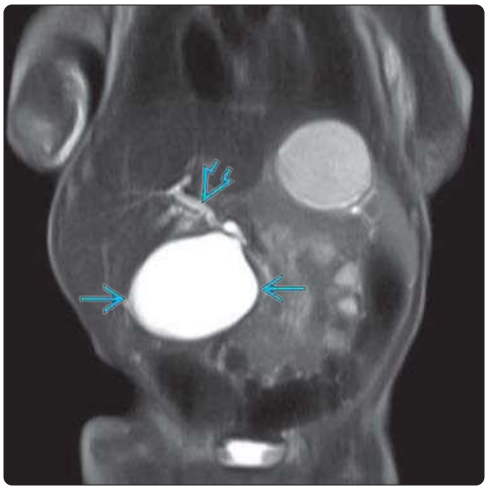
- Age
  - Congenital lesions, most often presenting < 2 years of age (up to 85%)
  - Up to 30% present in adulthood
- Epidemiology
  - Prevalence of 1 per 4,500 fetal/neonatal autopsies

Natural History & Prognosis

- Very good prognosis overall
- Complications include ulceration, perforation, hemorrhage, volvulus, intussusception
- Pancreatitis, acute or chronic, if cyst lies near pancreas
- Rare reports of malignant transformation
  - Most common with colonic duplications

Treatment

- Complete surgical resection is ideal
- Partial excision with removal of lining or marsupialization may be required in difficult regions



DIAGNOSTIC CHECKLIST

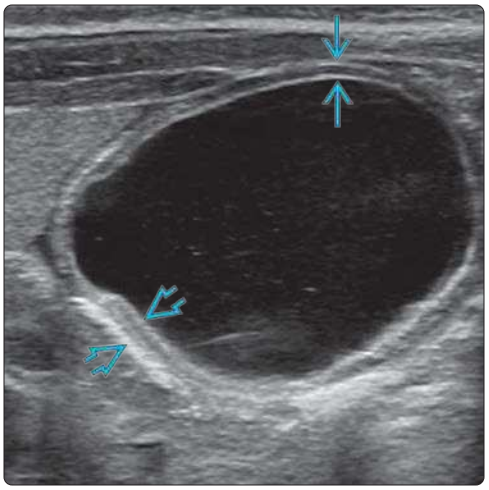


Image Interpretation Pearls

- Look for sonographic gut signature sign of cyst wall (5-layered wall is more specific than trilaminar appearance)
  - Trilaminar wall may also be seen with
    - Fluid-distended hollow organs (bowel, vagina, urinary bladder) or Meckel diverticulum
    - Alternate histologies occurring in layers (pseudogut signature)
    - Artifact

(Left) *Coronal SSFSE T2 MR in a 1-week-old with a prenatally detected anomaly shows a 3.5-cm cystic mass ⇨ inferior to the liver & immediately lateral to the dilated common bile duct (CBD) ⇨. A duodenal duplication cyst compressing the CBD was confirmed at surgery.* **(Right)** *Longitudinal ultrasound in a 1-month-old shows a well-circumscribed, round cyst of the right upper quadrant with a trilaminar gut signature wall ⇨, confirmed to be an enteric duplication cyst at surgery. Five layers can be seen in portions of the wall ⇨.*

(Left) *Right posterior oblique esophagram in a 12-year-old with dysphagia shows a tubular mediastinal mass ⇨ that filled with air & contrast during the exam. Note the compression & posterior displacement of the esophagus ⇨.* **(Right)** *Sagittal CECT in the same patient immediately after the esophagram demonstrates posterior displacement of the esophagus ⇨ by the air- & contrast-filled mass ⇨, consistent with a communicating tubular esophageal duplication that was 15 cm long.*

(Left) *Left posterior oblique high-pressure distal colostogram in an anorectal malformation patient shows overlapping opacification of parallel functional ⇨ & nonfunctional ⇨ limbs of a rectosigmoid tubular duplication.* **(Right)** *Axial T2 FS MR of the pelvis in the same patient shows the collapsed nonfunctional limb ⇨ of the tubular duplication adjacent to the gas-distended functional rectosigmoid colon ⇨.*

Small Bowel Intussusception

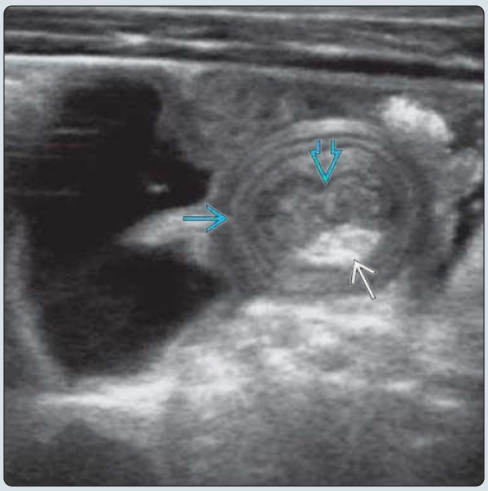
KEY FACTS

TERMINOLOGY

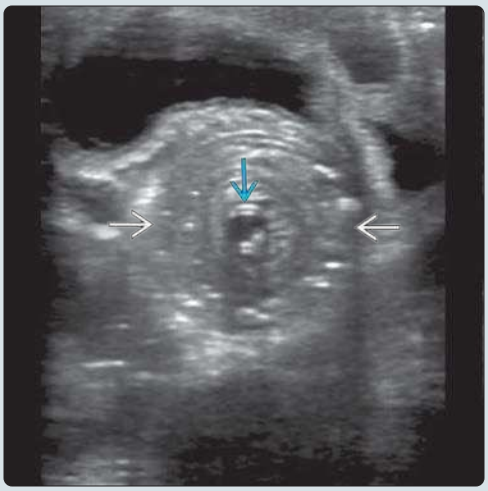
- Telescoping of proximal small bowel segment (intussusceptum) into contiguous distal small bowel segment (intussuscipiens)

IMAGING

- US or CECT show bowel within bowel appearance of round or tubular mass
  - Alternating layers of bowel wall ± mesenteric fat
  - Target appearance in cross section
- Continuity of central trapped fat with mesenteric fat
- Mesenteric vessels extend into or out of mass
- Normal terminal ileum up to ileocecal valve
- Small bowel intussusception (SBI) features that differentiate it from ileocolic intussusception (ICI)
  - Smaller diameter (mean of 1.5 vs. 2.6 cm)
  - Less hyperechoic mesenteric fat centrally
  - Entrapped lymph nodes are less common
  - More commonly periumbilical or in left abdomen

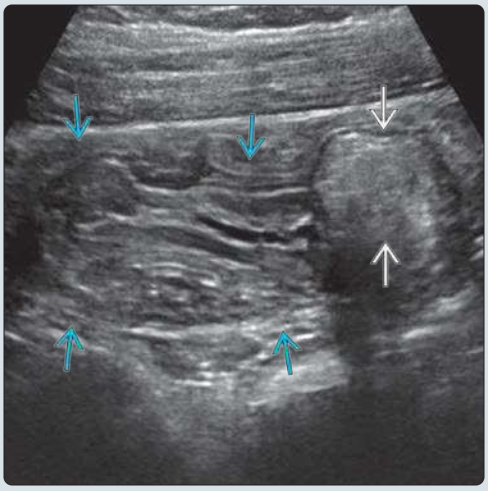


PATHOLOGY

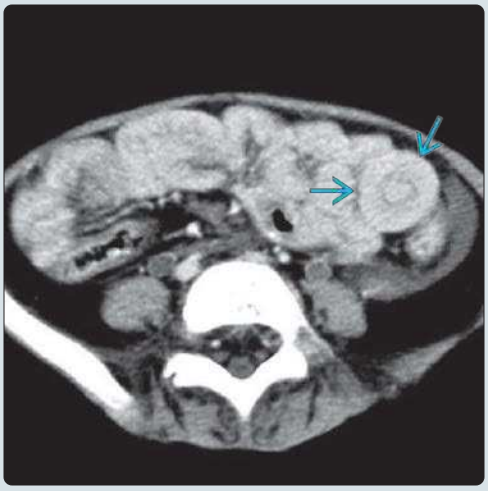


- Lead points (uncommon): Lymphoid hyperplasia, Meckel diverticulum, duplication cyst, adhesions, polyps, intramural hematoma, foreign body, enteric tubes, lipoma
- Associated pathology: Henoch-Schönlein purpura, malabsorption syndromes (celiac), cystic fibrosis
- May occur postoperatively

CLINICAL ISSUES



- Majority are self-limited & spontaneously reduce
- Sonographic findings that may indicate need for surgery
  - Length > 3.5 cm
  - Findings of small bowel obstruction (SBO) & ascites
  - Pathologic lead point (but US has low sensitivity)
- Postoperative SBI is typically surgically reduced
- Complications are more likely with delayed presentation & diagnosis: SBO, ischemia, necrosis



(Left) *Transverse US in an 11-month-old with vomiting shows a target appearance of the bowel in the left abdomen. A small amount of hyperechoic mesenteric fat ➡ is interposed between the intussuscipiens ⇨ & intussusceptum ⇨. The location & diameter are typical of a small bowel intussusception (SBI). This resolved during the exam.* **(Right)** *Transverse US in a 1-year-old shows the target appearance of a SBI ➡ caused by a nasojejunal tube ⇨ that has an echogenic shadowing rim.*

(Left) *Longitudinal US in a 12-year-old demonstrates an SBI that measures > 5 cm in length ⇨. An echogenic lipoma ➡ (discovered at surgery) served as a lead point. Note the lack of entrapped mesenteric fat or lymph nodes, typical of an SBI.* **(Right)** *Axial CECT in a child with pancreatitis shows an incidental left lower quadrant SBI ⇨ without entrapped fat or lymph nodes. Most SBIs are asymptomatic & resolve without intervention.*

TERMINOLOGY

Definitions

- Telescoping of proximal small bowel segment (intussusceptum) into contiguous distal small bowel segment (intussuscipiens)

IMAGING

General Features

- Best diagnostic clue
  - US or CECT: Round or tubular "mass" with alternating layers of bowel wall (bowel within bowel appearance)
    - Target appearance in cross section
  - Continuity of fat trapped in mass with mesenteric fat
    - Relatively little fat compared to ileocolic intussusception (ICI)
  - Mesenteric vessels extend into or out of mass
  - Normal terminal ileum insertion into ileocecal valve
  - ± proximal bowel dilation
  - ± pathologic lead point

Ultrasonographic Findings

- Focal mass demonstrating multiple internal layers of bowel wall, each with characteristic gut signature
  - Inner hyperechoic mucosa, middle hypoechoic muscular layer, outer hyperechoic serosa
  - ± trapped echogenic mesenteric fat
- Target appearance in cross section
- Features that differentiate small bowel intussusception (SBI) from ICI
  - Smaller diameter
    - Mean diameter of 1.5 cm (range: 1.1 cm-2.5 cm)
      - Size may ↑ with age, edema, hemorrhage or intramural mass
  - Less hyperechoic mesenteric fat centrally
    - Thin crescent or no visible fat
    - Ratio of central fat core diameter to outer wall thickness > 1.0 in all ICI & < 1.0 in all SBI
  - SBI is more commonly periumbilical or in left abdomen
  - Entrapped lymph nodes are less common in SBI
- Majority of SBIs are transient & spontaneously reduce during exam
- Sonographic findings that may indicate need for surgery
  - Length of SBI > 3.5 cm
    - Sensitive (93%) & specific (100%) independent predictor of need for surgery by one paper
  - Findings of small bowel obstruction (SBO) & ascites
  - Pathologic lead point (but US has low sensitivity)

CT Findings

- Layered, alternating bands of ↑ (enhancing bowel wall) & ↓ (mesenteric fat ± fluid) attenuation
- Target appearance in transverse plane

Imaging Recommendations

- US for initial imaging evaluation
  - Should be able to clearly trace small bowel into & out of intussusception (further differentiates SBI vs. ICI)
- CECT is occasionally used to further investigate if
  - Patient is symptomatic
  - Findings are present that may indicate need for surgery

DIFFERENTIAL DIAGNOSIS

Ileocolic Intussusception

- ICI extends from right lower quadrant into right upper quadrant (& possibly beyond into/through transverse colon)
- ICI has mean diameter of 2.6 cm in cross section
- Entrapped lymph nodes are more likely with ICI
- Vomiting, bloody stool, & leukocytosis are more likely

Meckel Diverticulum

- Tubular mass (± gut signature on US)
- Complications (20%): Obstruction, bleeding, inflammation, perforation, & intussusception

Henoch-Schönlein Purpura (IgA Vasculitis)

- Hypersensitivity reaction with small vessel vasculitis
- Purpuric rash on legs or extensor surfaces of arms
- Mural bleed predisposes to intussusceptions

Ruptured Appendicitis

- May have target appearance with walled-off perforation

PATHOLOGY

General Features

- Etiology
  - Abnormal peristalsis → invagination of proximal bowel & mesenteric fat into contiguous bowel segment
  - Lead points (uncommon): Lymphoid hyperplasia, Meckel diverticulum, duplication cyst, polyps, intramural hematoma, foreign body, enteric tubes, lipoma
  - Associated pathology: Henoch-Schönlein purpura, malabsorption syndromes (celiac), cystic fibrosis
  - Prior abdominal or nonabdominal procedures
    - > 85% of postoperative intussusceptions are SBIs

CLINICAL ISSUES

Presentation

- 65% are asymptomatic in one study
- May lead to pain, distention, vomiting, blood in stool

Natural History & Prognosis

- Majority are self-limited & spontaneously reduce

Treatment

- Asymptomatic patient without concerning imaging features: Conservative management (often spontaneously reduces during study)
- Symptomatic patient or concerning imaging features: Surgical consult ± CECT/follow-up US

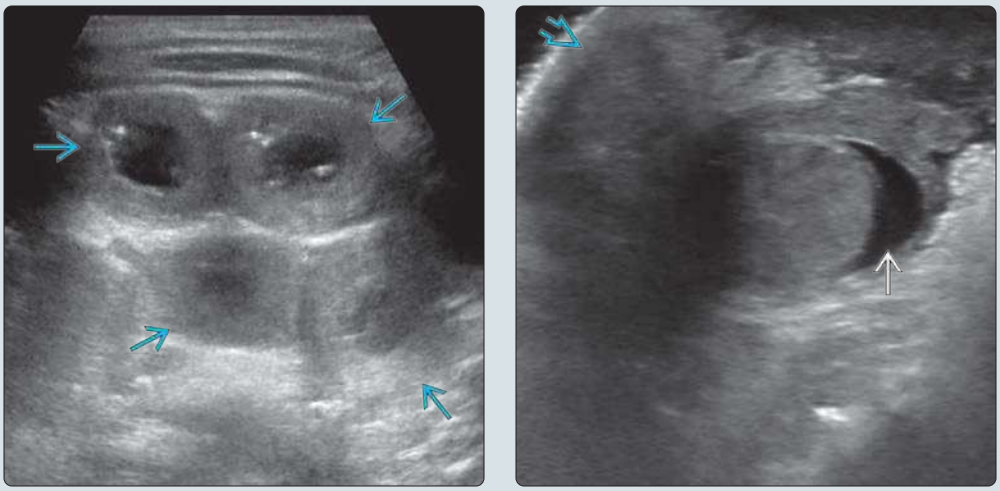
Henoch-Schönlein Purpura

KEY FACTS

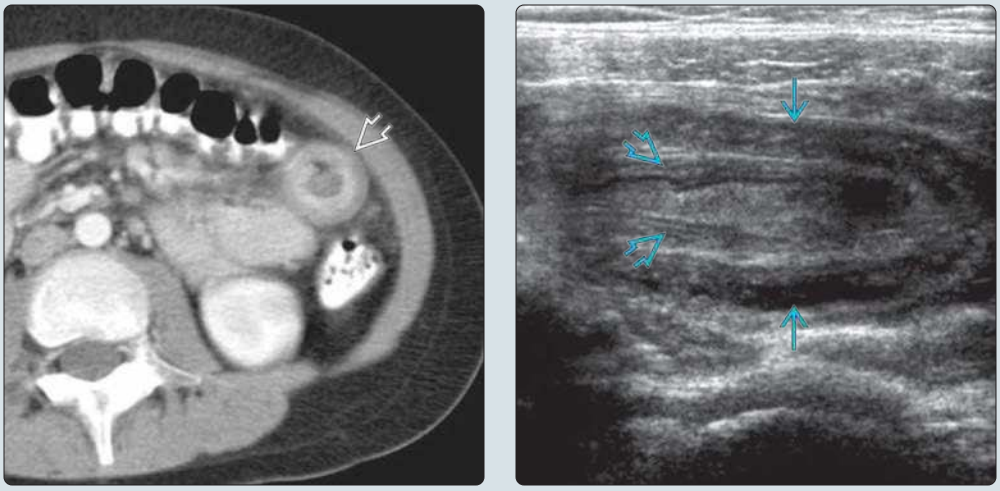
TERMINOLOGY

- Immune complex-mediated small vessel vasculitis commonly affecting skin, GI tract, urologic system, joints



IMAGING

- GI features (up to 75%)
  - Circumferential bowel wall thickening of discontinuous segments of variable lengths
    - Due to intramural hemorrhage &/or edema
    - Thumbprinting sign on radiographs
  - Intussusception, commonly ileoileal
- Urologic features (up to 60%)
  - Henoch-Schönlein purpura (HSP) nephritis
    - Normal or bilaterally enlarged & echogenic kidneys
  - Stenosing ureteritis
    - Hydroureteronephrosis & thick urothelium
  - Scrotal wall thickening, edema, & hyperemia
- Arthritis/arthralgias (up to 82%)
- Neurologic features (up to 2%)
  - Cerebral edema, intracranial hemorrhage, cerebral vein thrombosis, posterior reversible encephalopathy syndrome
- Pulmonary features (up to 5%)
  - Diffuse alveolar hemorrhage (DAH)
    - Alveolar infiltrates & ground-glass opacities
    - Pleural effusions, often large & requiring drainage



CLINICAL ISSUES

- Most common primary pediatric vasculitis at 49%
- Purpura or petechiae ultimately in 100%
- Peak age: 7 years
- Typically self-limited, resolves in 3-4 weeks
  - Treatment is largely conservative & directed to specific systems involved
  - Recurrence in up to 1/3 of cases
  - HSP nephritis: 20% develop nephritic/nephrotic syndrome
  - DAH: Up to 28% mortality

(Left) *Transverse ultrasound of the abdomen in a 7-year-old with intermittent pain shows relatively homogeneous thickening of multiple small bowel loops. The patient was ultimately diagnosed with Henoch-Schönlein purpura (HSP).* **(Right)** *Transverse ultrasound of the scrotum in the same patient shows scrotal wall edema in the setting of HSP. Note the small hydrocele around the normal testicle.*

(Left) *Axial CECT in a 9-year-old with HSP, vomiting, & abdominal pain demonstrates a thick-walled loop of small bowel with mucosal hyperenhancement & mild surrounding mesenteric inflammation.* **(Right)** *Longitudinal ultrasound in a 4-year-old with HSP & abdominal pain shows a small bowel-small bowel intussusception with well-delineated intussuscipiens & intussusceptum. There is no significant entrapped fat. This intussusception was > 5 cm long & required surgical reduction.*

TERMINOLOGY

Abbreviations

- Henoch-Schönlein purpura (HSP)

Synonyms

- IgA vasculitis

Definitions

- Systemic nonthrombocytopenic immune complex-mediated small vessel vasculitis

IMAGING

General Features

- Multisystem diffuse vasculitis most commonly affecting GI tract, urologic system, joints, & (to lesser extent) nervous system & lungs
- Imaging findings are nonspecific & must be considered in context of clinical & laboratory findings to make diagnosis

GI Findings

- Bowel wall edema with submucosal & intramural hemorrhage
  - Circumferential bowel wall thickening involving discontinuous segments of variable lengths
  - Thumbprinting sign from fold thickening on radiographs
  - Hypo- or hyperattenuating bowel wall on CECT
  - Hypomotility of involved bowel loops
- Mesenteric vascular engorgement
- ↑ attenuation or echogenicity of mesenteric fat
- Ileus or obstruction
- Intussusception occurs in up to 14% of HSP cases
  - Ileoileal most common (~ 50%)
- Rarely, ischemia, pneumatosis, & spontaneous bowel perforation
- Nonspecific lymphadenopathy
- Hydropic gallbladder

Urologic Findings

- HSP nephritis in 30-50% of HSP cases
  - Normal or bilaterally enlarged kidneys
  - Diffusely ↑ echogenicity of renal cortex
- Stenosing ureteritis
  - Secondary to ureteral/periureteral vasculitis
  - Hydroureteronephrosis, urothelial thickening
- Bladder & ureteral wall hematomas
- Acute scrotum
  - Scrotal wall edema & hyperemia ± hydrocele
  - Normal or slightly hyperemic testicles & epididymis
  - ± spermatic vein thrombosis
- Penile HSP
  - Diffuse edema of shaft & foreskin
  - Penile purpura may precede extremity rash
    - Hypoechoic avascular lesion
  - Thrombosis & priapism

Joint Findings

- Arthritis with synovitis & effusion, soft tissue swelling

Neurologic Findings

- Cerebral edema
- Intracranial hemorrhage
- Cerebral vein thrombosis
- Posterior reversible encephalopathy syndrome
  - Patchy cortical & subcortical white matter lesions are most pronounced in posterior circulation distribution (parietal, occipital, cerebellar)
    - Hypodense on CT; ↓ T1, ↑ T2 & FLAIR on MR, most without diffusion restriction
  - Due to hypertension or cerebral vasculitis

Pulmonary Findings

- Edema related to kidney failure
- Diffuse alveolar hemorrhage (DAH) in 0.8-5%
  - Alveolar infiltrates & ground-glass opacities
  - Reticulonodular opacities are less common
  - Pleural effusions, often large & requiring chest tube

DIFFERENTIAL DIAGNOSIS

Idiopathic Thrombocytopenic Purpura

- Life-threatening multisystem disorder with disseminated microvascular thrombi
- ↓ platelets (whereas HSP may have ↑ platelets)
- Anemia, petechiae, microscopic hematuria

Hemolytic Uremic Syndrome

- Microvascular lesions with platelet aggregation
- Caused by enterohemorrhagic strains of *Escherichia coli*, especially *E. coli* 0157:H7
- Transient, severe, crampy abdominal pain with bloody diarrhea; precedes renal failure by 3-14 days

Infectious or Inflammatory Colitis

- Abdominal pain & bloody diarrhea
- Pseudomembranous colitis is characterized by fever, diarrhea, & diffuse colonic mucositis, typically while on antibiotics
  - Toxin produced by *Clostridium difficile* is most important cause of antibiotic-associated colitis
- Crohn disease most commonly has ileocecal involvement

Child Abuse

- Bruising on extremities may simulate HSP rash
- Bowel hematomas can be seen in both HSP & child abuse

Juvenile Idiopathic Arthritis

- Arthralgias involving 1 or more joints: Knee (90%), ankle (70%), wrist (70%)
  - Joint effusion, synovial thickening/hyperemia, bone marrow changes ± erosions
- ± rash

Leukemia

- Numerous possible symptoms & signs, including petechiae, pain, swelling, adenopathy

Testicular Torsion

- Doppler demonstrates ↓ or absent blood flow of acutely painful testicle

Scrotal Cellulitis

- Lacks other features of HSP
- May have history of insect bite

PATHOLOGY

General Features

- Etiology
  - Inflammatory disorder of unknown cause; characterized by specific immune complexes in venules, capillaries, & arterioles

Gross Pathologic & Surgical Features

- HSP nephropathy demonstrates mesangial hypercellularity, endocapillary proliferation, necrosis, cellular crescents, & leukocyte infiltration
- HSP has no specific diagnostic laboratory markers
  - Serum IgA levels ↑; ± platelets high

Microscopic Features

- Leukocytoclastic angiitis initiated by deposition of immune complexes
- Renal biopsy is indistinguishable from IgA nephropathy
  - Changes range from minimal mesangial proliferation to severe necrotizing glomerulonephritis
  - Glomerular crescents associated with poor renal outcome & development of end-stage renal disease
- Pulmonary involvement
  - DAH is predominant finding

CLINICAL ISSUES

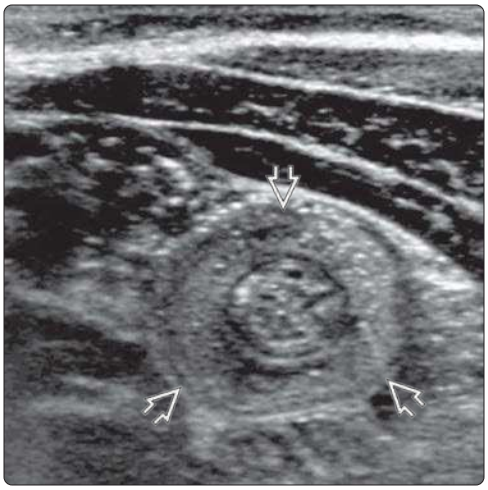
Presentation

- Consensus criteria for HSP
  - Purpura or petechiae with lower limb predominance & at least 1 of following
    - Abdominal pain
    - Arthritis or arthralgia
    - Renal involvement
    - IgA deposition on biopsy
- Purpura or petechiae (100%)
  - Lower limb predominance
  - May develop bullous lesions
  - May not be initial manifestation
- Arthralgia & arthritis (up to 82%)
  - Typically oligoarthritis of lower limbs
  - May precede rash in 25% of cases
- GI disturbances (50-75%)
  - Abdominal pain, vomiting, GI bleeding (which may be massive), intussusception, pancreatitis, hydropic gallbladder, protein-losing enteropathy
  - GI symptoms can precede rash in up to 43% of cases
- Renal (20-60%)
  - Hematuria, hypertension, proteinuria, acute renal failure
  - HSP nephritis may develop up to 6 months after acute presentation
- Urogenital (up to 27%)
  - Scrotal swelling, priapism, ureteral stenosis
  - 3% of all acute scrotal cases
- Neurological (2%)
  - Seizure, intracranial hemorrhage, headache, focal deficit, polyradiculopathy
- Pulmonary (0.8-5.0%)
  - Hemoptysis, dyspnea, chest pain
- Conditions associated with or preceding HSP include
  - Upper respiratory infection
  - Vaccinations with measles, yellow fever, typhoid
  - Environmental exposures, such as drugs, cold temperature exposure, insect bites

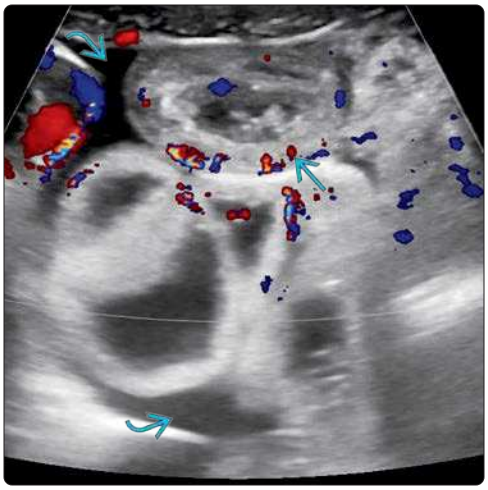
Demographics

- Most common primary pediatric vasculitis (49%)
- Majority occur between 3-15 years of age
  - Peak age: 7 years
- Annual incidence: 20 per 100,000
- Seasonal variation, most occur in winter

Natural History & Prognosis



- Typically self-limited, resolves in 3-4 weeks
- Recurrence in up to 1/3 of cases
- 20% of HSP nephritis cases develop nephritic or nephrotic syndrome
  - Long-term renal impairment in 20-44% of patients that develop nephritic or nephrotic syndrome
  - End-stage renal disease < 1%
- DAH is often severe: 50% require mechanical ventilation; 28% mortality



Treatment

- Conservative management of symptoms
  - Steroids for severe skin lesions
  - Oral prednisolone for GI disease is controversial
- Reduction of ileocolic intussusceptions
- Hemodynamic monitoring with possible endoscopy for GI bleeding
- HSP nephritis
  - No evidence-based treatment
  - Current therapeutic approach includes
    - Angiotensin-converting enzyme inhibitors
    - IV or oral corticosteroids
    - Cyclophosphamide if severe
    - Early-onset plasmapheresis

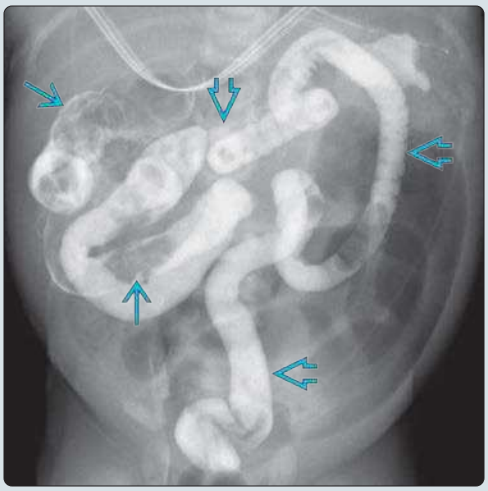
(Left) *Transverse ultrasound in a 5-year-old with HSP & abdominal pain demonstrates a small bowel intussusception in cross section with a target appearance. Multiple small bowel intussusceptions were encountered during the exam (not shown).* **(Right)** *Transverse ultrasound in an 8-year-old with a history of HSP & abdominal pain shows small bowel wall thickening & hyperemia with a small volume of ascites.*

(Left) *Longitudinal ultrasound in an 11-year-old with known HSP shows ↑ echogenicity of the renal cortex that is equivalent to or slightly greater than the adjacent liver. The patient presented with worsening hypertension (HTN).* **(Right)** *Axial FLAIR MR in the same patient with HSP nephritis & HTN (who developed seizures) shows superficial foci of ↑ signal intensity in the parietal & frontal lobes. The findings are consistent with posterior reversible encephalopathy syndrome (PRES).*

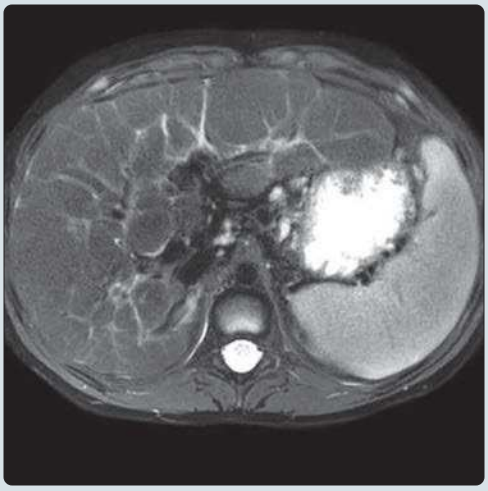
(Left) *Axial NECT in a 2 year-old with HSP, shortness of breath, & a drop in hemoglobin demonstrates bilateral patchy opacities, compatible with diffuse alveolar hemorrhage.* **(Right)** *Transverse ultrasound demonstrates marked scrotal wall thickening, a small hydrocele, & a normal testicle in a 21-month-old with HSP. Scrotal swelling can be the presenting symptom in HSP.*



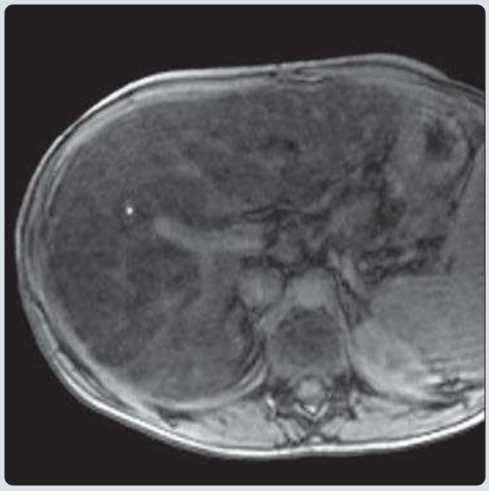
KEY FACTS

TERMINOLOGY

- Cystic fibrosis (CF): Autosomal recessive multisystem disorder caused by dysfunctional chloride ion transport across epithelial surfaces



IMAGING



- Pancreas: Abdominal organ most commonly involved in CF
  - Pancreatic insufficiency: Affects 85-90%
  - Pancreatitis: Can be acute or chronic
    - Acute: More common in patients with pancreatic sufficiency
    - Chronic: May appear as lipomatous hypertrophy, Ca^{2+}, &/or gland atrophy
  - Pancreatic cystosis: Rare sequela caused by occlusion of small ductules
- Intestinal
  - Gastroesophageal reflux disease: Prevalence is 6-8x higher than general population
  - Meconium ileus: Congenital bowel obstruction caused by tenacious meconium occluding terminal ileum
  - Distal intestinal obstruction syndrome (DIOS): Meconium ileus equivalent in older children
  - Constipation: Excess stool throughout colon
  - Intussusception: 10x higher than general population
  - Appendix: Enlarged without inflammation
    - Appendicitis rates are lower in CF patients
- Hepatobiliary: Most common cause of CF mortality after pulmonary complications
  - Hepatic fibrosis/cirrhosis: Occurs in 5-15% of children/adolescents with CF
  - Focal biliary cirrhosis: Most common cause of liver pathology in patients with CF
  - Microgallbladder: Caused by atresia/stenosis of cystic duct

(Left) *Frontal image from a water-soluble contrast enema in a neonate with distal obstruction shows a microcolon. The ileum is dilated & contains multiple filling defects, consistent with meconium ileus. In the absence of superimposed complication, this obstruction may respond to treatment with serial enemas to break up the impacted meconium.* **(Right)** *Axial T2 FS MR in a patient with cystic fibrosis shows diffuse fatty replacement of the pancreas.*

(Left) *Axial T2 FS MR in a patient with cystic fibrosis shows that the liver is enlarged with a nodular contour with linear regions of ↑ T2 signal. In addition, the spleen is enlarged. The findings are typical of advanced cystic fibrosis liver disease with portal hypertension.* **(Right)** *Axial T1 opposed-phase MR in a patient with cystic fibrosis shows diffuse loss of signal in the liver, consistent with steatosis. The measured fat fraction in this patient was 38% (normal is < 5%).*

TERMINOLOGY

Definitions

- Cystic fibrosis (CF): Autosomal recessive multisystem disorder caused by dysfunctional chloride ion transport across epithelial surfaces
  - Presenting symptoms of CF in infants & young children are most commonly GI related

IMAGING

General Features

- Associated conditions in CF patients
  - Pancreas: Abdominal organ most commonly involved
    - Pancreatic insufficiency: Affects 85-90%
    - Pancreatitis: Can be acute or chronic
      - Acute: Occurs in 10% of patients with pancreatic sufficiency
      - Chronic: May appear as lipomatous hypertrophy, Ca^{2+}, &/or gland atrophy
    - Pancreatic cystosis: Rare sequela caused by occlusion of small ductules
  - Intestinal
    - Gastroesophageal reflux disease (GERD): Prevalence is 6-8x higher than in general population
    - Meconium ileus: Congenital bowel obstruction (not ileus) caused by tenacious meconium occluding terminal ileum
      - Simple: Meconium causes bowel obstruction
      - Complex: Obstruction leads to complication, such as volvulus, perforation, pseudocyst, or atresia
    - Distal intestinal obstruction syndrome (DIOS): Meconium ileus equivalent occurring in all ages
      - Complete: Causes vomiting & complete obstruction
      - Incomplete: Causes abdominal pain & distention but not complete obstruction
    - Constipation: Excess stool throughout colon
    - Appendicitis: Occurs less commonly than in general population
      - Normal appendix is enlarged in CF: Mean diameter of 8.3 mm
    - Intussusception: 10x more common than general population
    - Malignancy: Intestinal malignancies occur 23x more commonly in CF patients (typically adults)
  - Hepatobiliary: Most common cause of mortality after pulmonary complications
    - Steatosis: Occurs in up to 2/3 of children & adolescents
    - Hepatic fibrosis/cirrhosis: Occurs in 5-15% of children/adolescents
    - Focal biliary cirrhosis: Most common cause of liver pathology
    - Microgallbladder: Caused by atresia/stenosis of cystic duct

Radiographic Findings

- Radiography
  - Meconium ileus: Distal obstruction bowel gas pattern occurring in newborn
    - Complication by in utero perforation may lead to peritoneal Ca^{2+} (meconium peritonitis) &/or fluid collection (meconium pseudocyst)
  - DIOS: Dilated small bowel loops with stool mass in right lower quadrant of older child
    - Complete: Fluid levels in dilated proximal small bowel, stool mass in distal small bowel
    - Incomplete: Stool mass in terminal ileum but no findings of bowel obstruction
  - Constipation: Large amount of stool throughout colon (not just confined to cecal region)
  - Chronic pancreatitis: Occasionally see scattered Ca^{2+}

Fluoroscopic Findings

- Upper GI
  - GERD: Retrograde propulsion of contrast from stomach to esophagus
  - Duodenal fold thickening
- Contrast enema
  - Meconium ileus
    - Microcolon with filling defects of abnormal meconium in terminal ileum
    - Complicated by ischemia, atresia, volvulus, or perforation in up to 50% of cases
    - Enema can be therapeutic in uncomplicated cases
      - Performed with N-acetylcysteine & Gastrografin
  - DIOS
    - Normal colon with filling defects in terminal ileum
    - Enema can be therapeutic
      - Performed with N-acetylcysteine & Gastrografin

CT Findings

- Acute pancreatitis: Appears as pancreatitis in patients without CF
- Chronic pancreatitis: Varying amounts of fatty replacement, pancreatic atrophy, Ca^{2+}
- Pancreatic cystosis: Multiple cysts of varying sizes in pancreas
- DIOS: Mass of stool in terminal ileum
- Appendix: Larger than in normal patients & often filled with inspissated secretions despite lack of inflammation
- Steatosis: Diffuse or patchy areas of low attenuation in liver
- Hepatic fibrosis/cirrhosis: Small liver with nodular contour; may have findings of portal hypertension
- Microgallbladder: Gallbladder < 2-3 cm long x 0.5-1.5 cm wide

MR Findings

- Steatosis: Loss of hepatic signal on opposed-phase images
- Hepatic fibrosis/cirrhosis: MR elastography to assess for liver fibrosis

Ultrasonographic Findings

- Meconium ileus: May create stool ball equivalent in dilated bowel
  - ± complex ascites &/or meconium pseudocyst from in utero bowel perforation
- Appendix: Larger than in normal patients & often filled with inspissated secretions without inflammation
- Intussusception: Target sign or pseudokidney sign
- Pancreatic lipomatosis: Echogenic pancreas (compared to kidney)

- Pancreatic cystosis: Multiple cysts of varying size in pancreas
- Steatosis: Hyperechoic liver (compared to right kidney) with poor visualization of portal triads & right hemidiaphragm

Imaging Recommendations

- Best imaging tool
  - Depends on patient symptoms
    - Neonate with vomiting or failure to pass meconium
      - Radiograph with distal obstruction pattern → contrast enema
    - Abdominal pain in older child
      - DIOS, constipation: Radiograph
      - Pancreatitis: Ultrasound followed by MR/MRCP
      - Intussusception: Ultrasound followed by air-reduction enema
    - Liver disease
      - US or MR can assess hepatic fat content, fibrosis, & findings of portal hypertension

DIFFERENTIAL DIAGNOSIS

Neonate With Failure to Pass Meconium

- Hirschsprung disease
- Meconium plug/small left colon
- Ileal atresia

PATHOLOGY

General Features

- Genetics
  - Autosomal recessive
  - CF transmembrane conductance regulator (*CFTR*) gene mutation (chromosome 7q31.2)
    - > 2,000 genetic defects can result in CF; ΔF508 is most common
      - Genotypes with less severe lung disease may have more severe extrapulmonary disease
- Etiology
  - *CFTR* gene mutation → lack of chloride ion secretion → ↑ sodium retention & fluid absorption → ↑ viscosity of luminal secretions → obstruction
  - CFTR protein is located in epithelial cells of airway, GI tract, sweat glands, & GU system
  - Most GI manifestations are due to combination of disordered motility, thickened secretions, pancreatic insufficiency, & medications
- Associated abnormalities
  - Pulmonary disease

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Meconium ileus: Failure to pass meconium ± emesis in newborn
  - Intussusception: Colicky abdominal pain, intermittent fussiness
  - Pancreatic insufficiency: Greasy stools, flatulence, bloating, failure to thrive
  - GERD: Heartburn, dysphagia, dyspepsia
  - DIOS: Crampy abdominal pain, distended abdomen, palpable right lower quadrant mass, anorexia, weight loss, flatulence
  - Constipation: Frequent or chronic abdominal pain, palpable mass of stool

Demographics

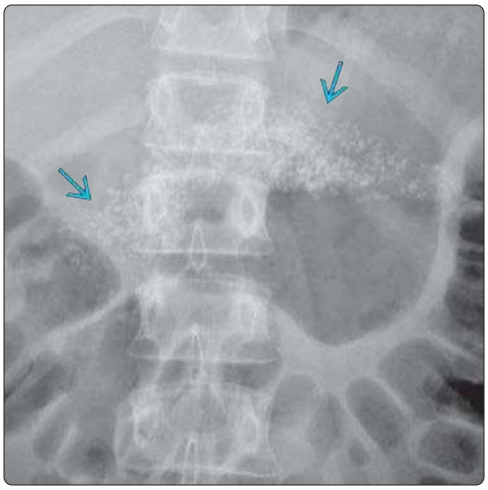
- Age
  - Meconium ileus occurs in neonates
  - Other findings can be found throughout life; patients may not manifest until later in childhood
  - Most patients are diagnosed with CF in 1st year of life during neonatal screening
- Epidemiology
  - CF is most common lethal genetic defect in White population
    - 1 in 2,500 White live births; 1 in 20 White = CF carriers
    - 1 in 17,000 Black live births

Natural History & Prognosis

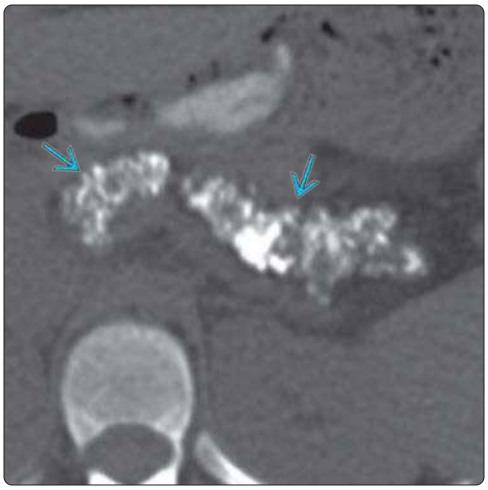
- Most common cause of death: Progressive lung disease
- Median survival: 41.1 years
  - Survival has ↑ > 10 years since 2002

Treatment

- CFTR modulators: New class of therapy designed to help CFTR protein function
  - Improves pulmonary function
  - Uncertain effect on extrapulmonary manifestations
- Meconium ileus
  - Simple: Dilute N-acetylcysteine & Gastrografin enema + patient hydration
  - Complicated: Surgery
- DIOS: N-acetylcysteine & Gastrografin enema + patient hydration
- Intussusception: Air-contrast enema
- Pancreatic insufficiency: Pancreatic enzyme replacement



DIAGNOSTIC CHECKLIST



Consider

- CF in neonate with distal bowel obstruction
- Abdominal manifestations of CF cause significant morbidity & can contribute to pulmonary complications

(Left) *AP radiograph of the upper abdomen in a patient with cystic fibrosis shows diffuse speckled calcifications of the pancreas due to chronic pancreatitis.* **(Right)** *Axial NECT in the same patient shows diffuse calcification of the atrophied pancreas. Up to 90% of patients with cystic fibrosis demonstrate pancreatic insufficiency.*

(Left) *Coronal CECT in a patient with cystic fibrosis shows numerous cysts replacing the pancreatic parenchyma. The finding is typical of pancreatic cystosis. Scattered calcifications are also noted.* **(Right)** *Axial CECT in a patient with cystic fibrosis shows a microgallbladder, which is defined as smaller than 2-3 cm long x 0.5-1.5 cm wide.*

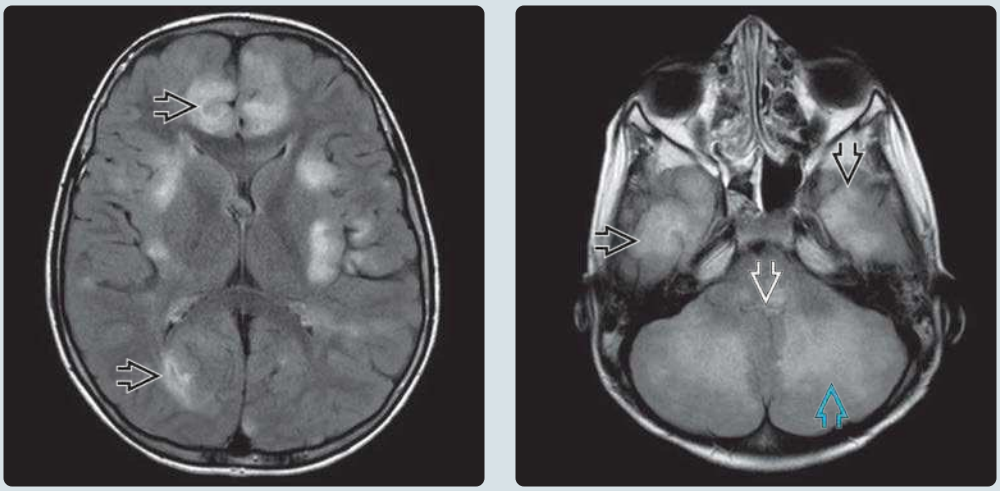
(Left) *Transverse ultrasound of the liver shows findings of cystic fibrosis liver disease. The liver has a heterogeneous appearance with ↑ echogenicity around portal triads.* **(Right)** *Coronal CECT in a cystic fibrosis patient with abdominal distention & pain shows dilated fluid-distended small bowel loops. Fecal material is present in some loops of small bowel, consistent with DIOS. Also note other sequelae of cystic fibrosis with atrophy & calcification of the pancreas as well as hepatic steatosis.*

Hemophagocytic Lymphohistiocytosis

KEY FACTS

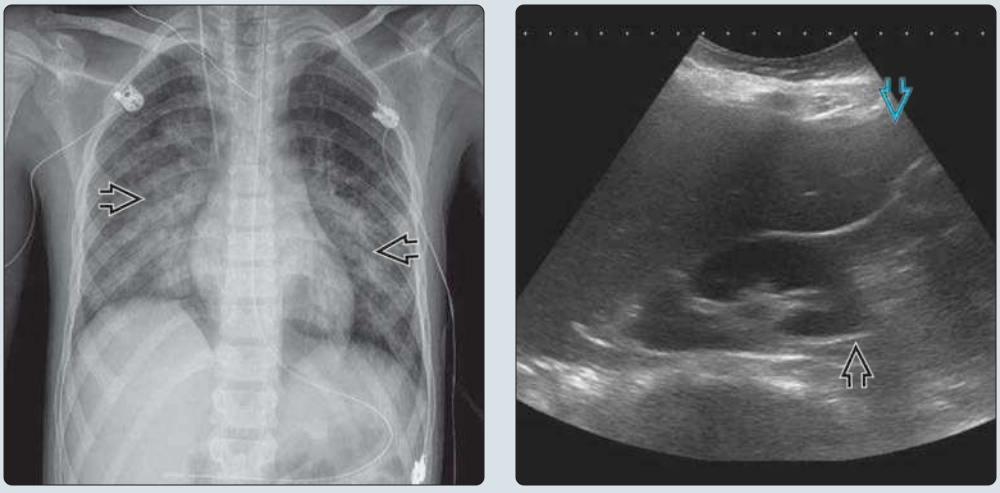
TERMINOLOGY

- Rare disorder of pathological immune activation resulting in systemic hyperinflammation
- Likely to represents wide spectrum, divided into 2 types
  - Genetic/primary/familial: Inherited genetic abnormalities
  - Acquired/secondary: Environmental or acquired mechanisms, such as infection, malignancy, autoimmune conditions, & immunocompromise



IMAGING

- Nonspecific findings, used to assess & monitor disease activity & response to treatment
- Chest radiograph, abdominal US, & brain MR are often obtained during work-up based on signs & symptoms
- Recent paper suggests consideration of PET to detect occult lymphoma; no standard protocol exists
- Thoracic findings: Alveolar opacities, interstitial thickening, atelectasis, volume loss, pleural effusions, pneumothorax
  - Can show rapid evolution & resolution
- Abdominal findings: Hepatosplenomegaly, nephromegaly, ↑ periportal echogenicity, hyperechoic kidneys, gallbladder wall thickening, ascites
- CNS findings: Multiple T2-hyperintense lesions ± contrast enhancement, edema, volume loss
- Generalized lymphadenopathy



CLINICAL ISSUES

- Diagnostic criteria: Known hemophagocytic lymphohistiocytosis (HLH) genetic defect or 5/8 of
  - Fever; splenomegaly; cytopenia ≥ 2 cell lines; hypertriglyceridemia; hypofibrinogenemia; soluble CD25 > 2,400 U/mL; hemophagocytosis in bone marrow, spleen, liver, or lymph nodes; low or absent NK-cell cytotoxicity
- Diagnostic criteria in setting of juvenile idiopathic arthritis (JIA)
  - Ferritin > 684 ng/mL & 2 of: Platelets ≤ 181 x 10^9/L, aspartate aminotransferase > 48 U/L, triglycerides > 156 mg/dL, fibrinogen ≤ 360 mg/dL

(Left) *Axial FLAIR MR in a 9-year-old boy presenting with progressive headache, vomiting, & unsteadiness over the past 3 months shows numerous hyperintense cortical, subcortical, & deep lesions within the brain parenchyma. He was subsequently found to have familial HLH.* **(Right)** *Axial FLAIR MR in the same patient shows numerous hyperintense, confluent lesions in the supra- & infratentorial parenchyma. Mass effect is demonstrated by effacement of the 4th ventricle.*

(Left) *Frontal chest radiograph in an ill child with HLH shows ill-defined perihilar opacities, right worse than left.* **(Right)** *Longitudinal grayscale ultrasound in a child with HLH shows the right lobe of the liver extending far below the inferior pole of the right kidney, suggesting hepatomegaly, a common but nonspecific finding in this disorder.*

TERMINOLOGY

Abbreviations

- Hemophagocytic lymphohistiocytosis (HLH)

Synonyms

- Hyperferritinemic inflammation
- Macrophage activation syndrome (MAS) when occurring in those with underlying rheumatologic or autoimmune syndrome
- Cytokine release syndrome (CRS) if related to iatrogenic immunosuppression therapy

Definitions

- Rare, life-threatening disorder of pathological immune activation resulting in extreme systemic hyperinflammation
- Despite name, hemophagocytosis is not required for diagnosis
- Likely to represent wide spectrum, divided into 2 types
  - Genetic/primary/familial
  - Acquired/secondary
- Genetic/primary or familial HLH
  - Inherited genetic abnormalities
  - Familial HLH: Autosomal recessive pattern, commonly associated with familial HLH genes
  - Primary HLH: Associated with immune deficiency syndromes, such as X-linked lymphoproliferative disease, Griscelli type 2, & Chediak Higashi
- Acquired/secondary HLH
  - Environmental or acquired mechanisms, such as infection, malignancy, autoimmune conditions, immunocompromise

IMAGING

General Features

- Best diagnostic clue
  - Nonspecific; imaging is not included in diagnostic criteria
  - Imaging is used to assess & monitor disease activity & response to treatment

Radiographic Findings

- Chest: Alveolar opacities, interstitial thickening, atelectasis, volume loss, pleural effusions, pneumothorax
  - Can show rapid evolution & resolution
- Bone: Rib fractures, diaphyseal periosteal reaction of long bones

CT Findings

- CNS
  - Edema, low-attenuation parenchymal lesions, foci of Ca^{2+}, volume loss
- Abdominal
  - Hepatosplenomegaly, nephromegaly, gallbladder wall thickening, ascites
- Thoracic
  - Alveolar opacities, interstitial thickening, atelectasis, pneumatoceles, pleural effusions, pneumothorax
- Lymphadenopathy

MR Findings

- CNS
  - Multiple T2-hyperintense lesions (supra- & infratentorial) ± contrast enhancement
  - Edema, intracranial hemorrhage
  - Brain parenchymal volume loss ± Ca^{2+}, associated enlargement of ventricles & extraaxial spaces
  - Rarely, leptomeningeal enhancement, foci of parenchymal restricted diffusion, extraaxial collections

Ultrasonographic Findings

- Hepatosplenomegaly, gallbladder wall thickening, ↑ periportal echogenicity, hyperechoic kidneys, ascites
- Lymphadenopathy

Imaging Recommendations

- Best imaging tool
  - Chest radiograph, abdominal US, & brain MR are often obtained during work-up as indicated by clinical signs & symptoms
  - Recent paper suggests consideration of PET to detect occult lymphoma
- Protocol advice
  - No agreed standard protocol exists

DIFFERENTIAL DIAGNOSIS

Acute Respiratory Distress Syndrome

- Can occur with HLH, making it difficult to separate these processes

Malignancy (Lymphoma, Leukemia, Solid tumors)

- More likely to present with large nodal mass/solid tumor

Infection (Viral, Bacterial, Parasitic)

- Difficult to differentiate on imaging alone

Autoimmune Disorders

- Difficult to differentiate on imaging alone

Langerhans Cell Histiocytosis

- More likely to present in combination with destructive bone lesion

Child Abuse

- Injuries of varying age incompatible with described mechanism

PATHOLOGY

General Features

- Gene-mediated &/or infection/malignancy-triggered defect of lymphocyte cytotoxicity or inflammasome activity
- Cycle of abnormal activation of mononuclear phagocytes & type 1 lymphocytes with overproduction of inflammatory cytokines

Staging, Grading, & Classification

- Diagnostic criteria for HLH
  - Genetic defect consistent with HLH or 5 of 8 clinical & laboratory criteria
    - Fever
    - Splenomegaly
    - Cytopenia in ≥ 2 cell lineages
    - Hypertriglyceridemia or hypofibrinogenemia
    - Hyperferritinemia

  - Soluble CD25 > 2,400 U/mL
  - Hemophagocytosis in bone marrow, spleen, lymph nodes, or liver
  - Low or absent NK-cell cytotoxicity
- Diagnostic criteria for HLH/MAS in setting of known juvenile idiopathic arthritis (JIA)
  - Ferritin > 684 ng/mL & 2 of 4 criteria
    - Platelet count ≤ 181 x 10^9/L
    - Aspartate aminotransferase > 48 U/L
    - Triglycerides > 156 mg/dL
    - Fibrinogen ≤ 360 mg/dL

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Can be multisystemic & show wide variation
  - Difficult to differentiate from more common diseases
  - Infections are often triggers, especially herpes & Epstein Barr virus groups
  - When associated with malignancies, they are most commonly hematologic in nature
    - In adults, malignancy is thought to be most common trigger but is much less common in pediatrics
  - Immunosuppression is also recognized as predisposition to HLH
  - When HLH is related to autoimmune disease (most commonly systemic onset JIA &SLE), it is referred to as MAS
  - Systemic
    - Fever, coagulopathy, cytopenia, multiorgan failure, lymphadenopathy, hyperferritinemia
  - CNS
    - Tends not to precede systemic findings but are present in > 1/2 of patients with HLH
    - Wide range: Headache, vomiting, psychiatric symptoms, dystonia, hemiparesis, visual disturbance, cognitive decline, seizures, cranial nerve palsies, encephalopathy, ataxia, gait disturbance, ↑ intracranial pressure, coma
  - Abdominal
    - Jaundice, hepatitis, liver dysfunction/failure, hepatosplenomegaly
  - Musculoskeletal
    - Skin rash, edema

Demographics

- Primary HLH usually presents within 1st few years of life; some cases of adult onset have been reported
- Secondary HLH can occur at any age; initial presentation is usually associated with infection, autoimmune condition, or malignancy
- Majority of adult HLH patients do not demonstrate underlying immune defect
- Incidence is likely underestimated
  - Retrospective study performed in Sweden estimated incidence of ~ 1.2/1 million children/year
  - More recent retrospective study performed in Texas suggests prevalence of 1/100,000 with median age at diagnosis of 1.8 years

Natural History & Prognosis

- Untreated disease is essentially fatal; with treatment, survival has ↑ significantly over last few decades
- Overall, current 5-year survival ~ 62%

Treatment

- Goal is to dampen cytokine storm & eliminate activated T cells & macrophages
  - Immunosuppressive chemotherapeutic drugs & biologics
    - Dexamethasone, etoposide, & cyclosporine A
    - Intrathecal methotrexate for CNS involvement
- Treatment of underlying trigger
- Allogenic stem cell transplantation is only cure for primary/familial HLH

(Left) *Longitudinal grayscale ultrasound in a 9-year-old patient with HLH shows splenomegaly, measuring 13.9 cm (with the upper limit of normal for age at 10.5 cm). While nonspecific, this is a common finding in HLH.* **(Right)** *Transverse grayscale ultrasound shows diffuse nonspecific gallbladder wall thickening in a child with HLH.*

(Left) *Frontal chest radiograph in a 4-month-old that met diagnostic criteria for HLH shows bilateral pulmonary opacities & small pleural effusions.* **(Right)** *Longitudinal ultrasound in the same patient with HLH demonstrates marked gallbladder wall thickening & pericholecystic edema. Also noted is mildly ↑ periportal echogenicity.*

(Left) *Longitudinal ultrasound in the same patient shows an enlarged kidney with ↑ echogenicity of the renal cortex & ↑ hepatic periportal echogenicity.* **(Right)** *Longitudinal ultrasound in the same patient shows splenomegaly, measuring up to 9.3 cm. The pulmonary opacities, gallbladder wall thickening, nephromegaly with ↑ cortical echogenicity, splenomegaly, & ↑ periportal echogenicity are nonspecific, but this patient met criteria overall for HLH.*

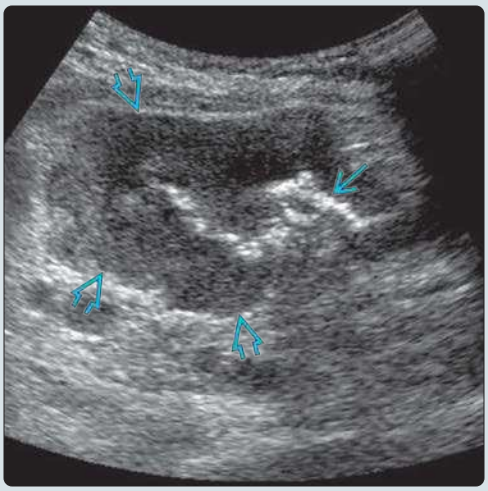
Burkitt Lymphoma

KEY FACTS

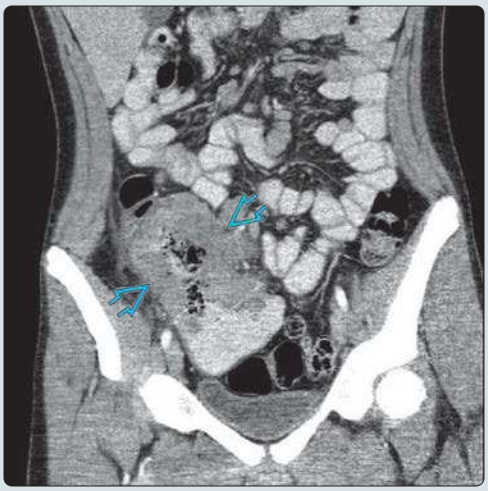
TERMINOLOGY

- Aggressive B-cell non-Hodgkin lymphoma (NHL)
- Most common form of NHL in children ≤ 15 years of age

IMAGING

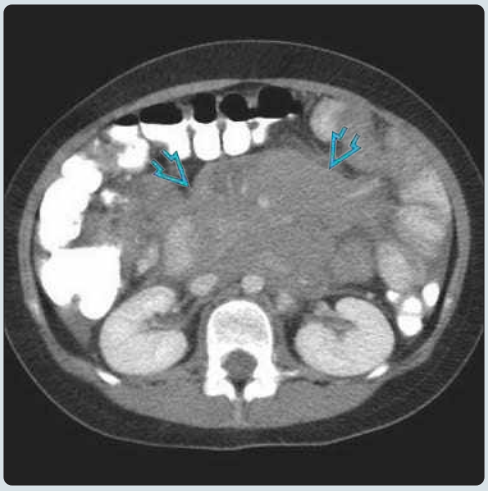


- Most common imaging appearance depends on type
  - Sporadic: Abdominal soft tissue mass &/or bowel wall thickening; may involve solid organs
    - Discrete or conglomerate masses &/or infiltrating, encasing, poorly defined lesions
  - Endemic: Head & neck soft tissue mass
- Ultrasound: Homogeneous, hypoechoic soft tissue mass(es)
  - Irregular bowel wall thickening; ± intussusception
- CT/MR
  - Moderately enhancing homogeneous mass(es) &/or thickened bowel wall (ileocecal region)
    - Hypoenhancing relative to involved organs
  - Enlarged lymph nodes
  - ± peritoneal thickening or nodularity

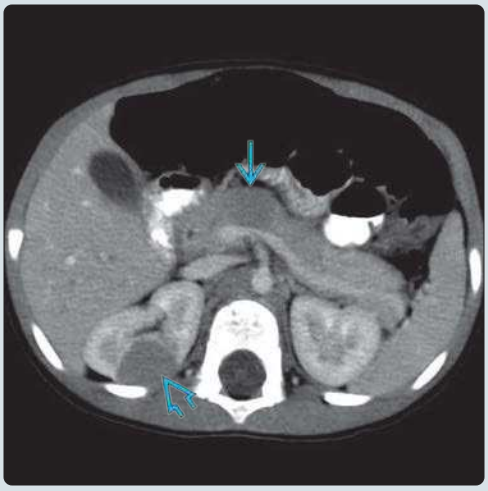


PATHOLOGY

- 3 distinct subtypes
  - Endemic
    - Commonly involves head & neck (mandible)
    - Almost always associated with EBV
    - More common in Africa & other sites along equator
  - Sporadic
    - Most commonly involves abdomen (60-80%)
      - Bowel, mesentery, solid organs, gonads
      - May involve head & neck, chest, superficial sites
    - Less commonly associated with EBV (15%)
    - More common in North America, Europe
  - Immunodeficiency related



CLINICAL ISSUES



- Mean age: 8 years
- Short doubling time of neoplasm (~ 24 hours) may lead to rapid growth, acute presentations
- With appropriate treatment, survival ~ 90%

(Left) *Transverse abdominal ultrasound in a 12-year-old boy with abdominal pain shows markedly hypoechoic & somewhat irregular bowel wall thickening in the right lower quadrant. The central echogenic foci represent gas within the compressed bowel lumen.* **(Right)** *Coronal CECT in the same patient shows marked nodular bowel wall thickening. Biopsy confirmed Burkitt lymphoma.*

(Left) *Axial CECT in a 9-year-old girl with abdominal pain shows a large, conglomerate lymph node mass engulfing bowel loops & multiple vessels. Biopsy confirmed Burkitt lymphoma.* **(Right)** *Axial CECT in a 5-year-old boy with Burkitt lymphoma shows a homogeneous, low-attenuation mass in the right kidney. A similar focus of tumor is visualized in the pancreatic neck. Additional lesions were also present in the left kidney (not shown).*

TERMINOLOGY

Synonyms

- Small non-cleaved-cell lymphoma

Definitions

- Aggressive B-cell non-Hodgkin lymphoma (NHL)
- Most common form of NHL in children ≤ 15 years of age
  - 40% of childhood NHL

IMAGING

General Features

- Location
  - Sporadic
    - Abdominal involvement is most common (60-80%)
      - Bowel wall, most commonly ileocecal region (including appendix)
      - Mesentery & peritoneal lining
      - Can involve solid organs, including kidneys & gonads
    - Head & neck
    - Others: Mediastinum, bone marrow, CNS
  - Endemic
    - Head & neck are most common
      - Classically involves mandible

Radiographic Findings

- Displacement or separation of bowel loops, narrowing of bowel lumen, organomegaly

Ultrasonographic Findings

- Grayscale ultrasound
  - Irregular bowel wall thickening
    - Thickened bowel wall is usually hypoechoic
    - May cause ileocolic intussusception
  - Solid, hypoechoic mass or enlarged lymph nodes
    - May be confluent with abnormal bowel
- Color Doppler
  - Internal blood flow due to tumor vascularity &/or vessel encasement
  - Thickened bowel wall causes less hyperemia than infectious or inflammatory etiologies

CT Findings

- CECT: Homogeneous, solid soft tissue mass
  - Moderate to marked irregular bowel wall thickening involving ileocecal region
  - Conglomerate mesenteric nodal masses encasing vessels
  - Nodular or mass-like peritoneal thickening

MR Findings

- T2 FS: Intermediate-signal soft tissue mass
  - Bowel wall thickening
  - Enlarged lymph nodes
- T1 C+ FS: Hypoenhancing relative to involved organ (e.g., kidney, spleen)
- DWI: Restricts diffusion

Nuclear Medicine Findings

- ↑ uptake on FDG PET

DIFFERENTIAL DIAGNOSIS

Other Potentially Extensive Abdominal Neoplasms

- Hodgkin lymphoma
- Rhabdomyosarcoma
- Ovarian neoplasm
- Desmoplastic small round cell tumor

Other Causes of Bowel Wall Thickening

- Inflammatory bowel disease
- Infectious enterocolitis

PATHOLOGY

General Features

- Translocation t(8:14)(q24:q32) in 70-80% of patients
  - Linked to deregulated expression of *MYC* oncogene

Staging, Grading, & Classification

- Classified into 3 distinct subtypes
  - Endemic
    - Africa, Papua New Guinea, & other locations clustered around equator
      - Linked to malaria
    - Almost always associated with EBV
  - Sporadic
    - North America, Europe
    - Less commonly associated with EBV (15%)
  - Immunodeficiency related
    - Associated with HIV infection

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Sporadic: Abdominal pain, distention, obstruction
  - Endemic: Head & neck mass, usually mandible
- Other signs/symptoms
  - Recurrent ileocolic intussusception
- Short doubling time of neoplasm (~ 24 hours) may lead to rapid growth, acute presentations

Demographics

- Mean age: 8 years; most common between 5-9 years
- Boys > > girls

Natural History & Prognosis

- With appropriate treatment, survival ~ 90%

Treatment

- Chemotherapy ± surgery, radiation therapy

Castleman Disease

KEY FACTS

TERMINOLOGY

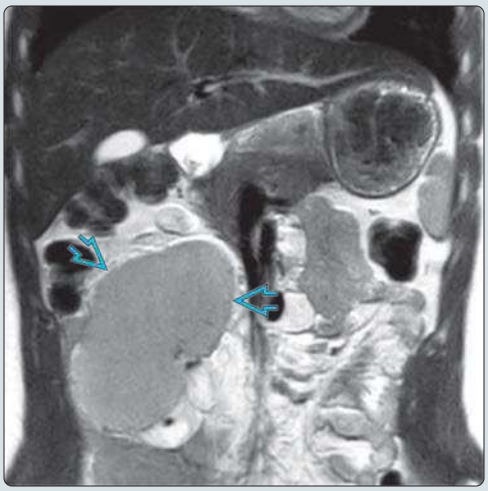
- Nonmalignant lymphoproliferative disorder
  - Also termed angiofollicular lymph node hyperplasia
- Can be unicentric (most common) or multicentric/systemic
  - Multicentric is more common in adults
    - Idiopathic or associated with HIV & human herpesvirus-8 infections, autoimmune disorders
- Most common location: Mediastinum
  - Can occur in abdomen & other nodal sites

IMAGING

- Radiographs: Soft tissue mass ± punctate Ca^{2+}
- Ultrasound: Hypoechoic, sometimes hypervascular mass
- NECT/CECT
  - Well-circumscribed, homogeneously enhancing mass
    - ± Ca^{2+} in branching (arborizing) pattern
- MR
  - Low to intermediate T1; intermediate to high T2
  - Homogeneous enhancement is most common
  - Typically restricts diffusion
- FDG PET
  - FDG avidity is typically < lymphoma

TOP DIFFERENTIAL DIAGNOSES

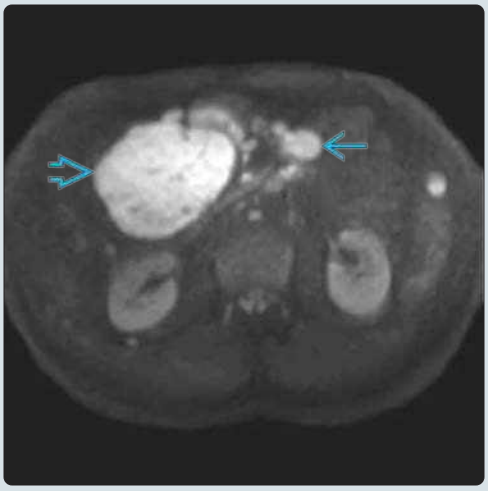
- Lymphoma
- Granulomatous infection
- Neurogenic tumor
- Inflammatory myofibroblastic tumor



PATHOLOGY

- Hyaline-vascular type
  - Most common, usually unicentric asymptomatic mass
  - Typically in adolescents & young adults
- Plasma cell type
  - Rare in children

CLINICAL ISSUES



- Unicentric form: Excellent prognosis with surgical excision
- Multicentric form: Systemic treatment; worse prognosis

(Left) *Coronal T2 SSFSE MR in a 16-year-old with abdominal pain shows an abdominal mass ⇨ of homogeneous intermediate signal intensity centered in the mesentery.* **(Right)** *Axial T1 C+ FS MR in the same patient again shows moderate homogeneous enhancement of the right mesenteric mass ⇨ as well as several enlarged mesenteric lymph nodes ⇨.*

(Left) *Axial DWI MR in the same patient shows marked hyperintense signal throughout the mass ⇨ & adjacent lymph nodes ⇨. The corresponding ADC map (not shown) confirmed restricted diffusion. Biopsy revealed Castleman disease.* **(Right)** *Coronal FDG PET/CT in a different patient shows moderate FDG avidity within a retroperitoneal mass ⇨ (maximum SUV of 3). Biopsy revealed Castleman disease.*

KEY FACTS

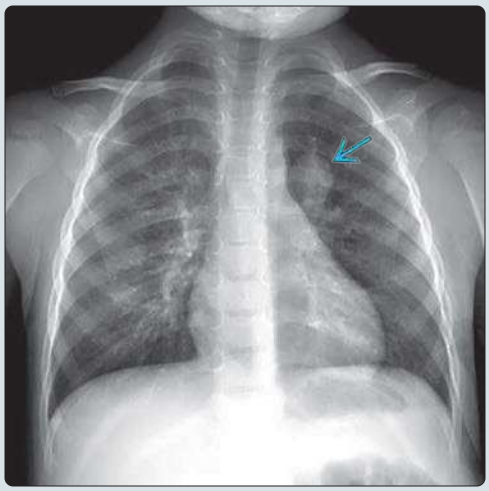
TERMINOLOGY

- Spindle cell neoplasm with intermediate malignant potential in children & young adults
- Synonyms: Inflammatory pseudotumor; plasma cell granuloma

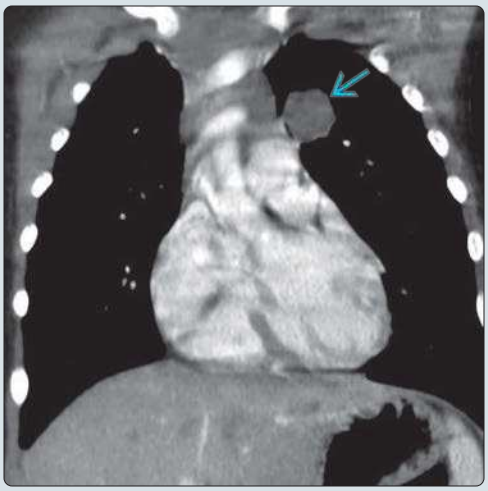
IMAGING

- Locations: Lung, abdominal solid organs, bowel, mesentery, urinary bladder
  - Most common primary lung neoplasm in children
- Typically well-defined, round or lobulated mass
  - May be discrete & bulky or infiltrative & ill-defined in mesentery & bowel
- Heterogeneously enhancing on CT/MR
  - ± delayed enhancement, central necrosis, or central Ca^{2+}
- May be T2 hypointense on MR with ↑ fibrous stroma

TOP DIFFERENTIAL DIAGNOSES

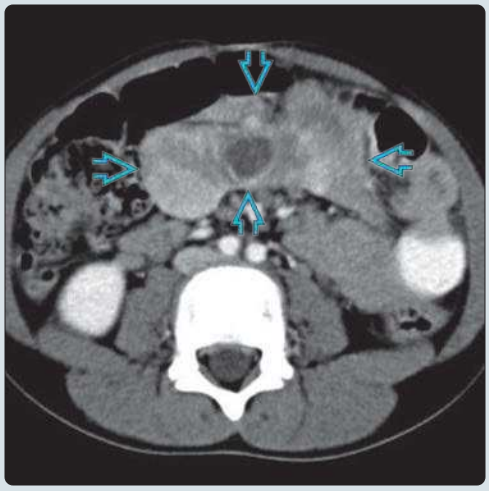


- Other fibrous lesions
- Soft tissue sarcomas
- Lymphoma
- Castleman disease
- Desmoplastic small round cell tumor

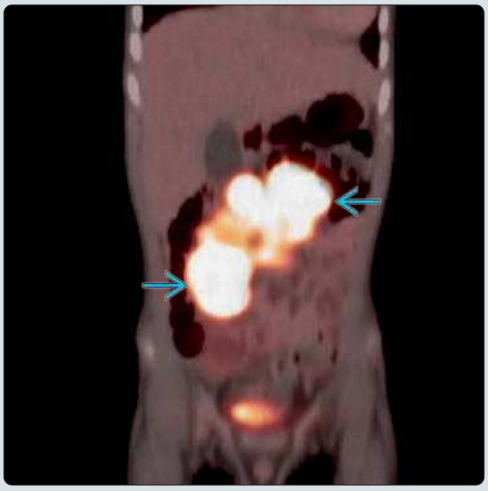


PATHOLOGY

- Spindle cell proliferation + inflammatory cells
- *ALK* gene mutation in ~ 60%



CLINICAL ISSUES



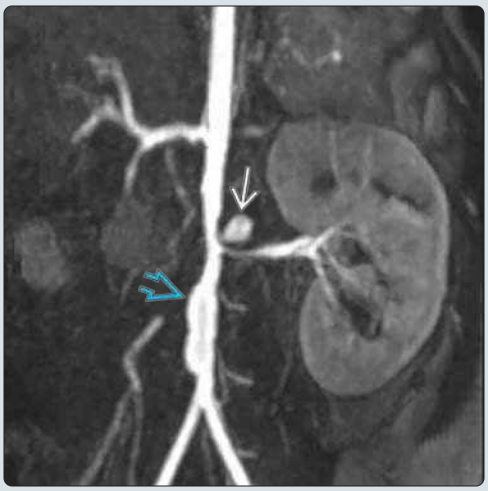
- Symptoms due to local mass effect ± nonspecific constitutional symptoms
- Low risk of distant metastases (~ 5%) with local/regional recurrence being more common
  - Most morbidity/mortality from local invasion/mass effect
- Excellent prognosis with complete surgical resection
  - If resection not feasible → chemotherapy ± steroids, targeted ALK or COX2 inhibitors

(Left) *Frontal chest radiograph in a 3-year-old boy with a cough shows a well-defined perihilar left upper lobe mass, ultimately confirmed to be an inflammatory myofibroblastic tumor (IMT).* **(Right)** *Coronal CECT in the same patient demonstrates a well-defined, nearly homogeneous, relatively hypoenhancing mass situated in the left upper lobe. IMT should be remembered as the most common pediatric lung neoplasm.*

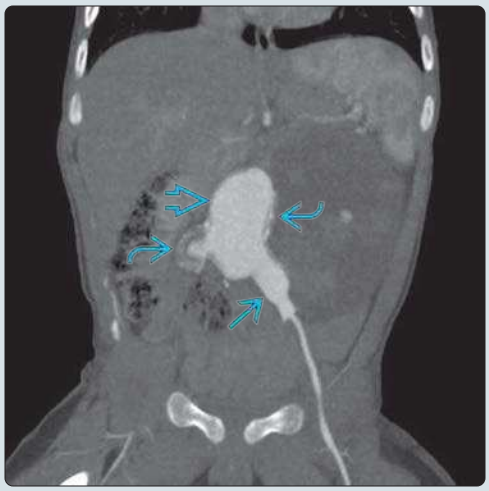
(Left) *Axial CECT in an 8-year-old boy shows a lobulated, heterogeneously enhancing mass centered in the mesentery, found to be an IMT at surgical resection. Central necrosis is suggested in this lesion, a finding of variable frequency in these tumors.* **(Right)** *Coronal fused FDG PET/CT in the same patient shows nearly uniform, intense FDG avidity by the mesenteric IMT except for the central focus of necrosis.*

KEY FACTS

TERMINOLOGY

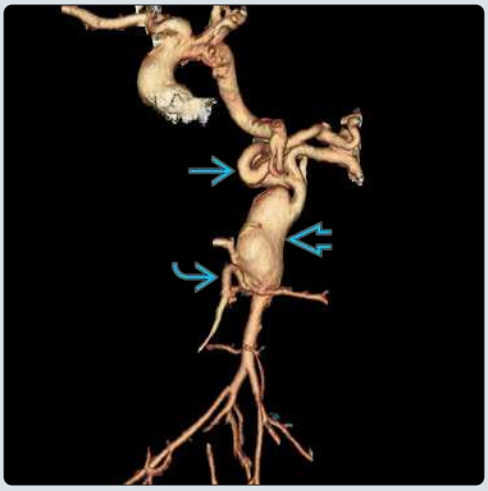


- Dilation of abdominal aorta &/or major arterial branches
- Often idiopathic, other etiologies include
  - Syndromic: Tuberous sclerosis, neurofibromatosis type 1, connective tissue disorders
  - Inflammatory arteritides: Takayasu, Kawasaki, Behçet
  - Infectious: Bacterial, mycobacterial, fungal
  - Traumatic: Iatrogenic (umbilical arterial catheter, etc.), blunt trauma

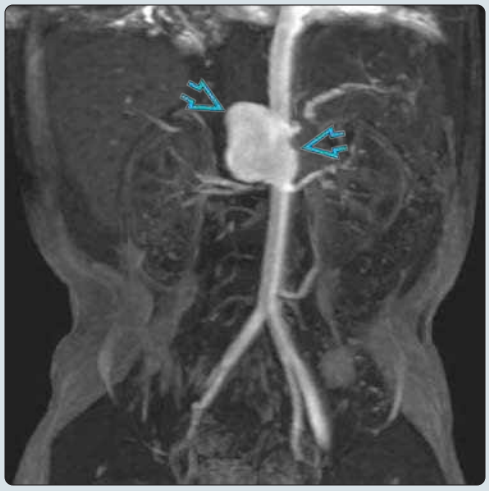


IMAGING

- Any portion of aorta & branches may be affected
  - ± dilation &/or stenosis of visceral branches
  - Normal aortic diameter varies with patient age & size
- Ultrasound for initial investigation of pediatric abdominal mass (± pulsation)
  - Layers of clot may mimic heterogeneous neoplasm
  - Color Doppler is essential to exclude aneurysm upon visualization of any "cystic" lesion
- Best imaging tool to define extent & branch involvement: CTA or MR angiography
  - Fusiform or saccular dilation of aorta &/or branches
  - Vessel wall enhancement in inflammatory etiologies
- Digital subtraction angiography (DSA) excellently depicts aneurysms & stenoses
  - Invasive, ↑ risk of complications



CLINICAL ISSUES



- Presentations include
  - Asymptomatic ± pulsatile abdominal mass
  - Stenosis &/or thromboembolism of branch vessels
    - End-organ hypoperfusion; renin-mediated hypertension if renal arteries are involved
  - Rupture (rarely) with abdominal pain & shock
  - Signs/symptoms of underlying systemic disease
- Treatment: Surgical repair vs. endovascular stent grafting
  - Medical therapy to ↓ inflammation, control blood pressure; IV antibiotics for infection

(Left) *Coronal oblique MIP image from a contrast enhanced MR angiogram in a 5-year-old child with neurofibromatosis type 1 & hypertension shows a saccular pseudoaneurysm arising from the abdominal aorta. There is also a fusiform aneurysm in the infrarenal aorta.* **(Right)** *Coronal MIP image from a CT angiogram in a 7-month-old boy shows aneurysmal dilation of the aorta with extension into the bilateral iliac arteries. Calcifications are present in the wall of the aortic & iliac aneurysms.*

(Left) *Oblique CTA 3D reconstruction in a 3-month-old with congenital anomalies & hypertension shows an aneurysm of the abdominal aorta with involvement of the celiac trunk & superior mesenteric artery (SMA). The patient also had occlusion of the lower thoracic aorta with resultant formation of multiple collateral vessels.* **(Right)** *Coronal MIP MR angiogram in a 7-year-old boy shows a large saccular abdominal aortic aneurysm. The origins of the celiac axis & SMA were involved (not shown).*

TERMINOLOGY

Definitions

- Dilation of abdominal aorta &/or its major branches
  - True aneurysm: All layers of arterial wall are expanded
  - Pseudoaneurysm: Focal rupture contained by adventitia

IMAGING

General Features

- Best diagnostic clue
  - Focally dilated aorta &/or visceral branches
    - Normal aortic dimensions vary with patient age & size
      - > 2.5-cm diameter is enlarged for any age
- Location
  - Can affect any portion of aorta & branches
  - Aortic aneurysm is associated with dilation &/or stenosis of visceral branches
    - Can also extend into iliac arteries
  - Distant aneurysms are often found with systemic diseases & idiopathic aneurysms
- Morphology
  - Aneurysm can be fusiform or saccular

Ultrasonographic Findings

- Grayscale ultrasound
  - Dilation of aorta/artery: Well-defined, pulsatile, anechoic round or tubular mass (cystic appearing)
  - Heterogeneous mural thrombus due to layers of clot ± Ca^{2+}; may compose majority of aneurysm
- Color Doppler
  - Confirms vascular nature of round or tubular anechoic structure (rather than cyst or fluid-filled tube)
  - ↑ velocity at stenosis; turbulent flow, parvus et tardus waveforms, & spectral broadening beyond stenosis

CT Findings

- CTA: ↑ luminal diameter of aorta
  - Look for associated aneurysms in visceral branches
  - Also associated with vascular stenoses
  - May see vessel wall thickening or enhancement if due to inflammatory causes (e.g., Takayasu arteritis)

MR Findings

- Pulsation artifact in phase-encoding direction
- ± layers of T1/T2 heterogeneous thrombus surrounding flow void in lumen
- ± vessel wall thickening & abnormal signal with inflammatory causes
  - T2 FS, T1 C+ FS, DWI
- MRA for luminal dilation ± associated stenoses

Imaging Recommendations

- Best imaging tool
  - CT angiography or MR angiography
  - Catheter-based digital subtraction angiography (DSA) may be employed in therapy
- Protocol advice
  - MR angiography ± gadolinium
  - Vessel wall imaging: Thin-section T1 C+ FS MR (spin-echo based with dark lumen)
    - Used with suspected inflammatory arteritis

DIFFERENTIAL DIAGNOSIS

Abdominal Cyst

- Well-defined cysts, such as ovarian, gastrointestinal duplication, mesenteric lymphatic malformation
- Color Doppler will show no significant internal flow

Solid Abdominal Mass

- Large, heterogeneous, partially thrombosed aneurysm may mimic neoplasm, such as Wilms or ovarian tumor

PATHOLOGY

General Features

- Etiology
  - Syndromes: Connective tissue disorders (Ehlers-Danlos, Marfan), tuberous sclerosis, neurofibromatosis type 1
  - Traumatic: Iatrogenic (umbilical artery catheter), blunt abdominal trauma (uncommon)
  - Inflammatory arteritides: Takayasu (most common), Kawasaki, polyarteritis nodosa, Behçet disease
  - Infectious: Bacterial, mycobacterial, fungal
  - Idiopathic
- Associated abnormalities
  - Various features of underlying syndromes
  - Multifocal abdominal &/or distant aneurysms are not uncommon, even in idiopathic setting

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic vs. pulsatile abdominal mass
  - Hypertension due to renal artery stenosis/compression → renin-mediated (renovascular) hypertension
- Other signs/symptoms
  - Abdominal pain & shock due to rupture (rare)
  - Signs/symptoms of associated syndromes or septic emboli in infectious setting

Natural History & Prognosis

- Rupture can lead to life-threatening hemorrhage
- Visceral organ hypoperfusion due to associated arterial stenoses or thromboses

Treatment

- Surgery vs. endovascular stent grafting
  - May require operative reimplantation of branches
- Medical therapy to ↓ inflammation, treat infection, control blood pressure

Embryology

A basic understanding of developmental anatomy will help explain the spectrum of congenital anomalies seen in the pediatric genitourinary tract.

During the 5th week of gestation, the mesonephric duct develops a budding tube (the ureteric bud) near its attachment to the cloaca. As this ureteric bud elongates, it reaches the metanephric blastema & undergoes a series of branchings to form the major & minor calyces, the renal pelvis, & the ureter. Signals from the ureteric bud induce changes in the metanephric blastema to form renal tubules, collecting tubules, & glomeruli of individual renal lobules. By 16- to 18-weeks gestation, the fetal kidneys are the major source of amniotic fluid for the fetus. The induction of mature renal lobules is complete by 32- to 36-weeks gestation.

While the kidney is forming, it migrates cephalad & rotates so that the renal pelves, which are initially directed anteriorly, are ultimately directed medially. At week 6, the kidneys lie in front of the primitive sacrum in the pelvis. By weeks 10-12, the kidneys have relatively ascended to their expected location along the upper lumbar spine. As the kidneys migrate, they pick up & discard nearby vascular attachments to both the aorta & inferior vena cava. This accounts for accessory vessels in normally located kidneys & for multiple vessels seen with ectopic & crossed fused kidneys.

Pediatric Genitourinary Tract Disorders

Congenital Abnormalities

Congenital anomalies of the kidney & urinary tract (CAKUT) are commonly discovered during the evaluation of pediatric patients. In fact, the urinary tract is the most common organ system affected by congenital anomalies. Many of these abnormalities are found incidentally, while others become symptomatic, causing infections, stone disease, pain, hematuria, renal failure, or, in severe bilateral cases, respiratory distress (due to pulmonary hypoplasia at birth).

The most commonly seen anomalies are ureteropelvic duplications, vesicoureteral reflux (VUR), ureteropelvic junction obstruction, & renal ectopia ± fusion anomalies.

Renal Cystic Disease in Pediatrics

Pediatric renal cystic diseases range from the often lethal autosomal recessive polycystic kidney disease (ARPKD) to simple cortical cysts. A myriad of other diagnoses fall in between these 2 extremes with variable degrees of symptoms & clinical impact. Some of the renal cystic diseases are due to ciliopathies, helping explain their multisystem organ involvement in many cases.

Multicystic dysplastic kidneys (MCDKs) are often diagnosed prenatally & confirmed with imaging in the newborn period. Anatomic imaging shows contiguous cysts of variable sizes in the renal fossa with no discernible renal parenchyma. The lack of renal function on nuclear studies can confirm the diagnosis. Typically unilateral, the rare bilateral form is classically fatal.

ARPKD is a rare disorder in which the renal parenchyma is virtually replaced by microscopic cysts & occasional macrocysts. In severe cases, the kidneys are massively enlarged, function only minimally, & cause oligohydramnios in utero, leading to lung hypoplasia. There is a variable degree of hepatic involvement in this disorder.

Autosomal dominant polycystic kidney disease (ADPKD) is characterized by macroscopic cysts that typically ↑ in both size & number over years. Patients are often aware of the family history of cystic renal disease in relatives with hypertension or renal insufficiency. Scattered cysts can be seen in very young children, but ADPKD typically presents in the teenage years, either incidentally or during the evaluation of hematuria.

Other renal cysts found in the pediatric population include simple cortical cysts, calyceal diverticula, cystic renal dysplasia (secondary to chronic obstruction), syndromic cysts (such as those seen with tuberous sclerosis, von Hippel-Lindau, Meckel-Gruber, & others), & cystic neoplasms (such as pediatric cystic nephroma).

Renal "Masses"

Hydronephrosis is by far the most common cause of an enlarged kidney in pediatric patients & can present as a palpable mass on physical exam, prompting imaging.

Wilms tumor is the most common pediatric renal malignancy with a peak incidence between 2 & 3 years of age. These tumors are heterogeneous on imaging, but their origin from the kidney provides an important clue to their diagnosis. Renal vein thrombus & vascular invasion are common.

Nephroblastomatosis is a rare entity often associated with syndromes & chromosomal abnormalities. It is defined as the persistence of primitive nephrogenic rests in the kidney after birth. The rests fail to differentiate into functional renal tissue & do not enhance like normal parenchyma on imaging. Its importance lies in its frequent degeneration into Wilms tumor.

Mesoblastic nephroma is the most common renal tumor in neonates. It has a peak age of 3 months as opposed to the 3-year range for Wilms. Mesoblastic nephroma is classically solid, but it can be cystic or have mixed solid & cystic components.

Pediatric cystic nephroma, previously known as multilocular cystic nephroma, is distinct from adult cystic nephromas, which are now classified as mixed epithelial & stromal tumors. Pediatric cystic nephromas are almost entirely cystic with many thin septations, occasionally herniating into the central renal pelvis. They have an important association with the *DICER1* mutation (resulting in predisposition to various other tumors).

Angiomyolipoma is a benign tumor of mixed cellularity, typically with prominent fatty components & vascularity that can result in hemorrhage. The fatty component provides the key to the imaging diagnosis. In children, these lesions are most often seen in association with tuberous sclerosis.

Renal medullary carcinoma is a very rare & highly aggressive tumor associated with sickle cell trait.

Uncommon renal masses in pediatrics include renal lymphoma (typically multifocal), clear cell sarcoma, ossifying renal tumor of infancy, renal cell carcinoma, & rhabdoid tumor.

Other Renal Processes

Pyelonephritis is imaged very frequently in pediatrics with the goal of identifying predisposing anatomic variants & complications of infection that require intervention.

Renal vein thrombosis may be seen in newborn infants & other ill children, particularly in the setting of dehydration &/or systemic disorders.

Renal stones are increasingly diagnosed in pediatric patients by ultrasound & CT.

Adrenal Abnormalities
The most important adrenal abnormality in children is neuroblastoma. This tumor typically is seen in children < 2 years of age. Imaging commonly shows a mass with Ca^{2+} encasing the adjacent aorta & inferior vena cava; the mass may also extend into the spinal canal. Venous tumor thrombus is rare, unlike in Wilms tumors. Bony metastases are more common in neuroblastoma vs. lung metastases in Wilms.

Uterine & Ovarian Abnormalities
Congenital abnormalities often present either in the newborn period (due to the influence of maternal hormones) or in adolescence at menarche. Imaging should always include a search for associated renal anomalies, which are frequently coincident.

Testicular Abnormalities
Torsion, infection, & inflammation are the most common reasons for testicular/scrotal imaging in pediatric patients. Congenital anomalies may predispose to inflammatory conditions or spermatic cord twisting that leads to ischemia. Tumors are less frequent & typically present as palpable masses without pain.

Bladder Abnormalities
Neurogenic bladder is the most common genitourinary entity imaged. Children typically show an evolution from a high-compliance, large-capacity bladder in new neurogenic bladders to a poorly distensible, low-capacity bladder in chronic neurogenic bladders. Bulking agents, such as Deflux, may be used to treat VUR & will be visible on follow-up imaging. Cloaca & other anorectal malformations are rarely imaged (except at dedicated centers). Bladder rhabdomyosarcoma is also uncommon but should be considered when a solid or heterogeneous mass is visualized in the bladder.

Imaging the Pediatric Genitourinary Tract

Ultrasound
Ultrasound is the mainstay of imaging in the pediatric genitourinary tract. Infants & children typically have excellent sonogenic body habitus. The advantages of ultrasound include that it is painless, noninvasive, portable, relatively inexpensive, & does not involve ionizing radiation or require sedation. Although ultrasound is user dependent, assessments of renal lengths & hydronephrosis should be reproducible from exam to exam. With the approval of ultrasound contrast agents, ultrasound is increasingly utilized for VUR evaluation. It is important to know that renal ultrasound may be normal in cases of pyelonephritis & VUR, a point that referring clinicians also need to recognize.

Instillation of ultrasound contrast into the bladder can be used in lieu of a conventional fluoroscopic cystogram for the evaluation of VUR.

Fluoroscopic Voiding Cystourethrogram
Fluoroscopic VCUGs are most often performed to exclude VUR but can also evaluate voiding dysfunction, enuresis, urethral abnormalities, & predisposing causes of infections. The study requires bladder catheterization by experienced health care providers, education of parents & children, optimal environmental distractions, & age-appropriate communication.

The VCUG is performed after aseptic bladder catheterization (with urine specimen collection optional). Standard views include a scout image of the pelvis & kidney regions, an early filling image of the bladder to exclude intraluminal abnormality, oblique views of the fully distended bladder to detect ureterovesical junction abnormalities, voiding images of the urethra, postvoid images of the pelvis & kidney regions, & spot views of any reflux or other abnormality.

Tips to aid with patient cooperation include the following: Providing distractions during the exam (such as videos, music, & toys; a child life specialist can be invaluable for both the physician & patient), pouring warm water over the perineum or toes if the patient has difficulty voiding, running water in the sink to provide an audible cue, or continuing to fill the bladder to 2x the estimated capacity, causing overflow incontinence (though this is not recommended in high spinal cord injury patients or postsurgical bladders).

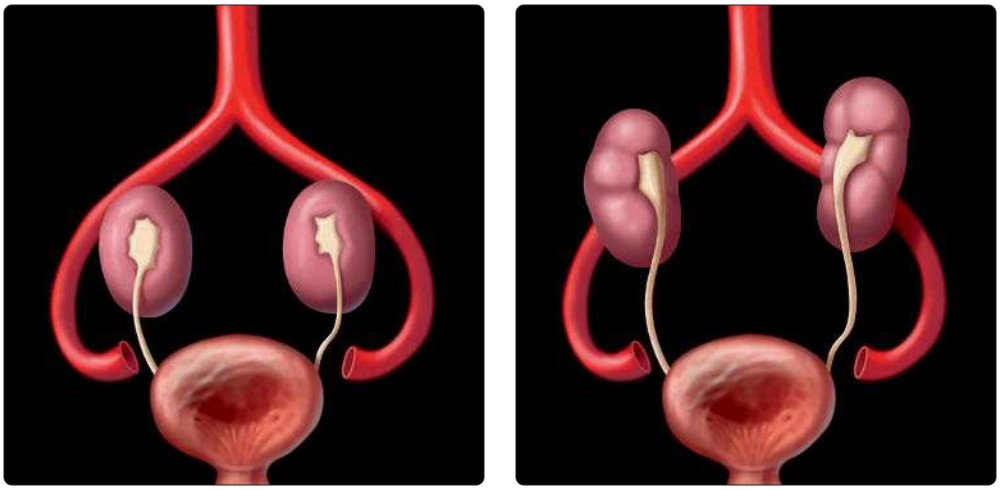
Nuclear Medicine
Nuclear imaging is 2nd only to ultrasound in terms of utility in working up pediatric genitourinary abnormalities. Nuclear imaging studies examine the physiologic function of the urinary tract, not just the anatomy. All nuclear exams require an injection or catheterization, making patient & parental acceptance < that for ultrasound.

Diuretic renal scans are widely used to monitor obstructive progression of hydronephrosis or surgical success.

Nuclear cystograms are widely used to follow VUR, though historically lower radiation exposures (compared to VCUG) are now less substantial due to current fluoroscopic equipment & techniques.

DMSA renal cortical scans are still more sensitive & specific than ultrasound for documenting pyelonephritis & renal scarring.

Glomerular filtration studies are indispensable in patients on chemotherapy & with chronic renal insufficiency.



Magnetic Resonance Imaging
MR provides exquisite detail of genitourinary anatomy, & MR urography is able to quantify renal uptake & excretion rates. In fact, MR urography has the capacity for complete anatomic & physiologic assessment during a single exam, which may be useful in complex disorders. MR studies are motion sensitive, often requiring sedation, & are more costly compared to the other modalities. Although contrast-enhanced studies or sedation require intravenous access, MR does not utilize ionizing radiation.

Computed Tomography
Due to the risks of ionizing radiation, CT use is limited in pediatrics, most often for trauma & stone disease.

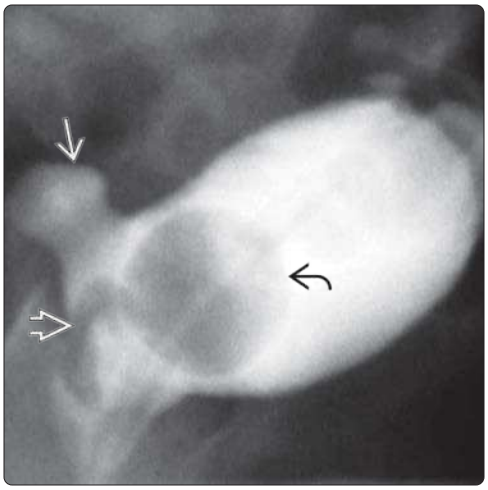
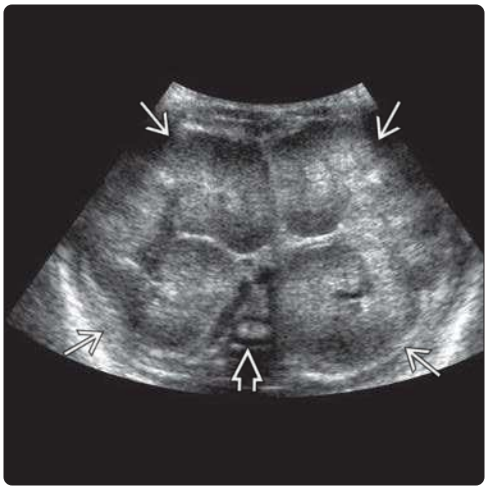
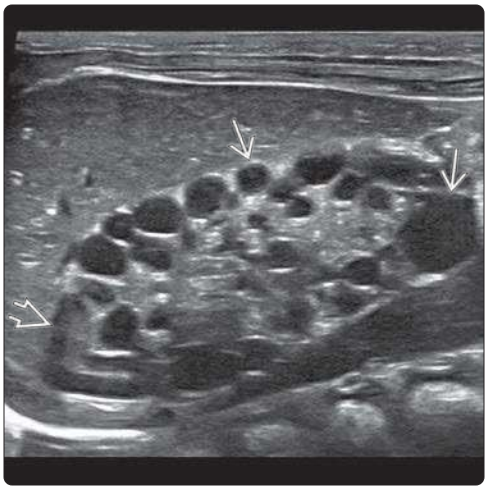
(Left) *Graphic shows early kidney formation as the ureteric bud extends from the primitive bladder/cloaca to the metanephric blastema & induces the formation of renal lobules. Note the low starting position of the kidneys, in front of the sacrum, & the anterior position of the renal pelves.* **(Right)** *Graphic shows early ascent of the kidneys up from the fetal pelvis with rotation of the renal pelves medially. The renal axis is still vertical, but this will become oblique along the psoas muscle with further ascent.*

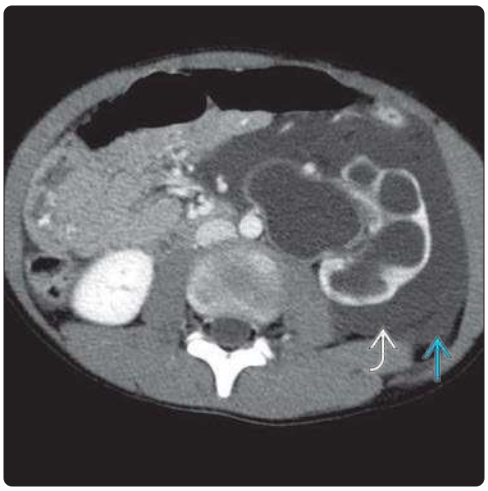


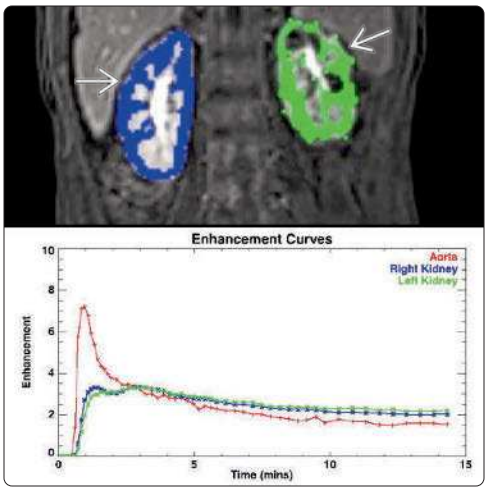
(Left) *Graphic from a lateral perspective of an early fetus shows the interrelated development of the genital & urinary organs. The mesonephric duct has differentiated into the ureteric bud & müllerian ducts budding from a common urogenital sinus in this female fetus. The hindgut lies posterior.* **(Right)** *Graphic depicts a later developmental stage with separate urinary & genital tracts, ascent & rotation of the kidneys, & development of the uterus & fallopian tubes. The colon is seen posteriorly.*



(Left) *Graphic illustrates the spectrum of renal ascent & fusion anomalies: (A) Pelvic kidney, (B) thoracic kidney, (C) crossed fused ectopia, & (D) horseshoe kidney. Note the aberrant blood supply to the ectopically located kidneys.* **(Right)** *Graphic shows typical normal anatomy with kidneys in the upper lumbar region & renal pelves directed medially with single ureters & single renal arteries.*







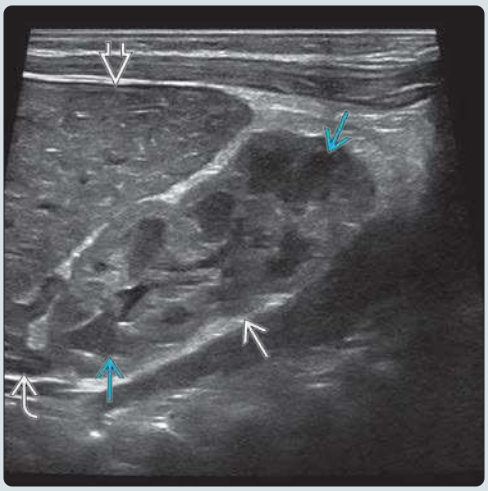
(Left) *Coronal MR urogram shows bilateral duplicated collecting systems & ureters in a teenager with flank pain & "giggle incontinence," likely related to the dilated right upper pole moiety inserting ectopically in the vagina (not shown).* **(Right)** *Voiding cystourethrogram shows an unusual case of a prolapsing ureterocele below the Foley catheter balloon. The ureterocele was causing intermittent bladder outlet obstruction. This patient also has a periureteral diverticulum.*

(Left) *Transverse anterior abdominal ultrasound in a newborn shows massively enlarged echogenic kidneys in a patient with autosomal recessive polycystic kidney disease. The spine is visible in the midline posteriorly.* **(Right)** *Longitudinal ultrasound in a newborn shows cysts of varying sizes completely replacing normal renal parenchyma in a case of multicystic dysplastic kidney. Note the normal newborn adrenal gland between kidney & liver.*

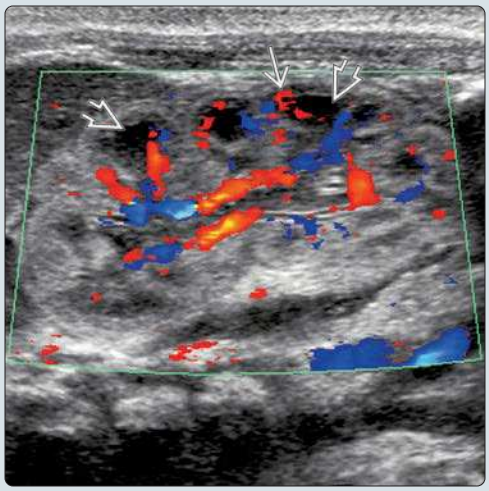
(Left) *Axial CECT shows marked hydronephrosis of the left kidney with a perinephric collection in a teenager following blunt abdominal trauma. The perinephric & paracolic gutter fluid are due to rupture of a previously undiagnosed ureteropelvic junction obstruction.* **(Right)** *Coronal contrast-enhanced MR urography illustrates the color-coded regions of interest for each kidney & the corresponding enhancement curves compared to the aorta in this normal study.*

Normal Neonatal Kidney

KEY FACTS

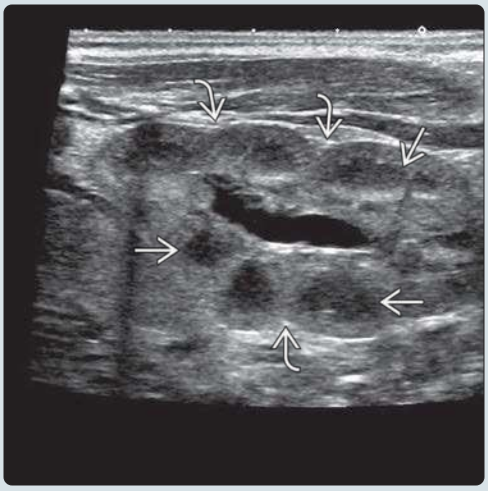


IMAGING



- Renal cortical echogenicity of normal term infant is often same as adjacent normal liver
  - Cortical echogenicity is ↑ in very premature infants compared to liver/spleen
- Medullary pyramids are large & hypoechoic
  - Renal cortex is thin relative to medullary pyramids
- Corticomedullary differentiation of infants & children is > adults
  - Partially due to differences in cellular composition
  - Partially due to ↑ resolution of higher frequency transducers penetrating less overlying tissue
- Central echo complex is less hyperechoic than adults
  - Less peripelvic fat in infants than adults
- Transient ↑ in echogenicity of pyramidal tips is commonly seen in neonates; etiology uncertain
  - Self-limited: Usually resolves within few days
- Fetal lobulation ("lobation") of kidneys persists into newborn period & sometimes into childhood/adulthood
  - Not to be mistaken for scarring
- Arterial resistive indices ↓ over 1st year of life

TOP DIFFERENTIAL DIAGNOSES



- Urinary tract obstruction
  - Pyramids do not interconnect as dilated calyces would
- Cystic renal disease
  - Normal pyramids line up around central echo complex
- Medical renal disease
  - Normal hyperechogenicity of neonatal renal cortex can mimic medical renal disease
  - Corticomedullary differentiation persists in normal kidneys of young children
- Renal scar
  - Fetal lobulation: Indentations between lobes/pyramids
  - Scars: Indentations within lobes/pyramids with dilated subtending calyces

(Left) *Longitudinal US of a newborn right kidney, adrenal gland, & liver shows echogenic cortex overlying each hypoechoic pyramid. The renal cortical echogenicity is similar to the adjacent liver.* **(Right)** *Longitudinal color Doppler US of a normal kidney in a 35-weeks-gestational age newborn shows normal branching vessels extending to the corticomedullary junctions, confirming that the hypoechoic foci are renal pyramids, not cysts or dilated calyces.*

(Left) *Longitudinal prone US of the left kidney with a high-frequency linear transducer shows relatively echogenic cortex & underlying hypoechoic pyramids. Cortical indentations are seen between each pyramid ("fetal lobation").* **(Right)** *Prone longitudinal US of a newborn kidney shows hyperechoic bands at the tips of several pyramids, related to solutes or proteins, a common transient phenomenon. This case also shows a junctional cortical defect between lobules of renal parenchyma.*

IMAGING

Ultrasonographic Findings

- Echogenicity of renal cortex in healthy term infant is often equal to adjacent normal liver
  - Renal cortex is less echogenic than liver in older children & adults
- Renal cortex echogenicity is typically ↑ in very premature infants compared to liver/spleen
  - May see striations in cortex & medulla
    - Due to vasculature in cortex & collecting ducts in medulla
- Corticomedullary differentiation of infants & children > adults
  - Partially due to differences in cellular composition of renal parenchyma
    - Greater density of glomeruli in renal cortex in neonates
  - Partially due to better resolution from higher frequency transducers with less tissue overlying kidney
  - If renal cortical echogenicity is much > adjacent liver, suspect underlying renal parenchymal disease
- Renal cortex is thin relative to medulla
- Medullary pyramids are large & hypoechoic
  - ↑ echogenicity at tips of pyramids is common in neonates, typically transient
    - Zone of maximal echogenicity at apex of pyramids with ↓ in echogenicity towards base of pyramids
      - Base of pyramids typically spared
    - Usually affects multiple pyramids but can range from 1 to all
    - Self-limited: Usually resolves within days as glomerular filtration rate ↑
      - May require 10 ≥ days, especially in premature infants
    - Historically attributed to transient precipitation of Tamm-Horsfall proteins
      - Proteins & other solutes passing out of developing nephrons likely contribute to ↑ echoes
      - Exacerbated by hypernatremic dehydration (similar to reversible appearance of hypernatremic dehydration with oliguria in older patients)
- Central echo complex is less hyperechoic than in adults
  - Less peripelvic fat in infants than in adults
- Neonatal kidneys are often more spherical than kidneys in older children & adults
- Fetal lobulation ("lobation") of kidneys persists into newborn period (& sometimes into childhood/adulthood)
  - Not to be mistaken for scarring
- Sulcation: Interrenicular junction line, Odonno sulcus, junctional parenchymal defect
  - Commonly occurring hyperechoic sulcus in upper pole; controversial etiology
  - Not to be mistaken for scarring
- Rapid growth of kidney in 1st few months
  - Mainly due to disproportionate growth of cortical renal tubules
- Doppler shows gradual ↓ of intraparenchymal renal arterial resistive indices (RI) during early life
  - RI in preterm neonate: Up to 0.9 is normal
  - RI < 1 year of age: 0.6-0.8 is normal
  - RI > 1 year of age: 0.5-0.7 is normal

Imaging Recommendations

- Best imaging tool
  - Ultrasound with high-frequency linear transducer
    - 14-6 MHz
  - Posterior or lateral decubitus approach

DIFFERENTIAL DIAGNOSIS

Urinary Tract Obstruction

- Normal hypoechoic pyramids in neonatal kidney can mimic dilated calyces (resulting in misinterpretation as hydronephrosis)
  - Pyramids are especially prominent due to hyperechoic cortex
- Normal pyramids line up around central echo complex
  - Pyramids do not interconnect as dilated calyces would
- Position of arcuate artery at corticomedullary junction can help identify hypoechoic structure as pyramid

Cystic Renal Disease

- Normal hypoechoic pyramids in neonatal kidney can mimic cysts
- Normal pyramids line up around central echo complex
- Position of arcuate artery at corticomedullary junction can help identify hypoechoic structure as pyramid

Medical Renal Disease

- Normal hyperechogenicity of neonatal renal cortex can mimic medical renal disease
  - Cortical echogenicity in newborn is same as or slightly > liver or spleen
- If echogenicity is much > liver/spleen, consider other causes
  - Look for loss of corticomedullary differentiation

Renal Scar

- Normal fetal lobulation/"lobation" of neonatal kidney with relatively thin cortex can mimic scarring
- Fetal lobulation: Indentations between lobes/pyramids
- Scars: Indentations within lobes/pyramids, often with dilated subtending calyces

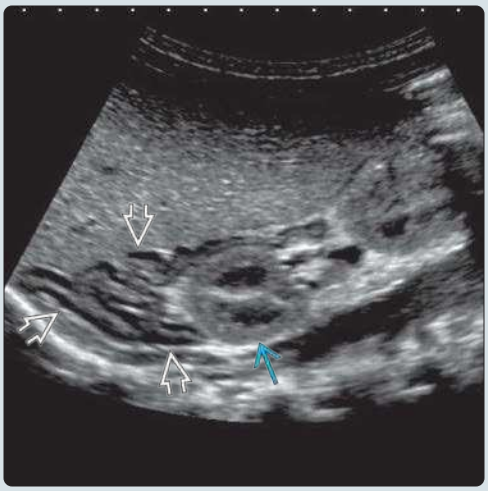
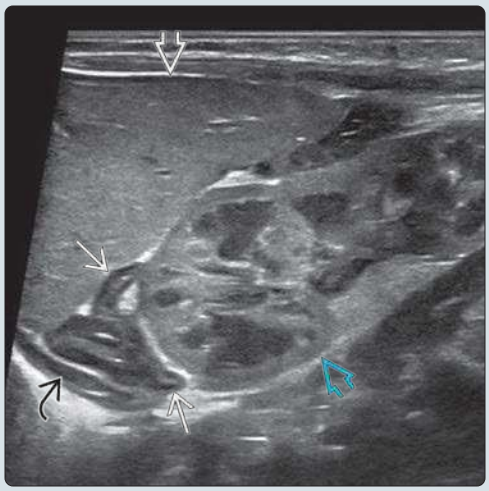
Normal Neonatal Adrenal Gland

KEY FACTS

IMAGING

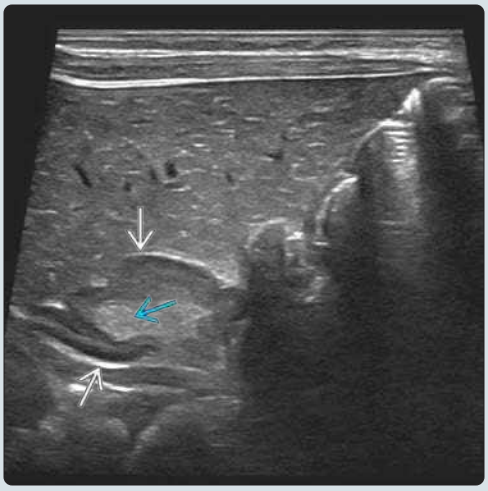


- Ultrasound nicely shows newborn adrenal gland
  - Doppler is useful in setting of neonatal adrenal lesions
- Normal outer hypoechoic fetal adrenal cortex & inner echogenic adrenal medulla have layered arrangement with mildly undulating margins
- Shape of newborn adrenal varies: Described as capital letters A, Y, V, X, or Z, or λ
- Flat shape when ipsilateral kidney is absent/ectopic
  - Lying down adrenal sign
- Appearance evolves during infancy
  - Newborn adrenal gland is quite large (5g), almost 2x weight of adult adrenal gland
  - Mainly due to prominent fetal cortex, which functions in utero & grows until term
    - Adrenal cortex is initially much thicker than medulla; overall contour convex outward
  - Fetal cortex starts to involute after delivery; gradually ↓ until almost inapparent by 6 months of age
    - After 2-3 months, cortex & medulla are equivalent in thickness; contour starts to flatten

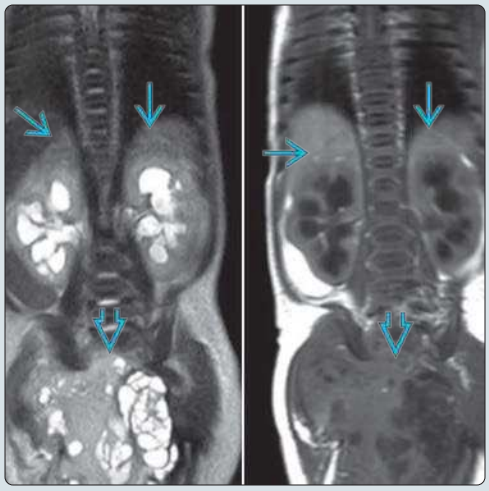


TOP DIFFERENTIAL DIAGNOSES

- Neonatal adrenal hemorrhage
- Congenital adrenal hyperplasia
- Neuroblastoma
- Extralobar bronchopulmonary sequestration
- Adrenal cyst
- Adrenal insufficiency
- Wolman disease



CLINICAL ISSUES



- Prominent newborn adrenal gland is typically noted incidentally on spinal or renal ultrasound
- Awareness of normal newborn adrenal appearance avoids inappropriate work-up

(Left) *Longitudinal ultrasound of the right upper quadrant shows the folded, alternating layers of a normal newborn adrenal gland draped over the right kidney. The outer fetal adrenal cortex is hypoechoic compared with the inner echogenic medulla.* **(Right)** *Longitudinal ultrasound of the left upper quadrant shows a coiled snake shape of the normal newborn adrenal gland situated between the spleen, left kidney, & diaphragmatic crus.*

(Left) *Transverse ultrasound of the right suprarenal region shows echogenic fat between the limbs of the normal newborn adrenal gland.* **(Right)** *Coronal SSFSE T2 (left) & T1 (right) MR images in a newborn with a sacrococcygeal teratoma show an undulating trilaminar appearance of normal neonatal adrenal glands. Note the bilateral hydronephrosis from obstructions of the distal ureters by the teratoma.*

TERMINOLOGY

Synonyms

- Suprarenal gland

Definitions

- Part of hypothalamic-pituitary axis that regulates many body functions & responds to stress
- **Adrenal cortex**: Largest part of adrenal gland; 3 layers produce different hormones (described below from superficial to deep)
  - **Zona glomerulosa**: Aldosterone (mineralocorticoid)
    - Retains sodium & wastes potassium; regulates fluid & electrolyte balance, helps maintain BP
  - **Zona fasciculata**: Cortisol (glucocorticoid)
    - Regulates metabolism of glucose, protein, & fat; responds to stress by ↑ blood glucose levels & cardiac output
  - **Zona reticularis**: Dehydroepiandrosterone
    - Sex hormone that works much like testosterone
- **Adrenal medulla**: Makes & stores epinephrine, norepinephrine

IMAGING

General Features

- Best diagnostic clue
  - Layered arrangement of outer hypoechoic fetal cortex & central echogenic medulla
  - Shape described as capital letters A, Y, V, X, or Z, or λ
  - Sandwich or flat shape when ipsilateral kidney is absent/ectopic
- Location
  - Cephalad to kidney
- Size
  - 0.9- to 3.6-cm length, 0.2- to 0.3-cm thick
- Morphology
  - Newborn adrenal cortex is much thicker than medulla; overall contour convex outward
    - Margins are mildly undulating throughout
    - Small (< 5-mm) round focus of accessory adrenal tissue (with similar layered echogenicity) is described in < 6% of neonates; typically not visible on follow-up
  - After 2-3 months, cortex & medulla are equivalent in thickness; contour starts to flatten
  - ~ 6 months, corticomedullary differentiation is lost on imaging; contours flatten
  - After 1 year, resembles adult gland with thin limbs & flat or concave margins

Imaging Recommendations

- Best imaging tool
  - Ultrasound nicely shows newborn adrenal gland
- Protocol advice
  - Doppler is helpful in evaluating adrenal lesions

DIFFERENTIAL DIAGNOSIS

Neonatal Adrenal Hemorrhage

- Perinatal bleeding into normal gland, leading to avascular mass distorting adrenal tissue; gradually resolves
- Associated with perinatal stress: Asphyxia, sepsis, labile blood pressure, birth trauma, coagulopathy
- Hemorrhage is bilateral in 10% → ↑ risk of adrenal insufficiency

Congenital Adrenal Hyperplasia

- Enlarged, bilateral adrenal glands with redundant folds of cortex & medulla resembling sulci & gyri of brain (cerebriform appearance)
- Length > 2 cm & width > 4 mm suggests diagnosis (gland weight may reach 15g)
- Due to deficiency in 1 of 5 enzymes necessary to produce hormones cortisol & aldosterone, leading to overproduction of androgen
  - Females manifest with ambiguous genitalia; males manifest with salt-wasting crisis

Neuroblastoma

- Most common malignancy in infancy
- Congenital/neonatal neuroblastoma tends to have good prognosis, even with disseminated disease (stage 4S/MS)
  - May spontaneously involute
- Neonatal neuroblastomas can be more cystic than tumors in older children

Extralobar Bronchopulmonary Sequestration

- Solid or mixed cystic & solid mass; can be in or below diaphragm above kidney

Adrenal Cyst

- Sequelae of prior hemorrhage or in association with Beckwith-Wiedemann syndrome

Adrenal Insufficiency

- Congenital aplasia is very rare; found in 10% with unilateral renal agenesis

Wolman Disease

- Rare autosomal recessive lipid storage disorder
- Deficiency of lysosomal acid lipase → triglycerides & cholesterol esters build up in liver, spleen, adrenal glands
- Markedly enlarged adrenals with dystrophic Ca^{2+}

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Prominent newborn adrenal gland is usually noted incidentally on renal or spine ultrasound
  - Awareness of normal newborn adrenal appearance avoids inappropriate work-up

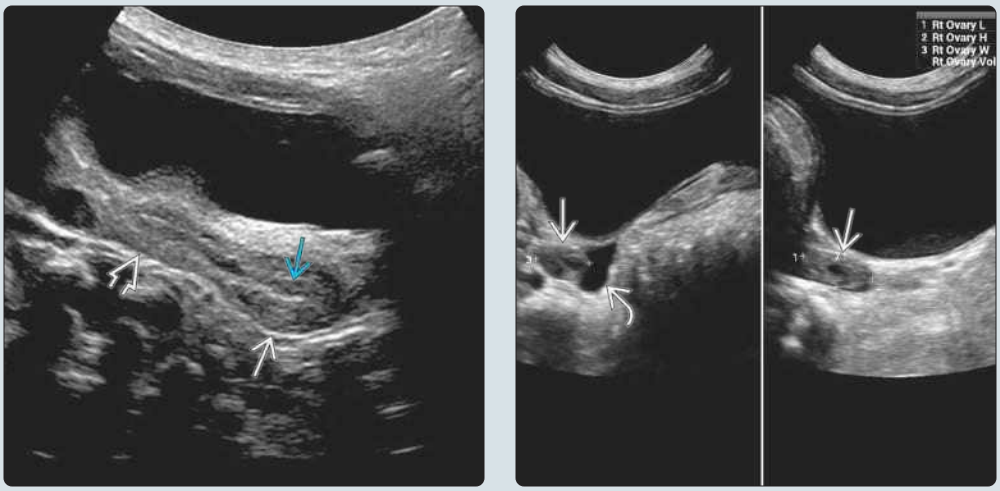
Normal Prepubertal Uterus and Ovaries

KEY FACTS

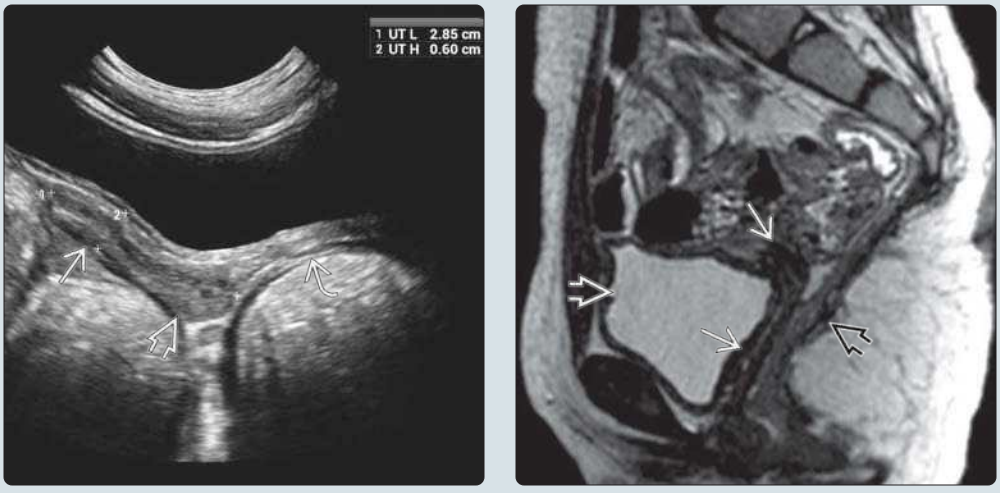
TERMINOLOGY

- Thelarche: Onset & progress of breast development
- Adrenarche: Onset & progress of pubic/axillary hair development
- Menarche: 1st episode of vaginal bleeding



IMAGING

- Uterus & cervix
  - Neonatal
    - Cervix larger than uterus, ~ 2:1 ratio
  - Prepubertal
    - Cervix & uterus are equivalent
  - Pubertal
    - Uterus enlarges > cervix, 2:1 or 3:1 ratio
- Ovaries
  - Volumes
    - Neonatal ovarian volume is generally < 1 mL
    - Prepubertal up to 3 mL (age 1-6 years)
    - Pubertal 3-20 mL
  - Morphology
    - Cysts can be seen in any age
    - If 3-5 cm, consider repeat scan in 6-8 weeks
    - Cysts can predispose to ovarian torsion
- **Best imaging tool**
  - Ultrasound screening
  - MR in complex cases



TOP DIFFERENTIAL DIAGNOSES

- Ambiguous genitalia
- Amenorrhea
  - Turner syndrome
  - Müllerian anomalies
  - Hypothalamic pituitary abnormalities
  - Constitutional/familial/other
- Prepubertal vaginal bleeding
  - Foreign body/abuse
- Ectopic ovary

(Left) *Midline longitudinal pelvic ultrasound in a newborn girl shows a relatively large cervix compared to the uterus due to maternal hormones. A thin ellipse of fluid is present in the lower uterine segment/upper cervical os.* **(Right)** *Transverse & longitudinal ultrasound just right of midline in a 2-year-old girl shows small follicles in the right ovary. The ovarian volume measures ~ 1 mL. A minimal amount of physiologic free fluid is present next to the ovary.*

(Left) *Midline longitudinal ultrasound through a distended urinary bladder in a 2-year-old girl shows a thin, tubular cervix & uterus above a collapsed vaginal vault. Note the lack of fundal broadening in this prepubertal girl.* **(Right)** *Midline sagittal T2 MR in a 6-year-old girl being followed for a sacrococcygeal tumor shows a typical tubular appearance of the vaginal vault, cervix, & uterus (all blending together) between the bladder & collapsed rectosigmoid colon.*

TERMINOLOGY

Definitions

- Varied appearance of uterus & ovaries with age
  - Prominence in newborns due to maternal hormones
  - Small, quiescent stage in ages 1-8 years
  - Growth with hormonal surge during puberty
- Thelarche: Onset & progress of breast development
- Adrenarche: Onset & progress of pubic & axillary hair development
- Menarche: 1st episode of vaginal bleeding

IMAGING

General Features

- Best diagnostic clue
  - Female genital organs are best imaged with ultrasound or MR
- Size
  - Uterus & cervix
    - Neonatal
      - Cervix larger than uterus, ~ 2:1 ratio
      - Uterus ~ 3.5 cm long x 1.5 cm thick
    - Prepubertal
      - Cervix & uterus are equivalent in size
      - Uterus ~ 2.5-4 cm long x 1 cm thick
    - Pubertal
      - Uterus enlarges > cervix, 2:1 or 3:1 ratio
      - ~ 5-8 cm long x 1.5 cm thick x 3 cm transverse
  - Ovaries
    - Neonatal volume generally < 1 mL
    - Prepubertal up to 3 mL (age 1-6 years)
    - Pubertal 3-20 mL
- Morphology
  - Uterus
    - Neonatal: Endometrial echoes visible, fluid possible
    - Prepubertal: Very thin endometrial line
    - Pubertal: Measurable endometrial stripe
  - Ovaries
    - Ovarian cysts can be seen at any age
    - If 3-5 cm, consider 4- to 6-week follow-up
    - Cysts can predispose to torsion

Ultrasonographic Findings

- Primary diagnostic modality for uterus & ovaries
- Bladder sonographic window may be problematic for patients not yet toilet trained
  - Repeat scanning often yields diagnostic exam
  - Alternatively, bladder filling by catheter

MR Findings

- Useful in complex anatomy or when ultrasound is indeterminate
- Multiplanar & 3D images are possible

CT Findings

- Genital findings may be seen incidentally in trauma/pain evaluation
- May be used in staging & follow-up of tumors

Imaging Recommendations

- Best imaging tool
  - Ultrasound; MR for complex cases
- Protocol advice
  - Endovaginal scanning is avoided until adolescents are sexually active or using tampons (postpubertal patients)
  - Transabdominal
    - Adequate hydration prior to exam as well-distended urinary bladder is needed for sonographic window
      - Use gentle transducer pressure on bladder to avoid inducing micturition
    - Alternatively, use Foley catheter to fill bladder
  - Limited need for Doppler

DIFFERENTIAL DIAGNOSIS

Ambiguous Genitalia

- Pelvic ultrasound in neonatal period searching for gonads: Include scrotum/labia
  - Female pseudohermaphroditism due to congenital adrenal hyperplasia
  - True hermaphroditism

Amenorrhea

- Turner syndrome
  - Typical prepubertal uterus & streak ovaries
  - 5-15% have normal pubertal onset: Mosaicism
- Müllerian anomalies
  - Müllerian agenesis
  - Obstructive müllerian anomalies
  - Nonobstructive müllerian anomalies
- Hypothalamic pituitary abnormalities
- Constitutional/familial/other

Prepubertal Vaginal Bleeding

- Foreign body/abuse
- Vaginal rhabdomyosarcoma
- Precocious puberty

Ectopic Ovary

- Canal of Nuck hernia containing ovary

Ureteropelvic Junction Obstruction

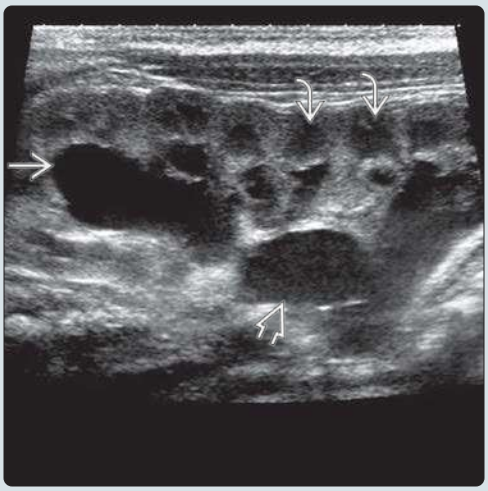
KEY FACTS

TERMINOLOGY

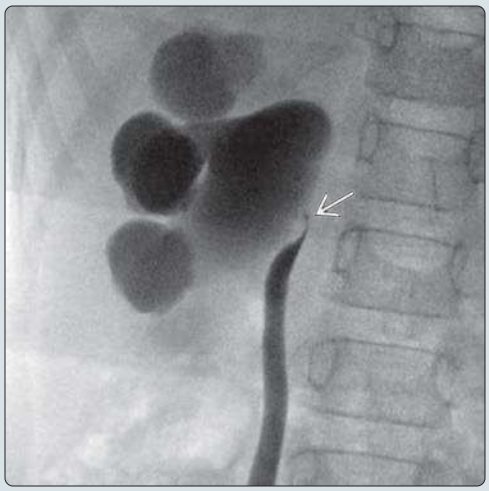
- Ureteropelvic junction (UPJ) obstruction is most common form of urinary tract obstruction in children

IMAGING

- Marked pelvocaliectasis that ends abruptly at UPJ with normal-caliber ureter downstream
- Dilated calyces are relatively uniform in size & distribution; all connect centrally to disproportionately dilated renal pelvis
- Thinned but otherwise intact renal parenchyma
- Doppler US shows ↑ renal resistive indices with obstruction
- Severity of delayed nephrogram, excretion, & collecting system drainage (on IVP, CECT, MRU, or nuclear renal scan) depends on degree of obstruction
- Contrast entering dilated collecting system (by excretion, retrograde injection, or vesicoureteral reflux during VCUG) may be very diluted due to mixing with retained urine
- ± crossing vessel at obstruction site on CECT, MRU, or US
- Nuclear medicine renal scan is well established for initial assessment & follow-up of renal function & obstruction
- MR urography may provide optimal combination of anatomic & physiologic assessment

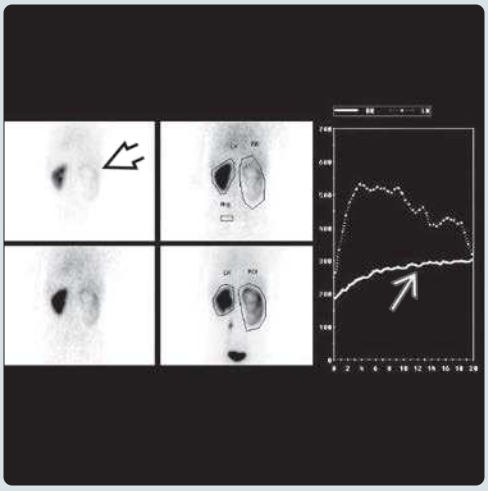


PATHOLOGY

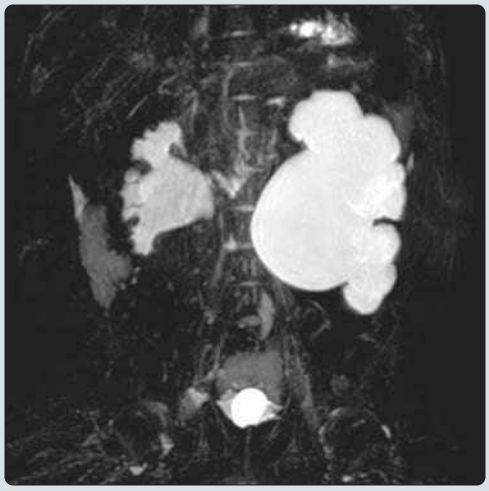


- Theoretical etiology of obstruction at UPJ
  - Abnormal smooth muscle arrangement impairs distensibility; abnormal innervation of proximal ureter (Hirschsprung equivalent)
  - Crossing vessel or fibrous scar at UPJ
- UPJ obstruction is associated with contralateral multicystic dysplastic kidney (MCDK)

CLINICAL ISSUES



- May be diagnosed antenatally or in infancy/childhood with urinary tract infection, intermittent abdominal/flank pain, vomiting, or hematuria
- Treatment: Pyeloplasty, ureteroureterostomy, or endoureteral balloon plasty/stenting (infants)



(Left) *Longitudinal US of an infant with prenatal hydronephrosis shows dilated central & peripheral calyces & a large renal pelvis (incompletely visualized). No ureteral dilation was seen, & a ureteropelvic junction (UPJ) obstruction was subsequently diagnosed. Note that hypoechoic renal pyramids are normal in infants.* **(Right)** *Frontal fluoroscopic image during cystoscopy & retrograde ureterography shows a dilated right renal collecting system & abrupt caliber change at the UPJ.*

(Left) *Posterior Tc-99m MAG3 diuretic renal scintigraphy shows minimal uptake in a dilated right kidney with central photopenia. The time activity curve for the right kidney shows progressive accumulation of counts with no washout during the exam, typical of a UPJ obstruction.* **(Right)** *Coronal MIP from heavily T2-weighted MR urography in a 2-month-old shows left worse than right collecting system dilation in a typical configuration of UPJ obstructions (with no ureteral dilation seen).*

TERMINOLOGY

Synonyms

- Pelviureteric obstruction

Definitions

- Ureteropelvic junction (UPJ) obstruction: Variable degree of blockage to urine flow at level of UPJ
- Most common urinary tract obstruction in pediatrics
- May be diagnosed antenatally with sonography or present in infancy or later childhood with urinary tract infection, intermittent abdominal pain, vomiting, &/or hematuria
  - Occasionally found incidentally during trauma work-up

IMAGING

General Features

- Best diagnostic clue
  - Marked pelvocaliectasis that ends abruptly at UPJ with normal-caliber ureter
  - Disproportionate enlargement of renal pelvis
  - Severity of delayed nephrogram, excretion, & collecting system drainage depends on degree of obstruction
- Morphology
  - UPJ obstruction has been likened to Hirschsprung disease with focal transition zone & aperistaltic segment
  - Obstruction may be extrinsic rather than intrinsic
    - Crossing vessel at UPJ in 25% of infants

Radiographic Findings

- Radiography
  - May see mass effect from enlarged hydronephrotic kidney; ± scoliosis/splinting with pain
- IVP
  - Delayed nephrogram
  - Delayed contrast excretion into dilated collecting system
    - Contrast gradually opacifies distended renal pelvis, which tapers abruptly
    - Contrast may be very diluted due to mixing with retained urine
  - Delayed ureteral visualization

Ultrasonographic Findings

- Grayscale ultrasound
  - Moderate to severe pelvocaliectasis without hydroureter
  - Dilated calyces are relatively uniform in size & distribution; all connect centrally to disproportionately dilated renal pelvis
  - Abrupt tapering of renal pelvis at UPJ
  - Thinned but otherwise intact renal parenchyma
- Pulsed Doppler
  - ↑ resistive indices (RIs) with obstruction
    - RIs may correlate with degree of obstruction (when contralateral kidney is normal & can serve as internal standard)
      - As normal RIs change with age, strict cutoff value for obstruction is not applicable in pediatrics
- Color Doppler
  - Search for crossing aberrant vessel at site of obstruction
  - Ureteral jets (in urinary bladder) are useful in excluding complete obstruction
- Shear wave elastography
  - May help discriminate degree of obstruction

Fluoroscopic Findings

- Voiding cystourethrogram
  - With ≥ grade 2 vesicoureteral reflux (VUR), contrast may be seen entering disproportionately dilated renal pelvis (relative to ureter)
    - Chronically dilated ureter may kink at UPJ, creating additional etiology for pelvocaliectasis
    - Look for delayed drainage of high-grade VUR
  - May see contralateral VUR
- Intraoperative retrograde ureterogram is variably used to confirm focal narrowing, identify crossing vessels (by negative impression), & search for intraluminal polyp or stone
  - Shows abrupt transition of normal-caliber ureter to dilated renal pelvis
  - Contrast entering renal pelvis becomes very diluted by retained volume of urine

CT Findings

- CECT
  - Delayed nephrogram in enlarged kidney
  - Marked renal pelvic > calyceal dilation with normal or nonvisualized ureter
  - May demonstrate crossing vessel at UPJ
  - Delayed contrast excretion into collecting system

MR Findings

- MR urography ± contrast is particularly helpful in visualizing crossing vessels
- Drainage curves & differential function can be used to guide timing of surgery

Nuclear Medicine Findings

- Renal scans show delayed uptake, excretion, & drainage of radiotracer
  - Early central photopenia of affected kidney
  - Gradual & progressive accumulation of radiotracer replacing central photopenia
  - Little to no ureteral activity; variable change with diuretic administration
- Time activity curve provides quantified assessment of radiotracer distribution throughout scan
  - Time to half of peak activity (T½) can measure severity of obstruction
    - T½ < 10 min is normal
    - T½ > 20 min is obstructed
    - T½ between 10-20 minutes is indeterminate
- Nuclear studies are used for initial assessment & follow-up of function & obstruction
  - Should be performed in standardized fashion with adequate hydration, bladder drainage, & diuretic administration

Imaging Recommendations

- Best imaging tool
  - Sonography is usually performed 1st
  - Nuclear renal scan is then used to grade degree of obstruction & determine if surgical intervention or percutaneous drainage is required
  - MR urography may be viable single test alternative, optimizing anatomic & physiologic assessment

- Protocol advice
  - Obstruction is often partial & can ↑ or ↓ over time
  - Affected children typically undergo serial exams every 6-12 months (if they remain asymptomatic) to determine when to intervene

DIFFERENTIAL DIAGNOSIS

Multicystic Dysplastic Kidney

- No discernible normal renal parenchyma
- Cysts do not interconnect
- Largest cyst is not usually located centrally

Ureteral Fibroepithelial Polyp

- Found in 5% of UPJ obstructions
- Increasing awareness with pediatric ureteroscopy

Megacalycosis or Congenital Megacalyces

- Idiopathic dilation & ↑ number of calyces without enlarged renal pelvis
- Drainage in megacalycosis is normal or minimally delayed
- Often presents with hematuria after minor trauma

Hydronephrosis of Other Etiologies

- VUR
- Urinary tract calculus
- Ureterovesical junction obstruction
- Ureterocele

Megaureter

- Dilated ureter with narrowed distal aperistaltic segment
- Obstructed or nonobstructed, refluxing or nonrefluxing

PATHOLOGY

General Features

- Etiology
  - At surgical resection, massively dilated pelvis is often too distorted to confirm any single theory
  - Theoretical etiology of obstruction at UPJ
    - Abnormal smooth muscle impairs distensibility
    - Abnormal innervation of proximal ureter (Hirschsprung equivalent)
    - Crossing vessel or fibrous scar at UPJ
- Associated abnormalities
  - UPJ obstruction is associated with contralateral multicystic dysplastic kidney (MCDK)
    - Requires prompt intervention since MCDK is nonfunctional & UPJ may compromise remaining renal function

Staging, Grading, & Classification

- Anteroposterior pelvic diameter > 10 mm in 3rd-trimester fetus or newborn suggests obstruction

Microscopic Features

- Obstructive nephropathy leads to tubulointerstitial fibrosis & loss of renal function
- Nerve fibers are depleted in muscular layer in ureteric walls
- Denervation results in dysfunction/atrophy of muscle fibers & ↑ collagen fibers within muscle layers
- Deficiency of Cajal cells (pacemaker cells in smooth muscles), which enhance ureteral peristalsis
- Abnormal accumulations of intercellular & interstitial collagen are also seen pathologically

CLINICAL ISSUES

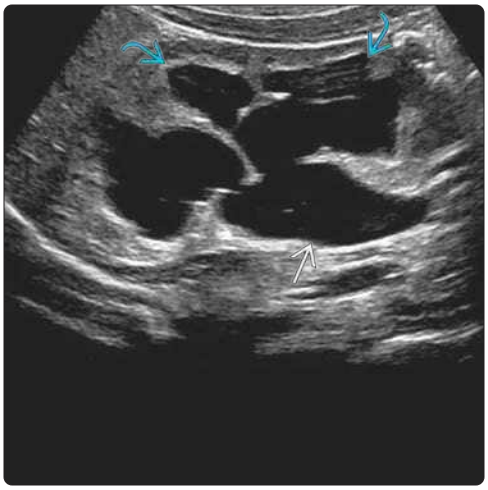
Presentation

- Most common signs/symptoms
  - Antenatally detected on fetal sonogram or MR
- Other signs/symptoms
  - Infants & children: Urinary tract infection, intermittent abdominal pain, flank pain, or hematuria
  - In older children who present with symptomatic UPJ obstruction, crossing vessel is causative in ~ 50%
  - Dietl's crisis: Episodic abdominal pain & UPJ obstruction

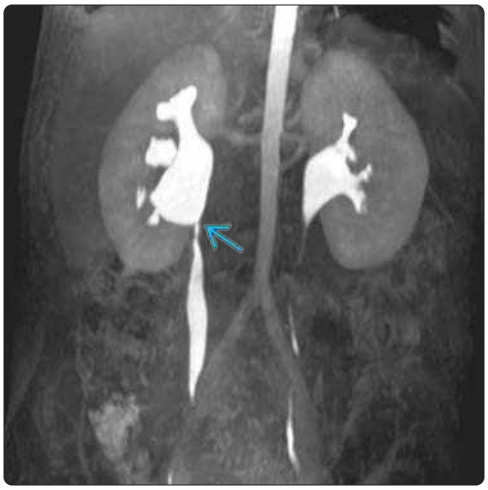
Demographics

- Males are affected 2-4x more than females
- L > R; bilateral in 10-15%
- Incidence of 1 in 75-1500 births

Natural History & Prognosis



- May improve or deteriorate spontaneously
- Prognosis is excellent if renal function has not been compromised by longstanding, high-grade obstruction
- Following successful surgery, pelvocaliectasis persists for years on sonography
- Appropriate renal growth & adequate drainage on nuclear scans help quantify surgical success



Treatment

- Pyeloplasty (open or laparoscopic surgery)
  - Tapered, dismembered pyeloplasty has been classic surgery for UPJ obstruction
  - Narrowed segment is resected, or crossing vessel is rerouted
  - Ureteral stents are often left in place (crossing surgical anastomosis) for several weeks postop
  - Open or laparoscopic procedures are preferable when crossing vessels or aberrant vessels are recognized
- Endoscopic incision (a.k.a. endopyelotomy)
- Endopyeloplasty (horizontal percutaneous suturing of conventional longitudinal endopyelotomy incision)
- Ureterocalicostomy, which is reconstructive option in rare patient with surgically failed UPJ or difficult anatomy due to fibrosis or other concurrent problems
- Endoureteral balloon plasty/stenting
- Percutaneous drainage, temporizing, if infected

(Left) *Longitudinal US in a 10-day-old shows moderate peripheral & central caliectasis with an enlarged renal pelvis that rapidly tapers without hydroureter.* **(Right)** *Coronal delayed postcontrast MRU MIP in the same patient shows focal narrowing at the UPJ but without a crossing vessel identified. This case was followed with imaging to monitor for progression vs. resolution.*

(Left) *Coronal T2 FS MR shows marked right pelvocaliectasis in this teenager with intermittent flank pain caused by a UPJ obstruction. A crossing vessel was not identified.* **(Right)** *Axial CECT shows marked hydronephrosis of the left kidney with an enlarged renal pelvis, cortical thinning, & marked perinephric fluid in a 12-year-old involved in a motor vehicle accident. This left UPJ obstruction ruptured in the collision.*

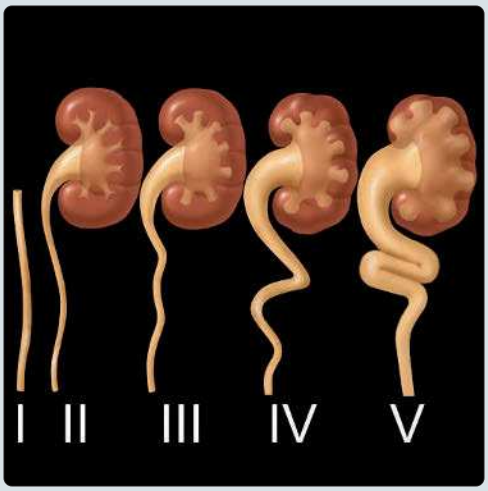
(Left) *Coronal CECT shows a markedly hydronephrotic right kidney with delayed enhancement. On adjacent images (not shown), the renal pelvis appeared dilated, but no ureter was visualized, consistent with UPJ obstruction.* **(Right)** *Coronal delayed postcontrast MRU MIP in a 14-year-old with a horseshoe kidney & left UPJ obstruction shows marked dilation of partially contrast-filled calyces & no visualization of a left ureter.*

Vesicoureteral Reflux

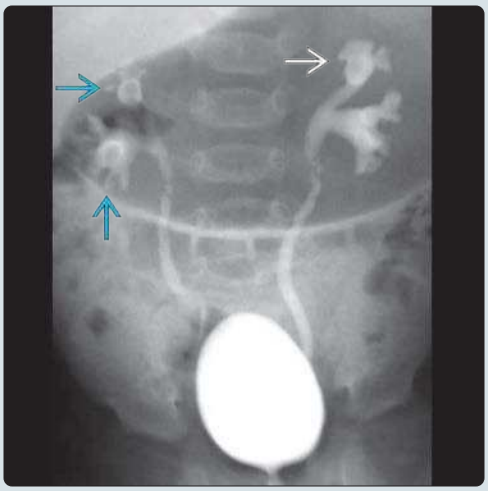
KEY FACTS

TERMINOLOGY

- Retrograde urine flow from bladder toward kidney(s)

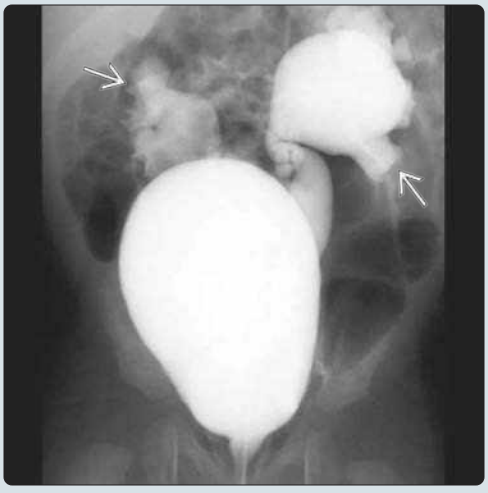


IMAGING

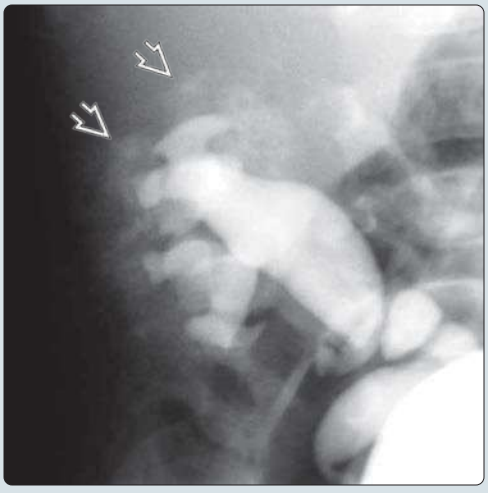


- International Reflux Study Committee grading system of vesicoureteral reflux (VUR)
  - I: Reflux into ureter but not reaching renal pelvis
  - II: Reflux reaching pelvis without blunting of calyces
  - III: Mild calyceal blunting
  - IV: Progressive calyceal & ureteral dilation
  - V: Very dilated & tortuous collecting system
  - ± intrarenal reflux as modifier to grade
- Voiding cystourethrogram has been preferred when anatomic detail of upper tracts/urethra is needed
- Nuclear cystogram has been preferred when anatomy is known (e.g., renal ultrasound is normal) &/or for follow-up studies
- Use of renal US alone for screening is controversial: Variable sensitivity & specificity for scar as compared to DMSA
- US contrast agent can be instilled into bladder for sonographic voiding cystogram

CLINICAL ISSUES



- Present in up to 2% of general population
- VUR is seen in 25-40% of children with acute pyelonephritis
- VUR is seen in 5-50% of asymptomatic siblings of children with documented reflux
- 80% outgrow VUR before puberty
- ↑ grade or longstanding VUR, more numerous urinary tract infections, & subsequent renal scarring → ↑ incidence of renal insufficiency, hypertension, & end-stage renal disease
- Treatment options
  - Prophylactic antibiotic therapy (medical management)
  - Ureteral reimplantation surgery (surgical management)
  - Endoscopic periureteral injections (minimally invasive endoscopic management)



(Left) *Graphic of the International Reflux Study Committee grading system is shown. Note the progressive level of reflux, dilation, calyceal blunting, & ureteral tortuosity from grade I on the left to grade V on the right.* **(Right)** *Voiding cystourethrogram (VCUG) in an infant shows bilateral vesicoureteral reflux (VUR). The calyces are sharp ⇨ on the right (grade II). On the left, the calyces are slightly blunted ➡, & the ureter is mildly dilated & tortuous, making this grade III VUR.*

(Left) *VCUG shows large-volume VUR into both kidneys, which have very dilated collecting systems ➡. Grade V reflux was diagnosed in this infant with prenatal hydronephrosis.* **(Right)** *Frontal VCUG shows high-grade VUR into the right kidney with a dilated tortuous ureter, blunted calyces, & intrarenal reflux into the tubules ➡. These findings constitute grade V VUR with intrarenal reflux. Intrarenal reflux is associated with cortical scarring.*

TERMINOLOGY

Abbreviations

- Vesicoureteral reflux (VUR)

Definitions

- Retrograde urine flow from bladder toward kidney(s)

IMAGING

General Features

- Best diagnostic clue
  - Contrast instilled into urinary bladder opacifies at least 1 ureter
  - Contrast may reach intrarenal collecting system
  - Findings are often seen only transiently

Fluoroscopic Findings

- Voiding cystourethrogram
  - Requires bladder catheterization for contrast installation
  - Preliminary scout film can be useful, especially when there has been prior surgery or urolithiasis
  - Early filling image of bladder is best to show intraluminal abnormalities: Ureterocele, polyp, mass
  - Contrast seen in ureter &/or renal collecting system confirms VUR
    - Estimated bladder volume/timing of VUR should be reported
  - Oblique views of distended bladder are helpful to show periureteral diverticula & ureteric insertion site
  - Ectopic ureters that insert below bladder neck only reflux during voiding (if they do drain to bladder)
    - May not visualize ectopic ureters unless they are inadvertently catheterized
    - In such cases, separate catheter should also be passed into urinary bladder to study other ureters for VUR
  - Voiding images of urethra are performed to exclude distal pathology, which may contribute to back pressure
    - Obtain voiding images without catheter in place
  - In cases of high-grade VUR, delayed upright image is used to assess drainage from upper tract & exclude concomitant ureteropelvic junction or ureterovesical junction obstruction
    - Note that contrast refluxed into obstructed, dilated system may become very diluted
- PIC during cystoscopy [positional instillation of contrast at ureteral orifice (PIC) during cystoscopy]
  - Higher positive results in laterally positioned & patulous ureteral orifices

Ultrasonographic Findings

- Varying degrees of renal collecting system &/or ureteral dilation ± urothelial thickening
  - Normal US without dilation does not exclude VUR, even high grade
- Look for signs of scarring: Globally small kidney or polar foci of cortical thinning subtended by dilated calyces
- Contrast-enhanced retrograde urosonography (CEUS cystogram)
  - US contrast agent can be instilled into bladder for sonographic cystogram
  - Bladder catheterization is still required; no ionizing radiation used
  - Urethral evaluation is possible with US probe on perineum
- Doppler optimized for low velocity (SMI/microvascular imaging) has been used to show retrograde flow in ureter without contrast or bladder catheterization

Nuclear Medicine Findings

- Nuclear cystogram
  - Study is performed with posterior gamma camera
  - Tc-99m pertechnetate is instilled into bladder via catheter
  - Imaging is performed continuously throughout bladder filling & voiding
  - With VUR, radiotracer activity extends cephalad from bladder in varying amounts
  - Grade I VUR is harder to see on nuclear cystogram due to bladder activity
  - Nuclear cystogram gives no information about urethral abnormalities
- Renal cortical scan
  - Study is performed with posterior pinhole imaging
  - Radiotracer: Tc-99m DMSA or MAG3
  - Photopenic renal cortical foci due to acute pyelonephritis or chronic scarring

Imaging Recommendations

- Best imaging tool
  - Controversial
  - American Academy of Pediatrics & National Institute for Health & Care Excellence (United Kingdom) guidelines advocate less imaging than historically performed
  - Traditionally
    - Voiding cystourethrogram (VCUG) is preferred when anatomic detail of upper tracts & urethra is needed
    - Nuclear cystogram is preferred when anatomy is known &/or for follow-up studies
    - CEUS cystography requires proficiency with exam & ultrasound contrast agents
  - Historic "bottom-up" approach to urinary tract infection (UTI) work-up
    - VCUG + renal US; DMSA if 1st-line studies are abnormal or with febrile UTI
  - Current "top-down" approach to UTI work-up
    - Renal US ± DMSA; VCUG if 1st-line studies are abnormal
  - Use of renal US alone for screening is controversial due to variable sensitivity (37-100%) & specificity (65-99%) for scar as compared to DMSA
  - DMSA is therefore advocated by some as better test for scarring, which serves as surrogate for high-grade VUR requiring treatment (with scarring in 50% of grades IV-V but < 10% of grades I-III VUR)
    - RIVUR trial showed no difference in progressive scarring on antibiotic prophylaxis vs. placebo
    - ↑ scars in older patients, higher-grade VUR, & those with recurrent febrile UTI
  - Though anatomic detail is < VCUG, continuous imaging of nuclear medicine ↑ detection of transient VUR so that nuclear cystogram is more sensitive for VUR

DIFFERENTIAL DIAGNOSIS

Fluoroscopic Mimics of Vesicoureteral Reflux

- Normal bowel wall contrasted by intraluminal air, enteric contrast or stool, or bony iliopectineal line can mimic contrast in ureter
  - Clarify with oblique views & comparison to scout image
- Ventriculoperitoneal tubing & other intraabdominal catheters can resemble contrast-filled ureter

Urolithiasis, Especially Staghorn Calculus

- Density may simulate contrast in renal pelvis
- Check scout image & watch for drainage; correlate with US

Sonographic Mimics of Vesicoureteral Reflux

- Normally peristalsing ureter or renal pelvis
- Distended distal ureter in patients with very full bladders
- Pathologies causing obstruction of ureter or renal pelvis

PATHOLOGY

General Features

- Etiology
  - Shortened or abnormally angulated insertion of ureter into bladder is theorized to result in primary VUR
  - Vast majority (80%) of pediatric patients outgrow primary VUR, presumably due to changes at level of ureterovesical junction
  - VUR may also be secondary to periureteral (Hutch) diverticulum, ureterocele, bladder outlet obstruction, voiding dysfunction, duplicated collecting system, or neurogenic bladder
  - Probable association of sterile reflux with renal scarring
    - Antibiotic prophylaxis after 1st UTI reduces febrile UTI recurrences, not scarring
  - Risk factors: Family history, sex, age at presentation, duplication, & other voiding dysfunctions
- Associated abnormalities
  - Multicystic dysplastic kidney
  - Ectopic kidney
    - Note that VUR most commonly involves contralateral orthotopic kidney
  - VUR is present in 25-40% with acute pyelonephritis
  - Duplicated collecting system: Upper pole moiety obstructs, lower pole moiety refluxes

Staging, Grading, & Classification

- International Reflux Study Committee grading system
  - I: Reflux into ureter but not reaching renal pelvis
  - II: Reflux reaching pelvis without blunting of calyces
  - III: Mild calyceal blunting
  - IV: Progressive calyceal & ureteral dilation
  - V: Very dilated & tortuous collecting system
  - ± intrarenal reflux as modifier to grade

Gross Pathologic & Surgical Features

- Deficiency or immaturity of longitudinal muscle in submucosal ureter
- Abnormal angle of ureteral insertion through bladder wall, which tends to correct as ureter grows & elongates
- Distortion of ureteral insertion by adjacent bladder anomaly

CLINICAL ISSUES

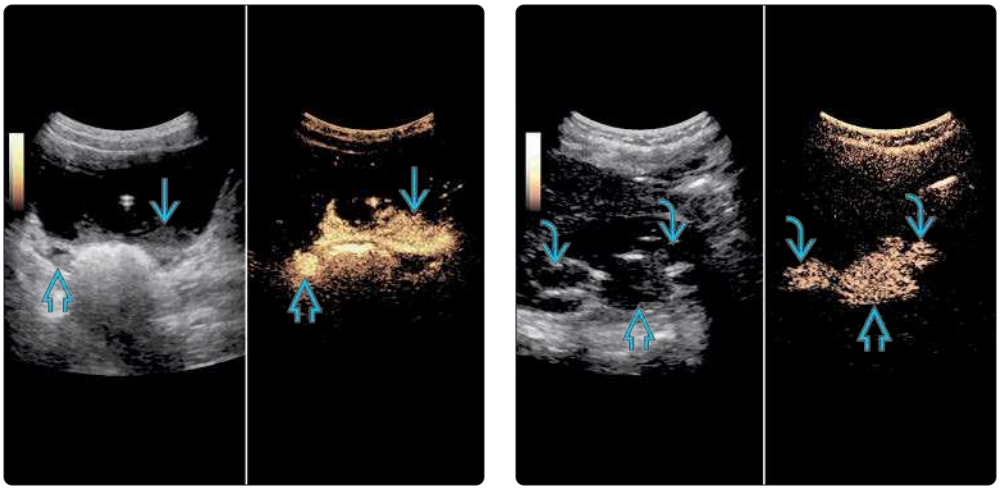
Presentation

- Most common signs/symptoms
  - Usually discovered during work-up of febrile UTI

Demographics

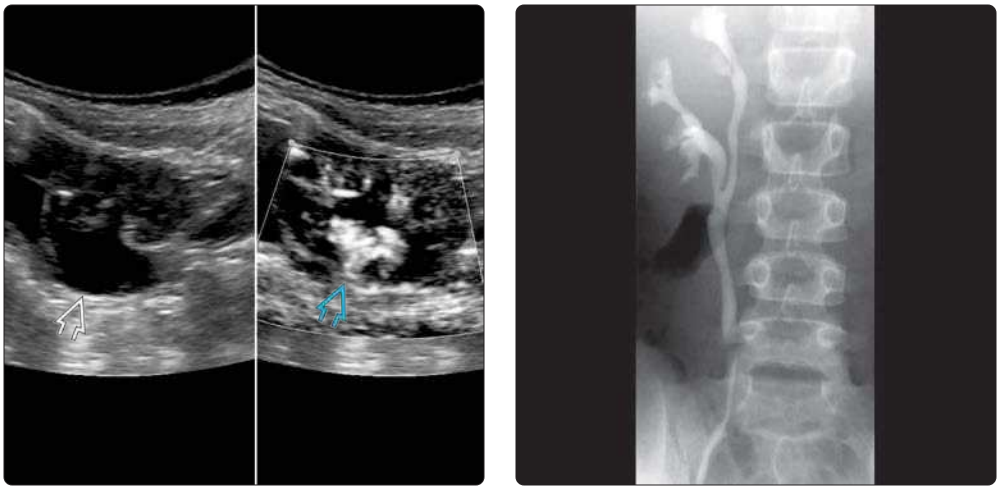
- Age
  - VUR is most common in children < 2 years old
  - 0.5x as likely in those 3-6 years old
  - 0.3x as likely in those 7-11 years old
  - 0.15x as likely in those 12-21 years old
- Sex
  - F:M = 2:1
- Epidemiology
  - Up to 2% of general population
  - VUR in 5-50% of asymptomatic siblings of children with documented reflux

Natural History & Prognosis



- 80% outgrow VUR before puberty
- ↑ grade or longstanding VUR, more numerous UTIs, & subsequent renal scarring → ↑ incidence of renal insufficiency, hypertension, & end-stage renal disease
- Intrarenal reflux is associated with ↑ renal scarring

Treatment



- Prophylactic antibiotic therapy (medical management)
  - Reduces febrile UTI recurrences, not scarring
- Ureteral reimplantation surgery (surgical management)
- Endoscopic periureteral injections (minimally invasive endoscopic management) utilizing inert material to alter shape of abnormal/refluxing ureterovesical junction
  - Treatment-induced hydroureteronephrosis following endoscopic procedures is uncommon & usually self-limited

(Left) *Transverse grayscale & contrast-only images from a contrast-enhanced ultrasound (CEUS) in a 4-year-old girl with recurrent UTIs show contrast filling the bladder ⇨ & refluxing into the ureter ⇨. (Courtesy S. Back, MD.)* **(Right)** *Longitudinal grayscale & contrast-only images from a CEUS in the same patient show refluxed contrast distending the right renal pelvis ⇨ & calyces ⇨, which are mildly blunted (grade III VUR). (Courtesy S. Back, MD.)*

(Left) *Prone posterior US shows the anechoic renal pelvis ➡ (left) with swirling echogenic urine refluxing into the pelvis ⇨ (right) by using Doppler SMI to detect slow velocity flow.* **(Right)** *VCUG shows VUR into a partially duplicated collecting system, which resembles the letter y. VUR can sometimes be seen fluoroscopically entering one limb of the y first, receding, & then filling the other limb, the so-called "yo-yo" reflux.*

(Left) *Frontal VCUG shows high-grade VUR into a triplicated ureter ➡ on the right + lower grade reflux into a duplicated ureter on the left ➡. Two of the 3 right ureters join inferiorly ➡.* **(Right)** *Posterior nuclear cystogram images show radiotracer extending into the left ureter & reaching the intrarenal collecting system ➡, likely corresponding to fluoroscopic grade II VUR. Note that reflux occurs early during bladder filling in this 2-year-old girl.*

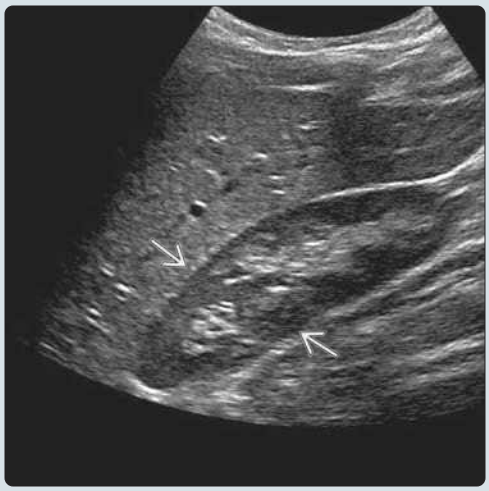
Ureteropelvic Duplications

KEY FACTS

TERMINOLOGY

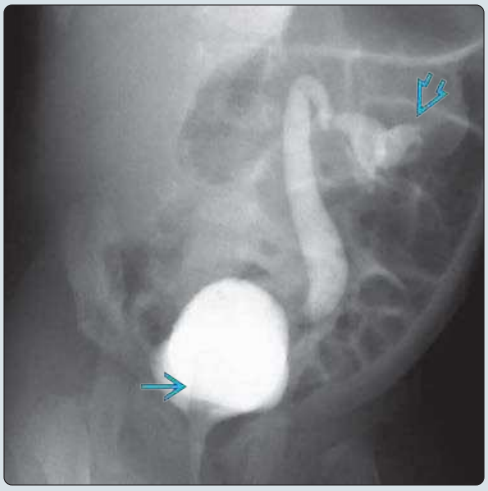
- Presence of 2 separate pelvicalyceal collecting systems in 1 kidney; 2 draining ureters may
  - Join above bladder: Partial duplication (most common, often of no consequence)
  - Insert into bladder separately: Complete duplication

IMAGING



- Central renal sinus fat is separated by bar of cortical tissue
  - Renal parenchyma is otherwise normal unless complications of vesicoureteral reflux (VUR) &/or obstruction are present
- Separate renal pelves are often visible on either side of this tissue, ± separate proximal ureters
- Duplicated kidneys tend to be larger than nonduplex kidneys, even without hydronephrosis
- With complete duplication, ureter draining upper pole (UP) of kidney inserts in bladder inferior & medial to ureter draining lower pole (LP) of kidney (Weigert-Meyer rule)
  - LP ureter inserts orthotopically in trigone
  - UP ureteral orifice is ectopic in location & often associated with ureterocele
- Corollary to Weigert-Meyer rule
  - UP tends to obstruct
  - LP tends to have VUR: Lack of dilation of ureter & collecting system in no way excludes VUR
- Drooping lily sign: Classic appearance of opacified LP collecting system on IVP or VCUG, displaced by mass-like UP hydronephrosis
  - Correlation with US is critical to confirm UP obstruction rather than other mass lesion

CLINICAL ISSUES



- Incidence of 12-15% in general population
- Treatment depends on extent of anomalies & complications
- Chronic obstruction, VUR, infection, &/or scarring may lead to secondary hypertension & renal insufficiency

(Left) *Coronal graphic shows a normal right kidney & completely duplicated left kidney with a poorly draining upper pole (UP) ectopic ureterocele seen in the bladder medial & inferior to the lower pole (LP) ureteral orifice. The LP ureter on the left inserts into bladder orthotopically at the trigone.* **(Right)** *Longitudinal ultrasound in a child shows a band of cortex ➔ separating the central sinus fat & other medullary structures in this duplicated kidney without any evidence of obstruction or hydronephrosis.*

(Left) *Frontal VCUG in a 1-month-old girl shows grade 4 vesicoureteral reflux (VUR) into an LP moiety ⇨, which is directed inferiorly by a nonvisualized obstructed UP system (the drooping lily sign). The UP moiety terminates as a ureterocele ⇨ (poorly seen due to the degree of bladder filling).* **(Right)** *Longitudinal ultrasound in the same patient shows the obstructed left UP moiety with severe thinning of the surrounding renal parenchyma ⇨. The LP appears normal despite the degree of VUR.*

TERMINOLOGY

Synonyms

- Duplicated kidney, duplex collecting system, partial/incomplete/complete duplication, bifid pelvis

Definitions

- Presence of 2 separate pelvicalyceal collecting systems in 1 kidney
  - 2 draining ureters may
    - Join above bladder (partial duplication)
    - Insert into bladder separately (complete duplication)

IMAGING

General Features

- Best diagnostic clue
  - Identification of 2 renal pelves or proximal ureters on any imaging modality
- Location
  - Duplication can involve any length of urinary tract (from renal parenchyma to urethra)
  - L > R
- Size
  - Duplicated kidneys tend to be larger than nonduplex, even without hydronephrosis
- Morphology
  - Central renal sinus fat is completely separated by bar of renal cortex; renal parenchyma is often otherwise normal
    - Unless vesicoureteral reflux (VUR) has led to scarring or obstruction has led to thinning/dysplasia
  - Duplex system has > 10 calyces, 2 renal pelves, & 1 or 2 ureters
  - > 1 renal artery & vein is very common
  - If duplication is complete, ureter draining upper pole (UP) of kidney inserts in bladder inferior & medial to ureter draining lower pole (LP) of kidney (Weigert-Meyer rule)
  - Corollary to Weigert-Meyer rule
    - UP tends to obstruct
    - LP tends to have VUR
  - UP ureteral orifice is, by definition, ectopic in location & may be associated with ureterocele

Ultrasonographic Findings

- Grayscale ultrasound
  - Band of renal cortex splits echogenic sinus fat
  - Separate renal pelves are often visible, ± separate proximal ureters
  - Distal ureters are more difficult to identify due to bowel gas near bladder
    - While dilated distal ureter may be suggestive of VUR, remember that
      - Lack of dilation of ureter & collecting system in no way excludes VUR
      - Severe VUR may not show dilation at US
  - Look for thin-walled ureterocele protruding into urinary bladder; assess for presence & location of ureteral jets
  - Remember to survey for concomitant genital anomalies, especially of uterus
- Color Doppler
  - May show elevated resistive indices (RIs) in obstructed moiety
  - Useful to define arterial anatomy
  - Used to confirm lack of blood flow in renal pelves & tubular ureters
  - Can show foci of hypoperfusion from superimposed infection (pyelonephritis)

Fluoroscopic Findings

- Voiding cystourethrogram
  - Look for VUR (LP > > UP)
  - Saddle VUR or yo-yo VUR is unique to partial duplications, which have single distal ureter
    - VUR contrast first enters 1 component of upper tract collecting system, drains, & then refluxes into 2nd component
  - Ectopic ureter may only be visualized when inadvertently catheterized (e.g., intersphincteric ureter)
    - If this occurs, contrast opacification can help delineate anatomy
    - However, catheterization of urinary bladder must also occur to look for VUR into other ureters

CT Findings

- CECT can demonstrate course of ureters (particularly with delay) & locate renal arteries
- Presence of supernumerary calyces & bifid pelvis can be more challenging to detect on axial imaging; multiplanar reformats are helpful

MR Findings

- MR urography
  - Anatomy: 3D T2 images (conventional vs. heavily T2-weighted/MRCP type) capitalize on fluid signal in urinary tract
  - Physiology: Dynamic postcontrast imaging (with quantitative processing) is used to guide surgical interventions
  - Often best test when ectopic ureter cannot be demonstrated with other imaging

Nuclear Medicine Findings

- Occasionally, nuclear study can be 1st to suggest renal duplication
- Renal scans are used to show differential function, drainage, & scarring
- Results help guide surgical intervention

Multimodality Findings

- Obstructed hydronephrotic UP moiety of duplicated system exerts mass effect on LP moiety, displacing/rotating it inferiorly
  - Drooping lily sign: Classic appearance of inferiorly displaced/rotated opacified LP collecting system on IVP or VCUG
  - Can be seen on coronal CT, MR, & US
  - Beware that UP or suprarenal masses can also create this fluoroscopic appearance, necessitating correlation with cross-sectional investigation (typically US)

Imaging Recommendations

- Best imaging tool
  - US is usually 1st-line study for suspected GU abnormality

- VCUG & nuclear studies generally complete imaging work-up if duplicated system is causing problems
- MR is useful in complex cases; can provide complete anatomic & physiologic work-up

- Protocol advice
  - When searching for ectopic ureter from poorly functioning &/or chronically obstructed UP, consider MR urography
  - MRU feed & sleep technique had 90% success rate in infants < 10 months old in one study

DIFFERENTIAL DIAGNOSIS

Column of Bertin

- Normal variant of junctional parenchyma, typically in midkidney; looks like focally thickened cortex

Segmental Multicystic Dysplastic Kidney

- UP dysplasia of duplicated system can mimic obstructed, hydronephrotic moiety

Adrenal Mass

- Can mimic drooping lily sign by displacing collecting system inferiorly

Other Suprarenal Mass

- Pulmonary sequestration, duplication cyst, etc.

PATHOLOGY

General Features

- Etiology
  - Early branching of ureteric bud or 2 ureteral buds arising from wolffian duct
  - Each bud induces formation of its own nephrons when it meets metanephric blastema
  - Abnormal branching of ureteric bud can also give rise to supernumerary kidney or triplicate collecting system (both very rare)
- Associated abnormalities
  - Duplications of bladder, urethra, & genital structures are associated with renal duplication
    - Genital anomalies in 50% of affected females
  - Ureteropelvic junction obstruction is more common in duplicated kidneys

Gross Pathologic & Surgical Features

- Almost always has 2 renal arteries & veins, often with separate renal artery orifice from aorta
- In absence of complications, renal parenchyma & collecting system tissue are normal

Microscopic Features

- Depends on complications: Scarring, hydronephrosis, fibrosis

CLINICAL ISSUES

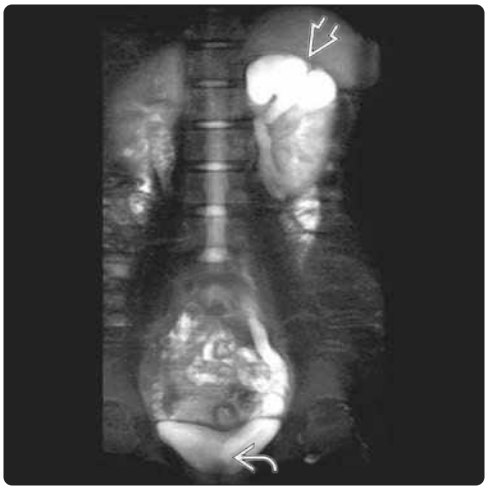
Presentation

- Most common signs/symptoms
  - Most often discovered antenatally or incidentally on imaging studies performed for other reasons
- Other signs/symptoms
  - Symptomatic duplications may lead to infection, obstruction, calculi, scarring, hematuria, abdominal or flank pain, voiding dysfunction, urinary retention

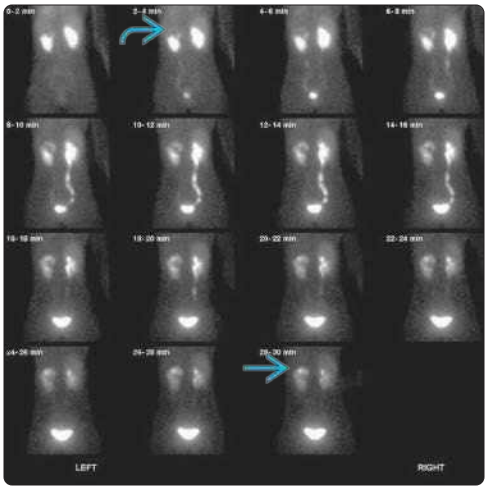
Demographics

- Age
  - Congenital; usually discovered early in life
- Sex
  - Complete duplications are much more common in women
  - Partial duplications have no sex predilection
- Epidemiology
  - Incidence of 12-15% in general population, but only 1% are found de novo in cadaveric renal donors

Natural History & Prognosis



- Prognosis varies with type of duplication & severity of complications
- Chronic obstruction, VUR, infection, &/or scarring may lead to secondary hypertension & renal insufficiency



Treatment

- Depends on extent of anomalies & complications
  - Associated ureteroceles are incised, unroofed, resected, or reimplanted
  - Ectopic ureter may be reimplanted if kidney it subtends retains good function; otherwise resected
  - Hydronephrosis is treated surgically to improve drainage
    - Cortical thinning & relative function are used to determine surgical course: Salvage vs. resection
  - Infections are treated with antibiotics & evaluated for urine stasis & VUR
  - VUR may be managed conservatively (medically) or treated surgically, depending on grade & associated anomalies
  - Calculi are removed, fragmented, or monitored
  - Voiding dysfunction is assessed to exclude ectopic ureter/ureterocele, prolapsing cecoureterocele, & bladder dyskinesia

(Left) *Coronal MIP MR urogram in a teenager shows a duplicated left kidney & obstructed UP moiety, which drains ectopically into the vagina. Note the cortical thinning of the left UP from chronic injury.* **(Right)** *Posterior images from a Tc-99m MAG3 renogram in the same patient show delayed uptake by the UP of the left kidney with poor function & excretion. The postdiuretic washout curve for the left UP showed no drainage (not shown).*

(Left) *Longitudinal oblique ultrasound in a patient with a duplicated right kidney shows severe dilation of the UP moiety with marked parenchymal thinning. There is also mild to moderate dilation of the LP moiety. Cursors mark the length of the kidney.* **(Right)** *Longitudinal oblique ultrasound in the same patient shows the tortuous course of the dilated right UP ureter.*

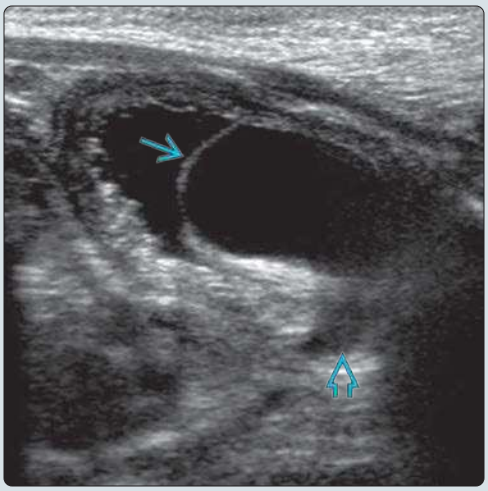
(Left) *Coronal 3D T2 MR urogram in a 10-month-old girl shows a UP moiety ureterocele outlined by a catheter in the bladder. The UP moiety is small relative to the ureterocele (ureterocele disproportion). Marked dilation of the LP moiety with parenchymal thinning was due to obstruction by the adjacent UP ureterocele.* **(Right)** *Coronal MIP MR urogram in a 17-year-old with giggle incontinence shows a small dysplastic left UP moiety with ectopic insertion of the ureter into the vagina.*

Ureterocele

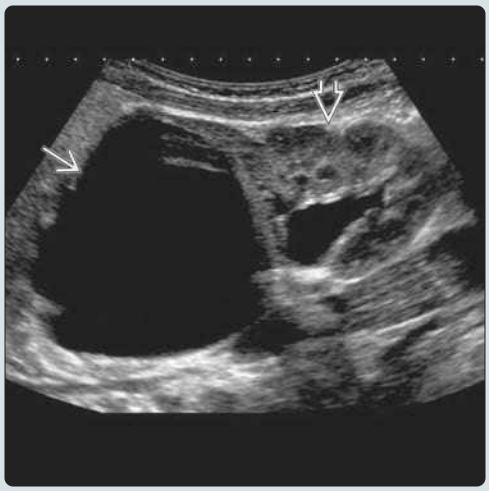
KEY FACTS

TERMINOLOGY

- Congenital cystic dilation of distal submucosal portion of 1 or both ureters within urinary bladder
- Categorized according to ureterocele position
  - Intravesical: Completely contained within bladder
  - Extravesical: Partially extends to bladder neck, urethra, vagina, prostate, seminal vesicles, or perineum
- Categorized according to ureterocele insertion
  - Orthotopic (simple): Orifice is located in normal anatomic position in bladder trigone
  - Ectopic: Orifice is located anywhere else
- Categorized according to type of kidney drained
  - Single system vs. duplicated system with 2 ureters
  - 1 ureter of duplicated system must be ectopic
- Weigert-Meyer rule: Ureter from upper pole (UP) moiety of duplicated kidney inserts inferior & medial to normal lower pole (LP) moiety insertion site at trigone
- Any ureterocele may obstruct & cause hydronephrosis

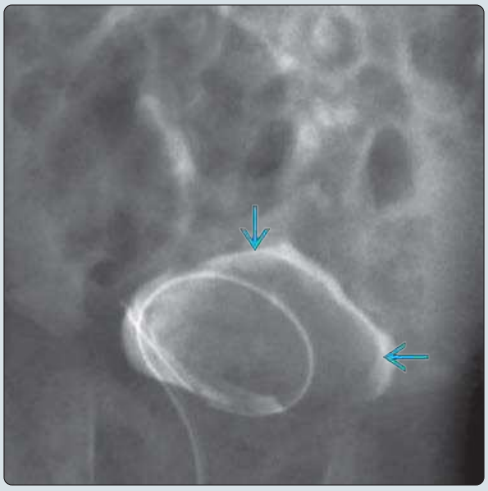


IMAGING

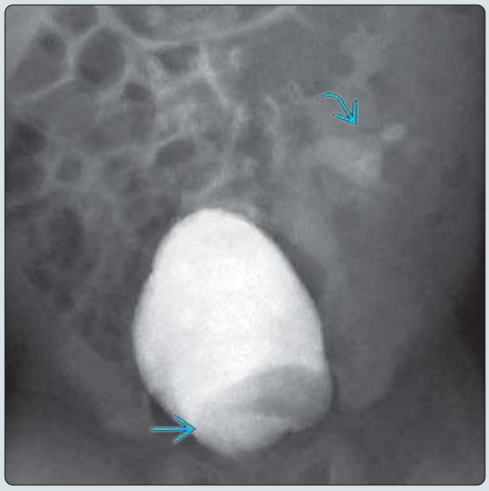


- Round/ovoid filling defect in urinary bladder
  - Thin-walled & cystic-appearing on US, MRU
    - Wall appears thicker, collapsed after surgery
- ± visualization of associated dilated distal ureter
- In duplicated system, UP moiety (associated with ureterocele) typically obstructs, & LP moiety typically refluxes
  - Varying degrees of hydronephrosis & parenchymal dysplasia of UP moiety
  - Vesicoureteral reflux into LP moiety classically shows drooping lily sign
    - Due to rotation of LP system by obstructed UP

CLINICAL ISSUES



- Ectopic variety > orthotopic variety by 3-4:1 ratio
- Typical treatment: Endoscopic incision of ureterocele, especially if infected or obstructed in neonate



(Left) *Longitudinal ultrasound of the urinary bladder in an 18-day-old with prenatally detected hydronephrosis shows a large, thin-walled cyst ⇨ filling much of the bladder lumen, typical of a ureterocele. The cyst connects to a dilated distal left ureter ⇨.* **(Right)** *Longitudinal ultrasound of the duplicated left kidney in the same patient shows severe pelvocaliectasis & parenchymal thinning of the left upper pole (UP) moiety ⇨. The lower pole (LP) moiety shows mild pelvocaliectasis with more normal-appearing renal parenchyma ⇨.*

(Left) *Frontal early filling image from a VCUG in the same patient shows the ureterocele as a large, ovoid filling defect ⇨ partially outlined by contrast in the urinary bladder.* **(Right)** *Postvoid VCUG in the same patient shows grade 2-3 vesicoureteral reflux (VUR) into the LP collecting system ⇨. The drooping lily configuration of contrast within the LP strongly suggests obstruction of a UP moiety (as confirmed on the ultrasound). The UP ureterocele ⇨ remains visible in the contrast-filled bladder.*

TERMINOLOGY

Definitions

- Congenital cystic dilation of distal submucosal portion of 1 or both ureters within urinary bladder
- Categorized according to ureterocele position
  - Intravesical: Completely contained within urinary bladder
  - Extravesical: Partially extends into bladder neck, urethra, or perineum
- Categorized according to ureterocele insertion
  - Orthotopic (simple): Orifice located in normal anatomic position in bladder trigone
  - Ectopic: Orifice located anywhere else
    - Ectopic ureter may drain to other genitourinary locations without ending as ureterocele
- Categorized according to type of kidney drained
  - Single-system ureterocele: Kidney gives rise to single collecting system with solitary ureter
    - Typically simple, intravesical ureterocele
  - Duplex-system ureterocele: Kidney has completely duplicated collecting system with 2 complete ureters
    - 1 ureteral insertion must be ectopic by definition (often extravesical)
- Cecoureterocele: Unique subtype elongated beyond ureteral orifice by tunneling under trigone & urethra
- Any type of ureterocele may become obstructed or prolapse into bladder neck & cause hydronephrosis

IMAGING

General Features

- Best diagnostic clue
  - Round or ovoid cystic filling defect in bladder
- Location
  - L > R; bilateral in 10%
  - Ectopic variety > orthotopic variety by 3-4:1 ratio
  - Weigert-Meyer rule: Ureter from upper pole (UP) moiety of duplicated kidney inserts inferior & medial to normal insertion site of LP moiety in bladder trigone
    - UP moiety typically obstructs, LP typically refluxes
  - Ureterocele may prolapse in & out of bladder

Fluoroscopic Findings

- Voiding cystourethrogram (VCUG)
  - Best seen on early bladder-filling image before contrast is too dense & intravesical pressure compresses ureterocele
  - Vesicoureteral reflux (VUR) is frequently seen in LP moiety
    - May create drooping lily sign where nonopacified obstructed UP moiety distorts opacified refluxing LP moiety
      - Long axis of opacified LP moiety collecting system points toward ipsilateral shoulder
  - If ureterocele everts, creates appearance of diverticulum & may cause VUR

Ultrasonographic Findings

- Grayscale ultrasound
  - Anechoic, thin-walled cyst inside urinary bladder
  - Ureteral jet & connection to dilated distal ureter may be demonstrated
  - ± duplicated kidney with hydroureteronephrosis
    - Single system kidney typically shows uniform degree of pelvocaliectasis
    - Obstructed UP moiety of duplex kidney is variable in morphology
      - Often shows worse pelvocaliectasis than LP
      - Variable degrees of UP parenchymal thinning ± cystic dysplasia
      - Variable size of UP moiety: Enlarged with severe pelvocaliectasis vs. small with dysplastic parenchyma in setting of large ureterocele (ureterocele disproportion)
  - After incision (to relieve obstruction), residual partially or totally collapsed ureterocele often has thick, undulating wall
- Color Doppler
  - Ureteral jet is useful to exclude complete obstruction of ureterocele
- 3D
  - "Virtual sonocystoscopy" may be useful preop tool
- Contrast-enhanced ultrasound
  - Round filling defect in contrast-filled bladder
  - Contrast may reflux after ureterocele incision

MR Findings

- MR urography
  - 3D T2-weighted sequences emphasize fluid-filled urinary tract anatomy
  - Dynamic postcontrast images can evaluate function & drainage of urinary tract
    - Can be processed for quantitative data
  - Associated gynecologic anomalies in 50% of females with duplication

Nuclear Medicine Findings

- Nuclear cystogram
  - Ureterocele is difficult to see on nuclear cystogram unless very large or prolapsing
- Nuclear renal scan
  - Used to assess function of obstructed or poorly functioning UP moiety
  - Poor function on nuclear scan is predictive of severe histologic changes in renal parenchyma; helps justify heminephrectomy

Imaging Recommendations

- Best imaging tool
  - VCUG & ultrasound are best 1st-line studies
  - Nuclear renal scan is most established technique for evaluating differential function in duplicated kidney
  - MRU & IVP have been reserved for difficult or complex cases; increasing use of MRU as comprehensive study of anatomy & function
- Protocol advice
  - VCUG is best test to assess dynamic nature of ureterocele: Everting, refluxing, prolapsing, &/or causing bladder outlet obstruction
    - Fluoroscopic vs. contrast enhanced

DIFFERENTIAL DIAGNOSIS

Bladder Mass

- Lacks communication with distal ureter; typically solid
  - Rhabdomyosarcoma, neurofibroma, polyp: Nonmobile with variable internal vascularity
  - Focal cystitis: Variety of infectious & noninfectious causes
  - Fungus ball, hematoma: Often mobile; no internal vascularity

Mass Effect From Sigmoid Colon

- Can appear as filling defect on VCUG: Get oblique views

Bladder Hutch Diverticulum

- Periureteral diverticulum; separate from distal ureter
- May mimic everted ureterocele; does not usually prolapse into bladder to cause filling defect

Ovarian Cyst

- May deform but does not typically bulge into bladder

PATHOLOGY

General Features

- Etiology
  - Embryology/anatomy
    - Thought to result from delayed canalization of Chwalla membrane during embryogenesis → obstruction of ureteral orifice
      - Chwalla membrane: Primitive separation of ureteral bud from developing urogenital sinus
- Associated abnormalities
  - VUR into lower pole of duplicated system: 50%
  - VUR in contralateral kidney: 25%

Microscopic Features

- In heminephroureterectomy specimens, histologic changes include chronic interstitial inflammation, fibrosis, tubular atrophy, glomerulosclerosis, & dysplasia
- Normal urothelium in dilated intramucosal or submucosal segment

CLINICAL ISSUES

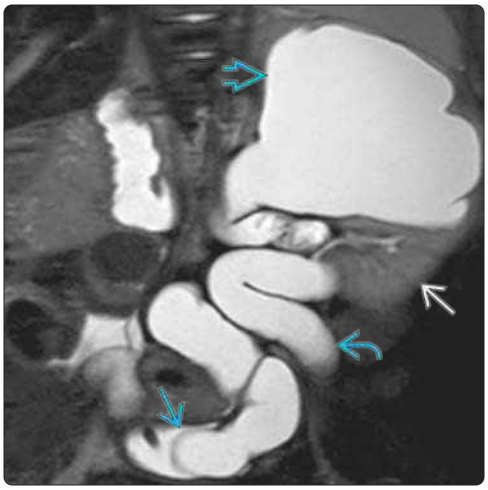
Presentation

- Most common signs/symptoms
  - Prenatal detection of hydronephrosis is typical
  - Febrile urinary tract infection (UTI) is most common postnatal presentation
- Other signs/symptoms
  - Simple ureterocele may not be diagnosed until adulthood
  - Ectopic ureterocele is usually diagnosed in infancy or shortly after toilet training: Presents with hematuria, UTI, chronic enuresis, or hydronephrosis
  - Rarely presents with prolapse & acute bladder outlet obstruction
  - Other rare presentations: Failure to thrive, cyclic abdominal pain, ureteral calculus

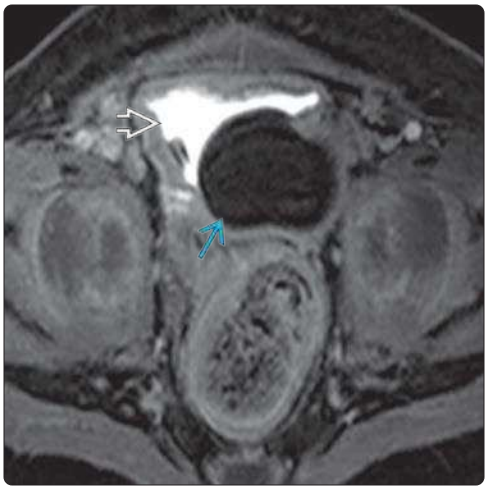
Demographics

- Age
  - Detected antenatally & in infancy
- Epidemiology
  - 1 in 4,000 children; less frequently diagnosed in adults
- Sex: Ectopic ureterocele F:M = 4-7:1

Natural History & Prognosis



- Prognosis is excellent if nonobstructing & nonrefluxing
- Prognosis is variable if prolonged obstruction or high-grade VUR has compromised renal function
- Antenatal diagnosis is reported to improve overall course: Fewer infections, fewer surgical procedures
- Ureteroceles diagnosed antenatally should be treated surgically within 1st weeks of life since rate of UTI exceeds 50% despite prophylactic antibiotics



Treatment

- Endoscopic incision (puncture or unroofing) of ureterocele, especially if infected or obstructed in neonate
  - Following incision, ureterocele wall appears thickened, irregular, even mass-like
  - Endoscopic incision may convert obstructed ureterocele into refluxing ureterocele
    - LP dilation may improve with UP ureterocele incision
  - Double-puncture technique: Double-J stent inserted into 2 punctured sites at poles of ectopic ureterocele, & tissue is fulgurated
- Ureteral reimplantation surgery: Extravesical reimplantation, ureteroureterostomy, ureteropyelostomy
  - Patients undergoing bilateral ectopic ureterocele repair are at ↑ risk for postoperative voiding dysfunction
    - Unclear if risk is present preoperatively or due to trigonal surgery
- Heminephroureterectomy if UP moiety is very poorly functioning
- Antenatal fetoscopic laser ablation of ureteroceles
  - Performed in fetuses with severe bilateral hydronephrosis, bladder outlet obstruction, & oligohydramnios with good results
- Success after single procedure is higher in single ureters; many require > 1 surgical procedure
- Best surgical management remains controversial

(Left) *Coronal T2 FS MR in an infant shows an ectopic ureterocele partially filling the urinary bladder & connecting to a markedly dilated UP ureter. There is severe UP hydronephrosis due to obstruction. Note the normal LP moiety.* **(Right)** *Delayed axial T1 C+ FS MR in the same patient shows no contrast in the ureterocele due to the longstanding UP obstruction with ↓ function. Contrast has filled the surrounding bladder by excretion from the remaining urinary tract. (Courtesy J.R. Dillman, MD.)*

(Left) *Longitudinal ultrasound shows a dilated distal ureter entering the bladder & forming a thin-walled bulbous end, typical of a ureterocele. This ureterocele is inserting low in the bladder base & is likely ectopic.* **(Right)** *Transverse ultrasound through the bladder base in a patient after a ureterocele incision shows a partially collapsed, relatively thick-walled ureterocele. After endoscopic incision, ureteroceles tend to decompress & may show wall thickening with an undulating contour, as in this case.*

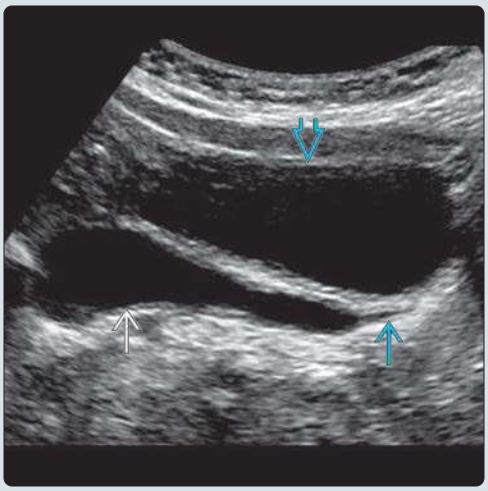
(Left) *Oblique VCUG shows prolapse of a ureterocele into the posterior urethra as voiding starts & the catheter is expelled. Voiding stopped seconds later due to urethral obstruction.* **(Right)** *Coronal 3D T2 MR urogram in a 10-month-old girl shows a UP moiety ureterocele outlined by a catheter in the bladder. The UP moiety is small relative to the ureterocele (ureterocele disproportion). Marked dilation of the LP moiety with parenchymal thinning was due to obstruction by the adjacent UP ureterocele.*

Primary Megaureter

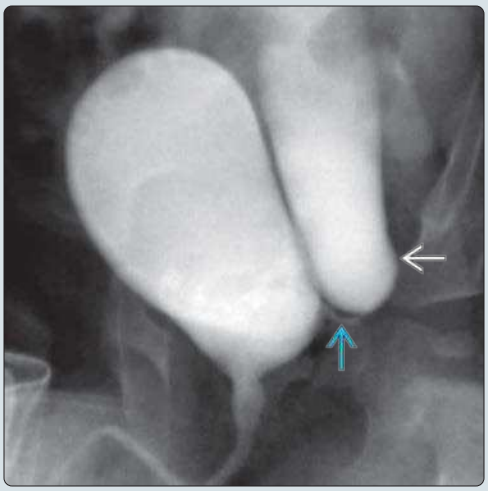
KEY FACTS

TERMINOLOGY

- Megaureter: General term for ureteral dilation
  - Can be due to vesicoureteral reflux (VUR), obstruction, both, or neither
- Primary obstructive megaureter: Functional obstruction at juxtavesical segment of ureter due to absent peristalsis

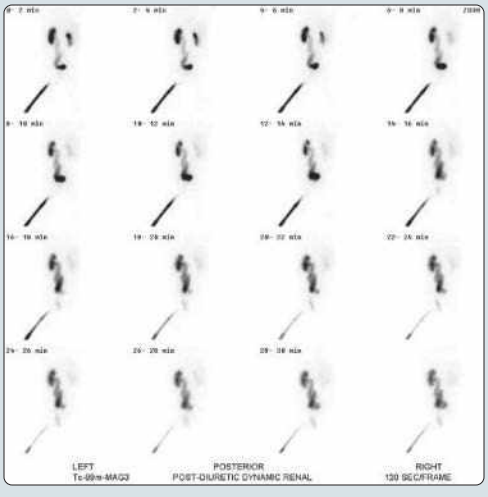


IMAGING



- Best imaging clues
  - Variable degree of hydroureteronephrosis with transition to nondilated distal ureter
    - Nondilated aperistaltic segment involves terminal 0.5-4 cm of ureter
    - Most commonly unilateral: 67% on left
  - VUR: Ipsilateral in 5%, contralateral in < 10%
  - ± debris, calculi in dilated ureter
  - Long-term obstruction can lead to parenchymal thinning & lack of renal growth
- Best imaging modalities
  - Ultrasound is best screening exam for urinary tract anomalies (pre- or postnatally)
  - Diagnostic & treatment considerations are refined with
    - Fluoroscopic VCUG (to assess for VUR &/or bladder outlet obstruction)
    - Nuclear medicine diuretic renography to assess for renal function & delayed ureteral drainage
    - MR urography can assess anatomy & physiology

CLINICAL ISSUES



- M:F = 4:1
- Diagnosed prenatally in nearly 50%; remaining cases present over wide range of ages
- May be asymptomatic but can present with urinary tract infections (UTIs), abdominal/flank pain, hematuria ± calculi, renal failure
- 70% regress spontaneously by 7 years of age
- Surgery is considered for worsening renal function or recurrent UTIs

(Left) *Longitudinal ultrasound at the left ureterovesical junction (UVJ) in a male infant shows a dilated left ureter tapering distally to a normal-caliber aperistaltic juxtavesical segment that shows urothelial thickening. The urinary bladder is seen anteriorly.* **(Right)** *Oblique fluoroscopic image from a voiding cystourethrogram in the same patient shows vesicoureteral reflux into the normal-caliber juxtavesical segment with transition to the proximally dilated ureter.*

(Left) *Dynamic posterior view postdiuretic images from a Tc-99m MAG3 renogram in the same patient show qualitatively slow drainage of the left dilated ureter. The T1/2 for drainage of the left ureter was > 20 minutes on the quantitative evaluation, consistent with obstruction.* **(Right)** *Oblique MIP from an MR urogram in a patient with a primary obstructive megaureter shows a narrow juxtavesical segment of the left ureter with proximal hydroureteronephrosis.*

TERMINOLOGY

Definitions

- Megaureter: Ureteral diameter ≥ 7 mm
- 4 types classified by presence of vesicoureteral reflux (VUR) &/or obstruction
  - Nonrefluxing obstructed (NR, O)
  - Refluxing obstructed (R, O)
  - Refluxing nonobstructed (R, NO)
  - Nonrefluxing nonobstructed (NR, NO)
- Primary obstructive megaureter: Congenital functional obstruction at juxtavesical segment of ureter
  - Presumably due to absent peristalsis in normal-caliber distal segment, though exact etiology is unclear

IMAGING

General Features

- Best diagnostic clue
  - Hydroureteronephrosis (HUN) with short segment of normal-caliber distal ureter
- Location
  - Transition from normal-caliber distal ureter to proximal dilation ~ 0.5-4 cm above ureterovesical junction (UVJ)
  - 60% are unilateral (of which 67% involve left ureter)

Ultrasonographic Findings

- Grayscale ultrasound
  - Unilateral or bilateral HUN
  - ± renal parenchymal thinning & lack of renal growth
  - Hyperperistalsis of dilated ureter down to distal aperistaltic normal-caliber segment
  - ± intraluminal debris (proteinaceous or infectious)
  - ± calculus formation

Fluoroscopic Findings

- Voiding cystourethrogram
  - If no VUR, study may appear normal
  - Ipsilateral VUR in 5%, contralateral in < 10%
  - When VUR is present, assess for obstruction
    - Delayed drainage of dilated ureter
    - Short segment of normal-caliber distal ureter
- Retrograde ureterogram (by urology service)
  - More reliably demonstrates distal adynamic ureter

Nuclear Medicine Findings

- Diuretic renography (Tc-99m MAG3 or DTPA)
  - Delayed clearance of radiotracer from dilated ureter & collecting system after furosemide administration
    - Prolonged ureteral ± renal T½ (> 20 minutes)

MR Findings

- MR urography
  - Comprehensive anatomic & functional evaluation
    - Can assess renal parenchymal function & urinary clearance, similar to nuclear medicine renal scan

DIFFERENTIAL DIAGNOSIS

Refluxing Nonobstructive Megaureter

- Usually high-grade VUR; drains into bladder at end of VCUG
- Much more common than primary obstructive form
- May be idiopathic or seen with neurogenic bladder, posterior urethral valves, prune belly syndrome, megacystis-megaureter, duplicated ureters, incised ureterocele

Nonrefluxing Nonobstructive Megaureter

- Idiopathic aperistaltic distal ureter may occur without quantitative obstruction
- Polyuria (diabetes insipidus) may cause general ureteral dilation

Mechanical Obstruction

- Unilateral (ureteral obstruction)
  - Stricture, ureterocele, urolithiasis, retrocaval ureter, extrinsic mass, ureteral valve (rare)
- Bilateral (bladder outlet or urethral obstruction)
  - Bladder outlet: Posterior urethral valves, cloaca with hydrocolpos, extrinsic mass
  - Urethral: Stricture, polyp, anterior valve, atresia, primary megalourethra; unclear: Prune belly syndrome

PATHOLOGY

General Features

- Etiology is unclear: Possibilities include ↑ collagen deposition, muscle hypertrophy, ↓ number of interstitial cells of Cajal

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic vs. febrile urinary tract infections (UTIs), abdominal/flank pain, hematuria ± calculi, gradual renal failure

Natural History & Prognosis

- 70% resolve spontaneously by 7 years of age
  - Initial ureteral diameter < 8.5 mm: Likely to resolve
  - Initial ureteral diameter > 15 mm: Likely to persist
- May develop renal dysfunction or recurrent UTIs

Treatment

- Conservative management
  - Prophylactic antibiotics; imaging every 6-12 months
- Surgical management: Temporary double J stent, various ureteral reimplantation options
  - Consider with worsening renal function or recurrent UTIs

Megaureter-Megacystis

KEY FACTS

TERMINOLOGY

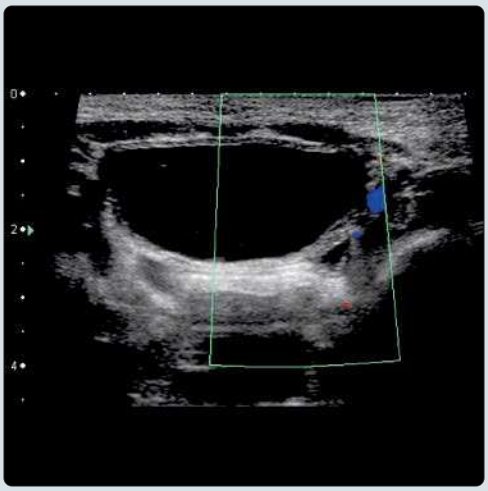
- Megaureter-megacystis syndrome (MMS): Marked vesicoureteral reflux (VUR) leads to large bladder due to repetitive recycling of urine

IMAGING

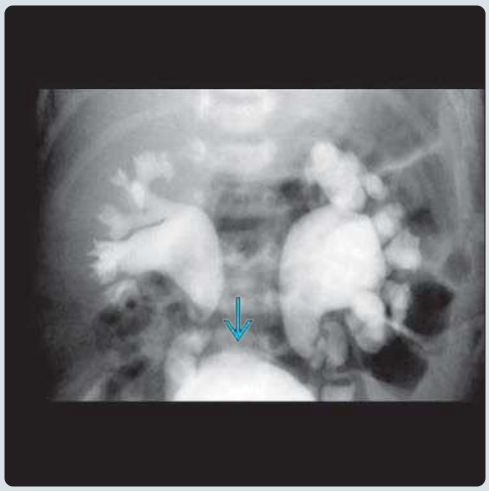
- On voiding cystourethrogram (VCUG)
  - Large urinary bladder with smooth, thin wall
    - > 2x estimated normal bladder capacity
  - Unilateral or bilateral high-grade VUR
    - VUR may occur (during filling &/or voiding) into single system or lower pole of duplex system
    - Usually grade IV or V VUR
  - Voiding demonstrates complete bladder emptying
  - However, bladder rapidly refills (almost to capacity) by drainage of retained refluxed contrast from dilated ureters & collecting systems
    - Termed aberrant micturition, though bladder neck & urethra are normal

TOP DIFFERENTIAL DIAGNOSES

- Mechanical bladder outlet obstruction
  - Posterior urethral valves
  - Extrinsic/intrinsic mass
  - Obstructing ureterocele
- Functional bladder outlet obstruction
  - Neurogenic bladder
- Megacystis of unclear etiology
  - Prune belly (Eagle-Barrett) syndrome
  - Megacystis-microcolon-intestinal hypoperistalsis
  - Megalourethra

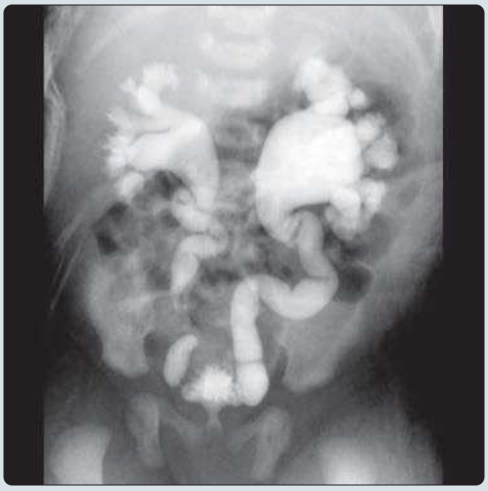


PATHOLOGY



- Ureter(s) & bladder act as common chamber

CLINICAL ISSUES



- Most commonly presents with urinary tract infections or abnormal prenatal ultrasound
- Bladder function may deteriorate if VUR is not improving

(Left) *Transverse ultrasound in a 5-day-old boy shows a well-distended urinary bladder with a dilated left distal ureter with moderate urothelial thickening, a nonspecific finding that can be seen in megaureter ± vesicoureteral reflux or could be related to infection.* **(Right)** *Frontal view of the kidneys during a voiding cystourethrogram (VCUG) in the same patient shows bilateral high-grade vesicoureteral reflux (VUR), L > R. Note the dome of a large thin-walled urinary bladder* ⇨.

(Left) *Frontal VCUG in the same patient immediately after voiding shows complete bladder emptying. However, the ureters & collecting systems are full of contrast.* **(Right)** *Frontal VCUG in the same patient 5 minutes after voiding shows that the refluxed contrast from the ureters & collecting systems have completely refilled the bladder. This is seen in patients with high-grade VUR & is consistent with megaureter-megacystis physiology. If the VUR does not improve, this physiology can cause bladder dysfunction.*

KEY FACTS

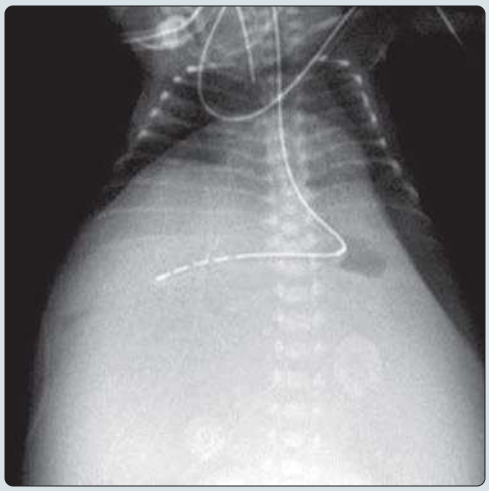
TERMINOLOGY

- Megacystis-microcolon-intestinal hypoperistalsis syndrome (MMIHS): Rare disease of smooth muscle dysfunction resulting in poor motility of GI & GU tracts
- Synonyms: Berdon syndrome (described by Berdon et al. in 1976), familial visceral myopathy

IMAGING

- Variably dilated, featureless small bowel
  - Poor/absent peristalsis
- Colon is not dilated: Unused microcolon, no haustrations
- Abnormal bowel fixation: Malrotation
- Variable pelvocaliectasis & hydroureter
- Bladder is very dilated with poor or no emptying
  - Nonobstructive urinary tract dilation
    - Polyhydramnios in utero with megacystis in female fetus is suggestive
  - Bladder aspiration improves urinary tract dilation
- Severe abdominal distention → pulmonary compromise

TOP DIFFERENTIAL DIAGNOSES

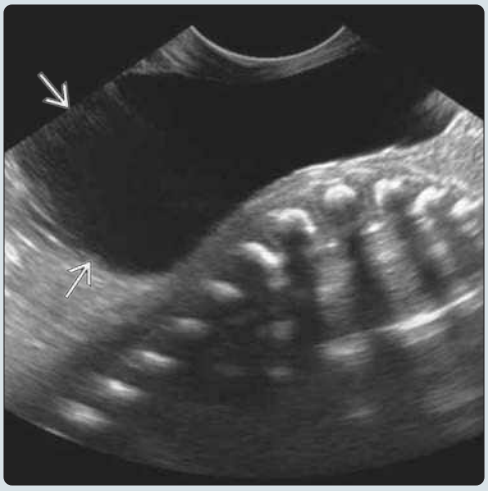


- Posterior urethral valves
- Prune-belly syndrome
- Congenital megalourethra
- Cloacal malformation
- Hirschsprung disease

PATHOLOGY

- Mutation in *ACTG2* gene → abnormal smooth muscle actin
- Autosomal dominant, often sporadic
- *MYH11*, *MYL9*, & other genes reported

CLINICAL ISSUES



- Sex: F > > M
- Clinical triad: Abdominal distention, bilious emesis, failure to pass meconium or urine
- Previously lethal within 1 year
- Survival has improved with TPN & multivisceral transplant

(Left) *Frontal view of the chest in a newborn with MMIHS shows massive abdominal distention impressing on the lung bases. Pulmonary function & development are compromised by mass effect both in utero & postnatally in MMIHS.* **(Right)** *Frontal upper GI through a nasogastric tube shows full-column gastroesophageal reflux into the mildly dilated esophagus ➡ with distal passage of contrast into the featureless tubular small bowel ➡ malpositioned in the right upper abdomen, consistent with malrotation.*

(Left) *Frontal contrast enema in a newborn with MMIHS shows a very small-caliber, unused microcolon without haustrations positioned in the midline abdomen. The cecum ➡ is overlying the spine. Marked hydronephrosis is displacing the bowel.* **(Right)** *Longitudinal ultrasound in a newborn with MMIHS shows a massively distended bladder ➡ extending toward the umbilicus, consistent with megacystis. A markedly enlarged bladder in utero is often the 1st clue to this diagnosis.*

Prune-Belly Syndrome

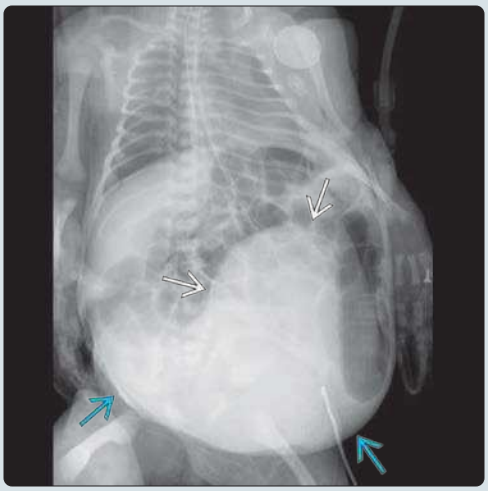
KEY FACTS

TERMINOLOGY

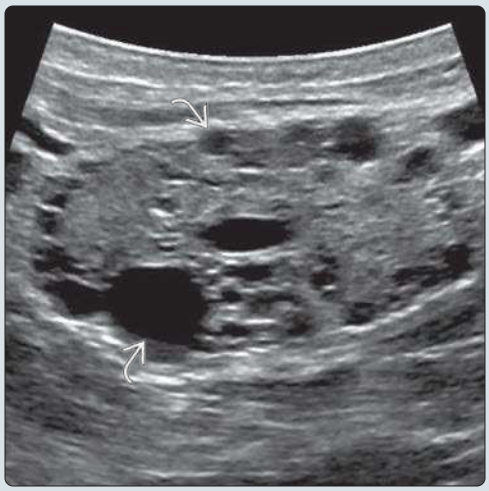
- Prune-belly syndrome (PBS): Congenital triad of
  - Urinary tract dilation
  - Cryptorchidism
  - Abdominal wall muscle deficiency/laxity (with thin, wrinkled skin resembling prune)

IMAGING

- Radiographs: Enlarged abdomen with laterally bulging flanks
  - ± undulation or wrinkling of redundant skin
  - ± centralization of bowel gas due to markedly dilated ureters &/or renal collecting systems
  - Small, bell-shaped thorax ± pneumothorax
- VCUG: Marked bilateral vesicoureteral reflux
  - Dilated posterior urethra, but true mechanical obstruction is uncommon
- US: Dilated bladder & ureters; ± caliectasis, cystic renal dysplasia, urachal anomalies
  - Empty scrotum (cryptorchidism)
- MR urography can help delineate complex anatomy & assess renal drainage & dysplasia

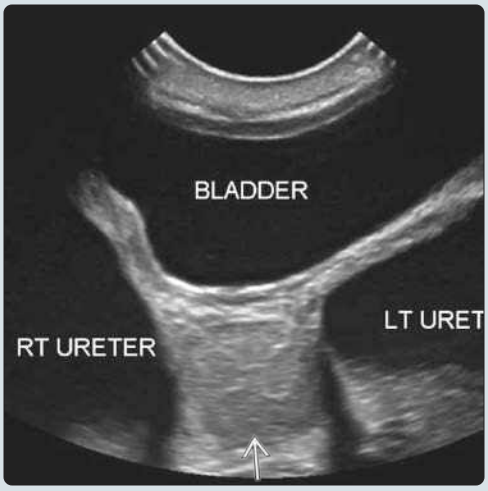


TOP DIFFERENTIAL DIAGNOSES

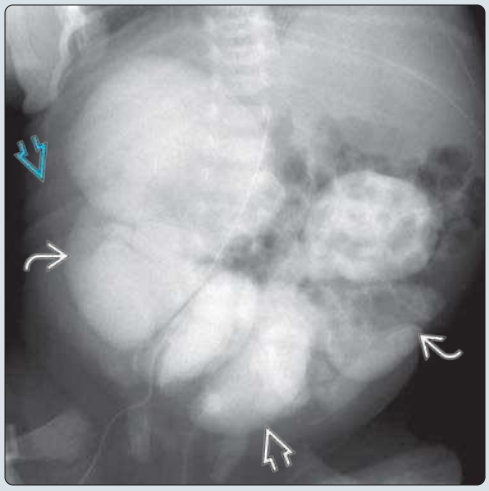


- Posterior urethral valves
- Severe vesicoureteral reflux
- Primary megaureter
- Cloacal anomaly

CLINICAL ISSUES



- Large flaccid abdomen with redundant skin, cryptorchidism, ± Potter facies
- 1 in 30,000-40,000 live births
- 95-99% male
- Variable renal impairment & pulmonary hypoplasia determine prognosis
- Many survivors but with chronic health issues
  - Dialysis or renal transplant in 10-20%



(Left) *Frontal babygram in a newborn with prune-belly syndrome (PBS) shows an enlarged abdomen with bulging flanks & a small thorax. The massively distended urinary bladder shadow is seen in the lower abdomen.* **(Right)** *Longitudinal US in the same newborn with PBS shows numerous cysts scattered through the echogenic renal parenchyma with poor corticomedullary differentiation. The findings are typical of cystic dysplasia of the kidneys, likely due to longstanding bladder outlet obstruction.*

(Left) *Transverse US of the pelvis in a newborn with PBS shows an enlarged urinary bladder with markedly dilated ureters surrounding the rectum.* **(Right)** *Frontal VCUG in a patient with PBS shows infused contrast filling the bladder & rapidly refluxing into markedly dilated, tortuous ureters bilaterally. The ureters hold several times the volume of the bladder. Note the wrinkled abdominal wall.*

TERMINOLOGY

Synonyms

- Eagle-Barrett syndrome, abdominal muscle deficiency, triad syndrome

Definitions

- Prune-belly syndrome (PBS): Congenital triad of
  - Urinary tract dilation
  - Cryptorchidism
  - Abdominal wall muscle deficiency/laxity (with thin, wrinkled skin resembling prune)

IMAGING

General Features

- Best diagnostic clue
  - Urinary tract dilation with abdominal distention & laxity

Radiographic Findings

- Enlarged abdomen with laterally bulging flanks
  - ± undulation or wrinkling of redundant skin
- ± centralization of bowel gas due to markedly dilated ureters &/or renal collecting systems
- Small, bell-shaped thorax ± pneumothorax
  - Longstanding oligohydramnios → pulmonary hypoplasia

Fluoroscopic Findings

- Dilated bladder with lobulation, elongation, wall thickening, diverticula, ± urachal anomaly
- Marked bilateral vesicoureteral reflux
- Dilated posterior urethra; true mechanical obstruction is uncommon

Ultrasonographic Findings

- Dilated bladder & ureters, ± caliectasis & cystic renal dysplasia (echogenic kidneys with small peripheral cysts)
- Urachal anomalies are common
- Empty scrotum (cryptorchidism)
- Deficient abdominal wall musculature

MR Findings

- MR urography can help sort through complex anatomy, assessing renal function & drainage

Nuclear Medicine Findings

- Delayed drainage of ureters is common

DIFFERENTIAL DIAGNOSIS

Posterior Urethral Valves

- "Keyhole" bladder with high-grade obstruction of posterior urethra by valve tissue in males

Severe Vesicoureteral Reflux

- May be associated with megacystis but is typically isolated

Primary Megaureter

- Adynamic distal ureter with proximal dilation

Cloacal Anomaly

- Failure of separation of distal genitourinary & gastrointestinal tracts → single perineal orifice
- Hydrocolpos can cause bladder outlet obstruction

Megacystis-Microcolon-Intestinal Hypoperistalsis Syndrome

- Prognosis is worse in megacystis-microcolon-intestinal hypoperistalsis syndrome (MMIHS)
- MMIHS is more common in females

Congenital Megalourethra

- Findings of bladder outlet obstruction, but entire urethra is dilated

Urethral Atresia

- Very rare; anhydramnios → pulmonary hypoplasia

PATHOLOGY

General Features

- Etiology
  - Controversial: Mesodermal defect vs. early obstruction of bladder outlet
  - Pseudo PBS: Unilateral/incomplete triad, or females
  - Debated whether PBS is truly unique entity vs. phenotype of various bladder outlet pathologies

CLINICAL ISSUES

Presentation

- Large, flaccid abdomen with wrinkled, redundant skin
- Cryptorchidism
- Potter facies if oligohydramnios

Demographics

- 95-99% male
- 1 in 30,000-40,000 live births

Natural History & Prognosis

- Variable renal impairment & pulmonary hypoplasia determine prognosis
  - Perinatal mortality 10-25%
  - Respiratory complications dominate in infancy
  - Renal complications dominate in childhood
- Many survivors but with chronic health issues
  - Genitourinary: 100%
  - Cardiovascular: 10%
  - Orthopedic: 20%
  - Gastrointestinal

Treatment

- Bladder outlet: Vesicostomy, cystoplasty, Mitrofanoff
- Dialysis or renal transplant in 10-20%
- Orchiopexy
- Abdominoplasty, rectus femoris grafts

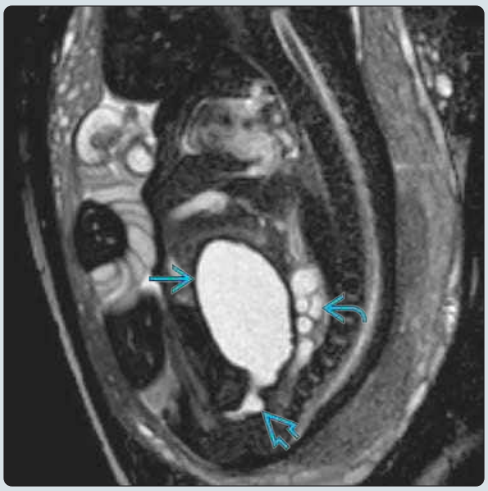
Posterior Urethral Valves

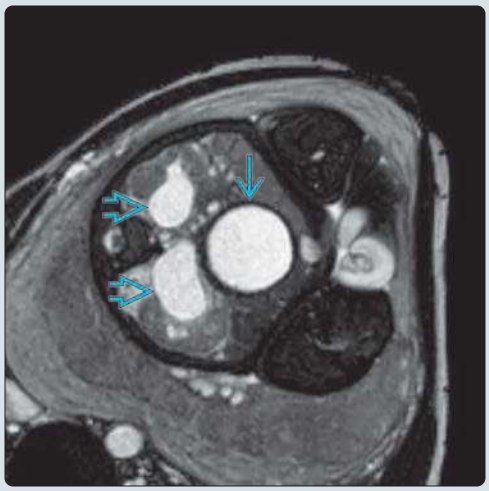
KEY FACTS

TERMINOLOGY

- Varying degrees of chronic urethral obstruction due to fusion &/or prominence of plicae colliculi (which are normal concentric folds within posterior urethra)
- Occurs exclusively in males

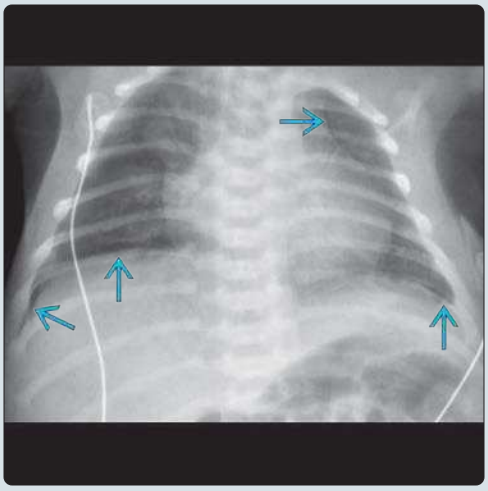


IMAGING

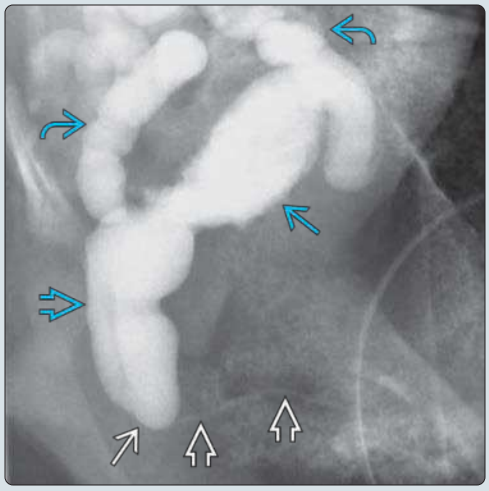


- Voiding cystourethrogram (VCUG)
  - Abrupt transition from dilated posterior urethra to small bulbar urethra at level of valvular tissue; actual valve tissue may not be visible
  - Bladder dilation, wall trabeculation, muscular hypertrophy, diverticula, ± patent urachus
  - Vesicoureteral reflux (50-70%)
- Ultrasound
  - Bilateral hydroureteronephrosis
  - Echogenic, dysplastic kidneys with poor corticomedullary differentiation ± cortical cysts, urinomas, ascites
  - Thickened, irregular bladder wall ± diverticula; dilated posterior urethra may be visible
  - Contrast-enhanced US (with transducer on perineum) can evaluate urethra during voiding

CLINICAL ISSUES



- Severity & duration of obstruction determine age of presentation & clinical symptoms, which include
  - Perinatal: Anuria, pulmonary hypoplasia → pneumothorax
  - Infancy: Urinary tract infection, sepsis, urinary retention, poor urinary stream, failure to thrive
  - Childhood: Abnormal voiding patterns, hesitancy, straining, poor stream, large postvoid residual, renal insufficiency/failure
- Catheterization at birth to relieve obstruction, followed by urgent endoscopic valve ablation
- 30-40% will eventually develop end-stage renal disease
- 75% have long-term urinary bladder dysfunction



(Left) *Sagittal SSFP MR in a 33-weeks-gestation male fetus shows a dilated bladder with wall thickening & irregularity. Note the dilated posterior urethra & ureteral dilation. There is also oligohydramnios with a small chest, suggesting pulmonary hypoplasia.* **(Right)** *Axial SSFP MR in the same fetus shows the dilated, thick-walled urinary bladder & oligohydramnios. Note the marked dilation of the bilateral renal pelves.*

(Left) *AP radiograph in the same patient after delivery shows small bilateral pneumothoraces due to pulmonary hypoplasia.* **(Right)** *Oblique VCUG 3 days later in the same patient shows marked dilation of the posterior urethra with thin valve tissue visualized at the transition to a small-caliber anterior urethra. The urinary bladder is trabeculated, & there is bilateral grade V vesicoureteral reflux (VUR), incompletely visualized on this image.*

TERMINOLOGY

Abbreviations

- Posterior urethral valves (PUV)

Definitions

- PUV: Varying degrees of chronic urethral obstruction due to fusion &/or prominence of plicae colliculi (which are normal concentric folds within posterior urethra)
- Valve bladder: Varying degrees of urinary bladder dysfunction secondary to chronic bladder obstruction

IMAGING

General Features

- Best diagnostic clue
  - Dilated posterior male urethra with distinct caliber change at level of valves
    - Actual valve tissue is very thin, may not be visible
  - Diagnosis is made on voiding cystourethrogram (VCUG), cystoscopy, or cystosonography
- Location
  - PUV lie just distal to prostatic urethra

Radiographic Findings

- Dilated urinary bladder creates pseudomass in pelvis, displacing bowel loops superiorly
- Perinephric urinoma, dilated ureters, & dilated renal collecting systems may cause additional mass effect
- ± small, bell-shaped thorax of pulmonary hypoplasia, ± pneumothorax & pneumomediastinum

Fluoroscopic Findings

- Voiding cystourethrogram
  - Hallmark: Abrupt caliber change in posterior urethra
    - Dilated posterior urethra gives rise to small-caliber bulbar & penile urethra
    - Actual valve tissue need not be seen on imaging to make diagnosis
    - Note that leaving urethral catheter in place during voiding may "stent" valve tissue, obscuring caliber change & pushing valve tissue against urethral wall
      - Removal of catheter for diagnostic purposes should be approved by clinical service (if bladder outlet obstruction is suspected prior to test)
  - Associated findings
    - Bladder dilation, wall trabeculation, muscular hypertrophy, diverticula
    - Vesicoureteral reflux (VUR) in 50-70%
    - Urinary ascites
    - Urinoma/perinephric urine collection
    - Reflux into utricle, vas deferens, or other ducts
    - Patent urachus

Ultrasonographic Findings

- Grayscale ultrasound
  - Bilateral or unilateral hydroureteronephrosis
  - Echogenic, dysplastic kidneys with poor corticomedullary differentiation ± cortical cysts, urinomas, ascites
  - Lobular bladder with thickened, irregular wall ± diverticula
  - Angling transducer toward bladder neck (or placing on perineum) may reveal dilated posterior urethra
- Cystosonography or contrast-enhanced US
  - Eliminates radiation of fluoroscopic VCUG
  - Exam is performed from transperineal approach
  - Catheterization (to instill bladder contrast) & voiding during imaging are still required

MR Findings

- Fetal MR
  - Shows bladder outlet obstruction with dilated posterior urethra as well as hydroureteronephrosis & cystic renal dysplasia
  - May be used to measure lung volumes in setting of oligohydramnios
- MR urogram
  - Anatomic findings mirror US, though dilated ureteral course is more discernible by MR
  - Physiologic study can be performed with dynamic contrast evaluation of renal function & drainage
    - Caution is required with low glomerular filtration rate due to concerns of gadolinium retention & nephrogenic systemic fibrosis

Nuclear Medicine Findings

- Cortical imaging for scarring & differential renal function
- Diuretic renogram to evaluate additional obstructing lesion of ureter or renal pelvis

Other Modality Findings

- At direct cystoscopy, valve tissue is translucent & may be pushed back against outer walls of urethra by inflowing irrigation fluid
- Similar drawbacks to fluoroscopic retrograde urethrogram, which may not show dynamic change in urethral caliber

Imaging Recommendations

- Best imaging tool
  - Fluoroscopic VCUG vs. cystosonography with contrast

DIFFERENTIAL DIAGNOSIS

Prune-Belly Syndrome (Eagle-Barrett)

- Hydroureteronephrosis
  - Posterior urethra is dilated but nonobstructed
  - Entire urethra may be dilated
- Absence/hypotonia of abdominal wall musculature
- Cryptorchidism

Anterior Urethral Valves

- Very rare entity where prominent semilunar fold obstructs anterior urethra

Voiding Dysfunction

- Detrusor external sphincter dyssynergia can resemble PUV transiently (due to opening of bladder neck with bulging posterior urethra & contracted external sphincter)
- Appearance is not persistent

Ureterocele

- Prolapse into posterior urethra can cause obstruction

Megalourethra

- Rare entity where entire length of urethra is markedly dilated due to absence of corpus spongiosum

Urethral Stricture

- Post surgical, post traumatic, or post infectious
- History is key to making this diagnosis

Megacystis-Microcolon-Intestinal Hypoperistalsis Syndrome

- M:F = 1:4
- Dilated hypoperistaltic bowel with malrotation
- Nonobstructive megacystis

Megacystis-Megaureter Association

- Large-volume VUR cycling between dilated upper tracts & bladder

PATHOLOGY

General Features

- Associated abnormalities
  - Longstanding oligohydramnios leads to pulmonary hypoplasia, which may not be survivable

Staging, Grading, & Classification

- Type I (most common): Anterior fusion of plicae colliculi
- Type II (rarest): Longitudinal folds from verumontanum to bladder neck
- Type III (rare): Disc, ring, or windsock-type tissue distal to verumontanum

Gross Pathologic & Surgical Features

- Valve tissue is typically very thin but functions like sail, causing near complete obstruction to antegrade flow of urine

Microscopic Features

- Valve tissue is thin, normal urothelium
- Bladder wall will show muscular hypertrophy & fibrosis
- Kidneys may show tubulointerstitial fibrosis & dysplasia

CLINICAL ISSUES

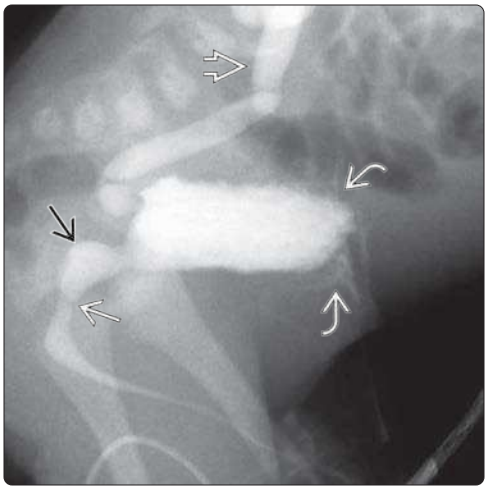
Presentation

- Most common signs/symptoms
  - Severity & duration of obstruction determine age of presentation & clinical symptoms, which include
    - Perinatally: Oligohydramnios, hydronephrosis ± renal dysplasia & renal failure, anuria, urinary ascites, urinoma, pulmonary hypoplasia
    - In infancy: Urinary tract infection, sepsis, urinary retention, poor urinary stream, failure to thrive
    - In childhood: Abnormal voiding patterns, hesitancy, straining, poor stream, large postvoid residual, renal insufficiency/failure
  - Classically 1/3 present at each age: Perinatal, infancy, childhood
    - Up to 1/2 of all cases are now diagnosed in utero

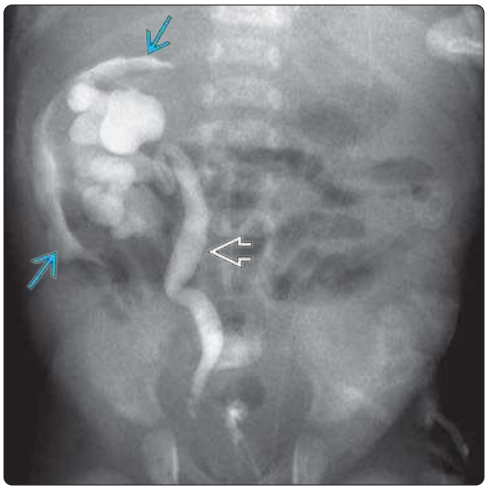
Demographics

- Sex
  - Males only
- Epidemiology
  - Incidence: 1 in 4,000-5,000 births

Natural History & Prognosis



- Varies with degree of renal dysplasia related to chronic obstruction & VUR
- Unilateral reflux & urinary ascites are protective for contralateral kidney (relieve pressure)
- Renal insufficiency has bimodal peak, developing in 1st months of life vs. adolescence after initial improvement
  - Lowest creatinine in 1st year of life (nadir Cr) has some prognostic value
- 17-40% will eventually develop end-stage renal disease
- 75% have long-term urinary bladder dysfunction
  - Poor bladder compliance, overactivity, & myogenic failure (incomplete bladder emptying, overflow incontinence)



Treatment

- Catheterization at birth to relieve obstruction
- Urgent endoscopic valve ablation
  - VUR ↓ by 30% after valve ablation
  - Improved renal function with early treatment
- Long-term follow-up is necessary to monitor renal function & bladder compliance
  - Urodynamics to assess bladder capacity, overactivity, contractility
  - Treated with anticholinergics, alpha-adrenergic blockers, bladder neck incision
- Secondary bladder surgeries are often needed: Bladder augmentation or continent diversion (Mitrofanoff)
  - ↑ risk of malignancy decades after bowel augmentation
- Dialysis, renal transplant for end-stage renal disease
  - 10-15% of pediatric renal transplants are due to PUV
  - Comparable transplant survival rates in PUV patients vs. patients with nonobstructive etiologies
- Fetal intervention is performed in cases of severe oligohydramnios; conflicting data on long-term renal function benefit, though procedures may ↑ "pulmonary survivors" needing renal replacement therapy
  - Serial amnioinfusions to restore normal amniotic fluid volume (to promote lung development)
  - Serial bladder taps vs. vesicoamniotic shunt
  - In utero cystoscopy with valve fulguration

(Left) *Lateral VCUG in a newborn with PUV shows the thin valvular tissue ➡ at the inferior margin of the dilated posterior urethra ⇨. The urinary bladder wall is markedly thickened with contrast extending between the trabeculations ➡. High-grade unilateral VUR ➡ is noted.* **(Right)** *Frontal VCUG in the same patient after voiding shows contrast pooling around the right kidney ⇨. This urinoma is due to high-pressure VUR ➡ causing a forniceal rupture in the setting of a chronic bladder outlet obstruction.*

(Left) *Longitudinal ultrasound of the left kidney in a newborn with PUV shows marked pelvocaliectasis ⇨ & cystic dysplastic changes of the renal cortex ➡ due to chronic obstruction in utero.* **(Right)** *Frontal prone radiograph during bilateral percutaneous nephrostomy tube placements ➡ shows contrast filling severely dilated ureters ⇨ & a lobulated urinary bladder ➡.*

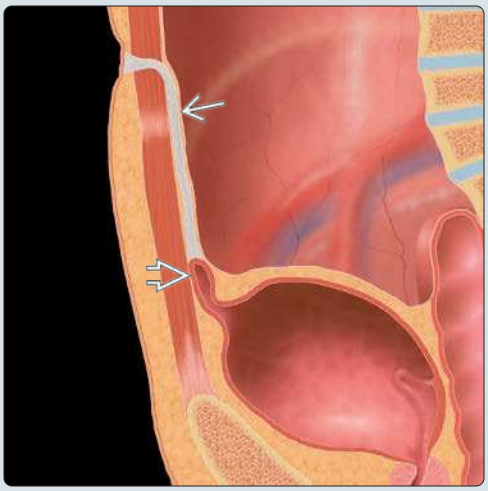
(Left) *Fluoroscopic image in a 4-month-old during VCUG voiding phase shows marked dilation of the posterior urethra ➡ with an abrupt change in urethral caliber ➡. Note the bladder wall hypertrophy ⇨ visible at the bladder base.* **(Right)** *Additional fluoroscopic spot image in the same infant just moments later shows contrast surrounding the valve tissue ➡, illustrating the dynamic nature of the VCUG findings in PUV. Bladder wall hypertrophy ⇨ & VUR ⇨ are also visible.*

Urachal Abnormalities

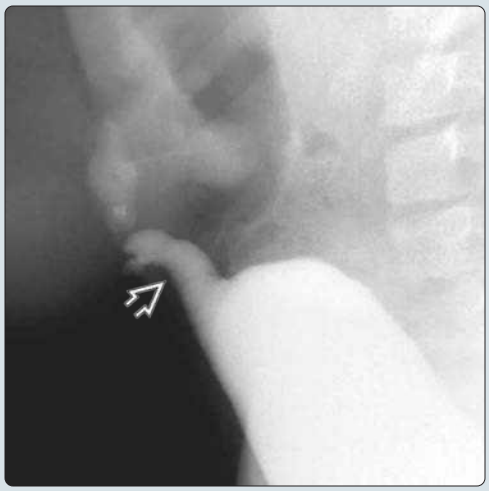
KEY FACTS

TERMINOLOGY

- Persistence of all or portion of connection between bladder dome & umbilicus; remnant of fetal allantoic stalk



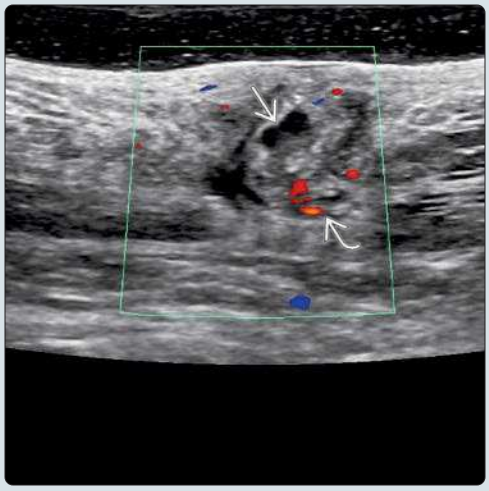
IMAGING



- Patent urachus or urachal fistula
  - Open channel from bladder to umbilicus through which urine can leak
- Urachal sinus
  - Persistence of superficial segment of channel opening onto skin surface
- Urachal diverticulum
  - Persistence of deep segment of tract, creating point or diverticulum off of anterior-superior bladder wall
- Urachal cyst
  - Persistence of intermediary segment with fibrous attachments to bladder & umbilicus
- Size & shape depend on type of remnant, location, & presence of inflammation
- Helpful hints for US scanning
  - Bladder should be fairly full
  - Patient should be relaxed as Valsalva maneuver can squeeze fluid out of patent tract
  - Begin scanning at inferior bladder level & sweep transducer upward toward umbilicus
  - Gentle pressure on bladder dome can push fluid into patent tract to aid visualization

CLINICAL ISSUES

- Incidence of patent urachus: 1 in 40,000
  - Other urachal anomalies are more common
  - More cases are now recognized with ↑ cross-sectional imaging
- Generally, prognosis is excellent
  - Urachal tract is resected; no further follow-up is needed
    - Open surgery previously, now laparoscopic
- Risk of malignancy in adults if not resected
  - Urachal malignancies: < 1% of all bladder cancers



(Left) *Sagittal graphic shows a urachal diverticulum ⇨ & fibrotic tract ⇨ to the umbilicus. When the entire tract remains open, it is called a patent urachus. The urachal sinus & urachal cyst are additional variations along this spectrum.* **(Right)** *Lateral voiding cystourethrogram (VCUG) in an infant with a history of umbilical drainage shows a tubular, contrast-filled connection ⇨ between the bladder dome & the umbilicus, consistent with a patent urachus.*

(Left) *Axial NECT in a teenager shows a low-density cyst ⇨ at the base of the umbilicus with thickening of the periumbilical tissues.* **(Right)** *Longitudinal US in the same patient shows mild hyperemia ⇨ & heterogeneity of the periumbilical tissues with a small fluid collection centrally ⇨. A small urachal cyst was resected. Additional considerations for this appearance could include an evolving hematoma, abscess, inflamed dermoid, or other lesions.*

TERMINOLOGY

Synonyms

- Patent urachus, urachal fistula, urachal remnant, urachal cyst, urachal sinus, urachal diverticulum

Definitions

- Partial or complete persistence of connection between bladder dome & umbilicus; remnant of fetal allantoic stalk

IMAGING

General Features

- Best diagnostic clue
  - Fluid or cyst along tract between bladder dome & umbilicus ± umbilical drainage
- Location
  - Midline between dome of bladder & umbilicus
- Size
  - Variable
- Morphology
  - Patent urachus or urachal fistula
    - Open channel from bladder to umbilicus through which urine can leak
  - Urachal sinus
    - Persistence of superficial segment of channel opening onto skin surface
  - Urachal diverticulum
    - Persistence of deep segment of channel creating point or diverticulum off of anterior-superior bladder wall
  - Urachal cyst
    - Localized, fluid-containing intermediary segment with fibrous attachments to bladder & umbilicus
    - Case reports of intravesical urachal cysts along anterior superior bladder wall

Ultrasonographic Findings

- Grayscale ultrasound
  - Size & shape depend on type of remnant, location, & presence of inflammation
    - Diverticulum of fully patent urachus is contiguous with anterior superior aspect of bladder
  - Often has thick, well-defined wall (especially if inflamed)
  - Wall may have layered appearance mimicking gut signature sign
  - Remnant may or may not contain fluid
  - Fluid-debris level may be present in urachal cyst
- Color Doppler
  - Doppler is useful in
    - Assessing degree of hyperemia when infected
    - Excluding vascular anomaly
- Helpful hints when scanning for urachal remnants
  - Bladder should be fairly full
  - Patient should be relaxed as Valsalva maneuver can squeeze fluid out of patent tract
  - Begin scanning at bladder level & sweep transducer upward toward umbilicus
  - Gentle pressure on bladder dome can push fluid into patent tract to aid visualization

Fluoroscopic Findings

- Voiding cystourethrogram (VCUG)
  - Best test to document patency of urachus
  - Tends to underestimate length or extent of remnant
  - Inflammation along tract can intermittently block lumen
  - True lateral views are necessary (with full bladder)
  - Radiopaque marker on umbilicus can be helpful

CT Findings

- Occasionally recognized incidentally on CT scans performed for other reasons
  - Infected urachal cyst may present with "rule out abscess" manifestations
- Look for round, triangular, or tubular, fluid-filled structure extending along anterior aspect of peritoneal cavity between urinary bladder & umbilicus
  - Lies superficial to parietal peritoneal layer
- Localized cyst may be seen when proximal & distal segments of tract are fibrotic
- Surrounding inflammation is common

MR Findings

- Similar findings as CT
- Often incidental finding on MR scan

Nuclear Medicine Findings

- Flow of renally excreted radiotracers into tract from urinary bladder may mimic other pathology
  - FDG PET could falsely suggest malignancy

Imaging Recommendations

- Best imaging tool
  - Ultrasound defines static anatomy well
  - VCUG will show flow dynamics & confirm patency

DIFFERENTIAL DIAGNOSIS

Granulation Tissue of Umbilical Stump

- Hypoechoic tissue often confused with urachal remnants, especially urachal sinus
- No deeper discrete fluid-filled tract is visible

Omphalitis

- Poorly defined, heterogeneous inflammation of anterior abdominal wall just deep to umbilicus
- Can be present in conjunction with urachal remnant
- In severe cases, may need to treat with antibiotics & reevaluate

Obliterated Median Umbilical Ligament

- Normally closed urachus may remain visible as nondistensible tract

Umbilical Hernia

- Usually readily discerned by physical exam & imaging
- Hernia may contain peristalsing bowel or omentum
- Helpful to scan patient upright & with Valsalva

Hemangioma of Umbilical Cord

- Doppler ultrasound will show high volume of low-resistance arterial blood flow in lobulated mass rather than stagnant fluid

PATHOLOGY

General Features

- Etiology
  - In embryos, allantois
    - Forms from caudal end of yolk sac
    - Functions as primitive bladder as well as blood-forming organ
    - Normally involutes by 12th week of gestation
    - Obliteration forms median umbilical ligament
    - Segments may persist as urachal remnants
  - Urachus lies in space of Retzius
    - Between transversalis fascia anteriorly & peritoneum posteriorly
- Associated abnormalities
  - Periumbilical associations
    - Omphalocele
    - Omphalomesenteric remnant
  - Bladder outlet associations
    - Posterior urethral valves
    - Urethral atresia
    - Cloacal anomalies
    - Urogenital sinus malformation
  - Miscellaneous associations
    - Myelomeningocele (perhaps because of neurogenic bladder)
    - Unilateral kidney & other renal anomalies
    - Vaginal atresia

Gross Pathologic & Surgical Features

- Well-defined stalk with mucosal lining & varying degrees of fibrosis/lumen obliteration

Microscopic Features

- Cellular histology varies, not simple urothelium
  - Transitional cell epithelium
  - Columnar epithelium
  - Glandular epithelium
  - Squamous epithelium
- Varied cell types explain variety of malignant cell lines found in adults with urachal tumors
- Fibrostromal histology has low risk of malignant transformation, while epithelial histology has higher risk
  - Imaging & symptoms do not differentiate between histologic subtypes

CLINICAL ISSUES

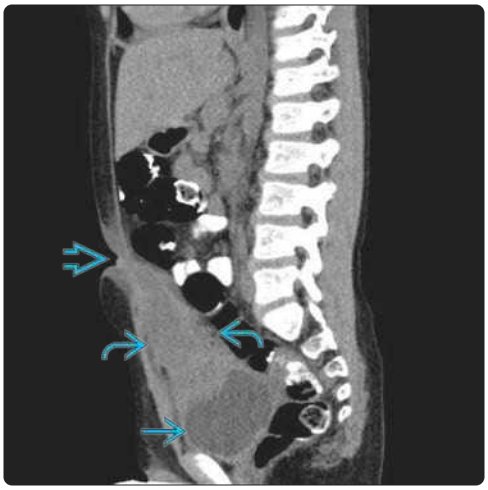
Presentation

- Most common signs/symptoms
  - Varies with type of urachal remnant
    - Patent urachus presents with drainage from umbilicus, urinary tract infection, & relapsing periumbilical inflammation
    - Occasionally, urachus remains patent in response to bladder outlet obstruction (posterior urethral valves, pelvic mass, etc.) & will close when outlet is repaired
    - Urachal sinus presents with periumbilical tenderness, wet umbilicus, or nonhealing granulation of umbilicus
    - Urachal cyst presents in childhood or adolescence with suprapubic mass, fever, pain, & voiding issues
    - Urachal diverticula are often asymptomatic & discovered incidentally; rarely, they enlarge, fail to drain during urination, & become predisposed to infection or stone formation

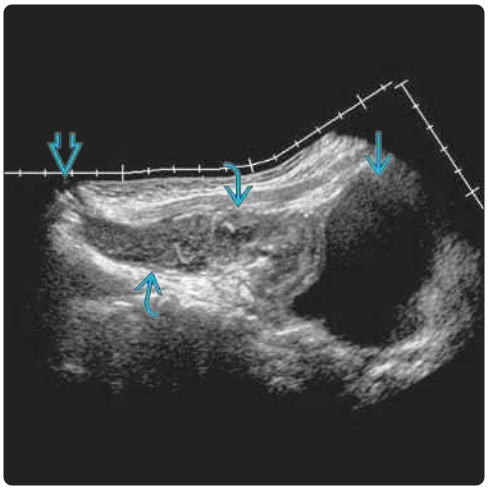
Demographics

- Age
  - Patent urachus is seen primarily in newborns
  - Urachal sinus is also typically diagnosed within 1st few months of life
  - Urachal cysts may go undetected until childhood or adulthood
  - Urachal diverticulum often goes undetected (autopsy finding)
- Epidemiology
  - Incidence of patent urachus: 1 in 40,000
  - Other urachal anomalies are more common, though reliable statistics are not available

Natural History & Prognosis



- Generally excellent prognosis
  - Urachal tract is resected; no further follow-up needed
- Risk of malignancy without resection: Adenocarcinoma, mucinous cystadenocarcinoma, villous adenoma, yolk sac carcinoma
  - Urachal malignancies: < 1% of all bladder cancers
  - Typically occur in patients 40-70 years of age
  - Majority of cancers occur in men (~ 75%)
  - Present with pain, hematuria, or mucinous micturition
  - Local tumor invasion is common at diagnosis of urachal cancer
  - Tumor rupture → pseudomyxoma peritonei
- Reports of using urachal remnant instead of appendix for Mitrofanoff



Treatment

- Resection of entire tract
  - Open surgery previously, now laparoscopic
- Often performed in staged fashion
  - Inflammation & infection are treated, allowed to heal
  - Definitive surgery is delayed
- When accompanied by bladder outlet obstruction
  - Surgery to fix outlet obstruction must be performed 1st
    - Patent urachus serves as pop-off valve in these cases
  - Following correction of bladder outlet problems, allow ~ 1 year for patent urachus to close independently
  - If drainage persists, reassess bladder outlet; if functioning well, resect tract

(Left) *Sagittal NECT in a 7-year-old boy with abdominal pain & fever shows mildly heterogeneous soft tissue density between the bladder & umbilicus. The appendix was normal (not shown), & US was ordered for further evaluation.* **(Right)** *Sagittal US in the same patient shows a complex collection extending from the bladder to the umbilicus. No flow of internal mobile contents to the bowel, bladder, or skin was demonstrated. At surgery, an infected urachal remnant was resected.*

(Left) *Longitudinal US in a 6-year-old boy with fever & periumbilical pain shows an irregularly shaped hypoechoic tract between the bladder & umbilicus. Foul smelling fluid/urine was expressed from the tract during the scan, consistent with an infected patent urachus.* **(Right)** *Longitudinal US in the same patient after a course of antibiotics shows a ↓ caliber of the patent urachus, which was subsequently surgically excised. Note the pointed shape of the bladder dome (which is usually round).*

(Left) *Coronal CECT performed for suspected appendicitis in a patient with pain shows a thin, triangular soft tissue lesion extending from the dome of the bladder toward the umbilicus, either a urachal remnant or bladder diverticulum.* **(Right)** *Sagittal SSFSE T2 MR of a fetus with bladder outlet obstruction shows high signal intensity fluid in a small-caliber patent urachus helping to decompress the thick-walled urinary bladder. Note the lack of amniotic fluid surrounding the fetus.*

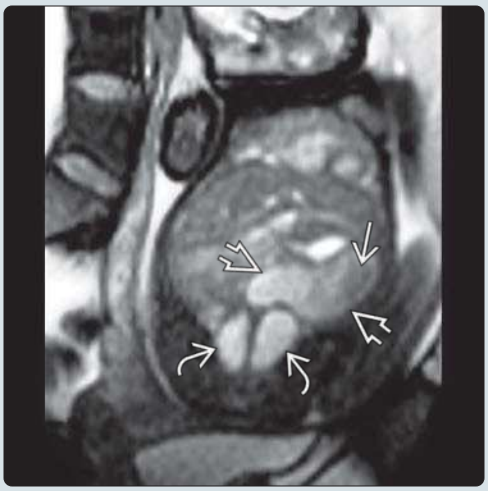
Cloacal Malformation

KEY FACTS

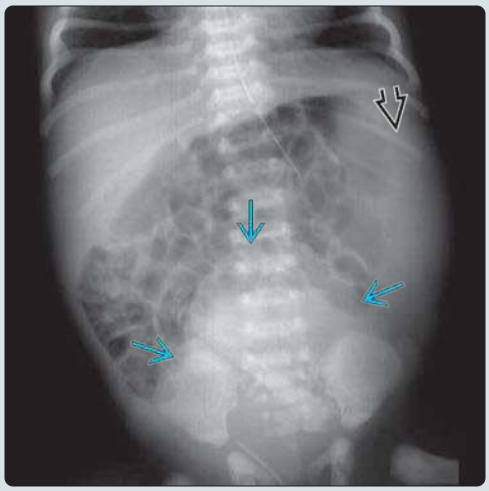
TERMINOLOGY

- Anorectal malformation of female patients in which rectum, urethra, & vagina converge to form common channel draining to single perineal orifice (which allows clinical diagnosis)
- Imaging is performed for operative planning & to evaluate associated malformations

IMAGING

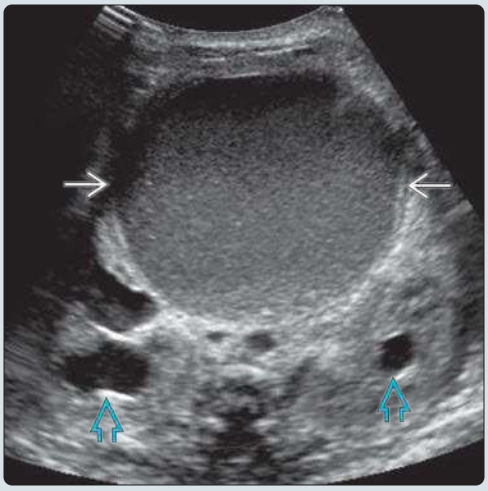


- Radiographs: Multiple dilated bowel loops, ± bowel Ca^{2+}
- US: Renal, pelvic, & spine
  - Cystic pelvic mass: Most commonly hydrocolpos (> 30% of all cloaca patients)
    - Rarely dilated bladder, meconium pseudocyst
  - ± hemivaginas/hemiuteri (40%)
  - ± hydroureteronephrosis
  - ± echogenic calcified meconium in dilated bowel or bladder
  - ± spinal anomalies
- Postcolostomy distal colostogram/cloacagram prior to definitive repair
  - Fluoroscopy, MR, or contrasted US

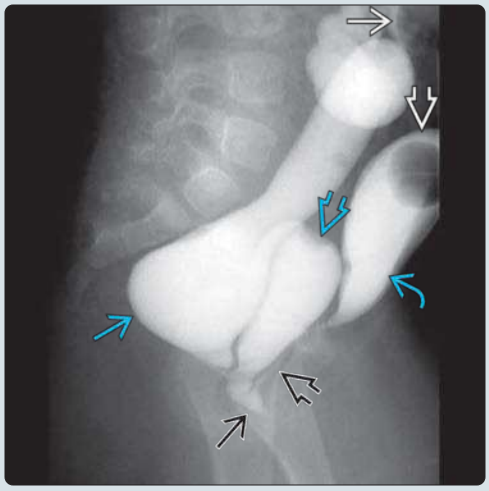


TOP DIFFERENTIAL DIAGNOSES

- Anorectal malformation
- Other low/distal neonatal bowel obstructions
- Isolated hydrocolpos
- Megacystis-microcolon-intestinal hypoperistalsis syndrome



CLINICAL ISSUES



- Hydrocolpos → ↓ renal function without urgent drainage
- Prognosis is based on common channel length
  - < 3 cm: Most common type (56%), less complex repair, better functional prognosis
  - > 3 cm: Less common type (44%), more complex repair, worse functional prognosis

(Left) *Coronal SSFP MR in a 31-weeks-gestation female fetus with a cloaca shows 2 dilated hemivaginas (HVs) & a dilated but tapering distal colon. The heterogeneous, low-signal material within the dilated colon suggests meconium ± calcification.* **(Right)** *AP abdominal radiograph in a 1-day-old girl with a cloaca shows a large soft tissue mass arising from the pelvis, displacing bowel superiorly & laterally, likely representing hydrocolpos. The left flank soft tissue mass is likely due to a meconium-filled colon.*

(Left) *Transverse ultrasound in the same patient shows a markedly distended vagina filled with echogenic fluid. There is moderate hydronephrosis of both kidneys. The urinary bladder & distal ureters (not shown) were compressed by the hydrocolpos.* **(Right)** *Injection of a mucous fistula & vesicostomy shows filling of the rectum, vagina (with cervical impression), & bladder + urethra. All of these structures drain into a common channel (or cloaca).*

TERMINOLOGY

Definitions

- Anorectal malformation in female patients in which rectum, urethra, & vagina converge to form common channel (CC) that drains to single perineal orifice (which allows clinical diagnosis)

IMAGING

General Features

- Best diagnostic clue
  - Dilated bowel + hydrocolpos in female fetus (or neonate with single perineal orifice)

Radiographic Findings

- Neonatal intestinal obstruction
  - Multiple dilated bowel loops with variable degree of rectal distention
  - Displacement of gas-filled bowel by dilated structures
    - Hydrocolpos (> 30% of all patients)
    - ± meconium filled colon
  - ± bowel or bladder Ca^{2+} from mixing of urine & meconium
  - ± curvilinear peritoneal Ca^{2} (if bowel perforation)
  - Additional findings
    - ± spinal/radial ray anomalies
    - ± cardiomegaly, pulmonary edema → congenital heart disease
    - ± proximal esophageal pouch → esophageal atresia
    - ± double bubble → duodenal atresia

Ultrasonographic Findings

- Grayscale ultrasound
  - Neonatal cystic pelvic mass: Commonly hydrocolpos
    - Dilated vagina(s) mimics bladder
  - Hemivaginas/hemiuteri (40%)
  - ± hydroureteronephrosis (HUN); other GU anomalies (renal agenesis, cross-fused ectopia, horseshoe kidney)
  - ± echogenic calcified meconium in dilated bowel or bladder
  - ± ascites
  - ± spinal cord anomalies
- Contrast-enhanced ultrasound
  - Catheterization of CC can be used to study cloaca after colostomy: Genitosonography & colosonography

Fluoroscopic Findings

- Voiding cystourethrogram
  - Not often helpful precolostomy; difficult bladder catheterization
  - Usually postrepair to check for vesicoureteral reflux, neurogenic bladder
- Fistulagram
  - Postcolostomy: Inject mucous fistula → opacify distal colon ± bladder, single/hemivagina(s), CC
    - Length of CC & urethra are important to operative planning, prognosis
  - ± cloacagram by rotational fluoroscopy or MR

DIFFERENTIAL DIAGNOSIS

Anorectal Malformation

- Other types in female patients: Imperforate anus + rectovestibular fistula, rectoperineal fistula, or no fistula
  - Isolated rectovaginal fistula is rare
  - > 1 perineal orifice is present clinically

Other Low/Distal Neonatal Bowel Obstructions

- Anus is present on physical exam
- Contrast enema to differentiate
  - Meconium ileus
  - Ileal atresia
  - Hirschsprung disease
  - Small left colon/meconium plug syndrome
  - Colonic atresia

Isolated Hydrometrocolpos

- Vaginal septum or imperforate hymen; anus is present on physical exam

Megacystis-Microcolon-Intestinal Hypoperistalsis Syndrome

- Large bladder may mimic hydrocolpos; anus is present on physical exam

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Single perineal orifice; abdominal distention

Natural History & Prognosis

- Hydrocolpos → ↓ renal function in neonate (due to bladder outlet obstruction) without urgent drainage
- Prognosis is based on CC length
  - < 3 cm: Most common (56%), less complex repair, better functional prognosis
  - > 3 cm: Less common (44%), more complex repair, worse functional prognosis

Treatment

- Surgical repair depends on length of CC
  - < 3 cm: Posterior sagittal anorectoplasty (PSARP) + urogenital mobilization
  - > 3 cm: PSARP ± laparotomy/oscopy + complex surgical reconstruction

Bladder Exstrophy

KEY FACTS

TERMINOLOGY

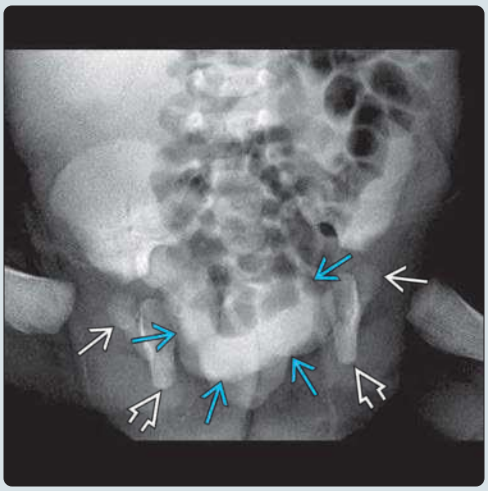
- Classic bladder exstrophy (CBE): Low midline abdominal wall defect with exposure of bladder plate & urethra + low-set umbilicus
  - Split lower abdominal skin & rectus abdominis + pubic symphysis diastasis
  - Bifid clitoris in females, epispadias in males
  - Deficient genitalia & pelvic floor muscles
- Epispadias: Abnormal dorsal urethral opening
  - With CBE, entire dorsal urethra is open with abnormal bladder sphincter

IMAGING

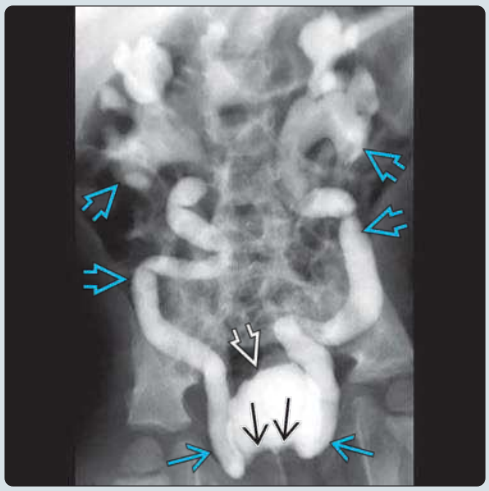
- Absent urinary bladder by prenatal sonography with normal amniotic fluid
- Pubic symphysis diastasis
- Lobular soft tissue at lower abdominal wall
- High rates of vesicoureteral reflux & dysfunctional bladder prior to ureteral reimplants & bladder neck reconstruction

TOP DIFFERENTIAL DIAGNOSES

- Cloacal exstrophy/OEIS complex
- Omphalocele
- Gastroschisis
- Impaired urine production (absent bladder)



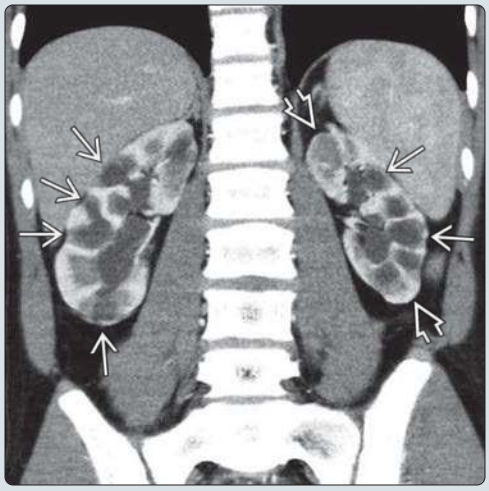
PATHOLOGY



- Cloacal membrane rupture due to failed mesodermal ingrowth

CLINICAL ISSUES

- Incidence of 1:10,000-1:50,000 live births
- 2.3-6:1 = M:F
- Modern staged repair vs. complete primary repair
  - Continence is achieved in up to 81%
  - Most perform clean intermittent catheterization



(Left) *AP pelvic radiograph in a neonate with bladder exstrophy shows lobular soft tissues of the open bladder plate with splayed pubic & ischial bones. Note the normal sacrum. This can help differentiate this entity from cloacal exstrophy in which the sacrum is dysplastic or hypoplastic.* **(Right)** *Frontal VCUG in a 3-year-old girl after bladder exstrophy repair shows a small lobulated bladder with elevated bladder base, J-shaped ureterovesical junctions, & bilateral high-grade vesicoureteral reflux (VUR).*

(Left) *Transverse US of the bladder in an adolescent with a history of bladder exstrophy shows a large echogenic stone with posterior shadowing at the dependent portion of the bladder. These may be treated by extracorporeal shock wave lithotripsy. Note the irregular bladder morphology.* **(Right)** *Coronal CECT in a 17-year-old boy with a history of repaired bladder exstrophy shows multifocal renal scars bilaterally with a globally scarred small left kidney secondary to VUR of infected urine after bladder closure.*

TERMINOLOGY

Synonyms

- Exstrophy-epispadias complex

Definitions

- Classic bladder exstrophy (CBE): Low midline abdominal wall defect (AWD) with exposure of bladder plate & urethra + low-set umbilicus
  - Split lower abdominal skin & rectus abdominis + pubic symphysis diastasis
  - Bifid clitoris in girls, epispadias in boys
- Epispadias: Abnormal dorsal urethral opening
  - In CBE, entire urethra is open with abnormal bladder sphincter

IMAGING

General Features

- Best diagnostic clue
  - Absent urinary bladder on prenatal US but normal amniotic fluid
  - Pubic symphysis diastasis on postnatal radiographs

Radiographic Findings

- Pubic symphysis > 1 cm
- Lobular soft tissues of lower abdominal wall from everted bladder
- ± inguinal hernias (with gas-filled bowel within hernia)

Fluoroscopic Findings

- Voiding cystourethrogram
  - Performed after bladder closure
  - High rate of vesicoureteral reflux (VUR)
  - Variable bladder capacity, shape
  - Postop findings: Potential bladder rupture, urethral stricture/fistula

Ultrasonographic Findings

- Prenatal
  - Nonvisualized urinary bladder but normal amniotic fluid
  - Low position of umbilicus
  - Lobular soft tissue at infraumbilical abdominal wall
  - Diminutive genitalia
  - Splayed echogenic pubic & iliac bones
- Postnatal
  - Variable bladder size, shape, & wall thickness post repair
  - VUR → pelvocaliectasis ± pyelonephritis & scarring

CT Findings

- External rotation of pubic & iliac bones, pubic bone shortening, acetabular retroversion

Nuclear Medicine Findings

- DMSA to evaluate renal split function & scarring

MR Findings

- Assessment of pelvic floor musculature deficiencies

Imaging Recommendations

- Best imaging tool
  - Prenatal ultrasound/MR, postnatal clinical exam

DIFFERENTIAL DIAGNOSIS

Cloacal Exstrophy/OEIS Complex

- Low midline AWD
- Absent bladder with normal amniotic fluid
- Exposed bladder halves divided by everted cecum
  - ± elephant trunk appearance of prolapsed ileum
- Omphalocele, imperforate anus, spine anomalies

Omphalocele

- Central AWD
- Bowel & other viscera herniate into umbilical cord base
  - Contents are covered by sac
- Lower abdominal wall & urinary bladder are intact

Gastroschisis

- Off-midline AWD: Bowel herniated right of umbilicus
  - No covering membrane
- Lower abdominal wall & bladder are intact

Impaired Urine Production (Absent Bladder)

- Bilateral renal abnormalities (same or combination) → oligo-/anhydramnios → pulmonary hypoplasia
  - Multicystic dysplastic kidney
  - Ureteropelvic junction obstruction
  - Polycystic renal disease, recessive
  - Renal agenesis

CLINICAL ISSUES

Demographics

- Sex
  - M:F = 2.3-6:1
- Epidemiology
  - 1:10,000-1:50,000 live births

Natural History & Prognosis

- Continence in up to 81%: Most perform clean intermittent catheterization, especially after augmentation

Treatment

- Modern staged repair
  - Stage I, newborn: Close AWD, bladder, & posterior urethra + iliac osteotomy
  - Stage II, age 6-12 months: Epispadias repair
  - Stage III, age 4-5 years: Reconstruct bladder neck + ureteral reimplants
- Complete primary repair ± ureteral reimplant

Renal Ectopia and Fusion

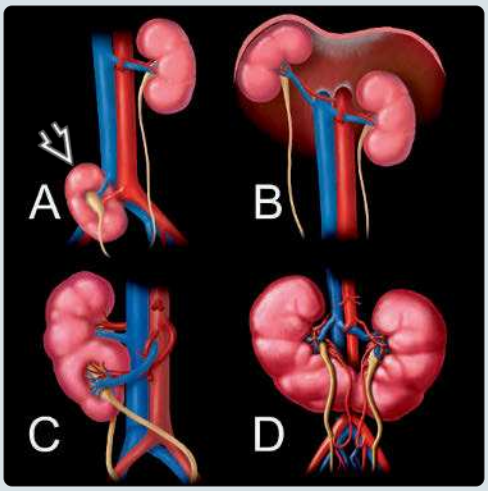
KEY FACTS

TERMINOLOGY

- Includes horseshoe or pancake kidney; crossed fused ectopia; pelvic, iliac/pelvic (ptotic/mobile), & thoracic kidneys
- Results from abnormal ascent & rotation of fetal kidney
- Found anywhere from presacral to intrathoracic; may be bilateral or unilateral; may cross midline
- Malpositioned kidneys are more susceptible to trauma, iatrogenic injury, obstruction, infection, & stones

IMAGING

- US is typically sufficient to document location & gross morphology of ectopic & fused kidneys
  - Accurate lengths are difficult to obtain due to more globular, less reniform shape & poor definition of margin with contralateral fused kidney
- Other modalities are used to answer specific questions (as needed): Drainage, stones, vascular supply, ureteral course
- Isthmus of horseshoe kidney may contain functioning renal tissue or fibrotic nonfunctional tissue
- Ureteral insertion site in bladder provides clue to site where kidney initially formed (i.e., lower pole ureter of crossed fused ectopia inserts into trigone on contralateral side)
- Colon typically occupies empty renal fossa

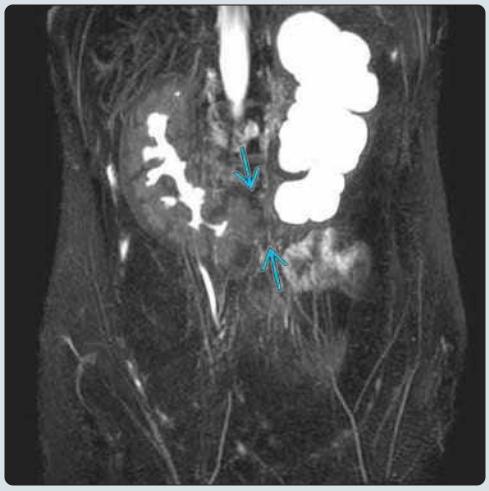


PATHOLOGY

- Horseshoe kidneys are associated with genital anomalies, VACTERL, Turner & other syndromes
- Adrenal ectopia is reported in association with renal ectopia
- Vesicoureteral reflux (20-30%), contralateral renal dysplasia (4%), cryptorchidism (5%), hypospadias (5%)

CLINICAL ISSUES

- Horseshoe kidney is most common: 1 in 400 births
- All types of ectopia are more common in boys than girls
- Primary concern: Avoidance of iatrogenic injury to renal parenchyma & supplying vessels during routine surgery
- Treat complications of obstruction, reflux, & stones



(Left) *Graphic shows variations of renal ectopia & fusion: (A) Pelvic kidney, (B) subdiaphragmatic/thoracic kidney, (C) crossed fused renal ectopia, & (D) horseshoe kidney.* **(Right)** *Longitudinal US shows a crossed fused renal ectopia in the left abdomen with a relatively normal upper moiety & a malrotated, globular lower moiety. Note that the long axis of each moiety is different, which helps distinguish this entity from a duplication. Also, no renal tissue will be seen in the contralateral renal fossa in this setting.*

(Left) *Longitudinal US shows a pelvic kidney (between cursors) abutting the bladder dome in the right lower quadrant. It is easy to imagine this kidney being injured during a laparoscopic appendectomy.* **(Right)** *Coronal oblique T2 FS MIP from an MR urogram in a 14-year-old with a horseshoe kidney shows marked left hydronephrosis secondary to a left moiety ureteropelvic junction (UPJ) obstruction. Note the bridging isthmus of renal tissue at the midline.*

TERMINOLOGY

Synonyms

- Includes horseshoe or pancake kidney; crossed fused ectopia; pelvic, iliac/pelvic (ptotic/mobile), & thoracic kidneys

Definitions

- Normal renal tissue in abnormal location
- Results from abnormal ascent & rotation of fetal kidney
- Kidneys form at sacral level & ascend to L1 by term; renal pelvis is initially directed anteriorly but rotates 90° medially as it ascends
- Malpositioned kidneys are more susceptible to trauma, iatrogenic injury, obstruction, infection, & stones
- High incidence of multiple renal arteries & veins

IMAGING

General Features

- Best diagnostic clue
  - Normal renal parenchyma with abnormal location, axis of orientation, or position of renal pelvis
- Location
  - Anywhere from presacral to intrathoracic, bilateral or unilateral; may cross midline
- Size
  - Overall renal parenchyma volume is similar to orthotopic kidneys; longitudinal measurements vary based on ectopic kidney shape
- Morphology
  - Normal cortex, pyramids, & collecting system; however, pelvocaliectasis is commonly associated
  - Isthmus or midline junctional zone of horseshoe kidney may contain functioning renal tissue or fibrotic nonfunctional tissue

Radiographic Findings

- Radiography
  - Renal shadows are altered from expected positions
  - May simulate midline or pelvic mass
  - Bowel gas may be
    - Displaced by ectopic kidney
    - Occupying renal fossa (with repositioning of splenic & hepatic flexures of colon most commonly)
- IVP
  - Functional renal parenchyma in atypical location; pelvocaliectasis is commonly associated
  - Ectopic kidneys, especially thoracic & horseshoe varieties, may appear mass-like on initial scout view
    - Expect bowel to occupy empty renal fossa
  - Early nephrogram may be missed on tightly coned films (not included in field of view)
  - Abnormalities of vasculature & ureter are also common
    - Ureteral insertion site in bladder provides clue to where kidney initially formed (i.e., lower pole ureter of crossed fused ectopic kidney inserts into trigone on contralateral side)
  - Oblique views are often helpful to profile abnormally rotated collecting system
  - May require fluoroscopic spot views to capture ureteral course
  - Pelvic compression devices should be avoided

Fluoroscopic Findings

- Renal ectopia may be noted incidentally during other fluoroscopic procedures: Gastrointestinal tract studies, voiding cystourethrogram (VCUG), or genitograms

Ultrasonographic Findings

- Grayscale ultrasound
  - Normal echotexture of abnormally positioned renal parenchyma
    - Hydronephrosis & scarring may alter echotexture & architecture
  - Accurate length measurements are difficult to obtain due to more globular & less reniform shape as well as poor definition of margin with fused contralateral kidney
    - Volumes can be helpful
  - May be difficult to see pelvic kidneys due to adjacent bowel gas
  - Colon typically occupies empty renal fossa
- Color Doppler
  - Useful in detecting aberrant vessels & localizing urinary bladder ureteral jets
- Power Doppler
  - Pyelonephritis has ↓ parenchymal perfusion in infected segments

CT Findings

- NECT
  - May initially be seen on renal stone CT
  - Soft tissue "mass" identified along with absence of renal tissue in renal fossa
  - Associated hydronephrosis or stone disease can be clue to aberrant renal position
    - Look for aberrant ureteral course during stone assessment
- CECT
  - Look for abnormal location, rotation, axis, & ureteral course
  - Expect normal renal enhancement & excretion of contrast, except in obstruction
  - Delayed imaging may be useful, depending on study indication
    - To assess parenchyma & collecting system for laceration in trauma setting
    - To localize distal ureters
- CTA
  - Occasionally used for mapping vessels preoperatively

MR Findings

- Similar to other modalities: Abnormal location, axis, & rotation

Nuclear Medicine Findings

- May be found incidentally on renal imaging studies or whole-body exams performed for unrelated reasons
- Nuclear renal studies are sometimes requested specifically to document presence of pelvic kidney that could not be appreciated on US due to intervening bowel gas
- Ectopic kidneys show normal uptake of radiopharmaceutical with variable degrees of pelvocaliectasis

Imaging Recommendations

- Best imaging tool
  - US is typically sufficient to document location & gross morphology of ectopic & fused kidneys
  - Other modalities are used to answer specific questions (as needed): Drainage, stone disease, vascular supply

DIFFERENTIAL DIAGNOSIS

Mass in Typical Ectopic Location

- Renal tissue is still visible in normal locations
- Thoracic considerations
  - Bronchopulmonary sequestration
  - Neuroblastoma
  - Hernia/eventration
- Abdominal
  - Lymphoma
  - Any large neoplasm or cyst of solid organ, viscus, or mesentery
- Pelvis
  - Ovarian tumors
  - Sacrococcygeal teratoma
  - Pelvic rhabdomyosarcoma

Pseudokidney of Intussusception

- Depending on image orientation, ileocolic intussusception can mimic reniform shape & architecture on US
- Real-time cross-sectional sweep or cine through entire length of intussusception will reveal nature of "mass"

Simulated Ectopia Related to Severe Kyphoscoliosis

- Mimics horseshoe kidney or crossed fused ectopia but lacks connection between right & left kidneys
- Cross-sectional imaging or orthogonal views clarify difference

Transplant Kidney

- Often located in pelvis adjacent to iliac vessels
- Native kidneys are often atrophic bilaterally

PATHOLOGY

General Features

- Genetics
  - Horseshoe kidney is associated with genital anomalies, VACTERL (vertebral, anorectal, cardiac, tracheoesophageal, renal, limb abnormalities), Turner & other syndromes
  - Other abnormalities of ascent & rotation are less frequently associated with syndromes
  - Geographic "hot spots" for ectopia suggest either common exposure to teratogenetic factors or hereditary condition with variable penetrance
- Associated abnormalities
  - Urologic abnormalities associated with simple ectopia
    - Vesicoureteral reflux (20-30%)
    - Contralateral renal dysplasia (4%)
    - Cryptorchidism (5%)
    - Hypospadias (5%)
  - Adrenal ectopia is reported in association with renal ectopia
  - Cardiac & skeletal anomalies are common
  - 25% of external ear malformations also have renal anomalies
- Parenchyma is developmentally normal, though secondary changes of obstruction, scarring, & nephrolithiasis are not uncommon
- Embryology/anatomy
  - Results from abnormal ascent & rotation of metanephric blastema after induction by ureteric bud
  - Multiple supplying vessels & draining ureters are common

CLINICAL ISSUES

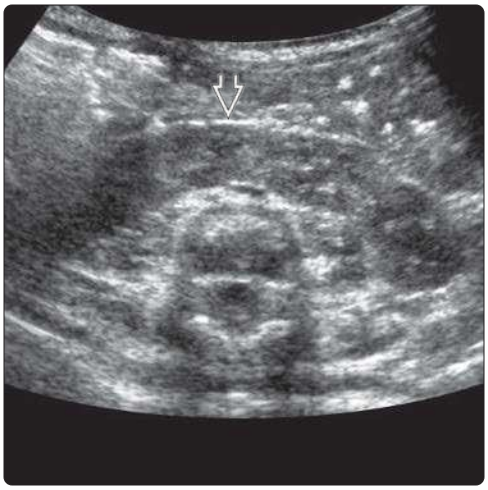
Presentation

- Most common signs/symptoms
  - Often discovered incidentally
  - May be suspected on antenatal US
  - Can present later in infancy as palpable mass or with urinary tract infection (UTI) or obstruction

Demographics

- Sex
  - All types of ectopia are more common in boys than girls
- Epidemiology
  - Horseshoe kidney incidence: 1 in 400 births; most common fusion anomaly
  - Crossed fused ectopic kidney is less common
    - 10% are crossed but not "fused"
  - Simple ectopia is seen in 1 in 900 (autopsy series)
  - Agenesis & pelvic kidney L > R

Natural History & Prognosis



- Aside from complications of obstruction, stone formation, UTI, & injury, most ectopic kidneys function normally
- Primary concern: Avoidance of iatrogenic injury to renal parenchyma & supplying vessels during routine surgery, especially laparoscopic surgery
- Slightly ↑ risk of Wilms & carcinoid tumors reported in horseshoe kidneys
- Prognosis is generally excellent
  - 1/3 of patients with horseshoe kidney are asymptomatic throughout life

Treatment

- Treat complications of obstruction, reflux, & stones

(Left) *Transverse US in a patient with a horseshoe kidney shows a band of renal parenchyma ⇨ crossing over the spine.* **(Right)** *Anterior view 3D reformation from a CECT scan in a patient with multiple congenital anomalies shows a horseshoe kidney with fused lower poles & anteriorly directed renal pelves.*

(Left) *Axial CECT in the pelvis of a 3-year-old shows a crossed fused pelvic kidney ⇨, lower in position than a typical horseshoe kidney. Several small vessels on the left ⇨ may reflect accessory vessels, which are commonly seen.* **(Right)** *Posterior (top) & anterior (bottom) Tc-99m DTPA images in the same patient, performed to assess differential function & GFR, show slightly greater contribution of the right moiety ⇨. Knowledge of ectopic renal position helps to appropriately position gamma cameras for nuclear studies.*

(Left) *Coronal CECT in a 9-year-old after a motor vehicle accident shows a grade III laceration ⇨ of the left inferior moiety of a horseshoe kidney, which is incompletely visualized on this image. A small perinephric hematoma ⇨ is noted, but no urine extravasation was seen on delayed images (not shown).* **(Right)** *Frontal fluoroscopic image during a VCUG shows a crossed fused kidney with the lower moiety ureter crossing the midline to the left side of the bladder ⇨ (since this kidney initially formed as a left kidney).*

Renal Agenesis

KEY FACTS

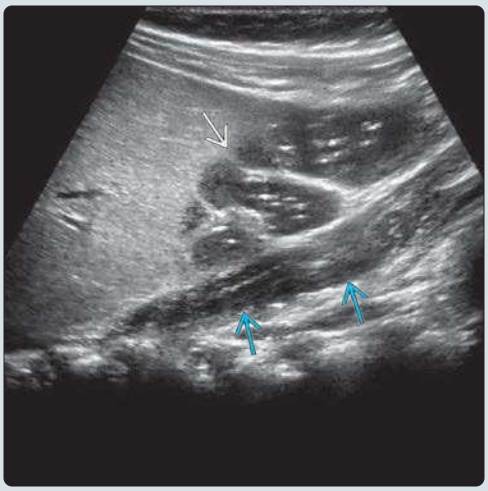
TERMINOLOGY

- Congenital absence of functioning renal tissue
- **C**ongenital **a**bnormality of **k**idney & **u**rinary **t**ract (CAKUT)

IMAGING

- Complete absence of 1 or both kidneys
  - No ectopia or fusion anomaly
- Bowel fills renal fossa
- Linear/flat configuration of ipsilateral adrenal gland
- ± compensatory hypertrophy of remaining kidney
- Best modality: Ultrasound (prenatal or post natal)

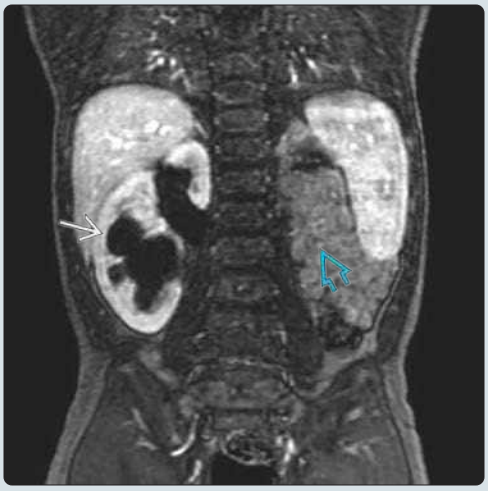
TOP DIFFERENTIAL DIAGNOSES



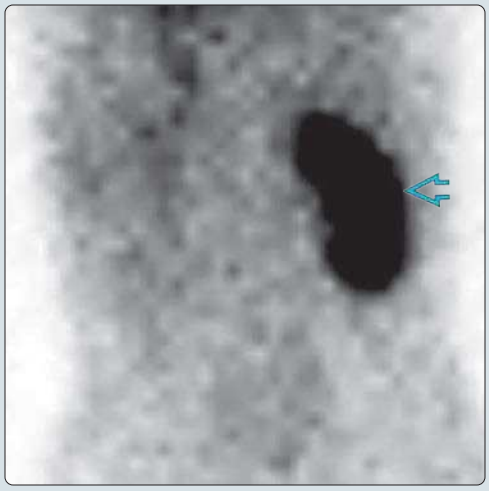
- Involuted multicystic dysplastic kidney
- Ectopic kidney
- Crossed fused renal ectopia
- Prior nephrectomy

PATHOLOGY

- Due to abnormal interaction between ureteric bud of mesonephric duct & metanephric mesenchyme
- Unilateral renal agenesis is associated with
  - Müllerian abnormalities
    - **O**bstructed **h**emi**v**agina, **i**psilateral **r**enal **a**genesis (OHVIRA syndrome)
  - Contralateral renal anomalies are common
  - Extrarenal anomalies in up to 30%
- Bilateral agenesis → Potter sequence: Oligo-/anhydramnios, lung hypoplasia, dysmorphic facies, ± fetal demise



CLINICAL ISSUES



- Unilateral: Usually asymptomatic; associated with medical renal disease later in life
- Bilateral: Classically fatal due to pulmonary hypoplasia & anuria
  - Serial amnioinfusions in utero may allow for "pulmonary survivor" needing dialysis & renal transplant

(Left) *Longitudinal ultrasound of the right renal fossa in a 1-day-old girl with right renal agenesis shows absence of the kidney in the expected location along the right psoas muscle. There are normal, fluid-filled bowel loops in the right renal fossa.* **(Right)** *Oblique ultrasound of the right renal fossa in a 1-day-old boy with right renal agenesis shows an elongated, linear adrenal gland ("lying down adrenal").*

(Left) *Coronal T1 C+ FS MR in a 3-year-old with left renal agenesis shows absence of renal tissue in the left renal fossa (which is filled with decompressed bowel). The right renal collecting system is dilated secondary to a ureteropelvic junction obstruction.* **(Right)** *Posterior coronal image from a Tc-99m DTPA renal scan in a 2-year-old with left renal agenesis shows normal radiotracer uptake in the right kidney with no radiotracer uptake on the left.*

TERMINOLOGY

Synonyms

- **C**ongenital **a**bnormality of **k**idney & **u**rinary **t**ract (CAKUT)
- Solitary kidney

Definitions

- Congenital absence of functioning renal tissue

IMAGING

General Features

- Best diagnostic clue
  - Ultrasound, CT, MR: Absence of kidney in renal fossa without fusion anomaly or ectopia

Radiographic Findings

- Radiography
  - Unilateral: Absence of normal renal shadow
  - Bilateral: ± Potter sequence due to oligohydramnios
    - Abnormal facies, ears
    - Pulmonary hypoplasia with small thorax
    - Respiratory distress, pneumothorax ± pneumomediastinum

Ultrasonographic Findings

- Absent kidney(s) without fusion anomaly or ectopia
- Ipsilateral elongated linear/flat adrenal gland ("lying down adrenal")
- Unilateral: ± compensatory hypertrophy of remaining kidney
- Bilateral: Typically detected by prenatal ultrasound
  - Oligo-/anhydramnios + lack of urinary bladder distention
  - No renal arteries by Doppler

Nuclear Medicine Findings

- Renal scans show lack of renal uptake & excretion

Imaging Recommendations

- Best imaging tool
  - Ultrasound (prenatal or post natal)
  - Nuclear medicine renal scan, CT/MR will demonstrate lack of renal tissue
    - Rarely required for confirmation
- Protocol advice
  - Consider pelvic imaging in girls due to association with müllerian abnormalities

DIFFERENTIAL DIAGNOSIS

Involuted Multicystic Dysplastic Kidney

- Gradual atrophy of reniform collection of cysts

Ectopic Kidney

- Often located in pelvis

Crossed Fused Renal Ectopia

- Contralateral kidney is normally positioned with ectopic kidney lying across midline & fused to lower pole
- Separate ureters insert normally into urinary bladder

Prior Nephrectomy

- Due to renal tumor, severe trauma, obstructed nonfunctioning kidney

PATHOLOGY

General Features

- Etiology
  - Renal development begins in 5th week of gestation
  - Agenesis results from abnormal interaction between ureteric bud of mesonephric duct & metanephric mesenchyme
- Associated abnormalities
  - Unilateral renal agenesis
    - Müllerian abnormalities in girls
      - **O**bstructed **h**emi**v**agina, **i**psilateral **r**enal **a**genesis (OHVIRA syndrome)
      - May be due to ectopic insertion of ureter with resultant obstruction & renal aplasia
      - Typically with uterine didelphys configuration
    - Contralateral renal abnormalities are common
      - Vesicoureteral reflux most common
      - Others: Contralateral ureteropelvic junction obstruction, megaureter, collecting system duplication
    - Extrarenal abnormalities present in up to 30%
  - Bilateral agenesis → Potter sequence: Oligohydramnios, lung hypoplasia, dysmorphic facies

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Unilateral agenesis is usually asymptomatic
  - Bilateral agenesis typically presents in utero with oligohydramnios & pulmonary hypoplasia ± clubfeet, fetal demise
    - At delivery → respiratory distress, abnormal facies, anuria

Demographics

- Epidemiology
  - Overall incidence ~ 1/2,000

Natural History & Prognosis

- Unilateral renal agenesis is associated with medical renal disease later in life
  - ↑ incidence of hypertension, impaired glomerular filtration rate, & proteinuria
    - May be due to hyperfiltration by remaining kidney
- Bilateral is classically fatal due to pulmonary hypoplasia
  - Can perform serial amnioinfusions in utero for oligohydramnios to create "pulmonary survivor" with need for dialysis & renal transplant; controversial

Multicystic Dysplastic Kidney

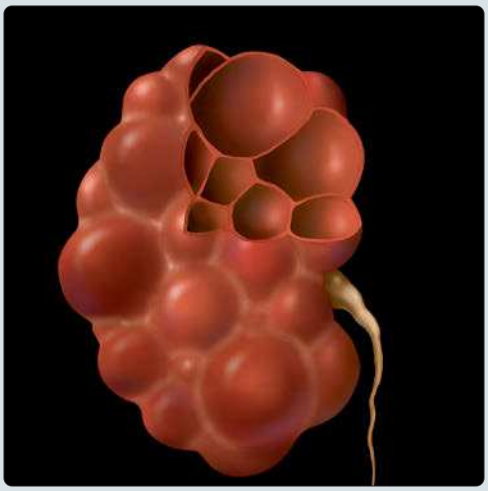
KEY FACTS

TERMINOLOGY

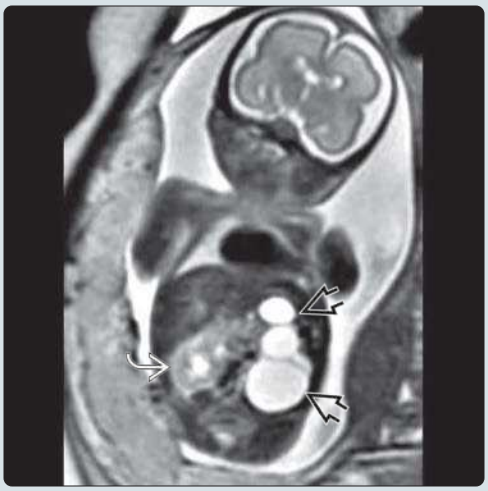
- Congenital, nonfunctional kidney is composed of numerous cysts & dysplastic tissue
- Tends to involute with time: Cysts shrink & residual tissue may lose reniform shape

IMAGING

- Reniform-shaped, multicystic mass occupying renal fossa
  - ± lobulated outer contour (due to cysts of variable size)
  - Wide range of sizes: Up to 15 cm in length in newborn period; may be only 1-2 cm after years of involution
- Cysts of varying size do not connect
  - Largest cyst typically peripheral, not central
- Poorly defined, intervening, echogenic parenchyma without normal corticomedullary architecture
- Can be segmental in duplicated kidneys or partially involve fused/horseshoe kidney
- Nuclear scintigraphy documents lack of renal function in MCDK (multicystic dysplastic kidney disease)



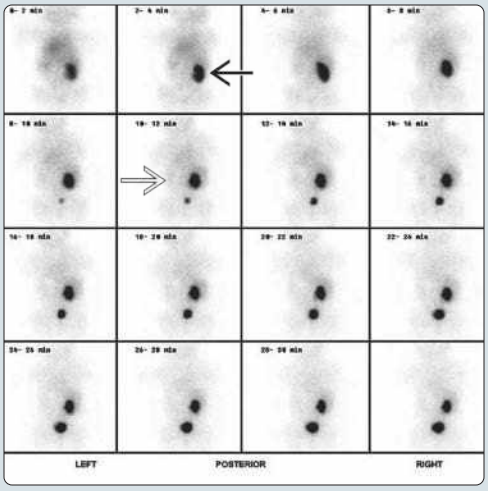
PATHOLOGY



- Probably due to atresia of ureter or ureteropelvic junction (UPJ) during metanephric stage of intrauterine development
- Up to 40% of patients with MCDK have contralateral renal abnormality
  - UPJ obstruction & vesicoureteral reflux most common

CLINICAL ISSUES

- ~ 70% are discovered antenatally or in infancy as palpable mass
- Unilateral MCDK with normal contralateral kidney: Excellent prognosis
  - Vast majority involute with time & remain asymptomatic
  - Rare reports of Wilms tumor developing in MCDK
- Unilateral MCDK with abnormal contralateral kidney: May develop renal insufficiency
- Bilateral MCDK: Lethal from pulmonary hypoplasia or absence of functioning renal tissue



(Left) *Frontal graphic of the right kidney shows multiple cysts of varying size replacing the renal parenchyma. There is minimal intervening dysplastic renal tissue. A ureter may or may not be recognizable at the renal hilum on imaging studies, but no renal pelvis should be seen.* **(Right)** *Coronal SSFSE T2 fetal MR shows a multicystic mass in the left renal fossa ⇨ with no discernible normal left renal tissue, most consistent with a left multicystic dysplastic kidney (MCDK). The right kidney ⇨ & volume of amniotic fluid appear normal.*

(Left) *Prone postnatal US of the left flank in the same patient shows multiple cysts ⇨ of varying size replacing the left kidney. A reniform shape is retained, but no normal left renal parenchyma is seen.* **(Right)** *Posterior images in the same infant during a Tc-99m MAG3 renal scan show normal function of the right kidney ⇨ but no function on the left side ⇨, confirming a left MCDK. Early transient activity in MCDK on nuclear scans merely reflects that the tissue is being perfused, but continued images show no function.*

TERMINOLOGY

Definitions

- Multicystic dysplastic kidney (MCDK): Congenital, nonfunctional kidney replaced by multiple cysts & dysplastic tissue
- 2 forms of MCDK are classically recognized
  - Pelvoinfundibular (more common): Theoretically results from atresia of ureter or renal pelvis; cysts are remnants of dilated calyces
  - Hydronephrotic (occurs less frequently): Results from atretic segment of ureter; cysts replace entire pelvocalyceal system
- Tend to involute with time: Cysts shrink & residual tissue may lose reniform shape

IMAGING

General Features

- Best diagnostic clue
  - Cysts & dysplastic, echogenic tissue replace entire kidney
  - Nuclear scintigraphy documents lack of renal function
    - If some delayed excretion is present, consider poorly functioning hydronephrosis
- Location
  - Renal fossa is most common but can occur ectopically from pelvis to chest
- Size
  - Wide range: Up to 15 cm in length in newborn period; may be only 1-2 cm after years of involution
- Morphology
  - Numerous cysts of varying size with dysplastic intervening parenchyma
  - No recognizable normal corticomedullary architecture
  - Renal shape is typically preserved, though cysts may result in lobulated contour
  - Can be segmental in duplicated kidneys

Radiographic Findings

- Radiography
  - Indirect evidence: Space-occupying lesion in flank
- IVP
  - No enhancement of or excretion from MCDK
  - May see transient blush during contrast bolus infusion due retained vascularity

Ultrasonographic Findings

- Grayscale ultrasound
  - Reniform-shaped multicystic mass occupying renal fossa
    - ± lobulated outer contour (due to cysts of variable size)
  - Cysts of varying size do not connect
  - Largest cyst is typically peripheral rather than central
  - Poorly defined, intervening, echogenic parenchyma without normal corticomedullary architecture
- Color Doppler
  - Minimal, if any, vascularity in parenchyma; central hilar vessels tend to be small
- Often followed with annual US scans to
  - Assess growth of contralateral kidney
  - Confirm involution of MCDK
    - Wilms tumor arising in < 0.1% of MCDK

CT Findings

- NECT
  - Low-attenuation cysts (though some may contain debris) replacing normal renal parenchyma
- CECT
  - No parenchymal contrast enhancement
  - No contrast excretion on delayed images
  - No hydronephrosis

MR Findings

- Cysts replace normal renal parenchyma
- May be noted incidentally on MR performed for other indications or may follow abnormal 2nd trimester US

Nuclear Medicine Findings

- MAG3 scintigraphy
  - Initial blood flow images may show slight perfusion of MCDK but sequential images show lack radiotracer uptake or excretion
- Tc-99m DMSA renal cortical scan
  - Radiotracer may localize to scattered tubular cells in dysplastic parenchyma

Other Modality Findings

- Retrograde ureterogram will show blind-ending ureter
  - Different from rapid change in caliber of ureter & communication with calyces seen in ureteropelvic junction (UPJ) obstruction or other causes of hydronephrosis

Imaging Recommendations

- Best imaging tool
  - Ultrasound for initial identification
  - Nuclear scan to confirm nonfunction of suspected MCDK & assess drainage of contralateral kidney

DIFFERENTIAL DIAGNOSIS

Hydronephrosis

- "Cysts" (dilated calyces) are relatively uniform in size & connect centrally
- Largest "cyst" (renal pelvis) lies central

Congenital Obstructive Uropathy

- Bladder outlet obstruction often leads to echogenic kidneys with small, peripheral cysts (cystic renal dysplasia)
- May rarely appear similar to MCDK
  - Presence of renal pelvis makes MCDK unlikely

Congenital Mesoblastic Nephroma

- Solid or mixed solid & cystic neonatal/infantile renal mass
- "Claw" of renal tissue splayed along tumor margin

Wilms Tumor

- Typically large, solid, heterogeneous round mass with "claw" of renal tissue splayed along tumor margin

Pediatric Cystic Nephroma

- Round renal mass in males 3 months to 4 years of age
- Numerous thin-walled cysts throughout mass with central herniation of cysts
- "Claw" of renal tissue splayed along tumor margin

Tuberous Sclerosis

- Numerous cysts &/or angiomyolipomas bilaterally
- Look for cardiac rhabdomyomas & brain manifestations

Autosomal Recessive Polycystic Kidney Disease

- Enlarged, echogenic bilateral kidneys with striated parenchyma & intermixed small cysts

HNF1B/TCF2 Mutations

- Can mimic bilateral MCDK

End-Stage Renal Disease

- Bilateral kidneys tend to be small & echogenic, resembling involuted MCDK
- Cysts may be present from underlying disease or secondary to dialysis

PATHOLOGY

General Features

- Etiology
  - Probably due to atresia of ureter or UPJ during metanephric stage of intrauterine development
- Genetics
  - Generally considered sporadic; reported familial cases of autosomal dominant inheritance with variable expression & penetrance
- Associated abnormalities
  - Genitourinary abnormalities in 25-40%
    - Up to 40% of patients have contralateral abnormality
      - UPJ obstruction & vesicoureteral reflux (VUR) are most common (VUR in 12-26%)
    - Megaureter
    - Cystic dysplasia of testis
    - Case reports of Zinner syndrome: Seminal vesicle cysts, ejaculatory duct obstruction, unilateral renal agenesis (vs. involuted MCDK)
  - Nonurologic abnormalities in 15%
    - Cardiac & musculoskeletal are most common
  - Associated syndromes: Turner, trisomy 21, chromosome 22 deletions, Waardenburg, others

Gross Pathologic & Surgical Features

- Walls of cysts vary in thickness; fibrotic dysplastic tissue replaces normal renal stroma; may be quite large & nonreniform in shape

CLINICAL ISSUES

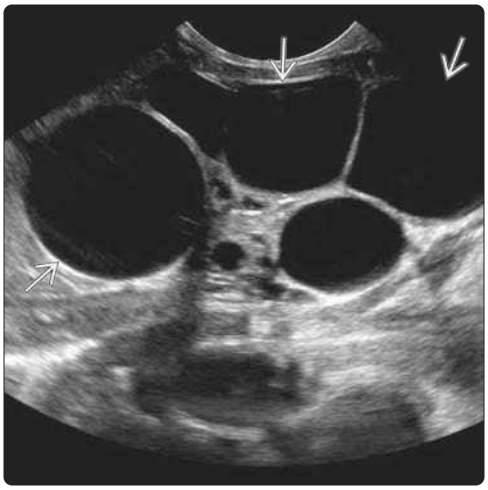
Presentation

- Most common signs/symptoms
  - ~ 70% are discovered antenatally or in infancy as palpable mass
  - Can have delayed presentation as incidental finding when
    - Symptoms of contralateral UPJ obstruction are evaluated
    - Patient is evaluated for urinary tract infection
    - Patient is imaged for traumatic injury or spine abnormality

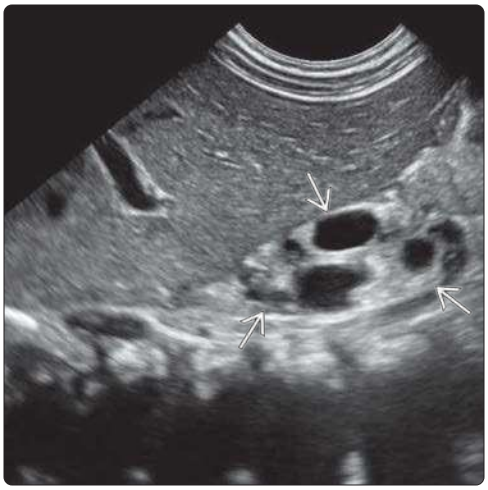
Demographics

- Age
  - Congenital abnormality, usually presents in infancy
- Incidence
  - 0.03% in autopsy series
  - 1 in 4,300 live births

Natural History & Prognosis



- Unilateral MCDK with normal contralateral kidney: Excellent prognosis
  - Vast majority involute with time & remain asymptomatic
    - ~ 50% involute in 1st decade
    - MCDK > 5 cm in newborn is less likely to involute
  - Can have complications of infection or mass effect
  - Rare reports of hypertension with unilateral MCDK
    - Less common than cystic renal dysplasia
    - In patients treated with nephrectomy for hypertension, blood pressure normalized in only 50%, suggesting other cause of hypertension
  - Wilms tumor developing in < 0.1% of MCDK
  - Reports of hyperfiltration in solitary kidney → renal insufficiency
  - Contralateral compensatory hypertrophy in 60%
- Unilateral MCDK with abnormal contralateral kidney
  - If contralateral kidney has delayed diagnosis of UPJ or ureterovesical junction obstruction or VUR, renal insufficiency can be problem
  - VUR into contralateral kidney is associated with smaller renal size during 1st year of life; may lead to recurrent pyelonephritis, scarring, hypertension (HTN)
- Bilateral MCDK: Lethal without dialysis/renal transplant; pulmonary hypoplasia (secondary to anhydramnios) may be lethal at delivery



Treatment

- Surgical excision when complicated by focal enlargement, mass effect, recurrent infections, HTN
- Otherwise, serial ultrasounds for 3-5 years to monitor

(Left) *Longitudinal US in a newborn shows a massive group of cysts ➡ measuring 8.8 cm in length occupying the left flank. This MCDK caused abdominal distention but no respiratory compromise & was managed conservatively.* **(Right)** *Longitudinal US shows only a few cysts in a 7-month-old with MCDK ➡. Note that the largest cysts are in the midkidney but do not connect (which helps to differentiate MCDK from hydronephrosis). Echogenic dysplastic tissue between the cysts becomes more evident as the cysts involute over months/years.*

(Left) *Longitudinal US shows an unusual case of a segmental MCDK in an infant with cysts on a prenatal scan. The 2 cysts in the upper pole of the kidney ➡ do not communicate, & there is echogenic, solid parenchyma between the cysts. The lower pole is normal. The contralateral kidney in this infant was congenitally absent.* **(Right)** *Axial CECT performed for trauma in this 19-year-old patient shows an involuted right MCDK ➡, discovered incidentally. The left kidney demonstrated compensatory hypertrophy.*

(Left) *Gross pathology shows numerous cysts replacing the renal parenchyma & distorting the contour of this MCDK. Note that the largest cyst in this specimen is in the upper pole, not in the renal hilum.* **(Right)** *This chart measures renal growth over serial exams in children. This particular patient has a shrinking right-sided MCDK & a rapidly growing normal left kidney, which would be expected to show compensatory hypertrophy.*

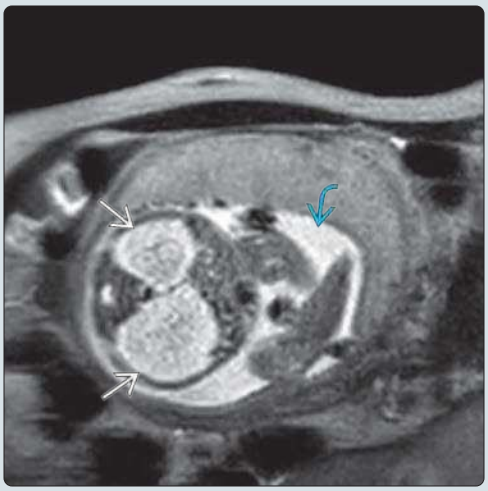
Polycystic Kidney Disease, Autosomal Recessive

KEY FACTS

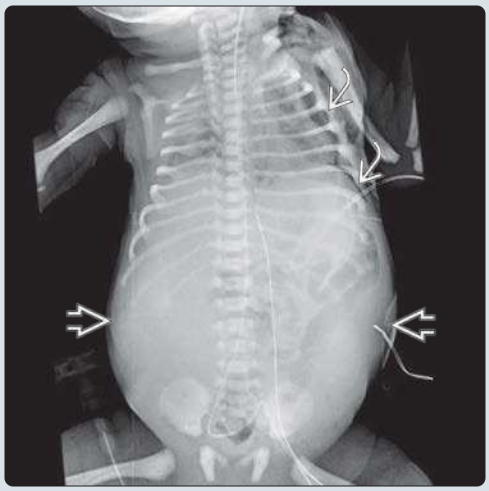
TERMINOLOGY

- Single gene ciliopathy with marked bilateral renal enlargement due to dilated, distal tubules & collecting ducts
- Synonyms: Infantile polycystic kidney disease

IMAGING

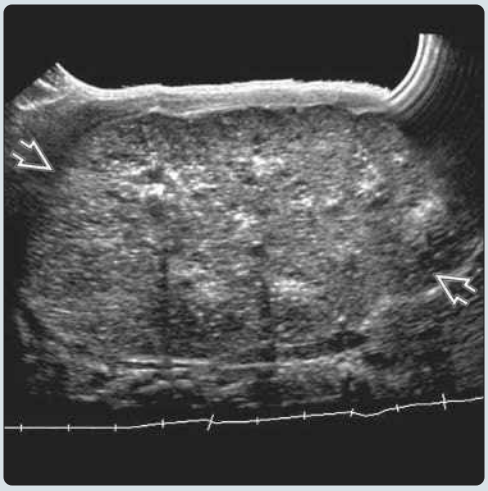


- Radiographs: Bilateral flank "masses" bulging lateral abdominal contours & displacing bowel gas centrally
  - Pulmonary hypoplasia with history of oligohydramnios
    - Bell-shaped thorax ± pneumothorax, pneumomediastinum
- US: Bilaterally enlarged, echogenic kidneys in newborn with loss of corticomedullary differentiation
  - 2-6 standard deviations (SD) above mean size for age
  - Dilated, radially arranged tubules on high-resolution linear transducers ± small cysts (< 1 cm)
  - Tiny, punctate, hyperechoic foci (likely calcium deposits) develop with time & correlate with renal failure
- MR: Large kidneys of diffusely high signal intensity on T2
  - Intervening low-signal septa
- Variable degrees of liver disease



PATHOLOGY

- Autosomal recessive, due to mutations of polycystic kidney & hepatic disease 1 gene (*PKHD1*) on chromosome 6p12.2
  - Risk of recurrence in subsequent pregnancies: 25%



CLINICAL ISSUES

- Perinatal presentation: More severe renal disease with pulmonary hypoplasia
  - Renal replacement therapy (dialysis or transplant)
- Juvenile presentation: Less renal disease, more hepatic issues
  - Portal hypertension & fibrosis develop in 50%
- Severity & outcomes vary within affected families
- Survival rate for milder forms is up to 82% at age 3 years & 79% at 15 years

(Left) *Axial SSFSE T2 MR of a 2nd-trimester fetus shows massively enlarged, hyperintense kidneys with absent corticomedullary differentiation & low amniotic fluid volume, typical of autosomal recessive polycystic kidney disease (ARPKD).* **(Right)** *Frontal radiograph in a newborn with a history of oligohydramnios shows bowel loops displaced centrally by bilateral flank "masses" (due to markedly enlarged kidneys). Note the bell-shaped thorax & left pneumothorax.*

(Left) *Extended field-of-view longitudinal US shows a newborn kidney measuring > 10 cm in length (usually is between 4-6 cm). There is loss of corticomedullary differentiation with replacement of the renal parenchyma by microscopic cysts & dilated tubules with hyperechoic walls.* **(Right)** *Longitudinal US in a patient with ARPKD shows nephromegaly with numerous punctate echogenic foci throughout the kidney. The echogenic foci likely represent calcium deposits & correlate with worsening renal function.*

TERMINOLOGY

Synonyms

- Infantile polycystic kidney disease

Definitions

- Autosomal recessive polycystic kidney disease (ARPKD): Single gene ciliopathy characterized by dilated, distal, convoluted tubules & collecting ducts

IMAGING

General Features

- Best diagnostic clue
  - Bilaterally enlarged kidneys, > 2-6 standard deviations (SD) above mean with loss of intrarenal architecture
  - Massive kidneys fill flanks & displace adjacent organs
  - Pulmonary hypoplasia with history of oligohydramnios further supports diagnosis
- Variable degrees of liver disease
  - Caroli syndrome, hepatic fibrosis, portal hypertension (HTN)

Radiographic Findings

- Radiography
  - Bilateral flank "masses" bulging lateral abdominal contours & displacing bowel gas centrally
  - Pulmonary hypoplasia with bell-shaped thorax ± pneumothorax, pneumomediastinum

Ultrasonographic Findings

- Enlarged, hyperechoic kidneys
  - Renal size is maximal by 1-2 years old
- Poor or absent corticomedullary differentiation
- Dilated, radially arranged tubules seen in 2/3 of affected kidneys by high-resolution linear transducers
  - Creates striated appearance
- Focal rosettes consisting of clusters of radially oriented, dilated collecting tubules also reported
- Small cysts may be present, generally < 1 cm in diameter; seen in ~ 1/2 of patients
  - Cysts > 1 cm only in minority of cases
- Diffuse microcystic appearance also described
- Tiny, punctate, hyperechoic foci develop with time & correlate with renal failure
  - Do not cause posterior acoustic shadowing but may cause ring-down artifact
  - Calcium citrate & oxalate crystals found histologically
- Doppler suggests random arrangement of intrarenal vessels rather than typical branching pattern
- Prenatal ultrasound findings
  - Renal size & renal circumference to abdominal circumference ratio > 2 SD above mean for gestational age
  - Enlargement may not occur until mid 2nd trimester
  - Cysts may be visible but do not predominate
  - Abnormal corticomedullary differentiation in variable patterns
  - Oligohydramnios
    - In 1st or 2nd trimester, carries poor prognosis
  - Fetal bladder is not visible
  - Associated musculoskeletal abnormalities due to mechanics: Oligohydramnios limits movement
- Liver involvement
  - Enlargement, ↑ or coarse echogenicity, periportal fibrosis with ↑ periportal echogenicity, ↑ parenchymal stiffness on elastography, intrahepatic bile duct dilation, cysts
  - Portal HTN: ↓ or reversed portal flow, splenomegaly, ascites
  - Caroli syndrome: Cystic dilation of intrahepatic ducts with central echogenic dot of portal radicles

MR Findings

- Large kidneys of diffusely high signal intensity on T2
  - May have striated appearance of dilated tubules ± small, discrete cysts with low-signal septa
- Uniform or grainy intermediate to low signal on T1
- MRU: Radially arranged, dilated tubules throughout kidney
- No urine in bladder
- Liver involvement
  - Caroli syndrome
    - Cystic intrahepatic biliary dilation: Delayed enhancement on hepatobiliary phase with hepatobiliary contrast agents
    - Central dot sign: Portal radicle enhancement on T1 C+ or flow void on T2/MRCP centrally in dilated intrahepatic duct
  - Hepatic fibrosis
    - ↓ T1 & ↓ T2, ↑ parenchymal stiffness on elastography
  - Portal HTN
    - Abnormal portal flow on MR venogram, splenomegaly, ascites

Nuclear Medicine Findings

- Hepatobiliary scintigraphy
  - Delay in maximal hepatocyte uptake & tracer excretion into biliary tree & gut; cystic foci of hepatic photopenia early with gradual & prolonged tracer accumulation
- Tc-99m DMSA renal cortical scans
  - Loss of kidney outline & internal structure; patchy tracer uptake with focal defects throughout kidneys

Imaging Recommendations

- Best imaging tool
  - Ultrasound
    - Fetal US with serial renal measurements if at risk
    - Diagnostic infant US with ↑ frequency linear transducer
    - Annual abdominal ultrasound
      - No clear prognostic value of kidney size on function
      - Kidney imaging mainly for decision making prior to nephrectomy/transplant
      - Evaluate for signs of portal HTN & fibrosis
  - MRCP if complications of liver disease

DIFFERENTIAL DIAGNOSIS

Bilateral Multicystic Dysplastic Kidney

- Macroscopic cysts of varying size with no normal renal parenchyma
- Essentially lethal disorder

Autosomal Dominant Polycystic Kidney Disease

- Renal enlargement is < autosomal recessive polycystic kidney disease (ARPKD), may be asymmetric
- Few small cysts may be visible in 3rd trimester; renal echogenicity is normal or with echogenic cortex; amniotic fluid is normal
  - Check family history & scan kidneys of parents
- Rare phenotype reported with homozygous mutations, resulting in enlarged echogenic kidneys similar to ARPKD

Cystic Renal Dysplasia

- Small with numerous cysts (frequently peripheral) & echogenic parenchyma
- Most commonly due to chronic obstruction
  - May be unilateral or asymmetric

Meckel-Gruber Syndrome

- Encephalocele, large polycystic kidneys, & polydactyly

Tuberous Sclerosis

- Rhabdomyoma: Echogenic cardiac mass
- Tubers & subependymal nodules in brain: May be difficult to detect in newborn
- Renal cysts: May be seen in utero
- Angiomyolipomas: Not usually seen in newborn

HNF1B/TCF2 Mutation

- Variable renal cystic disease, potentially mimics bilateral multicystic dysplastic kidney (MCDK)
- Early-onset diabetes mellitus

Joubert Syndrome & Related Disorders

- Ciliopathy with molar tooth malformation brainstem & cerebellum; variable renal cystic disease

PATHOLOGY

General Features

- Genetics
  - Autosomal recessive
  - Polycystic kidney & hepatic disease 1 gene (*PKHD1*)
    - Chromosomal locus 6p12.2
  - Carrier frequency: 1 in 70 of general population
- Associated abnormalities
  - Musculoskeletal abnormalities due to oligohydramnios
  - Pulmonary compromise due to oligohydramnios & elevation of diaphragm by enlarged kidneys

Microscopic Features

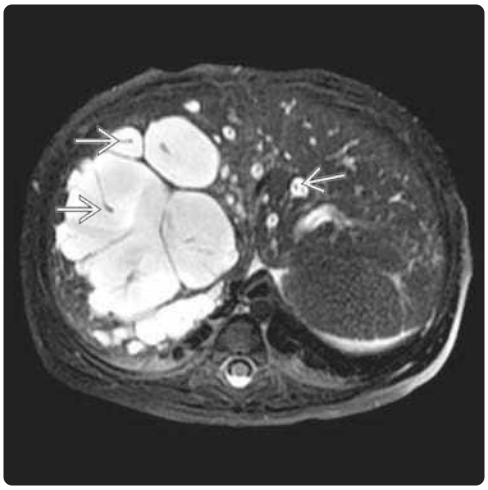
- Ectatic distal convoluted tubules & collecting ducts
- Tubules described as saccular or cylindrically enlarged

CLINICAL ISSUES

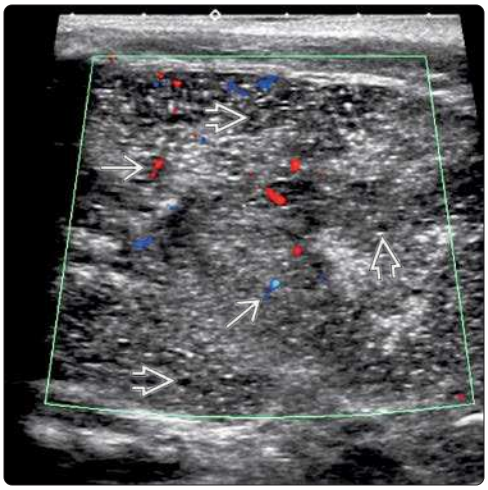
Presentation

- Most common signs/symptoms
  - Bilateral renal enlargement, renal insufficiency ± respiratory distress
    - Pulmonary hypoplasia may be life-limiting
- Other signs/symptoms
  - Fetal presentation: Enlarged kidneys at imaging
    - Majority detected > 24 weeks
    - Poor prognosis with fetal diagnosis
  - Marked nephromegaly may cause dystocia at birth

Natural History & Prognosis



- Perinatal presentation
  - Severe renal disease; pulmonary hypoplasia
  - Worst prognosis; high mortality in 1st month of life
  - Nephrectomy is common due to mass effect
- Perinatal survivors
  - Require renal replacement therapy (dialysis or transplant)
  - If prolonged survival, liver disease becomes relevant
- Juvenile presentation
  - Milder renal disease
  - Liver disease is more relevant in survivors
    - Portal HTN & fibrosis develop in ~ 1/2 of patients
  - Survival rate has ↑ for milder form to 82% at age 3 years & 79% at 15 years
- Severity & outcomes vary within affected families
  - Systemic HTN in 75%
  - Chronic ventilatory support in 30-50%



Treatment

- With fetal detection
  - Monitor fetal abdominal circumference for risk of dystocia
  - Counsel on outcomes, interventions (serial amnioinfusions, postnatal pulmonary & renal support) vs. comfort care options
  - Deliver at tertiary center
- With survivors
  - As needed, dialysis (peritoneal in infants) as bridge to renal transplant
    - Dialysis or transplant in 25-60% by 10 years old
  - Nephrectomy when renal size compromises respiratory status or peritoneal dialysis
  - Liver transplant when associated with progressive hepatic fibrosis
    - Combined liver kidney transplant (CLKT)
    - Kidney after liver transplant (KALT)

(Left) *Axial T2 FS MR in a patient with ARPKD & Caroli disease shows the dilated intrahepatic biliary tree affecting the right lobe of the liver more than the left. The central dots within these fluid-filled spaces are tiny portal vein branches. (Right) Color Doppler US in an infant with ARPKD demonstrates cysts & dilated tubules replacing the normal renal parenchyma. Also seen are small vessels coursing randomly in the replaced renal parenchyma (rather than in the organized pattern of normal interlobular & arcuate branches).*

(Left) *Coronal T2 FS MR in a 4-year-old with ARPKD & Caroli disease shows the enlarged, hyperintense kidneys replaced with tiny cysts & lace-like fibrous septa. A central dot pattern of biliary ductal dilation is noted. The progressive hepatic fibrosis has led to splenomegaly & ascites from portal hypertension (HTN). (Right) Axial T2 FS MR in a child with ARPKD & Caroli disease shows complete replacement of the kidneys with cysts & lace-like fibrous septa. The kidneys are markedly enlarged & hyperintense.*

(Left) *AP radiograph shows bulging flanks in a newborn with severe respiratory distress & pneumomediastinum. The patient has ARPKD with the massively enlarged kidneys causing the bulging flanks & displacing the bowel gas centrally. (Right) Longitudinal US of the left kidney in an 8-year-old with ARPKD & portal HTN shows the cursor (+) on the lower pole of this 13-cm long kidney. Note the presence of a few macrocysts in the kidney.*

Polycystic Kidney Disease, Autosomal Dominant

KEY FACTS

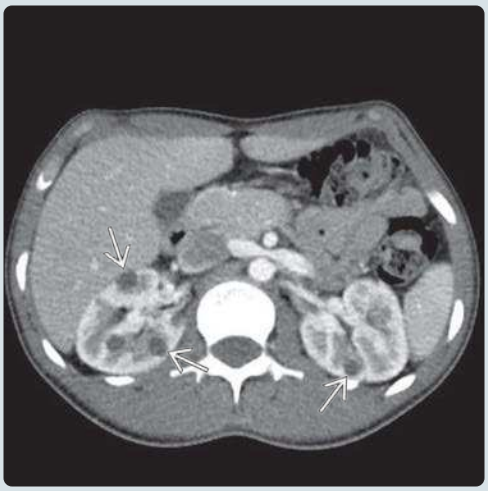
TERMINOLOGY

- Autosomal dominant polycystic kidney disease (ADPKD)
- Hereditary ciliopathy characterized by multiple renal cysts & various other systemic manifestations
- Cystic organ involvement: Kidneys (100%), liver (50%), pancreas (9%), brain/ovaries/testis (1%)
- Cerebral berry aneurysms (5-10% in adults)

IMAGING

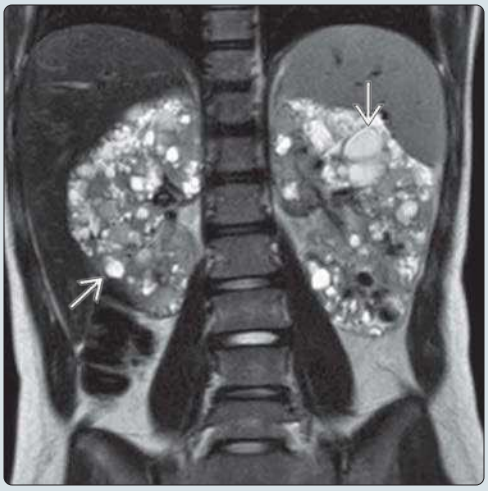
- Renal size within 2 standard deviations above normal at time of diagnosis in 1/2 of pediatric patients
- Scattered renal cysts of variable number & size
  - ↑ throughout life: 54% of ADPKD cysts appear in 1st decade; 72% occur within 2nd decade
  - ± complication by hemorrhage, infection, or rupture
- Renal parenchyma is often otherwise normal
- Rare phenotype appearing like ARPKD (enlarged, echogenic kidneys) with variant homozygous mutations

PATHOLOGY



- 90% autosomal dominant; 10% spontaneous mutations
- Types of ADPKD is based on gene location
  - *PKD1*: Short arm of chromosome 16 (90%)
  - *PKD2*: Long arm of chromosome 4 (10%)
- Family history lacking in almost 1/2 of patients

CLINICAL ISSUES



- Typically asymptomatic in childhood
  - Discovered incidentally or when screening children of affected adults
  - Flank pain, hematuria, hypertension (HTN), & renal failure are also reported in children
- Prognosis is excellent in childhood
- Prognosis in adulthood is variable: Hemorrhage, infection, rupture; renal failure; HTN; rarely malignancy

(Left) *Longitudinal ultrasound in a 17-year-old patient undergoing treatment for lymphoma shows an incidental simple cyst ➡ in the midkidney. The patient developed additional cysts over time & had a family history of renal failure.* **(Right)** *Axial CECT in the same patient several years later shows multiple low-density, nonenhancing cysts ➡ in both kidneys, consistent with autosomal dominant polycystic kidney disease (ADPKD).*

(Left) *Coronal T2 MR in a 13-year-old patient with a family history of ADPKD shows numerous high signal intensity cysts ➡ of varying size.* **(Right)** *Longitudinal power Doppler ultrasound shows normal blood flow in normal-appearing renal parenchyma between multiple simple-appearing cysts ➡. Vascular compression by the enlarging cysts is one theory to explain progressive renal insufficiency in ADPKD.*

TERMINOLOGY

Synonyms

- Autosomal dominant polycystic kidney disease (ADPKD), adult polycystic kidney disease

Definitions

- Hereditary ciliopathy characterized by multiple renal cysts & various other systemic manifestations
  - Pei Ravine criteria: ≥ 3 uni- or bilateral cysts if ≥ 15-years-old; <15-years-old with positive family history, ≥ 1 kidney cyst &/or renal enlargement is considered highly suggestive of ADPKD
- Cystic organ involvement
  - Kidneys (100%), liver (50%), pancreas (9%), brain/ovaries/testes (1%)
- Noncystic manifestations
  - Cardiac valve (26%), hernias (25%), colonic diverticula
  - Aneurysms: Cerebral berry aneurysms (5-10%); aortic or coronary aneurysms are less common

IMAGING

Ultrasonographic Findings

- Grayscale ultrasound
  - Multiple well-defined, round, anechoic cysts bilaterally
  - Renal contour, size, & echotexture are typically normal early in life
  - Renal contour may become lobulated as more cysts form
  - Rare phenotype: Appears more like ARPKD (enlarged echogenic kidneys in fetus/neonate) with variant homozygous *PKD1* mutations

MR Findings

- T1WI
  - Uncomplicated cysts: Hypointense
  - Complicated (hemorrhagic cysts)
    - Signal intensity varies with age of hemorrhage
    - Classic appearances suggesting blood products: Hyperintense, fluid-fluid levels
- T2WI
  - Uncomplicated cysts: Hyperintense contents, thin wall
  - Complicated: Variable signal intensity, blood products may be hypointense & layering; mural thickening

Imaging Recommendations

- Best imaging tool
  - Ultrasound (sensitivity, specificity, accuracy 97+%)

DIFFERENTIAL DIAGNOSIS

Autosomal Recessive Polycystic Kidney Disease

- Very enlarged newborn kidneys
- Echogenic parenchyma with dilated tubules & loss of corticomedullary differentiation; few small cysts

Isolated Simple Cysts

- Very few in number, normal renal function

Tuberous Sclerosis

- Fat-containing renal angiomyolipomas + cysts
- Characteristic brain & cutaneous findings

Multicystic Dysplastic Kidney

- Congenital, nonfunctioning mass of cysts replacing kidney
- Rarely bilateral (fatal)

Acquired Cystic Disease of Dialysis

- Early stage: Small kidneys with multiple cysts
- Advanced stage: Indistinguishable from ADPKD

PATHOLOGY

General Features

- Genetics
  - 50% chance of child inheriting mutant gene from parent
  - Types of ADPKD based on gene location
    - *PKD1*: Short arm of chromosome 16 (90%)
    - *PKD2*: Long arm of chromosome 4 (10%)
- Associated abnormalities
  - Cystic changes in other organs, including liver, pancreas, spleen, thyroid, lung, brain, gonads, & bladder
  - Cardiac & aortic abnormalities include valvular disease, coarctation, & aneurysms
    - 10% of adults with ADPKD die from rupture of intracranial berry aneurysm
  - Slightly ↑ risk of renal cell carcinoma
  - Up to 3% of tuberous sclerosis patients have ADPKD
    - *TSC2* gene is adjacent to *PKD1* on chromosome 16

CLINICAL ISSUES

Presentation

- Typically asymptomatic in childhood
  - Discovered incidentally or when screening children of affected adults
- Flank pain, hematuria, hypertension (HTN), & renal failure

Demographics

- Variable age at diagnosis: in utero to 8th decade
  - Prevalence of cysts ↑ with age
    - 54% appear in 1st decade of life
    - 72% occur within 2nd decade
- Incidence: 1 in 400 to 1,000 live births

Natural History & Prognosis

- Prognosis is excellent in childhood
- Prognosis in adulthood is variable
  - Hemorrhage, infection, rupture, renal failure, HTN, rarely malignancy

Wilms Tumor

KEY FACTS

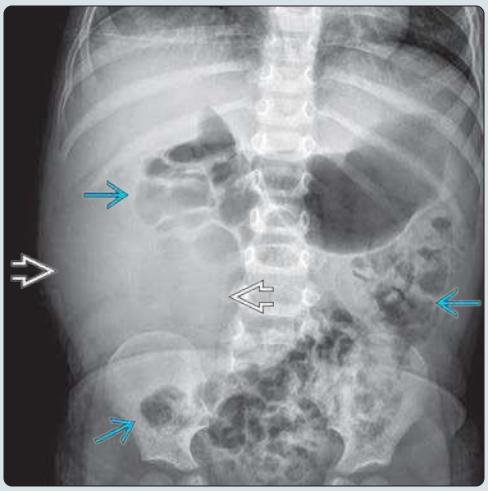
TERMINOLOGY

- Malignant tumor of primitive metanephric blastema in younger child

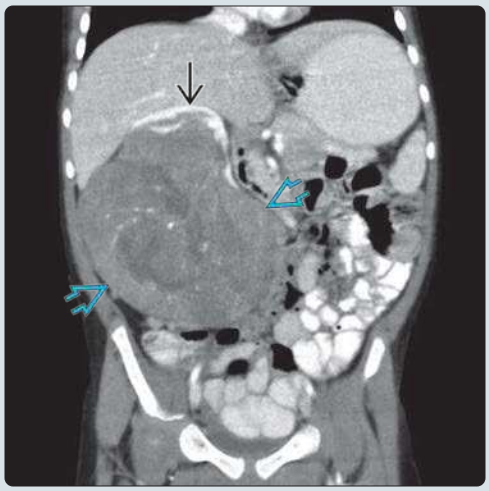
IMAGING

- Ultrasound is frequently 1st study performed
  - Large, heterogeneous but predominantly solid hypoechoic mass
  - Can have cystic foci, rarely Ca^{2+}
- Contrast-enhanced CT/MR: Characterizes tumor, extent, multifocality → staging
  - Hypoenhancing solid mass, often heterogeneous; restricts diffusion
    - Purely cystic form is rare
  - Look for local extension, tumor thrombus (renal vein, IVC), & lymph node enlargement
    - Moderate/complex ascites may indicate tumor rupture
  - Assess contralateral kidney for synchronous masses
- Chest CT: Lung metastases in 10-20% at presentation

TOP DIFFERENTIAL DIAGNOSES

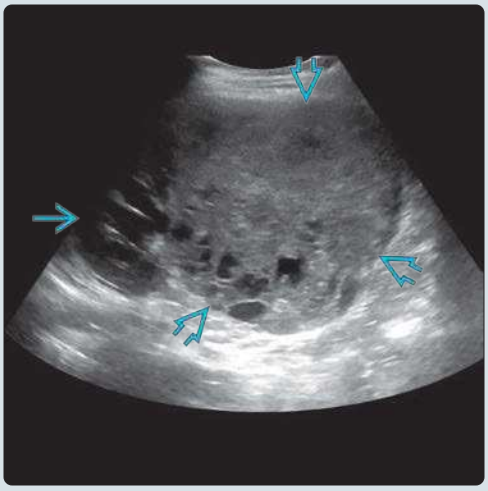


- Neuroblastoma: Extrarenal, more often calcified
- Congenital mesoblastic nephroma: < 3-12 months
- Clear cell sarcoma: May have bone metastases
- Renal cell carcinoma: Older child, adolescent

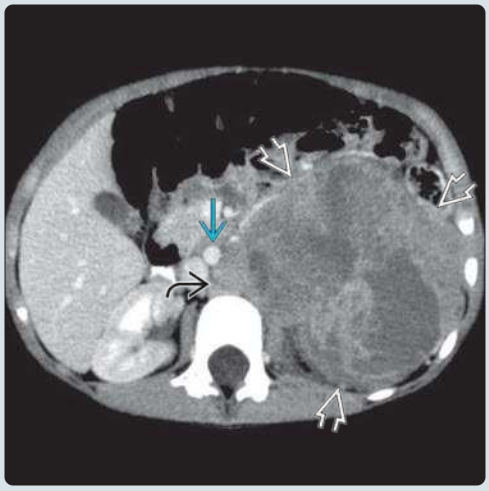


PATHOLOGY

- Associated predisposing syndromes in 10%



CLINICAL ISSUES



- 80% occur in children < 5 years old
- Typical presentation: Incidentally discovered palpable mass
- Preferred treatment: Up front complete surgical resection
  - Preoperative chemotherapy for unresectable tumors, bilateral tumors, or extensive tumor thrombus
  - Postoperative chemotherapy ± radiation
- > 90% 5-year-survival for localized abdominal disease

(Left) *AP radiograph in a 3-year-old child with a firm, palpable mass shows leftward & inferior displacement of bowel loops by a right-sided soft tissue mass. CT was performed next in this child due to suspicion for a Wilms tumor.* **(Right)** *Coronal CECT in the same patient confirms a large, heterogeneous, solid mass arising from the right kidney. A residual "claw" of normal renal tissue is splayed along the upper pole of this Wilms tumor. No contralateral lesions or venous invasion were identified.*

(Left) *Longitudinal US in a 5-year-old with hypertension & abdominal fullness shows a round, heterogeneous mass extending out of the lower pole of the left kidney. Wilms tumor was confirmed upon surgery.* **(Right)** *Axial CECT shows a large, poorly defined, heterogeneous Wilms tumor arising from the left kidney in a 4-year-old girl. Note the enlarged lymph node displacing the aorta anteriorly & to the right.*

TERMINOLOGY

Synonyms

- Nephroblastoma

Definitions

- Malignant tumor of primitive metanephric blastema
- Most common abdominal neoplasm ages 1-8 years

IMAGING

General Features

- Best diagnostic clue
  - Large, heterogeneous renal mass in young child ± tumor thrombus in renal vein/inferior vena cava (IVC)
- Location
  - > 90% unilateral, 5-10% bilateral
- Size
  - Typically large (mean diameter: 5-10 cm)
- Morphology
  - Usually spherical; sometimes lobulated or multicentric
  - Usually smooth contours; may have local extension

Radiographic Findings

- Mass displacing adjacent bowel
- Ca^{2+} visible in 10%

Ultrasonographic Findings

- Grayscale ultrasound
  - Large, typically hypoechoic but heterogeneous mass
    - May see adjacent enlarged lymph nodes
  - Look for "claw" of splayed residual kidney surrounding mass
- Color Doppler
  - Evaluate renal vein/IVC for tumor thrombus

CT Findings

- NECT
  - Ca^{2+} in 15%
  - Lung metastases in 10-20% at time of diagnosis
    - Well-defined, solid nodules
- CECT
  - Large, poorly enhancing, heterogeneous mass
    - "Claw" of residual renal tissue splayed along tumor margin
  - Often has well-defined margins or pseudocapsule
  - Displaces adjacent organs, especially bowel
  - ± enlarged retroperitoneal lymph nodes
  - ± tumor thrombus in renal vein, IVC, right atrium
  - May have local extension into perirenal fat or gross tumor rupture with ascites

MR Findings

- T1: Typically heterogeneous, predominantly intermediate to low signal; may have foci of high signal due to blood products
- T2: Typically heterogeneous, solid, & predominantly of high signal
  - Purely cystic lesions are uncommon
- T1 C+: Heterogeneous & hypoenhancing relative to normal renal parenchyma
- DWI: Solid portions restrict diffusion
- Multiphase postcontrast imaging may be helpful to evaluate for tumor thrombus

Nuclear Medicine Findings

- PET
  - Problem-solving tool in selected cases
    - May be helpful in suspected recurrences
  - Tumor &/or metastatic lesions are typically FDG avid

Imaging Recommendations

- Best imaging tool
  - Ultrasound to confirm presence of renal mass
  - Contrast-enhanced CT/MR to further characterize tumor, local extent, staging
    - MR is typically preferred in suspected bilateral Wilms
  - Chest CT for staging
- Protocol advice
  - Contrast-enhanced CT/MR is adequate to evaluate for tumor thrombus
    - Doppler ultrasound if needed in specific cases

DIFFERENTIAL DIAGNOSIS

Neuroblastoma

- Suprarenal (adrenal gland) or paraspinal (sympathetic chain)
  - Typically displaces rather than invades kidney
- Much more likely than Wilms to contain Ca^{2+}, cross midline, & engulf or "lift" adjacent vessels

Congenital Mesoblastic Nephroma

- Solid or mixed solid & cystic tumor of infants
  - > 90% diagnosed in 1st year of life

Multilocular Cystic Renal Tumor

- Entirely cystic mass with numerous thin septations
- Classically herniates into renal pelvis
- Associated with *DICER1* mutation

Renal Cell Carcinoma

- Solid renal mass typically seen in 2nd decade of life

Renal Rhabdoid Tumor

- Nonspecific solid renal mass in young child
- Subcapsular fluid collection is suggestive
- May have synchronous intracranial rhabdoid tumor

Clear Cell Sarcoma

- Solid renal mass ± bone metastases

Pyelonephritis

- Developing abscess can mimic cystic neoplasm (but is typically more infiltrative)
- Patients often have clinical & laboratory features of upper urinary tract infection

Renal Medullary Carcinoma

- Poorly defined, infiltrating renal mass
- Typically adolescent/young adult; associated with sickle cell trait or disease

Nephroblastomatosis

- Multiple nonenhancing foci of residual primitive nephrogenic rests in infant, usually bilateral
- Individual lesions are relatively small & homogeneous

Lymphoma

- Multifocal, solid, hypoenhancing renal masses, typically with other evidence of lymphoma

PATHOLOGY

General Features

- Etiology
  - Primitive metanephric blastema differentiates by 34-weeks gestation
  - Persistence of metanephric blastema is termed "nephrogenic rests" (NRs)
    - Found in 1% of infant autopsies; most spontaneously regress
    - Multiple NRs = nephroblastomatosis
    - Perilobar NRs = multifocal, peripheral
      - Associated with hemihypertrophy, Beckwith-Wiedemann syndrome
    - Intralobar NRs = central, often solitary, ↑ risk of Wilms
      - Associated with WAGR syndrome, Denys-Drash
    - NRs are present in 30-40% of unilateral Wilms tumors
    - NRs are present in 94% of patients with metachronous contralateral Wilms tumors
      - 1% of unilateral Wilms tumor patients develop metachronous disease
    - NRs are present in 99% of patients with synchronous bilateral Wilms tumors
      - Represent 4-7% of all Wilms tumors
      - Present at slightly younger age than unilateral Wilms tumor (2.6 vs. 3.3-3.6 years)
- Genetics
  - Numerous somatic & germline mutations described
    - 10-20% have 11p13 (*WT1*) gene mutation
  - Only 2% of Wilms tumors are familial
- Associated abnormalities
  - Genitourinary anomalies
  - Overgrowth syndromes (Beckwith-Wiedemann syndrome, isolated hemihypertrophy, CLOVES)
  - WAGR syndrome: Wilms tumor, aniridia, genitourinary anomalies, mental retardation
  - Sporadic aniridia
  - Denys-Drash syndrome
  - Trisomy 18
  - Sotos syndrome
  - Bloom syndrome

Staging, Grading, & Classification

- Similar systems used by Children's Oncology Group (COG)/National Wilms Tumor Study Group (NWTSG) or Société Internationale d'Oncologie Pediatrique (SIOP)
  - I: Confined to kidney, completely excised
  - II: Local extension, completely resected
  - III: Incomplete resection, no distant metastases
  - IV: Distant metastases to lung, liver, brain, or bone
  - V: Bilateral synchronous tumors

Microscopic Features

- 4-10% have unfavorable (anaplastic) histology

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic palpable mass, abdominal pain, rarely hematuria
- Other signs/symptoms
  - Hypertension (vascular compression), fever (tumor necrosis), anemia

Demographics

- Age
  - 80% of cases occur in children < 5 years old
  - Peak: 3.6 years
    - Syndromic tumor occurrence is typically younger

Natural History & Prognosis

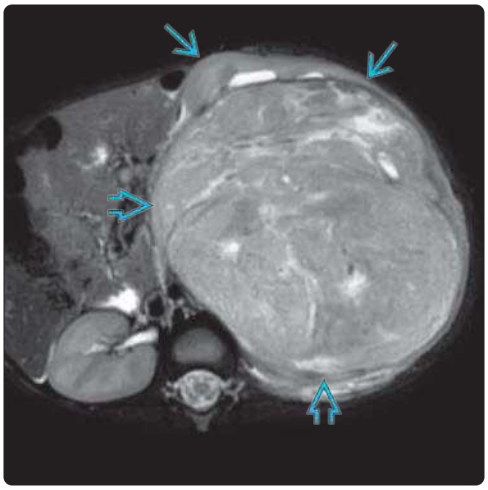
- Prognosis is based on stage, histology
- 5-year survival for localized abdominal disease > 90%

Treatment

- Up front complete surgical resection (nephrectomy) is preferred
  - Partial nephrectomy is rarely feasible in unilateral cases
- Preoperative chemotherapy for unresectable tumors, bilateral tumors, or extensive tumor thrombus
- Bilateral tumor undergoes partial nephrectomies after chemotherapy, if feasible
- Postoperative chemotherapy ± radiation
- Bone marrow transplant is usually reserved for relapses

DIAGNOSTIC CHECKLIST

Consider



- Children with predisposing syndromes require ultrasound screening every 3 months until 8 years of age

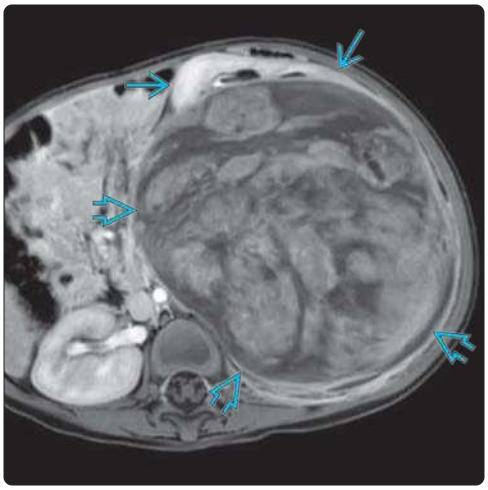


Image Interpretation Pearls

- Careful assessment of renal vein & IVC, adjacent soft tissues & lymph nodes, contralateral kidney, & lungs
  - Doppler assessment of renal vein/IVC is not needed if CT/MR images are normal
- Moderate or complex ascites may suggest tumor rupture

(Left) *Axial T2 FS MR in a 2-year-old with a palpable left abdominal mass shows a large, heterogeneous, solid Wilms tumor ⇨ arising from a splayed "claw" of residual left kidney ⇨. (Right) Axial T1 C+ FS MR in the same patient with Wilms tumor shows a large, heterogeneously hypoenhancing left renal mass ⇨ with residual distorted kidney & collecting system displaced anteriorly ⇨.*

(Left) *Axial T2 FS MR in a 5-month-old shows a very large solid mass ⇨ displacing the splayed left kidney anteriorly to the right ⇨. There is a smaller round, mildly T2-hyperintense mass in the right kidney ⇨, consistent with bilateral (stage V) Wilms tumor. (Right) Axial T1 C+ FS MR in the same child with bilateral Wilms tumors shows ↑ conspicuity to the hypoenhancing right renal mass ⇨. The large, lobulated left renal mass ⇨ is also heterogeneously hypoenhancing relative to normal kidney ⇨.*

(Left) *Sagittal (left) & coronal (right) CECT images show tumor thrombus ⇨ extending through the left renal vein, up the inferior vena cava, & into the right atrium from a Wilms tumor ⇨ in the left kidney. (Right) Coronal FDG PET/CT in a child with a history of left nephrectomy for Wilms tumor shows a contralateral recurrence with metabolically active tumor ⇨ in the right upper kidney.*

Nephroblastomatosis

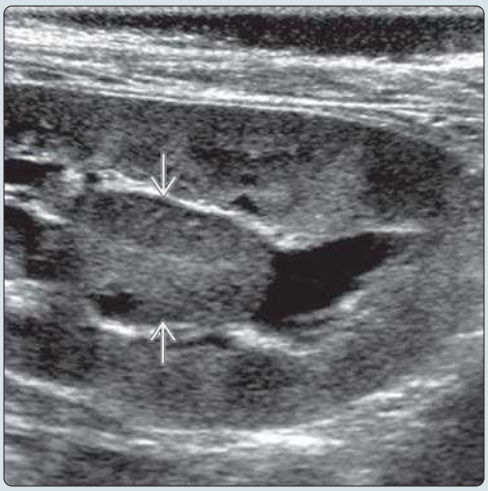
KEY FACTS

TERMINOLOGY

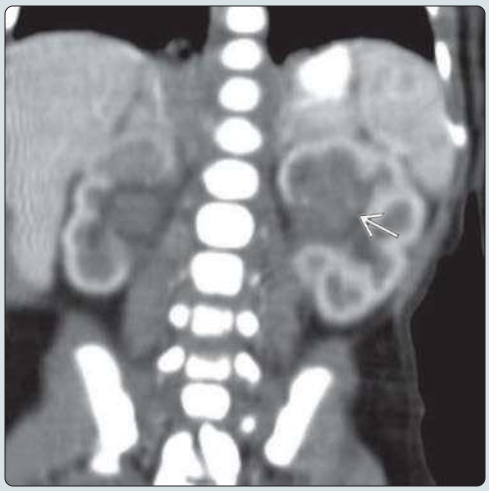
- Nephrogenic rests (NR): Persistent metanephric blastema; precursor to Wilms tumor
  - Perilobar NR: Occur at periphery of kidney
  - Intralobar NR: Occur within kidney
- Nephroblastomatosis: Multiple or diffuse NR

IMAGING

- Homogeneous multifocal ovoid or subcapsular rind-like renal masses that enhance less than normal kidney on CT/MR
  - Diffuse disease: Thick, uniform, homogeneous rind of hypoenhancing abnormal tissue
  - Multifocal disease: Scattered nodules resembling normal renal cortex on precontrast imaging
- Differentiating NR from Wilms tumor
  - NR: Cutoff measurement of 1.75 cm has 100% negative predictive value & 81% positive predictive value
  - Wilms tumor is usually spherical in shape & more likely to be exophytic
- Imaging findings suggesting conversion of NR to Wilms
  - Rapid ↑ in size
  - Stable or ↑ size while on chemotherapy
  - Nodule within initial lesions
  - New heterogeneous appearance of mass

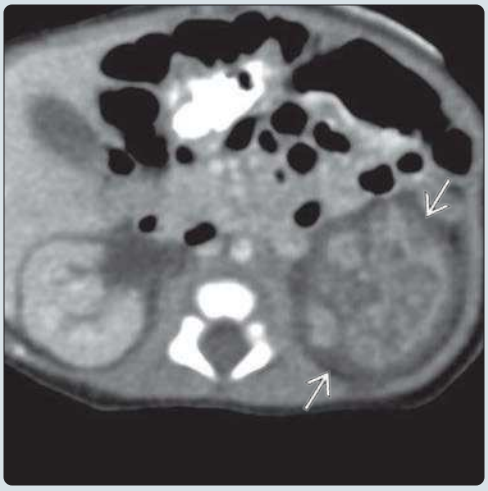


PATHOLOGY

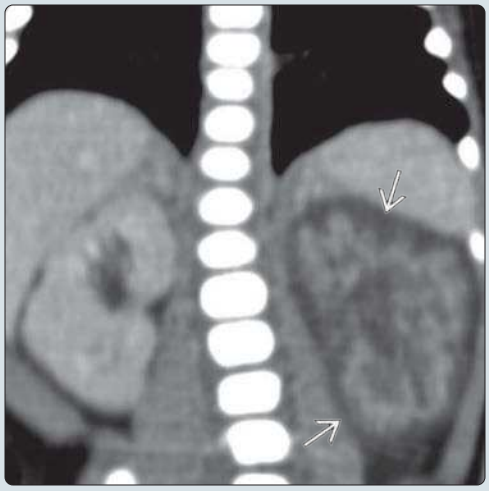


- Biopsy to distinguish NR from Wilms tumor; tumor/parenchymal border is most helpful for accurate distinction

CLINICAL ISSUES



- Most NR spontaneously regress
  - Currently, no specific treatment protocol is advocated
- Common associated syndromes: Beckwith-Wiedemann syndrome, hemihypertrophy, sporadic aniridia, & WAGR syndrome



(Left) *Longitudinal US of the left kidney in a 4-day-old shows a centrally located, ovoid, isoechoic nephrogenic rest ➡. Intralobar nephrogenic rests are less common than the perilobar form but have a higher risk of malignant transformation to Wilms tumor.* **(Right)** *Coronal CECT of the abdomen in the same patient shows a homogeneously hypodense intralobar nephrogenic rest ➡. Intralobar rests are associated with the WT1 gene, sporadic aniridia, & Drash syndrome.*

(Left) *Axial CECT in a neonate shows unilateral diffuse perilobar nephrogenic rests as a thin rind of homogeneously hypodense tissue ➡ surrounding the left kidney.* **(Right)** *Coronal CECT in the same patient shows the unilateral diffuse perilobar nephrogenic rests ➡ of the left kidney. Perilobar nephrogenic rests are more common than the intralobar form & are associated with the WT2 gene, Beckwith-Wiedemann syndrome, & hemihypertrophy.*

TERMINOLOGY

Definitions

- Nephrogenic rests (NR): Metanephric blastema that persists after 36-weeks gestation; precursor to Wilms tumor
- Nephroblastomatosis: Presence of multiple or diffuse NR
- Intralobar NR: Occur anywhere in renal parenchyma
- Perilobar NR: Occur in peripheral cortex

Associated Syndromes

- Perilobar NR: Beckwith-Wiedemann syndrome, hemihypertrophy, Perlman syndrome, trisomy 18
- Intralobar NR: Drash syndrome, sporadic aniridia, WAGR syndrome

IMAGING

General Features

- Best diagnostic clue
  - NR: < 1.75 cm nonspherical mass
  - Nephroblastomatosis: Multifocal ovoid vs. subcapsular rind-like homogeneous renal masses that enhance much less than normal kidney
    - ↓ enhancement due to hypovascularity
  - 2 main patterns of disease, similar on all modalities
    - Diffuse disease: Thick, uniform, homogeneous rind of hypoenhancing abnormal tissue
    - Multifocal disease: Scattered nodules resembling normal renal cortex on precontrast imaging
  - Perilobar rests are more likely to have homogeneous imaging appearance
- Location
  - Intralobar: Occur within kidney
  - Perilobar: Occur at periphery of kidney
- Size
  - Microscopic to several centimeters (usually < 3 cm)
- Morphology
  - Kidneys are enlarged in diffuse disease
    - May lose normal corticomedullary differentiation
  - NR may deform renal surface, creating nodular or lobulated appearance
  - In diffuse perilobar NR, interfaces between hypoenhancing NR & centrally located normal parenchyma can be jagged or irregular

Ultrasonographic Findings

- Grayscale ultrasound
  - Homogeneously hypoechoic or isoechoic to renal parenchyma
    - May not be able to distinguish NR from background kidney
  - Enlarged, distorted kidneys in diffuse disease
    - Poor renal corticomedullary differentiation
- Color Doppler
  - Hypovascular lesions

CT Findings

- NECT: Isodense to slightly hyperdense to renal cortex
- CECT: Homogeneous hypodense lesions enhancing < normal renal tissue

MR Findings

- T1WI
  - Homogeneous masses isointense to slightly hypointense to renal parenchyma
- T2WI
  - Homogeneous masses isointense to renal parenchyma
- DWI
  - Can restrict diffusion
- T1WI C+
  - Homogeneous, hypointense masses that enhance < renal parenchyma

Nuclear Medicine Findings

- PET
  - Avid FDG uptake in Wilms tumor

Imaging Recommendations

- Best imaging tool
  - MR is equivalent to CT in evaluation of single Wilms tumor
    - However, MR is more likely to identify additional lesions
  - Intravenous contrast administration is essential
    - Most sensitive method to identify NR

Differentiation From Wilms Tumor

- Best differentiator: NR is < 1.75 cm
  - Has 100% negative predictive value & 81% positive predictive value
- Other differentiators
  - Wilms tumor is more likely to have spherical shape & be exophytic
  - Homogeneous imaging appearance is more likely to be perilobar NR
  - Wilms tumor is surrounded by fibrous pseudocapsule (not visible on imaging)
- Imaging findings suggesting conversion from NR to Wilms tumor
  - Rapid ↑ in size
  - No change or growth while patient on chemotherapy
  - Nodule within initial lesions
  - Newly heterogeneous appearance of mass

DIFFERENTIAL DIAGNOSIS

Wilms Tumor

- Solid mass with heterogeneous enhancement
- Bilateral in 4-13% of patients
- NR: Precursor to Wilms tumor
  - NR is present in 30-40% of unilateral Wilms tumor cases
  - NR is present in 94% of patients with metachronous contralateral Wilms tumor
    - 1% of unilateral Wilms tumor patients develop metachronous disease
    - ↑ risk in children < 12 months of age with NR at diagnosis
  - NR is present in 99% of patients with synchronous bilateral Wilms tumors
    - Represent 4-7% of all Wilms tumors
    - Present at slightly younger age than unilateral Wilms tumor (2.6 vs. 3.3 years)

Renal Lymphoma

- Multifocal, homogeneous, hypodense lesions on CECT
- Other manifestations of disease are typically present
  - Multifocal &/or confluent adenopathy
  - Splenomegaly
- Unusual in infants & young children

Pyelonephritis

- Wedge-shaped foci of renal parenchymal hypoenhancement (CT/MR) or hypoperfusion (color Doppler US)
- Can cause striated nephrogram

PATHOLOGY

General Features

- Etiology
  - Metanephric blastema that persists beyond 36-weeks-gestational age

Staging, Grading, & Classification

- 2 pathologic subtypes
  - Perilobar rests (90%): In renal cortex or at corticomedullary junction
    - Associated with 1-2% risk of developing Wilms tumor
  - Intralobar rests (10%): Deeper in renal parenchyma
    - Associated with 4-5% risk of developing Wilms tumor
- 3 patterns of distribution: Unifocal, multifocal, & diffuse
- 4 developmental phases
  - Incipient/dormant
    - Contains primitive epithelial cells
    - Rarely progresses to Wilms tumor
  - Regressing/sclerosing
    - Cells show signs of maturation or sclerosis
    - Rarely progresses to Wilms tumor
  - Hyperplastic
    - Adenomatous benign neoplasms that ↑ in size
  - Neoplastic

Gross Pathologic & Surgical Features

- Diffuse nephroblastomatosis
  - White plaques or whorls of tissue replacing renal parenchyma
    - ± peripheral rind
    - ± small cysts
    - ± masses of hyperplastic or neoplastic (Wilms) tissue

Microscopic Features

- Biopsy is helpful in distinguishing NR from Wilms tumor; important to look at tumor/kidney border
  - Wilms tumor has pseudocapsule separating tumor from kidney
  - Perilobar nephrogenic rests have abrupt interface with adjacent kidney & lack pseudocapsule
  - Intralobar nephrogenic rests intermingle with renal parenchyma at periphery of lesion

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic vs. flank mass
  - Incidental finding of ipsilateral or contralateral kidney in setting of Wilms tumor

Demographics

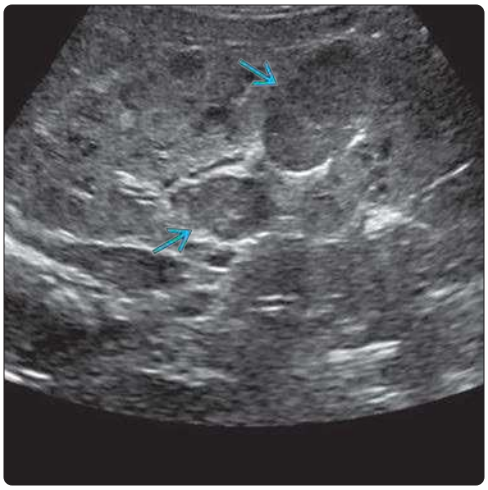
- Age
  - Most common in infancy
    - May not be detectable on initial imaging study
  - Incidence ↓ with age
- Sex
  - M = F
- Epidemiology
  - NR are present in 1% of perinatal autopsies
    - Incidence ↓ significantly in 1st months of life
  - Most are sporadic, but ↑ risk with some syndromes

Natural History & Prognosis

- Risk for developing Wilms tumor
  - Only small percentage of patients with NR will develop Wilms tumor
  - NR are present in 30-40% with unilateral Wilms tumor
  - Found in up to 99% of bilateral Wilms tumors
  - Risk for developing Wilms tumor is highest in younger children; ↓ with age
  - 35% of diffuse hyperplastic perilobar NR develop Wilms tumor (highest risk group)

Treatment

- Most NR spontaneously regress
- Currently, no specific treatment protocol is advocated
  - Can be treated empirically with chemotherapy
- Children with syndromes at risk for Wilms tumor are typically screened regularly with imaging for development of nephroblastomatosis/Wilms tumor
  - Screening renal sonography at 3-month intervals up to 8 years of age
  - US is more useful to identify Wilms tumor than NR
    - On US, look for new/enlarging spherical mass
- MR C+ or CECT if renal ultrasound shows mass → follow-up with MR > CECT to minimize radiation
- ↑ size of nephroblastomatosis is sometimes treated empirically as stage 1 Wilms tumor without biopsy



DIAGNOSTIC CHECKLIST

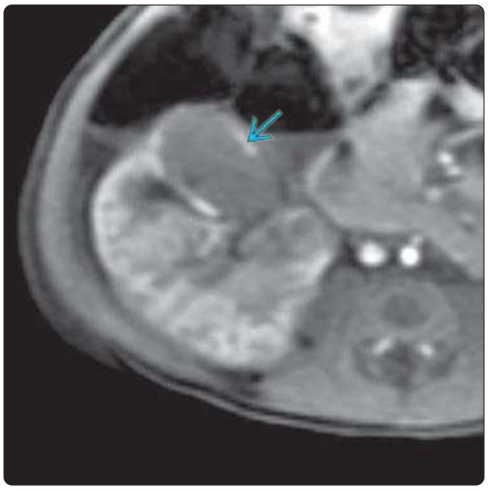


Image Interpretation Pearls

- Nephroblastomatosis enhances much less than surrounding kidney
- Wilms tumor tends to be heterogeneous

(Left) *Longitudinal US in a newborn with Beckwith-Wiedemann syndrome shows multiple hypoechoic nephrogenic rests within the right kidney.* **(Right)** *Axial T1 C+ FS MR in the same patient shows the large perilobar nephrogenic rest. Note how the nephrogenic rest shows typical hypoenhancement relative to the renal cortex. Multiple other small nephrogenic rests were visible on the remainder of the MR.*

(Left) *Longitudinal US in a child with a left Wilms tumor shows a poorly defined echogenic nephrogenic rest in the superior pole of the right kidney.* **(Right)** *Coronal T2 FS MR in the same patient shows a large left Wilms tumor. A multilocular mixed cystic & solid mass in the superior pole of the right kidney corresponds to the prior US findings. At resection, this right upper pole mass was confirmed to be a perilobar nephrogenic rest.*

(Left) *Coronal CECT in a young child shows a large hypoenhancing mass occupying the mid-portion of the right kidney. At resection, this was confirmed to be a large hyperplastic nephrogenic rest. Multiple other small perilobar nephrogenic rests were not visible on imaging. Typically nephrogenic rests are not spherical in shape & are smaller than 1.75 cm.* **(Right)** *Axial T1 C+ FS MR of the kidneys in a young patient shows diffuse bilateral hypoenhancing perilobar nephrogenic rests.*

Multilocular Cystic Nephroma

KEY FACTS

TERMINOLOGY

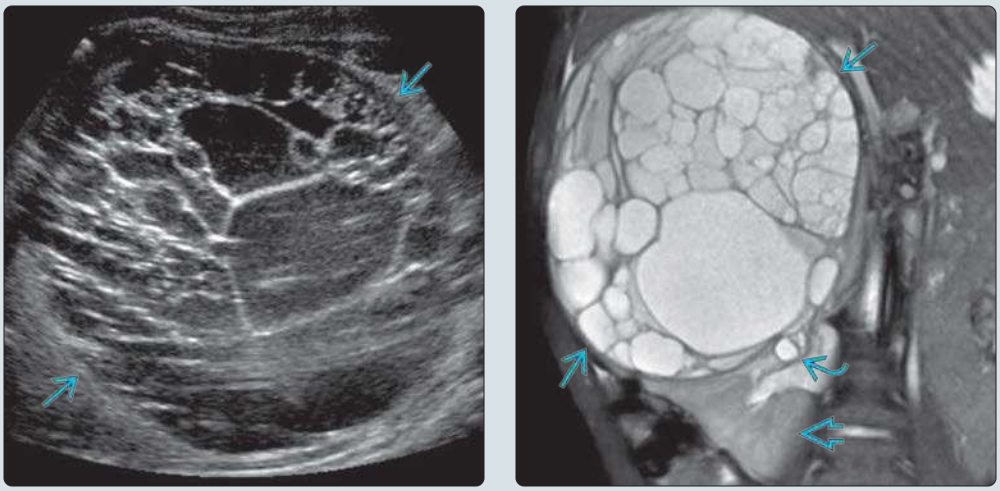
- Multilocular cystic nephroma (MLCN): Benign mixed mesenchymal & epithelial renal neoplasm

IMAGING

- Large, multilocular, cystic renal mass in young child
- Cystic components generally follow imaging characteristics of simple fluid on all modalities
- Septa show variable enhancement
  - No excretion of contrast into cysts
- Mass may herniate into renal hilum
- "Claw" of normal, splayed/compressed renal tissue at periphery of mass

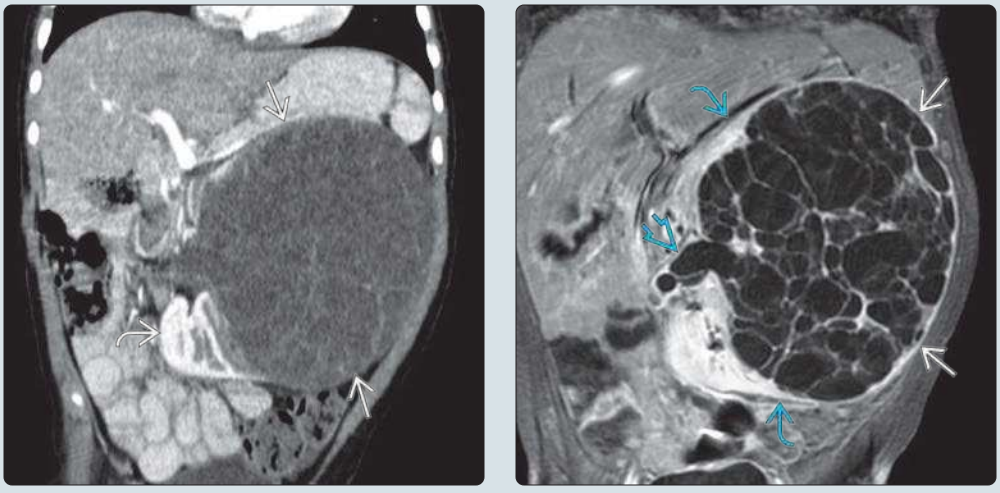
TOP DIFFERENTIAL DIAGNOSES

- Cystic Wilms tumor
- Multicystic dysplastic kidney
- Mesoblastic nephroma
- Renal cyst



PATHOLOGY

- > 70% of MLCNs have *DICER1* gene mutation
  - Tumor predisposition syndrome at risk for pleuropulmonary blastoma & other malignancies
  - Anaplastic sarcoma of kidney may arise in *DICER1*-associated MLCN
- Cystic partially differentiated nephroblastoma (CPDN): Indistinguishable at imaging from cystic nephroma, but septa contain blastema
  - *DICER1* mutations are not present in CPDN



CLINICAL ISSUES

- M:F = 2-3:1; occurs between 3 months & 2 years
- Presentation
  - Painless abdominal/flank mass
  - Hematuria & urinary tract infection are less frequent in children
- Benign mass with excellent prognosis overall
  - Resection is usually curative

(Left) *Longitudinal ultrasound through the right renal fossa in a young child shows a multiloculated mass with innumerable thin septations & no visible nodular component or renal tissue.* **(Right)** *Coronal 2D SSFP MR in the same child shows that the multiloculated mass involves the upper pole of the right kidney, the remainder of which is displaced inferiorly. A portion of the mass herniates into the renal collecting system, a specific sign of multilocular cystic nephroma.*

(Left) *Coronal CECT shows a large cystic mass occupying the upper pole of the left kidney in a young child. The normal lower pole of the kidney is displaced inferiorly & medially by the mass.* **(Right)** *Coronal T1 C+ FS MR in the same patient shows only septal enhancement of the large multicystic renal mass, which otherwise followed fluid signal on all sequences. There is a "claw" of renal tissue along the medial border of the mass, & a portion of the cystic nephroma herniates into the renal pelvis.*

TERMINOLOGY

Definitions

- Multilocular cystic nephroma (MLCN): Benign mixed mesenchymal & epithelial renal neoplasm

IMAGING

General Features

- Best diagnostic clue
  - Large, multilocular, cystic renal mass in young male

CT/MR/US

- Large, well-defined, multiloculated cystic mass
- Splayed "claw" of normal, compressed renal tissue stretched along mass periphery
- Mass may herniate into renal hilum
  - Can distort collecting system & cause obstruction
- Cystic components have attenuation/signal/echogenicity equal to or slightly > water
  - Small locules with closely packed septa may appear as solid mass
  - Cyst contents may vary due to hemorrhage or protein
- Septa have variable enhancement
  - Fibrous septa & capsule are hypointense on T1 & T2 MR
- No excretion of contrast into cystic components of mass

Imaging Recommendations

- Best imaging tool
  - US: Excellent for investigating palpable mass in child
  - CT or MR with contrast: Further characterize mass & define extent

DIFFERENTIAL DIAGNOSIS

Wilms Tumor

- Most common renal neoplasm of childhood
- Predominantly cystic form is uncommon

Multicystic Dysplastic Kidney

- Presents in utero/neonate, unlike MLCN
- Involves entire kidney (no normal renal parenchyma), unless duplicated

Mesoblastic Nephroma

- Presents < 1 year of age, often 0-3 months
  - Most common renal neoplasm of infancy
- Can be mixed cystic & solid (cellular subtype)

Renal Cyst

- Sharply marginated round/ovoid lesion with water density/echogenicity & imperceptible wall
- Uncommon in young children
- Septated cyst can mimic multicystic renal tumor

PATHOLOGY

General Features

- Etiology
  - May arise from metanephric blastema
    - Old hypothesis: Continuum of degeneration from MLCN to cystic partially differentiated nephroblastoma (CPDN) to Wilms tumor
    - New hypothesis: MLCN & CPDN are different lesions
      - *DICER1* mutations are present in MLCN, not CPDN
- Genetics
  - *DICER1* (14q32.13) mutation inactivates tumor suppressor gene → autosomal dominant tumor predisposition syndrome, at risk for
    - Pleuropulmonary blastoma (PPB)
    - MLCN: > 70% have *DICER1* mutation
      - > 80% of these patients develop PPB
    - Ovarian sex cord-stromal tumor
    - Embryonal rhabdomyosarcoma of urinary bladder or uterine cervix
  - Low penetrance (15%) → no tumors in most carriers

Microscopic Features

- Septa are lined by flattened or cuboidal epithelium with areas of eosinophilic cuboidal cells protruding into lumen
- MLCN & CPDN are differentiated by septa
  - MLCN: No undifferentiated elements
  - CPDN: Contain blastemal ± other embryonal elements

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Painless abdominal/flank mass
- Other signs/symptoms
  - Hematuria & urinary tract infection are less frequent in children

Demographics

- 3 months to 2 years of age: 2-3x more common in males
- *DICER1*-associated MLCN: < 4 years of age
- Adult lesion also previously referred to as MLCN is now known as mixed epithelial & stromal tumor of kidney

Natural History & Prognosis

- MLCN: Benign mass with excellent prognosis in isolation
- Reports of *DICER1*-associated anaplastic sarcoma of kidney (ASK) arising in MLCN

Treatment

- Complete or partial nephrectomy is usually curative

DIAGNOSTIC CHECKLIST

Consider

- *DICER1* genetic testing, annual chest radiographs (for PPB)

Congenital Mesoblastic Nephroma

KEY FACTS

TERMINOLOGY

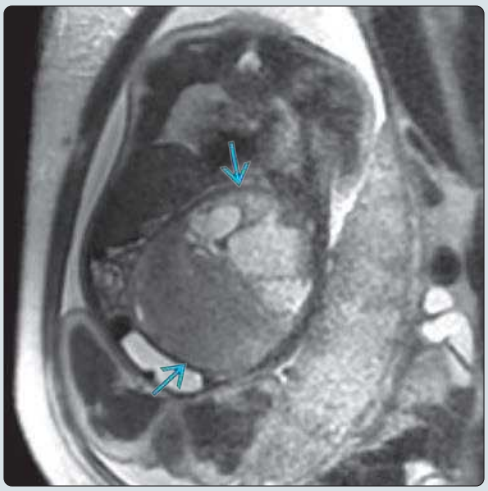
- Congenital mesoblastic nephroma (CMN): Hamartomatous renal tumor of young infants
- Composed predominantly of elongated spindle cells
- Classic benign vs. more aggressive cellular type vs. mixed
  - Studies vary on which type is more common

IMAGING

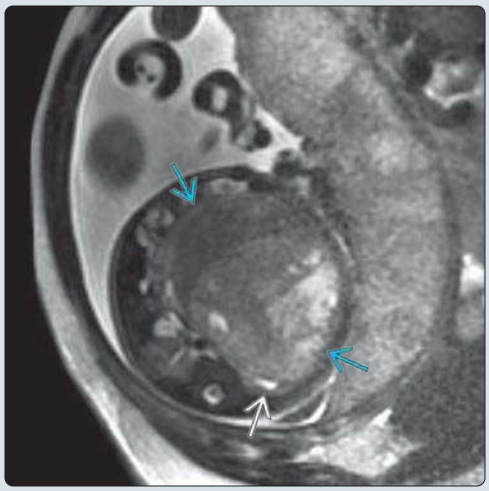
- Solitary renal mass in fetus or young infant
- Oval/round mass which may have poorly defined margins
  - Classic type is usually solid, smaller
  - Cellular type is usually larger with cystic/necrotic/hemorrhagic foci

PATHOLOGY

- Classic type (33-50%) is similar to infantile myofibroma
- Cellular type (40-63%) is similar to infantile fibrosarcoma
  - Local recurrence, metastases
- Mixed (< 15%)

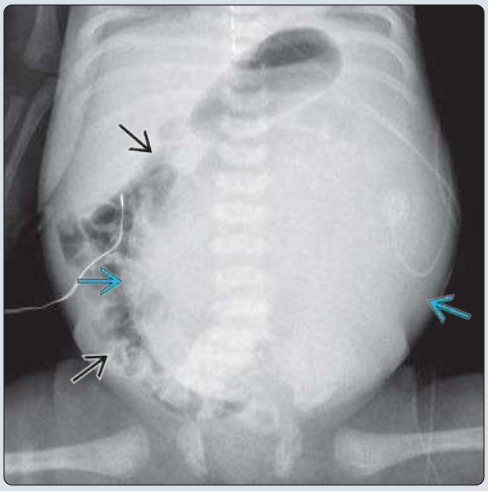


CLINICAL ISSUES

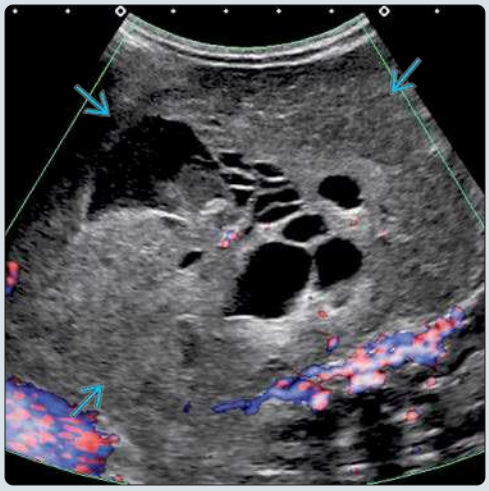


- 3-6% of childhood renal tumors
- Presentations include
  - Palpable abdominal mass in young infant
  - Hypertension, hypercalcemia, hematuria
  - Prenatally detected renal mass with polyhydramnios, preterm labor
- Most CMNs are diagnosed < 1-3 months of age
  - Classic type is more common in this time frame
- After 1-3 months
  - Wilms tumor becomes more common
  - Remaining CMNs are more likely to be cellular
- Nephrectomy with wide margins is usually curative
  - 5-year survival of 94-100%

DIAGNOSTIC CHECKLIST



- Preoperative feature for best differentiating solid renal masses in children: Age



(Left) *Coronal T2 SSFSE MR in a 37-weeks-gestation fetus shows a large mixed cystic & solid mass ⇨ in the left fetal abdomen.* **(Right)** *Axial T2 SSFSE MR in the same fetus shows the relationship of the large mass ⇨ to the residual left kidney ➡, though it is difficult to tell if the kidney is splayed over the mass or merely compressed by it. Additionally, the amniotic fluid volume is > typically seen for this gestational age.*

(Left) *Postnatal AP radiograph of the abdomen in the same patient shows displacement of gas-filled bowel loops ⇨ into the right abdomen by a large round mass ⇨.* **(Right)** *Longitudinal color Doppler US of the abdomen in the same patient shows the 11-cm mixed cystic & solid mass ⇨ with little detectable internal vascularity. The cellular subtype of mesoblastic nephroma was confirmed upon resection.*

TERMINOLOGY

Synonyms

- Congenital mesoblastic nephroma (CMN), fetal renal hamartoma, Bolande tumor
  - Bolande described CMN as histologically distinct from Wilms tumor in 1967

Definitions

- Hamartomatous renal tumor of young infants composed predominantly of elongated spindle cells
  - Types: Classic benign CMN vs. more aggressive cellular variant vs. mixed

IMAGING

General Features

- Best diagnostic clue
  - Solitary renal mass in fetus or neonate
- Location
  - Intrarenal but may replace entire kidney & cross midline when large
  - Metastases are very uncommon
- Size
  - Variable, from < 1 cm diameter to > 15 cm
    - Cellular variant is often much larger than classic type
- Morphology
  - Oval/round mass, which may have poorly defined margins with kidney
    - Usually solid
    - Cystic/necrotic/hemorrhagic foci imply more aggressive cellular variant
  - Claw of residual renal parenchyma splayed along tumor margin helps confirm renal origin
  - Hydronephrosis & vascular invasion are not typical
  - Irregularity/discontinuity of margins, infiltration of adjacent soft tissues, surrounding fluid &/or free pelvic fluid suggest tumor rupture
    - More common with cellular type

Ultrasonographic Findings

- Grayscale ultrasound
  - Smaller masses leave renal shape largely intact
    - Smooth contours to mass by imaging
  - Larger masses may fill abdomen & cross midline
  - Variable internal echogenicity
    - Greater heterogeneity & large cystic components are more typical of cellular type
  - Hyper- & hypoechoic ring pattern at periphery more common in classic type
    - Corresponds to CECT double layer sign
  - Prenatal findings include polyhydramnios, rarely hydrops
- Color Doppler
  - Vascular invasion is not seen

CT Findings

- NECT
  - Ca^{2+} is not typically seen
  - Pockets of high attenuation correspond to hemorrhage in cellular type
- CECT
  - Heterogeneous enhancement of solid components
    - Hypoenhancement is typical in classic type
  - Cystic/necrotic/hemorrhagic foci of nonenhancement are typical of cellular type
  - Double layer sign: 2 enhancing rims at margin of classic type
  - Intratumor pelvis sign: Portion of renal pelvis encapsulated by tumor in classic type

MR Findings

- T1WI
  - Intermediate to dark
  - Hemorrhage may be bright
- T2WI
  - Variable for solid components
  - Bright cystic foci ± fluid-fluid levels from hemorrhage
- T1WI C+
  - Heterogeneous enhancement of solid components
  - Rim/septal enhancement of cystic foci

Imaging Recommendations

- Best imaging tool
  - US best initial tool for investigating palpable abdominal mass in child
  - MR will better define local extension, adenopathy

DIFFERENTIAL DIAGNOSIS

Wilms Tumor

- Most common pediatric renal tumor
- Imaging appearance may be identical to CMN
- Best preoperative discriminator from CMN: Age
  - Average presentation of Wilms: 3-4 years of age
  - Rare in utero

Neuroblastoma

- Suprarenal/paraspinal mass displacing (or rarely invading) kidney
- Often contains Ca^{2+}
- Frequently engulfs & displaces vessels, crosses midline

Adrenal Hemorrhage

- Avascular cystic or heterogeneous suprarenal mass in newborn
- ↓ size over time
- No claw of surrounding renal tissue

Multicystic Dysplastic Kidney

- Cysts of varying size completely replace renal parenchyma
  - Not cysts within well-defined round mass

Ossifying Renal Tumor of Infancy

- Extremely rare tumor characterized by ossification/Ca^{2+}

Rhabdoid Tumor

- Aggressive rare solid renal tumor of infancy
- Association with CNS atypical teratoid-rhabdoid tumors

Clear Cell Sarcoma of Kidney

- 2nd most common pediatric renal tumor
- Classically causes bone metastases
- Average presentation: 1-4 years of age

Multilocular Cystic Nephroma

- Large multicystic mass herniating into central collecting system
- Average presentation: 3 months to 2 years of age

PATHOLOGY

General Features

- Genetics
  - Sporadic
  - No recurrence risk in siblings
  - Cellular subtype of CMN shares t(12;15)(p13;q25) chromosomal translocation with infantile fibrosarcoma (IFS)
    - Fusion of genes *ETV6* & *NTRK3*
    - Trisomy 11 occurs less frequently

Staging, Grading, & Classification

- 3 histologic subtypes: Reports vary regarding most common
  - Classic (33-50%): Similar features to infantile myofibroma/fibromatosis
  - Cellular (40-63%): Similar features to IFS
  - Mixed (< 15%)
- Staging by Wilms tumor criteria

Gross Pathologic & Surgical Features

- Classic: Infiltrative without capsule ± entrapped renal parenchymal islands
- Cellular: Cystic, hemorrhagic foci

Microscopic Features

- Classic: Bundled spindle cells, entrapped tubules & glomeruli, few mitoses
- Cellular: Sheets of randomly arranged spindle cells with few bundles, high mitotic rate, nuclear atypia

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Palpable abdominal mass in young infant
  - Prenatally detected renal mass with polyhydramnios, preterm labor
- Other signs/symptoms
  - Hypertension, hypercalcemia, hematuria

Demographics

- Age
  - Most CMNs are diagnosed before 3 months of age; 16% are found prenatally
    - Classic type is most likely in this period
  - After 1-3 months
    - Wilms tumor becomes more common
    - Remaining CMNs are more likely to be cellular variants
- Ethnicity
  - No ethnic predisposition
- Epidemiology
  - 3-6% of childhood renal tumors
  - 93% of renal tumors detected in utero
  - 90% are diagnosed before 1 year of age

Natural History & Prognosis

- Can show rapid growth despite benign histology
- Large abdominal circumference may result in dystocia at delivery
- Excellent prognosis for classic subtype
  - Complete surgical resection is curative
- Cellular subtype is more aggressive
  - 10% relapse with local recurrence or metastases
    - Most common metastatic site: Lung
    - Liver, heart, brain, & bone metastases are also reported

Treatment

- Amnioreduction for polyhydramnios
- Referral to pediatric surgeon/urologist
- Resection in neonatal period
  - Nephrectomy with wide margins is usually curative
  - Adjuvant chemotherapy for patients > 3 months of age with stage III (incomplete resection/positive margins) cellular type
- 5-year event-free survival of 94-100%

DIAGNOSTIC CHECKLIST

Consider

- Best differentiating factor for solid renal masses in children: Age

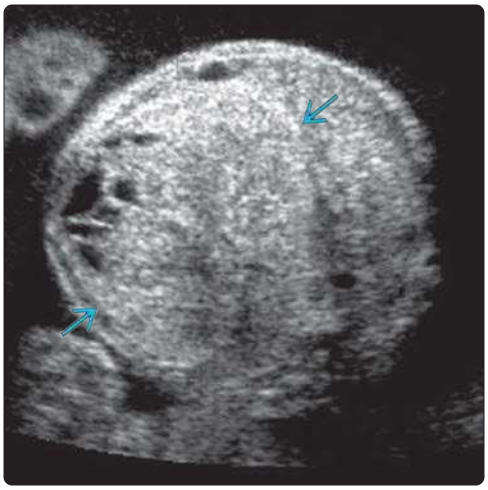


Image Interpretation Pearls

- Look for incomplete splayed rim of renal parenchyma along tumor margins (claw sign)
  - Helps confirm renal origin
  - Inferiorly displaced, distorted kidney with concave but intact cortex suggests suprarenal lesion
- Look for findings related to rupture
  - Surrounding soft tissue findings & free fluid may suggest preoperative tumor rupture
  - Cysts predispose to intraoperative rupture

(Left) *Axial CECT in a patient with cellular mesoblastic nephroma shows a crescent of residual right kidney* ➪ *splayed along the posterior margin of the heterogeneous mass* ⇨. *This claw sign helps to identify the kidney as the organ of origin for the tumor.* **(Right)** *Transverse US in a 2nd-trimester fetus with polyhydramnios shows a large, predominantly solid mass* ⇨ *in the right abdomen. No right kidney could be identified. Mesoblastic nephroma was confirmed postnatally at resection.*

(Left) *Longitudinal US in a newborn shows a relatively small, solid (but heterogeneous) mass* ⇨ *involving only the lower pole of this kidney. The patient age, tumor size, & imaging features are typical for the classic type of mesoblastic nephroma.* **(Right)** *Longitudinal panoramic US in a 5-day-old with abdominal fullness shows a large, heterogeneous mass* ⇨ *in the left flank replacing most of the left kidney.*

(Left) *Axial T2 FS MR in the same patient shows a heterogeneous mass* ➪ *in the left flank. The layering fluid-fluid levels* ⇨ *are typical of hemorrhage within cysts. A claw of the splayed residual left kidney is seen posteriorly* ➪. **(Right)** *Coronal T1 C+ FS MR in the same patient shows heterogeneous enhancement of the tumor* ➪ *with large foci of nonenhancement. A claw of residual renal parenchyma is seen superiorly* ➪. *Resection of this cellular mesoblastic nephroma was complicated by intraoperative rupture/spill.*

Renal Rhabdoid Tumor

KEY FACTS

TERMINOLOGY

- Rare, highly aggressive neoplasm in young children
- Commonly arises from kidney
- Extrarenal sites include CNS, soft tissues > liver, lung

IMAGING

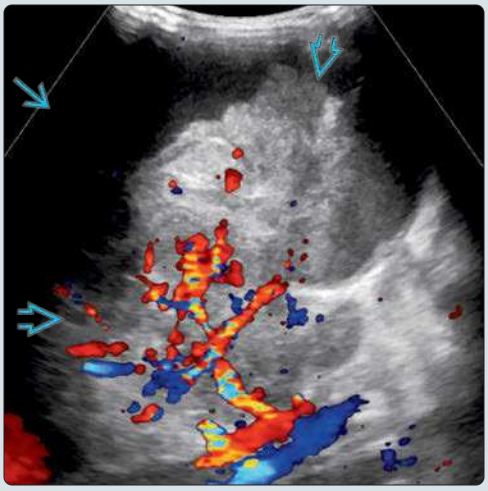
- Contrast-enhanced CT or MR is most useful
  - Large, heterogeneous renal mass
    - Foci of hemorrhage, necrosis, &/or Ca^{2+} separating tumor lobules
      - Ca^{2+} is more common than Wilms
  - Crescentic subcapsular fluid collection is characteristic
  - Sinus/hilar, local, & vascular invasion are common
  - Metastasizes most frequently to lungs

PATHOLOGY

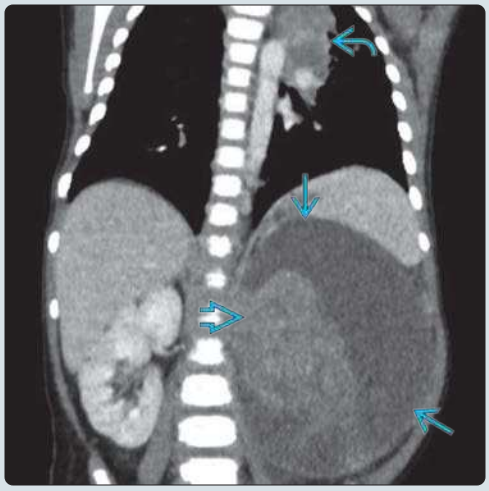
- ~ 2% of pediatric renal tumors
- Associated with inactivation or deletion of *SMARCB1* (*INI1*) gene on chromosome 22q11

CLINICAL ISSUES

- Mean age of presentation: ~ 11 months
  - Younger than mean age for Wilms tumor
- Signs/symptoms
  - Most common: Palpable abdominal mass, hematuria (gross or microscopic)
  - Others include fever, anemia, hypercalcemia
- Aggressive neoplasm with poor prognosis
  - Patients often present with advanced disease
    - Stages 3-4 in ~ 70% at presentation
  - Overall 5-year survival ~ 20%
  - Prognosis is worse in younger patients (< 6 months of age)



DIAGNOSTIC CHECKLIST



- Consider brain MR to evaluate for synchronous or metachronous CNS neoplasm

(Left) *Coronal T2 FS MR in an 11-month-old boy ultimately diagnosed with a rhabdoid tumor shows a large, heterogeneous, lobulated mass replacing the right kidney. A subcapsular fluid collection is noted at the periphery of the mass.* **(Right)** *Axial T1 C+ FS MR in the same patient demonstrates heterogeneous enhancement of the large right renal rhabdoid tumor. Note the hilar invasion by the tumor lobules.*

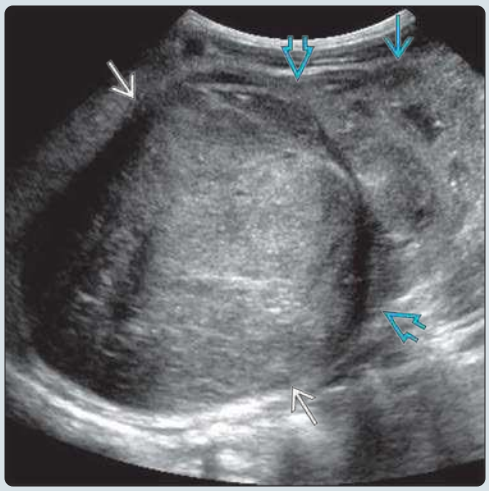
(Left) *Longitudinal color Doppler ultrasound in a 1-year-old shows a large subcapsular fluid collection overlying a lobulated & highly vascular mass that replaces the left kidney. The patient age & findings favor a malignant rhabdoid tumor.* **(Right)** *Coronal CECT in the same patient shows the solid mass & large subcapsular collection replacing the left kidney. Multiple lung metastases were present in this patient with a renal rhabdoid tumor, but no intracranial lesions were found.*

KEY FACTS

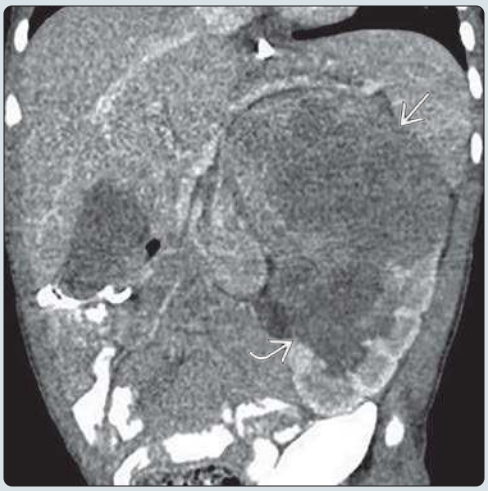
TERMINOLOGY

- "Bone metastasizing tumor of childhood"
- Rare malignant renal neoplasm in young children
  - 5% of pediatric renal tumors

IMAGING

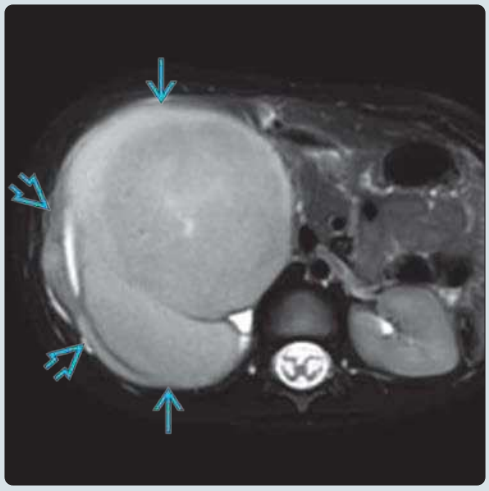


- CECT or MR is best for characterizing tumor & evaluating local extension
  - Best clue: Large, solid renal mass in young child
    - Most commonly heterogeneous, well-circumscribed mass
      - Can be homogeneous
    - Ca^{2+}: 25%
    - Vascular invasion: 5%
    - Regional lymph node involvement: Up to 30%
    - Delayed recurrence in brain, bones
- Metastatic work-up: Chest CT & nuclear medicine (FDG PET)

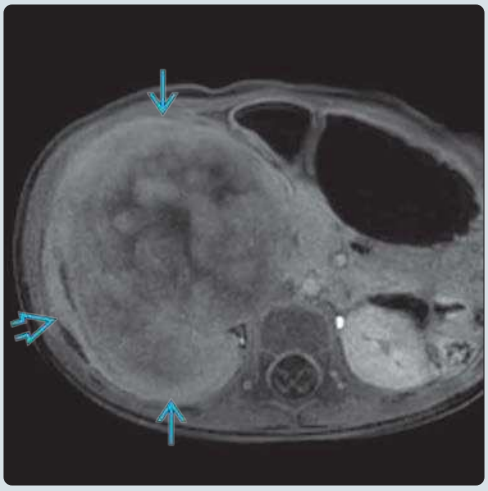


PATHOLOGY

- Variable histological patterns
  - Most have *BCOR* gene duplications
- Staging similar to Wilms tumor
  - Most present with stage II or higher



CLINICAL ISSUES



- Most common presentation: Palpable abdominal mass ± hematuria
  - Rarely presents with pain from osseous metastases
- Mean age at presentation: 36-45 months
- Male predominance of 2:1
- 5-year survival = 73-86%
  - Up to 98% for stage I disease
  - ~ 50% for stage IV disease
- Treatment: Combination chemotherapy, surgery, & radiation (depending on stage)

(Left) *Longitudinal ultrasound in a 2-year-old boy with a palpable abdominal mass shows a solid mass arising from the upper pole of the left kidney. Note the splayed residual left renal parenchyma forming the claw sign.* **(Right)** *Coronal CECT in the same patient shows a large, hypoenhancing mass arising from the upper pole of the left kidney. The mass is causing obstruction of the lower portion of the left renal collecting system. Clear cell sarcoma was confirmed at resection.*

(Left) *Axial T2 FS MR in a 16-month-old girl with a palpable abdominal mass shows a relatively homogeneous, well-circumscribed T2-hyperintense mass arising from the right kidney.* **(Right)** *Axial T1 C+ FS MR in the same patient shows heterogeneous enhancement of the right renal mass with central areas of nonenhancement likely representing necrosis. Note the splayed "claw" of residual enhancing renal parenchyma.*

Renal Cell Carcinoma

KEY FACTS

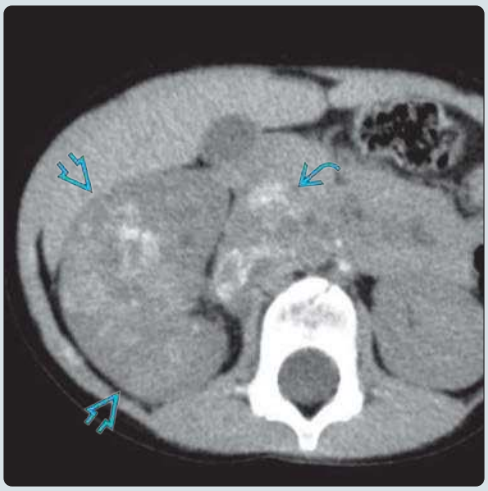
TERMINOLOGY

- Malignant renal tumor that is more common in adolescents & young adults
  - 2-6% of renal malignancies in children
  - > 50% of renal tumors > 14 years of age
- tRCC or TFE RCC = translocation subtype (most common)

IMAGING

- Best clue: Solid or mixed solid/cystic renal mass in adolescent/young adult
  - Metastases to lymph nodes, lung, liver, bone
- NECT: Can be mildly ↑ attenuation due to hemorrhage
  - Ca^{2+} in 40-60%
- CECT: Heterogenous enhancement but ↓ vs. adjacent normal kidney
  - Usually well-defined margins, may see enhancing capsule
  - Enlarged retroperitoneal lymph nodes are common
- T2: Heterogeneous, ± foci of ↓ signal from hemorrhage
- T1 C+: Heterogeneous enhancement is typical
  - ± enhancing capsule on delayed images

TOP DIFFERENTIAL DIAGNOSES



- Wilms tumor, clear cell sarcoma, rhabdoid tumor, angiomyolipoma, renal medullary carcinoma

PATHOLOGY

- Translocation subtype (tRCC) is most common
  - Xp11.2 translocation → *TFE3* gene overexpression
- Papillary subtype is 2nd most common
- TMN staging is similar to adult RCC

CLINICAL ISSUES

- Clinical presentation: Abdominal/flank pain, palpable mass
  - Rarely hematuria
  - Frequently incidental
- Treatment: Radical nephrectomy & lymph node sampling &/or dissection
  - Targeted therapies > cytotoxic chemotherapy
  - XRT limited role, palliative

(Left) *Axial NECT in a 9-year-old girl with flank pain, found to have renal cell carcinoma (RCC), shows a right renal mass with high-attenuation foci. Note the enlarged retroperitoneal lymph nodes, which also contain heterogeneous high-attenuation, likely due to* Ca^{2+}. **(Right)** *Axial CECT in the same patient shows heterogeneous enhancement of the right renal mass with multiple enlarged retroperitoneal lymph nodes.*

(Left) *Coronal T2 FS MR in a 15-year-old with shoulder pain (due to metastatic RCC in the humerus, not shown) demonstrates a heterogeneous left renal mass with a rim of low signal due to hemosiderin from prior hemorrhage.* **(Right)** *Axial T1 C+ FS MR in the same patient shows a hyperintense solid mass in the left kidney with a low-signal rim. Note the residual left kidney anteriorly. The majority of the mass showed precontrast T1 shortening due to internal blood products.*

TERMINOLOGY

Abbreviations

- Renal cell carcinoma (RCC)

Synonyms

- tRCC or TFE RCC = translocation subtype (most common) of RCC

Definitions

- Malignant renal tumor that is more common in adolescents & young adults
  - 2-6% of renal malignancies in children

IMAGING

General Features

- Location
  - tRCC is typically located in renal medulla
- Size
  - Mean size of tRCC = 6-7 cm
- Morphology
  - Usually round, well circumscribed

Ultrasonographic Findings

- Heterogeneous mixed solid/cystic mass
  - Can have hyperechoic foci due to Ca^{2+}

CT Findings

- NECT
  - Can be mildly ↑ in attenuation relative to normal kidney
  - Ca^{2+} in 40-60%
- CECT
  - Heterogenous but ↓ enhancement vs. normal kidney
  - Usually well-defined margins, may see enhancing capsule
  - Enlarged retroperitoneal lymph nodes are common
  - Metastases to lymph nodes, lung, liver, bone

MR Findings

- T1WI
  - Iso- to mildly hyperintense due to hemorrhage, Ca^{2+}
- T2WI FS
  - Heterogeneous, ± foci of ↓ signal from hemorrhage
- DWI
  - Typically hyperintense, can be heterogeneous
- T1WI C+ FS
  - Heterogeneous enhancement is typical
  - May have nonenhancing necrotic areas
  - ± enhancing capsule in tRCC

DIFFERENTIAL DIAGNOSIS

Wilms Tumor

- Most common pediatric renal malignancy
- 80% present < 5 years of age
- Typically large

Clear Cell Sarcoma

- 2nd most common renal malignancy < 10 years of age
- Bone metastases are classic

Malignant Rhabdoid Tumor

- Uncommon aggressive renal malignancy
- 80% present < 2 years of age
- Subcapsular fluid collection may be present

Angiomyolipoma

- Typically contains macroscopic fat
- Usually seen with tuberous sclerosis complex

Renal Medullary Carcinoma

- Heterogeneous infiltrating malignancy in adolescents & young adults with sickle cell trait

PATHOLOGY

General Features

- Translocation subtype (tRCC) is most common
  - Xp11.2 translocation; *TFE3* gene overexpression
- Papillary subtype is 2nd most common
- Clear cell RCC (most common in adults) is rare; may be seen with von Hippel Lindau syndrome

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Abdominal/flank pain, palpable mass
  - Hematuria is less common
  - Often found incidentally

Demographics

- Age
  - Older children, adolescents, young adults
    - > 50% of renal tumors ≥ 14 years of age
- Epidemiology
  - ↑ risk with history of treatment for prior malignancy

Natural History & Prognosis

- More advanced stage (III or IV) is common at presentation
- Stage I, II = > 90% survival
- Stage IV = < 30% survival

Treatment

- Radical nephrectomy & lymph node sampling &/or dissection; rarely partial nephrectomy
- Targeted therapies > cytotoxic chemotherapy
- XRT has limited role, usually palliative

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Remember to look for abnormal lymph nodes
- Metastatic disease to lung, liver, bone

Renal Medullary Carcinoma

KEY FACTS

TERMINOLOGY

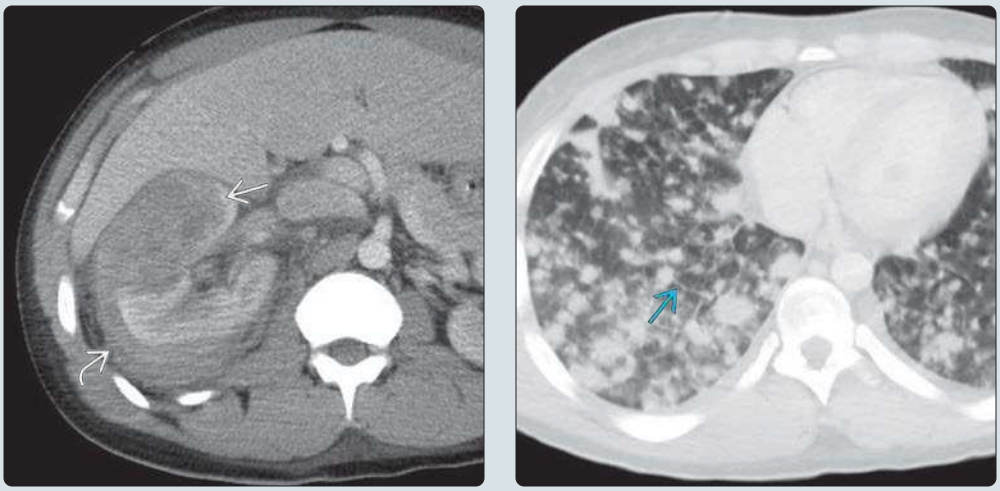
- Rapidly growing tumor of renal medulla

IMAGING

- Best clue: Infiltrating, poorly defined renal mass in young adult with sickle cell trait
  - Tumor arises in renal medulla with extension toward renal sinus & cortex
  - Heterogeneous tumor enhancement due to necrosis
    - Can mimic abscess
  - Kidney may maintain reniform shape
  - Central masses may cause caliectasis
  - Extension to perinephric tissues is common
- 60% occur in right kidney
- Mean size: 6.5 cm
- Lung metastases & lymph node involvement are common
  - Lung metastases often have lymphangitic pattern with clustered or diffuse poorly defined nodules intermixed with interstitial thickening

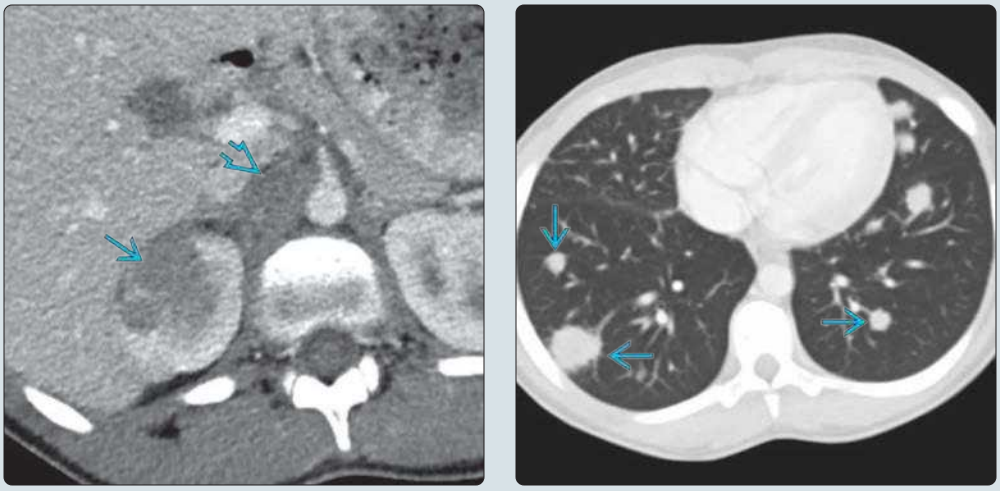
TOP DIFFERENTIAL DIAGNOSES

- Pyelonephritis with developing abscess
- Renal cell carcinoma
- Wilms tumor



PATHOLOGY

- 88% occur in patients with sickle cell trait
  - May be related to sickling blood & local renal environment



CLINICAL ISSUES

- Most common presenting symptoms: Hematuria & pain
- Other symptoms: Weight loss, respiratory symptoms, nausea, & vomiting
- 3.2x more common in males
- Therapy has not not been effective
  - Typically treated with nephrectomy & chemotherapy
  - Poor prognosis with median overall survival of 5 months

(Left) *Axial CECT in a young adult with sickle cell trait & renal medullary carcinoma (RMC) shows a poorly defined infiltrative & heterogeneous mass of the right kidney with perinephric extension.* **(Right)** *Axial CECT in the same patient shows extensive lung metastases with nodular opacities intermixed with interstitial thickening, typical of lymphangitic spread. Metastases are common in RMC, with the most common sites being lymph nodes, lungs, & liver.*

(Left) *Axial CECT in an adolescent with RMC shows an infiltrative, poorly defined mass in the upper pole of the right kidney. An enlarged right retroperitoneal lymph node is also present.* **(Right)** *Axial CECT in the same patient shows multiple pulmonary metastases. Many of the lesions demonstrate a spiculated border.*

TERMINOLOGY

Definitions

- Rapidly growing tumor of renal medulla

IMAGING

General Features

- Best diagnostic clue
  - Infiltrating renal mass in adolescent/young adult with sickle cell trait
  - Kidney may maintain reniform shape
- Location
  - Arises in renal medulla with extension toward renal sinus & cortex
  - 60% occur in right kidney
- Size
  - Mean size: 6.5 cm

Radiographic Findings

- IVP
  - Mass distorts renal collecting system

CT Findings

- Infiltrative, poorly defined mass growing from renal medulla toward cortex
- Central masses may cause caliectasis
- ↓ enhancement compared to renal parenchyma
  - Necrotic components can mimic abscess
- Extension to perinephric tissues is common
- Lung metastases & lymph node involvement are common
  - Lung metastases often have lymphangitic pattern with clustered or diffuse nodules intermixed with interstitial thickening

MR Findings

- Similar imaging findings as on CT
- Hemorrhagic products may be conspicuous on gradient-echo images

Imaging Recommendations

- Best imaging tool
  - CECT to evaluate lungs & kidney

DIFFERENTIAL DIAGNOSIS

Renal Cell Carcinoma

- 2nd most common renal malignancy in children
- Typically occurs in adolescents
- Well-defined, heterogeneous, small- to moderate-sized mass; often superficial (distorting renal contour)

Wilms Tumor

- Most common renal malignancy in children; 80% < 5 years of age
- Well-defined, typically large, round heterogeneous mass replacing most of kidney
  - "Claw" of residual renal parenchyma is splayed around tumor margin

Pyelonephritis With Developing Abscess

- Relatively uncommon complication of commonly occurring renal parenchymal infection
- Poorly defined, heterogeneous parenchymal mass with retained reniform shape
- ± systemic features of infection, positive urinalysis

PATHOLOGY

General Features

- Etiology
  - 88% of cases occur in patients with sickle cell trait
  - Thought to be related to sickling blood & local renal environment

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hematuria & pain
- Other signs/symptoms
  - Weight loss, respiratory symptoms, nausea, & vomiting

Demographics

- 3.2x more common in males

Natural History & Prognosis

- Poor prognosis; median overall survival: 5 months
- Metastases at presentation in 88%
  - Most common sites: Lymph nodes, lungs, & liver

Treatment

- Typically treated with nephrectomy & chemotherapy
- No known effective therapies

Angiomyolipoma

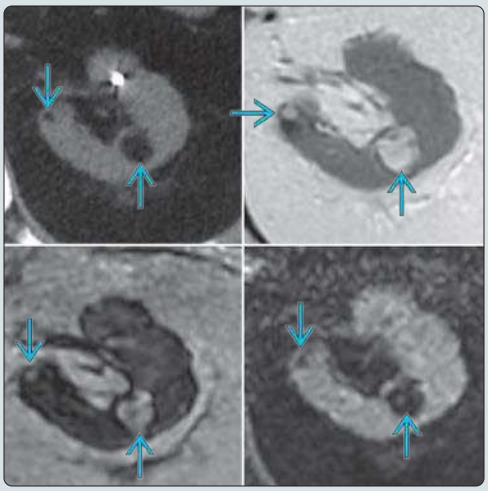
KEY FACTS

TERMINOLOGY

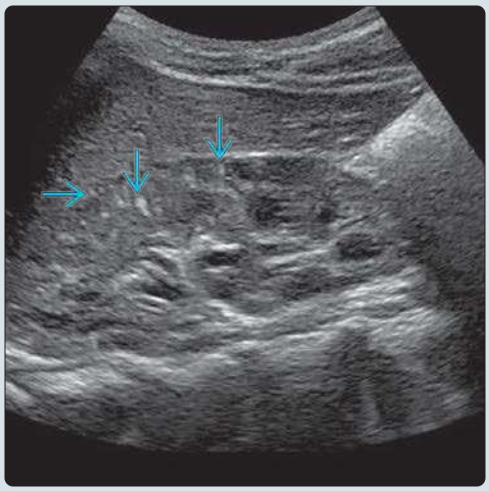
- Angiomyolipoma (AML): Benign hamartomatous tumor consisting of abnormal blood vessels, smooth muscle, & fat
  - Vast majority of AMLs occur in kidneys
- Almost always associated with tuberous sclerosis complex (TSC) in children

IMAGING

- Renal masses showing variable amounts of fat
  - Fat-containing renal mass is diagnostic of AML in child
    - Signal dropout on opposed-phase MRs
    - Contrast is not needed for diagnosis with known TSC
      - Potentially useful for vascular evaluation
- Bilateral in 85-95% of TSC patients with AMLs
- Tortuous vessels ± aneurysms in larger AML
  - Vessels may be splayed by fatty components or cysts
- Benign renal cysts are also common in TSC

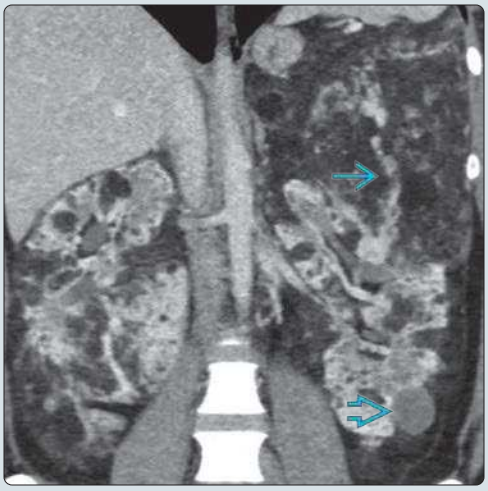


PATHOLOGY



- 2 patterns of disease: Sporadic vs. TSC-associated AML
  - Sporadic lesions are extremely rare in children
- Underlying mutations of tumor suppressor genes *TSC1* or *TSC2* → dysregulation of mammalian target of rapamycin (mTOR) → ↑ cell growth & division
- Frequency, severity, & risk of bleeding are higher in patients with *TSC2* mutation

CLINICAL ISSUES



- Pediatric AMLs are usually asymptomatic
  - Children typically have clinical (especially cutaneous & neurologic) manifestations of TSC
- Conservative symptomatic management for AMLs in TSC
  - mTOR inhibitors are used for lesions > 3 cm
- Possible life-threatening spontaneous hemorrhage
  - Hemorrhage rare if AML ≤ 4 cm or aneurysm < 5 mm
  - Treated with arterial embolization

(Left) *Axial (clockwise from upper left) NECT, T1 MR, T1 FS MR, & opposed-phase MR images show a fat-containing angiomyolipoma (AML) in a patient with tuberous sclerosis complex (TSC). Note that the signal drop is only seen at the margins of these lesions containing macroscopic fat on the opposed-phase images.* **(Right)** *Longitudinal ultrasound in a child with TSC shows multiple tiny echogenic lesions of the right renal parenchyma, consistent with AMLs.*

(Left) *Coronal CECT in a patient with TSC shows AMLs replacing both kidneys. The largest AML is in the upper pole of the left kidney & extends to the top of the image. The large AML contains multiple tumoral vessels. A cyst is also present in the lower pole of the left kidney.* **(Right)** *Axial opposed-phase MR in the same patient shows signal dropout where the fat-containing tumor & tumoral vessels share the same imaging voxel.*

TERMINOLOGY

Abbreviations

- Angiomyolipoma (AML)

Definitions

- Benign hamartomatous tumor consisting of abnormal blood vessels (angio), smooth muscle (myo), & fat (lipoma)

Associated Syndromes

- Almost always associated with tuberous sclerosis complex (TSC) in children

IMAGING

General Features

- Best diagnostic clue
  - Renal masses containing variable amounts of fat
  - Benign renal cysts are also common in patients with TSC
    - Variable signal depending on proteinaceous content
    - Cysts do not contain fat or enhance
- Location
  - Vast majority of AMLs occur in kidneys
    - Can occur in liver, pancreas, & other abdominal organs
    - Hepatic AMLs occur in 15-30% of TSC patients with renal AMLs
      - Hepatic AMLs are typically small; median of 1 cm
      - Renal AMLs are typically diffuse in this setting
- Size
  - Variable: Range from tiny (mm) to large (many cm)
- Morphology
  - Variable shape, fat content, & number in kidneys
  - Bilateral in 85-95% of TSC patients with AMLs

CT Findings

- NECT
  - Renal mass with tumoral fat → diagnostic of AML in children with TSC
  - Fat-poor lesions are isodense to slightly hyperdense compared to kidney
- CECT
  - Contrast is not needed in setting of known TSC
  - Lesions may significantly enhance with contrast (depending on extent of vascular component)
  - Fat-poor AMLs show homogeneous & prolonged enhancement
- CTA
  - ± aneurysmal renal vessels in large AMLs

MR Findings

- T1WI
  - Mass contains variable amounts of high-signal fat
  - Low signal in fatty portion on fat-saturated images
  - Fat-poor lesions are hypointense compared to renal parenchyma
- T2WI
  - Mass contains variable amounts of high-signal fat
  - Low signal in fatty portion on fat-saturated images
  - Fat-poor AMLs are hypointense compared to renal parenchyma
- T1WI C+
  - Contrast is not needed for diagnosis in setting of known TSC
  - Variable enhancement
    - With high fat content, may show minimal enhancement
    - With high vessel content, may show marked enhancement
- In phase/opposed phase
  - Signal dropout when fat & water share same voxel on opposed-phase images
    - Small lesions have complete signal dropout
    - Large lesions have signal dropout at border with vessels & normal renal parenchyma
  - No signal dropout for fat-poor AMLs
  - Opposed phase is useful to identify extrarenal AMLs

Ultrasonographic Findings

- Grayscale ultrasound
  - Hyperechoic mass relative to normal kidney & liver
  - Fat-poor AMLs are usually isoechoic compared to kidney
- Color Doppler
  - Can detect aneurysms in larger lesions

Angiographic Findings

- Characteristic tortuous vessels with multiple aneurysms
- Vessels may be splayed by larger fatty lesions or cysts

Imaging Recommendations

- Best imaging tool
  - MR is recommended at diagnosis of TSC to evaluate potential renal lesions
    - Minimize CT as these patients will undergo many studies during their lifetimes
    - Renal MR is performed at same time as brain MR
    - Surveillance MR is performed every 1-3 years depending on imaging findings & patient symptoms
  - Routine US is not preferred in children with known TSC
    - Fat-poor AMLs are not visible
    - Tumor & cyst measurements are not reproducible
- Protocol advice
  - MR with in-phase/opposed-phase sequences is most sensitive for detecting small lesions
  - T1 & T2 MR performed with & without fat saturation
  - IV contrast is not necessary for diagnosis in patients with known TSC

DIFFERENTIAL DIAGNOSIS

Renal Cell Carcinoma

- Rare in children
- Rarely reported to contain fat
  - Fat-poor AML may mimic renal cell carcinoma (RCC)
- Ca^{2+} in mass is highly suggestive of RCC
  - Ca^{2+} is extremely rare in AML
- Association of RCC with TSC is controversial
  - Even if risk is ↑, RCC remains very rare in TSC
  - Fat-poor AMLs are much more common

Renal Cyst

- Commonly seen in patients with TSC
- Fat-saturated MRs help differentiate fat from proteinaceous fluid

Wilms Tumor

- Most common pediatric renal malignancy
- Solid mass that rarely contains fat
- ± invasion of renal vein & inferior vena cava
- Metastases to lymph nodes, liver, lung
- ↑ frequency in certain syndromes
  - Beckwith-Wiedemann
  - Hemihypertrophy
  - Congenital aniridia
  - WAGR syndrome

Retroperitoneal Teratoma

- Heterogeneous, fat-containing mass; ± Ca^{2+}
- Displaces/compresses kidney rather than arising from it

PATHOLOGY

General Features

- Etiology
  - Benign renal tumor with mixed vessel, muscle, & fat elements
  - 2 main patterns of disease
    - Sporadic AML
      - ~ 80% of AMLs overall; however, sporadic AMLs are extremely rare in children
      - Usually solitary
      - More common in females due to stimulation by estrogen/progesterone
      - Risk of hemorrhage in lesions ≥ 4 cm in size
    - TSC-associated AML
      - Occur in 55-80% of patients with TSC
      - Multiple, bilateral tumors
      - Typically larger than sporadic AML
      - ± ↓ risk of hemorrhage vs. sporadic lesions
- Genetics
  - 2 tumor suppressor genes are associated with TSC
    - *TSC1*, band 9q34, encodes for hamartin
    - *TSC2*, band 16p13.3, encodes for tuberin
  - Hamartin & tuberin help inhibit activation of mammalian target of rapamycin (mTOR)
    - Mutations lead to uncontrolled cell size & division
  - Frequency, severity, & risk of bleeding are higher in patients with *TSC2* mutation
- Associated abnormalities
  - LAM: Numerous thin-walled cysts throughout lungs
    - Likely represent metastatic AMLs

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Characteristic skin & neurologic stigmata of TSC
  - AMLs are usually asymptomatic
- Other signs/symptoms
  - Renal failure (usually not until adulthood)

Demographics

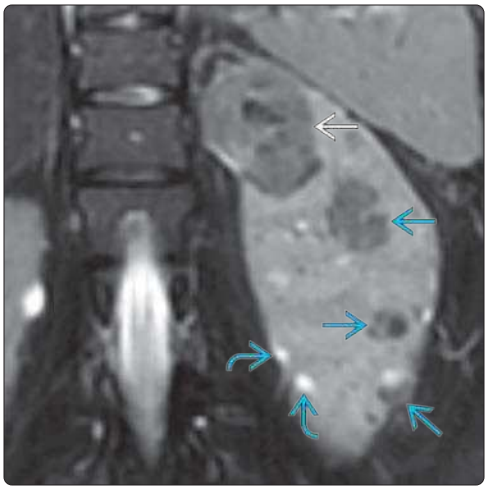
- Age
  - Frequency of renal lesions ↑ with age
  - Small AMLs in TSC patients in early childhood
    - 45% have renal cysts or AMLs by 6 years of age
- Sex
  - TSC-associated AMLs are slightly more common in females
  - Sporadic AMLs are much more common in females
- Epidemiology
  - Sporadic AML in 0.3-3% of population at autopsy
  - AMLs are present in 55-80% of TSC patients

Natural History & Prognosis

- Untreated TSC-associated AMLs enlarge into adulthood
- Possible life-threatening spontaneous hemorrhage
  - Presents with flank/abdominal pain, hematuria
  - Bleeding occurs in up to 15% of TSC patients with AML
  - Risk factors for spontaneous hemorrhage
    - AML size > 4 cm
    - Aneurysm size > 5 mm
    - Age between 20 & 30 years
    - Risk ↓ with mTOR inhibitor therapy

Treatment

- Conservative, symptomatic management for patients with TSC-associated AMLs
  - Lesions can ↓ in size with mTOR inhibitors; reserved for lesions > 3 cm in size



DIAGNOSTIC CHECKLIST

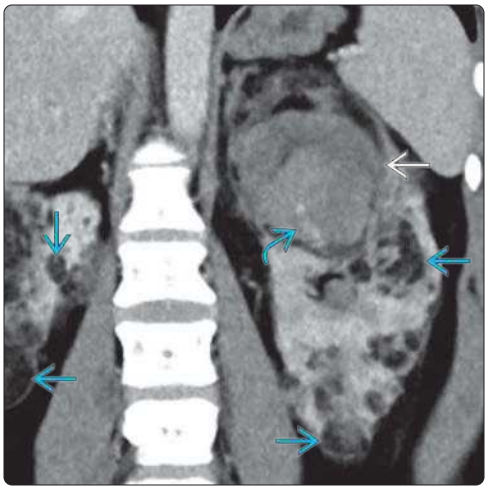


Image Interpretation Pearls

- Classic appearance: Well-circumscribed, fatty renal mass
- 3 renal lesion types are seen on MR in patients with TSC
  - Classic AML: Bright on T1 & T2; ↓ signal with fat saturation; signal dropout on opposed phase
  - Fat-poor AML: Isointense to muscle on T1 & T2; no change with fat saturation or opposed phase
  - Cyst (typical): Dark on T1, bright on T2; no change with fat saturation
    - Hemorrhage/protein in cyst may alter internal signal

(Left) *Coronal T2 FS MR in a patient with TSC shows multiple renal AMLs & small cysts with a dominant heterogeneous AML in the upper pole of the kidney.* **(Right)** *Subsequent coronal CECT in the same patient shows that the dominant upper pole AML has ↑ in size due to hemorrhage. A blush of contrast at the base of the tumor represents active bleeding of the AML. Note the numerous fat-containing AMLs bilaterally.*

(Left) *AP projection from a left renal artery DSA in the same patient shows multiple tiny aneurysms & tumoral vessels. The largest aneurysm shows active hemorrhage.* **(Right)** *Axial T1 opposed-phase MR in a patient with TSC shows signal dropout at the periphery of 2 hepatic AMLs. Hepatic AMLs occur in 15-30% of TSC patients with renal AMLs.*

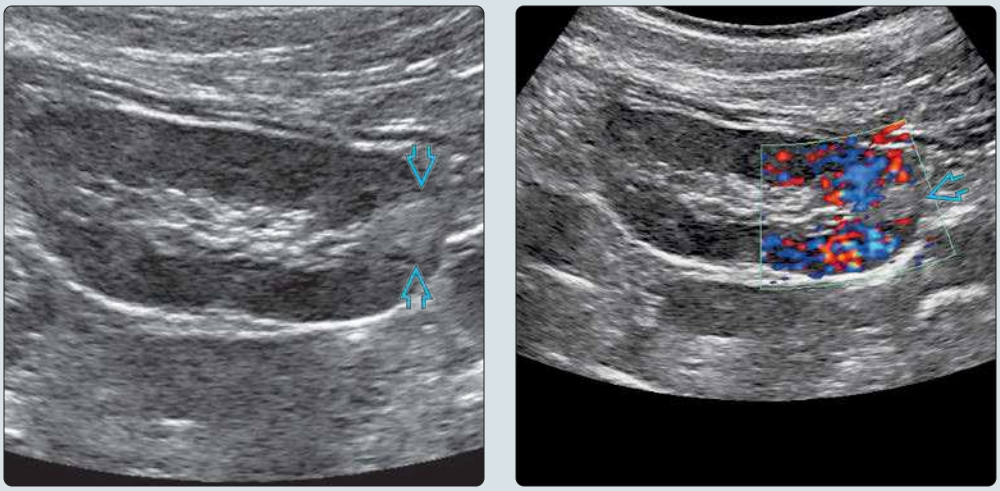
(Left) *Coronal T1 MR in a patient with TSC shows a hypointense lipid-poor AML of the lower pole of the left kidney. The AML maintains the normal reniform shape of the kidney.* **(Right)** *Coronal T2 FS MR in the same patient with TSC redemonstrates a hypointense lipid-poor AML in the lower pole of the left kidney. The AML maintains the normal reniform shape of the kidney.*

Pyelonephritis

KEY FACTS

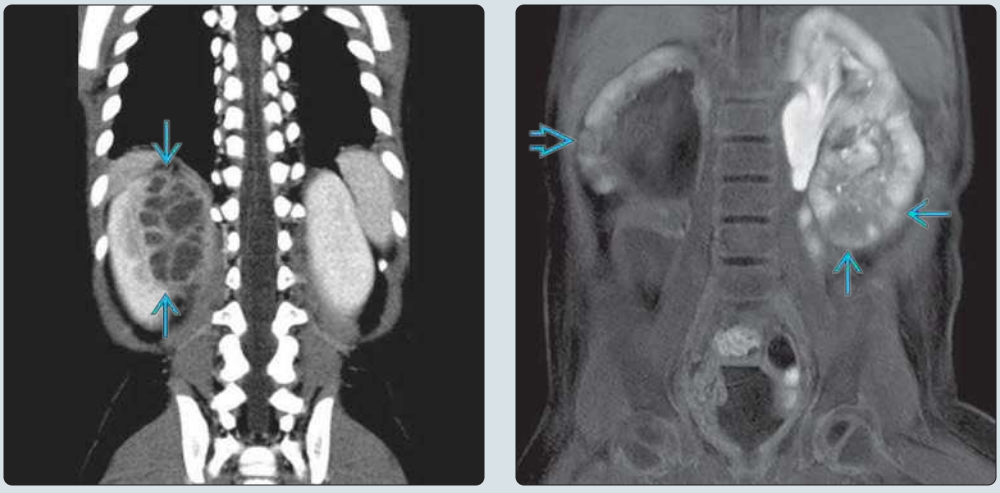
TERMINOLOGY

- Acute infection of renal parenchyma; often difficult to clinically distinguish from lower urinary tract infection (UTI)
- Classic imaging appearance: Focal swelling & ↓ perfusion of affected parenchyma visible on nuclear scintigraphy, US, CECT, MR, & IVP
  - Imaging work up of is UTI controversial
    - See professional society guidelines



IMAGING

- Marked inflammatory response to infection causes swelling that alters normal tissue properties & effectively ↓ radiologic contrast agent delivery to site, which results in
  - Photopenic focus on nuclear cortical scan
  - ↓ perfusion on Doppler imaging with altered echotexture on grayscale US
  - Striated or wedge-shaped foci of ↓ enhancement on CECT/MR/IVP
  - Developing abscess may be mass-like, ± cystic foci
- US with Doppler is least invasive & readily available but less sensitive than nuclear renal cortical scans, CT, & MR
- US is frequently performed to search for associated complications (abscess, stones, scarring), congenital anomalies, & hydronephrosis



CLINICAL ISSUES

- Symptoms nonspecific: Malaise, irritability, fever, abdominal/flank pain, vomiting, hematuria, dysuria, change in urinary habits/enuresis
- Treatment: 7- to 14-day course of antimicrobial therapy; may be started IV & changed to oral
- Imaging work-up for VUR & congenital anomalies
- Complications: Perirenal abscess, necrotizing papillitis, pyonephrosis (obstruction), & cortical scarring
- Permanent scarring is more likely < 2 years old
- Recurrent infections & subsequent scarring lead to end-stage renal disease in small but significant percentage of pediatric patients

(Left) *Longitudinal US of the left kidney in a 4-year-old girl with fever & abdominal pain shows a focus of ↑ echogenicity in the lower pole ⇨.* **(Right)** *Color Doppler US of the left renal lower pole in the same patient shows ↓ blood flow ⇨ in the echogenic focus, consistent with pyelonephritis. US findings of pyelonephritis can be subtle, & color (especially power) Doppler is useful to localize an abnormality.*

(Left) *Coronal CECT in a 5-month-old with fever shows a predominantly fluid-attenuation, multiseptated mass ⇨ with irregular walls & adjacent parenchymal & perinephric edema, consistent with pyelonephritis with abscess. Antibiotic therapy led to resolution without requiring drainage.* **(Right)** *Coronal T1 C+ FS MR in a 32-month-old with a history of urinary anomalies shows swelling, ↓ enhancement, & perinephric edema in the left lower pole ⇨ due to acute pyelonephritis. Scarring was noted on the right ⇨.*

TERMINOLOGY

Synonyms

- Acute lobar nephronia, focal bacterial nephritis

Definitions

- Acute infection of renal parenchyma
- Overview
  - Classic imaging appearance: Focal swelling & ↓ perfusion of affected parenchyma visible on nuclear scintigraphy, US, CT, & MR
  - Associated vesicoureteral reflux (VUR) in ~ 1/3 of cases
  - Permanent scarring is more likely in children < 2 years old
  - Variable presentation: Fever, lethargy, irritability, vomiting, abdominal/flank pain, hematuria, or dysuria
- Imaging work-up of urinary tract infection (UTI) is controversial; professional society guidelines vary internationally

IMAGING

General Features

- Best diagnostic clue
  - Inflammatory response to infection causes swelling that alters normal tissue properties & effectively ↓ radiologic contrast agent delivery to this site, which results in
    - Photopenic area on nuclear cortical scans
    - ↓ perfusion on Doppler imaging & altered echotexture on grayscale US
    - Striated or wedge-shaped areas of ↓ enhancement on CT or IVP
    - Focal ↓ contrast enhancement on MR
- Morphology
  - Areas of infection tend to be peripheral & wedge-shaped; can be more rounded & mass-like when inflammation is more severe

Radiographic Findings

- IVP
  - Striated nephrogram is classic, though IVPs are rarely performed in pediatric patients

Ultrasonographic Findings

- Grayscale ultrasound
  - Localized or generalized swelling; unilateral renal enlargement may be only clue to pyelonephritis
  - Poor corticomedullary differentiation & focal areas of ↑ or ↓ echogenicity
  - Occasionally rounded or mass-like areas of altered echotexture are noted, particularly with developing abscess
- Color Doppler
  - ↓ perfusion in areas of pyelonephritis
    - Adding power Doppler improves accuracy & sensitivity
  - Nonspecific ↑ resistive indices with parenchymal edema
- Contrast-enhanced ultrasound & microvascular imaging
  - ↓ perfusion noted in areas of pyelonephritis

CT Findings

- CECT
  - Wedge-shaped or round areas of poor enhancement
  - May have streaky enhancement, striated nephrogram
  - Inflammatory changes in perirenal fat
  - Occasionally mass-like; may distort normal renal contour & appear as partially cystic neoplasm during abscess development

MR Findings

- T1WI
  - Loss of corticomedullary differentiation
- T2WI
  - High signal intensity in affected renal parenchyma, potentially heterogeneous
  - May also see inflammatory changes in perirenal fat
  - Fat suppression techniques are more sensitive
- DWI
  - ↑ sensitivity for acute parenchymal inflammation
- T1WI C+ FS
  - Similar to CECT: Foci of ↓ enhancement

Nuclear Medicine Findings

- Nuclear scintigraphic findings
  - ↓ accumulation of renal cortical agents, typically wedge-shaped with apex pointed toward renal hilum
    - Tc-99m DMSA or glucoheptonate
    - Pinhole collimation & SPECT imaging improve diagnostic sensitivity & accuracy
  - No volume loss until scarring ensues
  - Findings persist for up to 6 weeks after acute infection

Imaging Recommendations

- Best imaging tool
  - Ultrasound with Doppler is least invasive & readily available but less sensitive than nuclear renal cortical scans, CECT, & MR
  - Ultrasound is frequently performed to search for associated complications (abscess, stones, scarring), underlying congenital anomalies, & hydronephrosis
- American Academy of Pediatrics Clinical Practice Guidelines
  - Renal & bladder US in febrile infants with UTI
  - VCUG is not performed routinely for 1st febrile UTI
    - Performed if US shows hydronephrosis, scarring, or other findings of high-grade VUR or obstructive uropathy as well as in other atypical or complex clinical circumstances

DIFFERENTIAL DIAGNOSIS

Renal Infarction

- Wedge-shaped pattern of ↓ perfusion
- Retained thin rim of capsular enhancement
- May see Doppler abnormalities of vessels

Renal Scarring

- Typically more superficial than pyelonephritis
- Associated cortical volume loss & dilated calyx

Renal Mass

- Heterogeneous, well-circumscribed mass, typically round
- Large masses (Wilms tumor, mesoblastic nephroma, etc.) may only show "claw" of residual splayed renal parenchyma along margin of tumor
  - Usually solid ± foci of necrosis; rarely entirely cystic or hemorrhagic

- Extremely rare but aggressive renal medullary carcinoma (RMC) can be very poorly defined & infiltrative, mimicking pyelonephritis/abscess & surrounding inflammatory change; check for history of sickle trait

Renal Contusion/Laceration

- Focal ↓ enhancement (often jagged or linear) with surrounding fluid in setting of trauma

PATHOLOGY

General Features

- Infection may occur via ascending route (VUR), hematogenous spread, or recent instrumentation
- Vast majority of urine cultures grow gram-negative bacilli, typically normal inhabitants of intestinal tract (*Escherichia coli is* most common)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Often nonspecific: Malaise, irritability, fever, abdominal/flank pain, vomiting, hematuria, dysuria, change in urinary habits/enuresis
- Other signs/symptoms
  - Strong smelling urine in any age
- Laboratory studies
  - Urine dipstick for nitrite, leukocyte esterase; both are associated with higher likelihood of positive urine culture
  - Urine for Gram stain; *E. coli* is causative in > 80% of 1st-time UTIs, *Klebsiella* is 2nd most common
    - Urine specimen for culture: Catheter specimen, clean-catch midstream, or suprapubic aspirate
    - Urine culture is considered positive when single organism grows as follows
      - > 1,000 colony-forming units (cfu)/mL for suprapubic aspirate
      - Or > 10,000 cfu/mL for catheter specimen
      - Or > 100,000 cfu/mL for clean-catch midstream specimen
  - Bloodwork: Leukocytosis, occasionally positive blood cultures as well
- Complications
  - Perirenal abscess, necrotizing papillitis, pyonephrosis (obstruction), & cortical scarring
  - Recurrent infections & subsequent scarring lead to end-stage renal disease in small but significant percentage of pediatric patients
  - Recent study found that 1/2 of all patients with acute pyelonephritis went on to develop scarring
  - Some studies have found risk of scarring to be greater in younger patients
  - Xanthogranulomatous pyelonephritis is unusual, rare form of chronic renal suppuration often associated with renal stone disease

Demographics

- Epidemiology
  - Associated with VUR in ~ 25-40%
  - Higher incidence in obstruction, duplicated kidneys, other anomalies
- Sex: At least 2x as common in girls vs. boys

Natural History & Prognosis

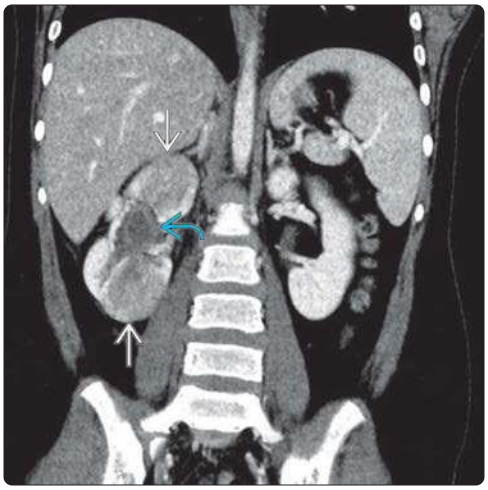
- Generally excellent, unless there are complications or recurrent infections
- Potential sequelae of renal scarring, chronic renal failure, hypertension, & pregnancy-related complications

Treatment

- 7- to 14-day course of antimicrobial therapy; may be started IV & changed to oral
- Imaging work-up for VUR & congenital anomalies
- Prophylactic antibiotics for VUR & other predisposing conditions is controversial

DIAGNOSTIC CHECKLIST

Consider



- May be difficult clinically to distinguish lower UTI (cystitis) from pyelonephritis

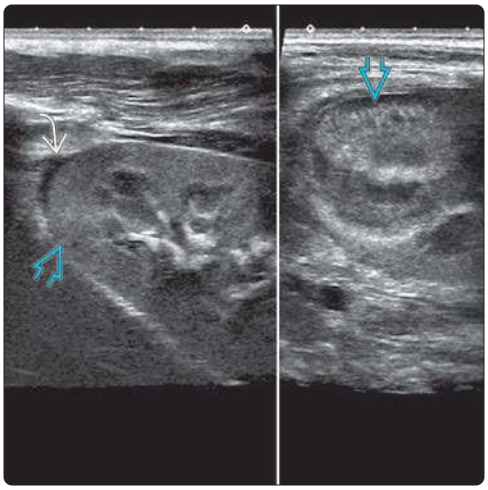


Image Interpretation Pearls

- Partially cystic renal mass could be abscess, particularly if small to moderate in size with surrounding inflammation
  - Pyelonephritis is much more common than tumor
  - Abscess does not always cause positive urine testing
  - In correct clinical setting, consider short-term follow-up after antibiotics
- Conversely, very uncommon RMC is often poorly defined & infiltrative, mimicking pyelonephritis/abscess
  - Check for history of sickle trait (associated with RMC) if clinical history of pyelonephritis is not apparent

(Left) *Coronal CECT in a 9-year-old with pain shows foci of swelling & ↓ contrast enhancement in both the upper & lower poles of the right kidney. Note the urothelial thickening & enhancement of the renal pelvis in this case of pyelonephritis.* **(Right)** *Longitudinal US images of the kidneys with a high-frequency linear transducer show areas of altered cortical echogenicity + a crescent of fluid adjacent to the right renal upper pole in this patient with bilateral pyelonephritis.*

(Left) *Posterior pinhole images from Tc-99m DMSA renal cortical scintigraphy show absent radiotracer in the lower pole of the right kidney, consistent with acute pyelonephritis. Large, wedge-shaped photopenic areas suggest pyelonephritis, while smaller, crescent-shaped cortical defects suggest scarring.* **(Right)** *Longitudinal US images of the left kidney in an 8-week-old girl show altered echotexture in the upper pole with associated ↓ perfusion on a microvascular Doppler image.*

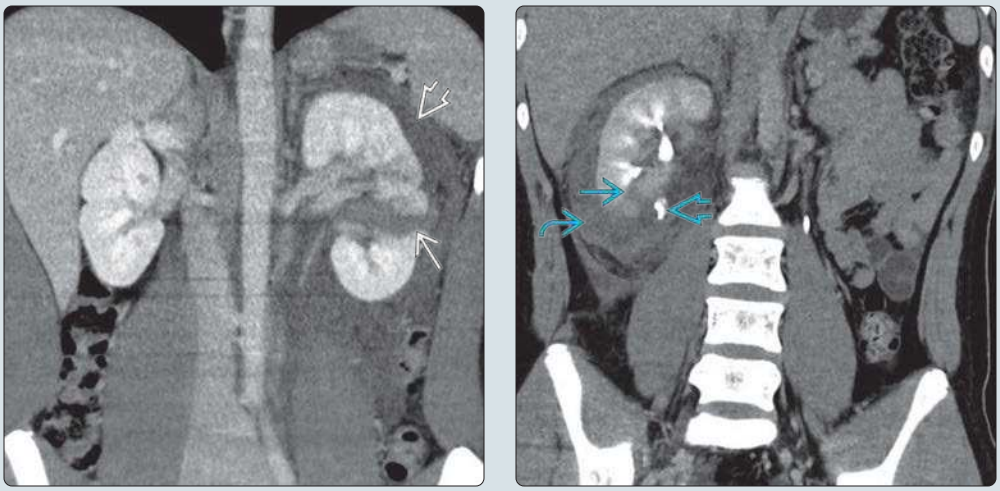
(Left) *Axial CECT in a patient with immune compromise shows multiple fluid-density foci in the right kidney, suggesting developing abscesses. With subsequent ↑ size & confluence, drainage was ultimately required.* **(Right)** *Coronal anterior SPECT images from a Tc-99m DMSA cortical scan in the same patient show multiple defects in the right kidney, consistent with pyelonephritis & developing abscesses seen on the patient's CECT scan. The left kidney was normal.*

Renal Injury

KEY FACTS

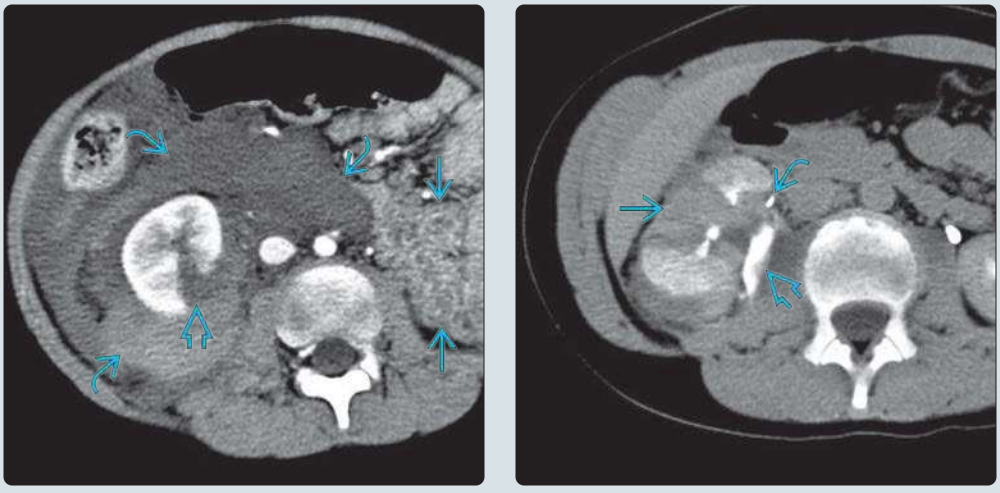
IMAGING

- Protocol
  - CECT in late cortical or early nephrographic phase
  - Obtain delayed images to detect ureteral injury or collecting system injury (if parenchymal laceration or perinephric fluid is present on initial images)
- Imaging findings
  - Renal parenchymal contusion, laceration
  - Subcapsular or perinephric/perirenal hematoma
  - Collecting system/ureteropelvic junction (UPJ) laceration
    - Fluid attenuation of 0-40 HU: Unclotted blood &/or urine
    - Intermediate attenuation of 40-80 HU: Clotted blood &/or urine
    - High attenuation of > 150-200 HU on delayed images only: Urinary contrast leak
  - Complete UPJ avulsion: Unopacified ipsilateral ureter distal to injury on delayed images
  - Active hemorrhage: High attenuation (isodense to vessel) nonanatomic collection on initial images; accumulates on delayed images
  - Vascular thrombosis or avulsion: Delayed or persistent renal enhancement vs. subtotal or global nonenhancement (± preservation of thin, enhancing rim due to capsular arterial supply)



PATHOLOGY

- Etiology: Blunt trauma 90%, penetrating trauma 10%



CLINICAL ISSUES

- Most common presentations: Flank pain, hematuria
- Successful nonoperative management in hemodynamically stable patients: 85%
  - Most common complication: Urinoma
- Possible predictors of intervention: Vascular contrast extravasation, collecting system clot, interpolar urinoma, urinoma > 4.3 cm, perirenal hematoma > 3.5 cm, dissociated renal fragments, > 25% devitalized fragments

(Left) *Coronal CECT in a 17-year-old with an American football injury shows a grade III laceration that extends to the renal pelvis with a subcapsular hematoma. No urinary extravasation was seen on delayed images.* **(Right)** *Delayed coronal CECT from a follow-up study in a 14-year-old after a skiing accident shows a grade IV laceration with urinary contrast extravasation from the lower pole collecting system. The perinephric urinoma had ↑ in size since the initial study. A ureteral stent was required.*

(Left) *Axial CECT in a 5-year-old hemodynamically unstable child after a bike accident shows a renal laceration & a large surrounding hematoma. Note the shock bowel appearance due to hypoperfusion.* **(Right)** *Delayed axial CECT in a 15-year-old boy after a snowmobile accident shows a right renal grade IV laceration that extends to the ureteropelvic junction (UPJ). Extravasation of contrast-opacified urine is noted. The ureter distal to the injury is opacified with contrast, indicating that the UPJ tear is incomplete.*

TERMINOLOGY

Definitions

- Trauma to parenchyma &/or collecting system of kidney

IMAGING

General Features

- Best diagnostic clue
  - Defect of renal parenchymal enhancement + perirenal hematoma on CECT
    - ± extravasation of contrast-opacified urine or blood

CT Findings

- CECT
  - Contusion
    - Region of ↓ parenchymal enhancement with ↑ attenuation on delayed images (persistent nephrogram); may be radiologically occult
  - Hematoma
    - Fluid-attenuation collection; ↑ density of 40-80 HU upon clot formation
    - Subcapsular
      - Peripheral crescentic or lentiform collection
      - Flattening/indentation of underlying parenchyma
    - Perinephric/perirenal
      - Between renal parenchyma & Gerota fascia
      - Thickened, lateral conal fascia
      - May displace (but not indent) kidney; may have mass effect on colon
  - Parenchymal laceration
    - Irregular, linear fluid-attenuation defect; 40-80 HU if clotted blood is present
  - Collecting system/ureteropelvic junction (UPJ) laceration
    - Perinephric collection of fluid attenuation or higher
      - Urine or urine mixed with hematoma
    - Collection attenuation & size ↑ on delayed images
    - Delayed images with UPJ/proximal ureter injury show
      - Opacification of ureter distal to injury: Partial tear
      - Unopacified ureter distal to injury: Complete tear/avulsion
  - Main renal artery thrombosis
    - Partial or complete lack of arterial enhancement
    - Subtotal/global renal nonenhancement: Infarction
      - Cortical rim sign: Rim of enhancing peripheral cortex remains perfused by collateral flow from renal capsular artery; may be absent in first 8 hours
    - Retrograde opacification of renal vein from inferior vena cava
  - Segmental vascular infarct
    - Triangular, nonenhancing, parenchymal focus
    - Injury due to accessory, capsular, or intrarenal segmental arterial branches
  - Pseudoaneurysm
    - ↑ density of round focus (isodense to aorta) directly adjacent to artery
    - Stable size with contrast washout on delayed images
  - Active hemorrhage
    - Irregular ↑ density collection (isodense to adjacent vessel) on initial images; ↑ in size on delayed images
  - Main renal vein thrombosis
    - Enlarged vein with filling defect of thrombus
    - Nephromegaly with delayed nephrogram & excretion
    - Less common than main renal artery thrombosis

Ultrasonographic Findings

- Grayscale ultrasound
  - Hematoma
    - Parenchymal, subcapsular, or perinephric collection
    - Echogenicity varies with age of blood products
    - Can be difficult to differentiate from urinoma
  - Laceration
    - Hypoechoic linear/branching defect interrupting renal architecture; hyperechoic if contains clot
- Color Doppler
  - Thrombosis: Various aberrant waveforms are possible depending on extent & location of thrombus
    - Tardus-parvus waveform distal to proximal nonocclusive arterial thrombus/stenosis
    - Reversal of diastolic flow with thrombosis of renal vein or distal artery
    - Absence of flow in occluded vessel
  - Parenchymal ischemia/infarct: Focally or globally ↓ or absent color Doppler signal
- CEUS
  - Improved detection of segmental & subcapsular infarcts
  - Improved confidence for diagnosing renal artery & vein occlusion as well as differentiating complete vs. partial occlusion
  - Allows visualization of hyperechoic active extravasation
  - Lack of microbubble urinary excretion limits evaluation
- Sensitivity & specificity vary widely across multiple studies
  - FAST US: Sensitivity 23-100%, specificity 98-100%
  - Abdominal US: Sensitivity 36-90%, specificity 98-100%
  - CEUS: Sensitivity 69%, specificity 99%

Imaging Recommendations

- American Urological Association (AUA) recommends
  - CECT for initial evaluation
    - Portal venous phase (late cortical or early nephrographic phase)
    - Delayed (5-15 minutes) images to evaluate for urinary contrast leak in stable patient with suspicion for ureteral injury or renal laceration &/or perinephric fluid on initial images
  - Follow-up CECT in 48 hours for
    - Grade IV or V injuries (due to ↑ complication rates)
    - Injury grade < IV with clinical signs of complication
- American Association for the Surgery of Trauma (AAST)
  - Recommends CECT but notes US may be used for
    - Initial evaluation & follow-up if hemodynamically stable
    - In those with mild symptoms, minimal clinical findings, hematuria < 50 RBC/HPF & no other CT indications

DIFFERENTIAL DIAGNOSIS

Normal Variant Contour

- Dromedary hump, column of Bertin, fetal lobation

Pyelonephritis

- Enlarged kidney with delayed or striated nephrogram in patient with flank pain, fever, abnormal urinalysis

- Abscess can mimic multicystic mass with irregular rim/septal enhancement

Renal Neoplasm

- Most pediatric renal tumors
  - Present with distention, palpable mass, &/or hematuria
  - Have overlapping imaging features
    - Differential is best determined by patient age & history
  - Can rupture or hemorrhage (causing pain)
- Angiomyolipoma (AML) is unique
  - Fat-containing renal masses typically associated with tuberous sclerosis in children
  - AML > 4 cm or aneurysm > 5 cm is prone to spontaneous hemorrhage (uncommon in children)

PATHOLOGY

General Features

- Etiology
  - Blunt trauma in 90%, penetrating trauma in 10%
  - Common causes: Falls, sports related, motor vehicle related, bicycle accidents, assault, child abuse
  - Rapid deceleration: ↑ risk of vascular pedicle & UPJ injury
  - Children are at ↑ risk compared to adults due to ↑ organ mobility & relative size, ↓ perirenal fat, low renal position, elastic rib cage with ↓ renal coverage, & fetal lobations (which may act as cleavage plane)
  - Preexisting renal abnormalities predispose to injury
- Associated abnormalities
  - Other organ injuries: Liver: 22%, lungs: 19%, spleen: 16%

Staging, Grading, & Classification

- AAST
  - Grade I: Subcapsular hematoma &/or parenchymal contusion without laceration
  - Grade II: Perirenal hematoma confined to Gerota fascia; laceration ≤ 1 cm depth without urine extravasation
  - Grade III: Laceration > 1 cm depth without collecting system rupture/urine extravasation; vascular injury (pseudoaneurysm or arteriovenous fistula) or active bleeding contained in Gerota fascia
  - Grade IV: Laceration extending into collecting system with urine extravasation; renal pelvis laceration or ureteropelvic disruption; segmental renal vein/artery injury; segmental or complete kidney infarction due to thrombosis without active bleeding; active bleeding beyond Gerota fascia
  - Grade V: Main renal artery/vein laceration or hilar avulsion; devascularized kidney with active bleeding; shattered kidney (loss of identifiable renal anatomy)
  - Advance 1 grade for bilateral injuries up to grade III

CLINICAL ISSUES

Presentation

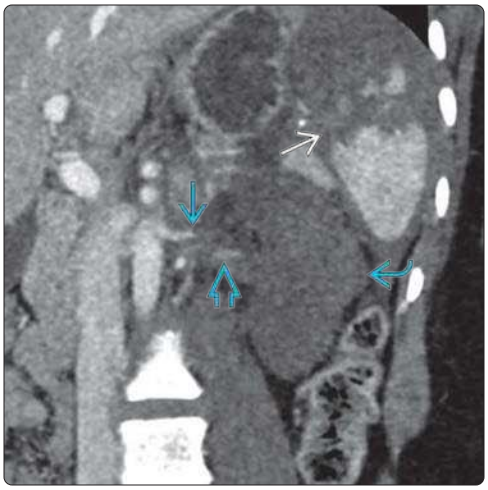
- Most common signs/symptoms
  - Flank pain/tenderness, hematuria, ecchymosis
    - Hematuria may be absent, even in high-grade injury

Natural History & Prognosis

- Majority are low-grade injuries (I-III): 79%
- Of all renal injuries, 85% are managed conservatively
- 50% of grade V & 44% of penetrating injuries are managed operatively
- Findings associated with nonoperative management failure
  - Vascular contrast extravasation, medial urinary extravasation/urinoma, collecting system clot, interpolar contrast urinoma, urinoma > 4.3 cm, dissociated renal fragments, > 25% devitalized fragments, perirenal hematoma > 3.5 cm, lack of ureteral opacification
- Early complications (< 4 weeks)
  - Urinoma: Most common; most reabsorb
  - Delayed bleeding: Due to arteriovenous fistula/pseudoaneurysm, usually 2-3 weeks after injury
  - Perinephric abscess, sepsis, infected urinoma
- Late complications (> 4 weeks)
  - Hypertension due to Page kidney
  - Hydronephrosis, calculi, chronic pyelonephritis

Treatment

- Nonoperative management is generally recommended in hemodynamically stable patients with grade I-V injuries
  - UPJ or proximal ureteral avulsion warrants prompt intervention, endoscopic or operative
- Ureteral stent ± percutaneous urinoma drain &/or percutaneous nephrostomy for complications of ↑ urinoma, ↑ pain, ileus, fistula, or infection
- Renal artery thrombosis: Thrombolysis, stent
- Angioembolization in hemodynamically stable patients to control ongoing/delayed bleeding (if readily available)
- Surgery in hemodynamically unstable patients or those failing nonoperative management



DIAGNOSTIC CHECKLIST

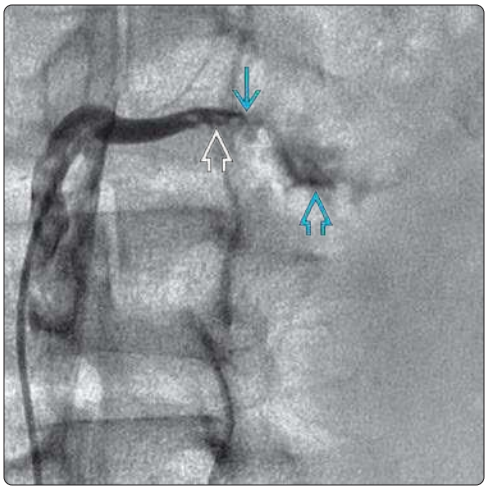


Image Interpretation Pearls

- View CECT in multiple planes (as transverse lacerations may be occult on axial images)

(Left) *Coronal oblique CECT in a 13-year-old girl with a grade V renal injury shows truncation of the left renal arterial opacification with adjacent contrast extravasation. The left kidney is devascularized. A grade IV splenic injury is also noted.* **(Right)** *Frontal view from a catheter angiogram of the same left renal artery shows complete left renal artery avulsion with proximal vessel thrombosis & distal contrast extravasation. A revascularization attempt failed.*

(Left) *Axial CECT in a 14-year-old that fell off of a horse demonstrates a grade III injury. There is a laceration that extends to the renal hilum with an associated subcapsular hematoma. The focal rounded area of contrast is compatible with a traumatic pseudoaneurysm.* **(Right)** *Coronal CECT in a 14-year-old after a motor vehicle accident (MVA) shows a laceration < 1 cm with associated small subcapsular hematoma, compatible with a grade II injury.*

(Left) *Posterior view from a 2-month follow-up Tc-99m DMSA scan in a 15-year-old with a right grade V renal injury from a sledding accident shows that the right kidney has normal uptake in the upper pole but none in the lower pole. The split renal function was 60% left & 40% right.* **(Right)** *Coronal CECT in a 13-year-old after a skiing accident shows a grade IV injury with a left kidney lower pole segmental infarction. Also seen are lacerations, active bleeding, & a perinephric hematoma.*

Renal Stones

KEY FACTS

TERMINOLOGY

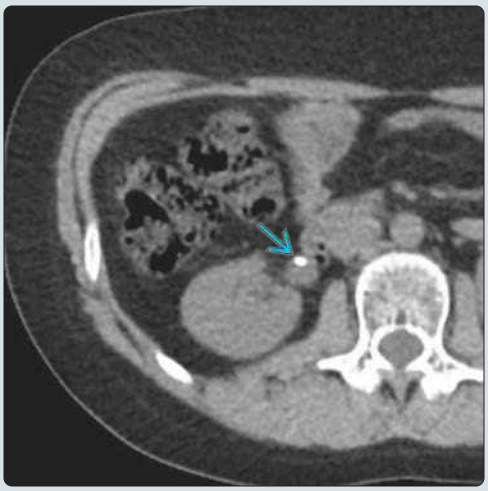
- Concretion in urinary system

IMAGING

- Most stones are seen in kidneys & upper urinary tract
- Range in size from 1-2 mm to > 1 cm
- NECT is most sensitive modality to detect stones
  - Calcified density in urinary system
- Ultrasound shows hyperechoic urinary tract focus with posterior acoustic shadowing &/or twinkling artifact
- Important to report signs of obstruction
  - Hydroureteronephrosis
  - Nephromegaly
  - Perinephric/periureteral edema
  - Lack of ureteral jet in urinary bladder on Doppler ultrasound
  - High-resistance renal artery flow on Doppler ultrasound
  - Delayed renal enhancement & excretion after IV contrast administration

TOP DIFFERENTIAL DIAGNOSES

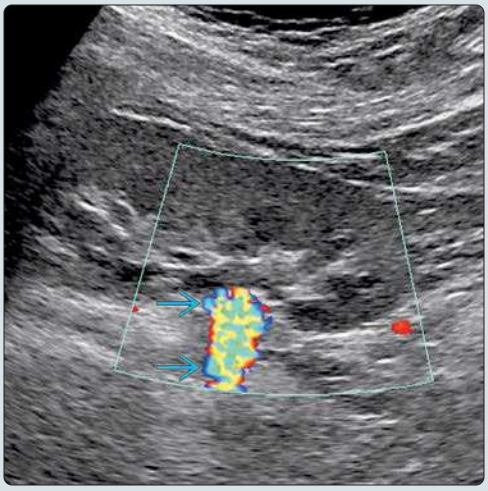
- Fecal material
- Phleboliths
- Nephrocalcinosis
- Ureteropelvic junction obstruction



PATHOLOGY

- 75-85% of children have identifiable metabolic predisposition

CLINICAL ISSUES



- Presentations
  - 94% of adolescents have colicky flank pain
  - Nonspecific symptoms (abdominal pain, nausea, vomiting, & irritability) in younger children
  - Microscopic hematuria in up to 90% of patients
- Treatment depends on stone size, location, presence of obstruction, & underlying etiology

(Left) *Axial NECT shows a calcified urinary stone in the right ureter near the ureteropelvic junction. While the proximal ureter is dilated, there is no hydronephrosis or perinephric stranding.* **(Right)** *Sagittal NECT in the same patient shows the urinary stone in the proximal ureter. The renal collecting system is not dilated, & there is no perinephric or periureteral stranding to suggest obstruction.*

(Left) *Longitudinal color Doppler ultrasound of the right kidney in the same patient shows considerable twinkling artifact in & deep to the stone. Note the lack of renal collecting system dilation.* **(Right)** *Retrograde ureterogram in the same patient shows a filling defect from a urinary stone at the ureteropelvic junction. The mild dilation of the collecting system is secondary to the injection pressure.*

TERMINOLOGY

Synonyms

- Nephrolithiasis, nephrolith, urolithiasis, urolith, urinary stone, kidney stone, renal calculi

Definitions

- Concretion in urinary system

IMAGING

General Features

- Best diagnostic clue
  - Calcific density in renal collecting system, ureters, or urinary bladder
- Location
  - Usually seen at renal collecting system, ureteropelvic junction (UPJ), or ureterovesical junction (UVJ)
    - Most stones are seen in kidneys & upper urinary tract
- Size
  - Range in size from 1-2 mm to > 1 cm

Radiographic Findings

- Radiography
  - Irregular, calcified density over region of kidneys, ureters, or bladder
  - If stone is seen on radiograph, can be used to follow disease
- IVP
  - Uncommonly used modality to identify obstructive calculi in known stone formers
  - Often modified for children to ↓ radiation dose
  - Signs of urinary obstruction
    - Enlarged kidney
    - Hydronephrosis
    - Hydroureter up to stone
    - Filling defect at level of calculus
    - Delayed & prolonged nephrogram with delayed collecting system excretion

Ultrasonographic Findings

- Grayscale ultrasound
  - Considered as 1st-line imaging study due to lack of radiation; however, overall sensitivity & negative predictive value are low (66% & 79%, respectively)
  - Hyperechoic focus with posterior acoustic shadowing
    - Shadow artifact may not be present on machines with harmonic or spatial compounding
    - Shadow artifact is considered as specific finding
  - Stones are usually visible in renal collecting system (at UPJ, UVJ, or bladder)
    - Midureteral stones are difficult to find due to bowel gas
  - Ultrasound can be used to identify obstruction of urinary system
    - Grayscale signs of obstruction
      - Hydronephrosis
      - Hydroureter to level of urinary stone
      - Enlarged kidney
      - Perinephric fluid
- Color Doppler
  - Twinkling artifact: Rapidly changing random mixture of color in/posterior to stone
    - Thought to be due to rough but strongly reflective surface of stone
    - Twinkle artifact has high specificity but low sensitivity for detecting stones
  - Signs of obstruction
    - High-resistance renal artery flow
    - Lack of ureteral jet in urinary bladder

CT Findings

- NECT
  - Most sensitive modality to detect urinary stones
  - Stone appears as calcified density in renal collecting system, ureters, or bladder
  - Stones can obstruct urinary system
    - Most stones are not obstructive
    - Signs of obstruction
      - Hydronephrosis
      - Hydroureter
      - Enlarged kidney
      - Perinephric or periureteral stranding
      - Loss of slightly hyperattenuating pyramids
- CECT
  - Not primarily used for detection of urinary tract calculus
  - Findings are similar to IVP

Imaging Recommendations

- Best imaging tool
  - Ultrasound as 1st test; NECT if ultrasound is negative & suspicion for stones remains high
  - NECT is most sensitive modality to detect stones
    - Many perform CT in prone position to better distinguish UVJ vs. bladder stone
    - Beware of multiple CTs due to radiation dose
  - In known stone formers, presence or absence of obstruction may be only imaging question
    - Ultrasound detects urinary obstruction without radiation

DIFFERENTIAL DIAGNOSIS

Fecal Material

- Colonic contents may overlie kidneys, ureters, or bladder on radiographs & mimic nephrolithiasis

Phleboliths

- Round Ca^{2+} with lucent center in abnormal stagnant vein
- Most common in pelvis, near bladder

Nephrocalcinosis

- Ca^{2+} within renal parenchyma
- ± cortical, medullary, or diffuse

Ureteropelvic Junction Obstruction

- Chronically dilated renal collecting system due to intrinsic or extrinsic process; no visible stone

Transient Neonatal Renal Medullary Hyperechogenicity

- Evenly distributed echogenic renal pyramid tips
- Incidental, benign finding lasting up to 3 weeks
- Not clearly due to Tamm-Horsfall proteinuria

PATHOLOGY

General Features

- Etiology
  - 75-85% of children with stones have identifiable predisposition
    - Metabolic cause of stones in 75-90% of patients
    - Infection in 4% of patients
- Metabolic causes of pediatric stone disease
  - Calcium stones
    - Hypercalciuria: Most common metabolic abnormality causing pediatric stones
      - Accounts for 34-50% of children with identifiable metabolic cause of stones
    - Hyperuricosuria: Can be caused by excess purine production or ingestion, renal tubular disorders, medications, or juvenile gout
      - Present in 2-20% of children with stones
    - Hypocitruria: Can be caused by renal tubular acidosis
      - 10% of children with stones
    - Hyperoxaluria: Can be caused by primary hyperoxaluria or ↑ intestinal absorption due to bowel disease
      - Found in 10-20% of children with stones
  - Uric acid stones: Seen with excessively acidic urine, such as in diarrheal states or diet high in animal protein
    - Radiolucent stones
  - Struvite stones: Caused by infection with urease-splitting bacteria
    - Often appear as staghorn calculi
- Hereditary causes of pediatric stone disease
  - Adenine phosphoribosyltransferase deficiency
    - Autosomal recessive inborn error of adenine metabolism
    - Most common manifestation: Radiolucent stones
    - Pathognomonic round/brown DHA crystals in urine
  - Cystinuria
    - Most common cause of inherited kidney stones
    - Accounts for up to 25% of pediatric stones
    - Defect in proximal tubular resorption of filtered cystine
    - Average age of 1st stone: 12-13 years
    - Pathognomonic hexagonal crystals in urine

CLINICAL ISSUES

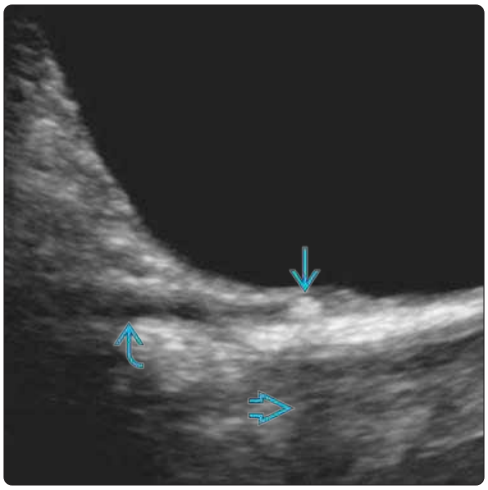
Presentation

- Most common signs/symptoms
  - Depends on age
    - 94% of adolescents present with colicky flank pain
    - Nonspecific symptoms (abdominal pain, nausea, vomiting, & irritability) in younger children
  - Microscopic hematuria in up to 90% of patients
- Other signs/symptoms
  - Gross hematuria in 14-32%
  - Concomitant urinary tract infection in 8-20%

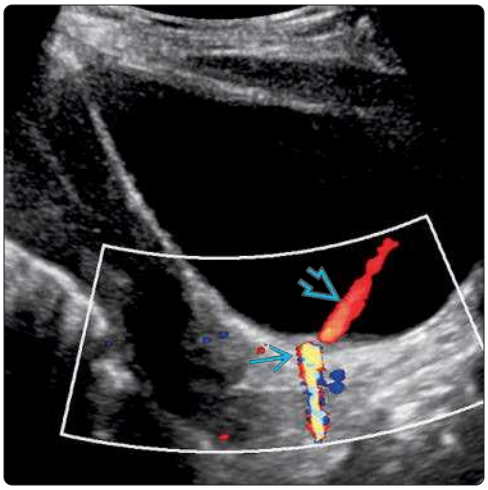
Demographics

- Age
  - Can occur at any age
  - Median age of nephrolithiasis onset: 4.4 years for boys, 7.3 years for girls
- Ethnicity
  - More common in White patients
- Epidemiology
  - Incidence of stones in kids is increasing 6-10% annually
    - 18 per 100,000 patients in 1999; 50 per 100,000 in 2018
    - Overall incidence ↑ 5x over last 2 decades
  - Potential causes for ↑ prevalence
    - ↑ obesity & related poor dietary habits
    - ↓ water intake coupled with ↑ sodium & protein intake
    - ↓ dietary calcium (from milk)
    - ↑ use of CT (improved detection)
    - Global warming: ↑ incidence with ↑ temperatures

Natural History & Prognosis



- Higher morbidity of stone disease in children
  - Longer hospital stay
- Stones < 5 mm may pass spontaneously
- Residual stones can act as nidus for more stones



Treatment

- Treatment depends on underlying etiology
- ↑ fluid intake
  - Poor long-term compliance
- Expectant management
  - Up to 60% of stones < 5 mm pass spontaneously
- Medical treatment depends on underlying cause
  - Hypercalciuria: ↑ fluid intake, ↓ dietary sodium, & ↓ dietary calcium to recommended levels
    - Thiazide diuretics can ↓ urinary calcium
  - Hyperoxaluria: Potassium citrate & calcium supplements may ↓ intestinal oxalate absorption
  - Hyperuricosuria: Urinary alkalinization
- Surgical management is required in 22%
  - Extracorporeal shock wave lithotripsy (ESWL)
    - Used for treatment of proximal ureteral calculi & mid or upper pole stones < 2 cm
  - Ureteroscopy: Currently most commonly used option for children
    - Improved stone-free rates (88-100%) compared to ESWL for ureteral stones
    - Similar stone-free rates compared to ESWL for intrarenal stones (58-62%)
  - Percutaneous nephrolithotomy
    - Reserved for larger stone burden/treatment failure

(Left) *Longitudinal ultrasound of the bladder in an adolescent shows an echogenic stone ⇨ at the ureterovesical junction. The stone causes mild posterior acoustic shadowing ⇨, & the distal ureter is mildly dilated ⇨.* **(Right)** *Longitudinal color Doppler ultrasound in the same patient shows twinkling artifact ⇨ from the stone at the ureterovesical junction. The presence of a ureteral jet ⇨ in the urinary bladder confirms that the stone does not cause complete obstruction.*

(Left) *AP radiograph of the abdomen in a child with cerebral palsy shows numerous calcified stones ⇨ within the bilateral renal collecting systems.* **(Right)** *Axial CECT in bone windows in the same patient shows numerous calcified stones ⇨ layering dependently within the urinary bladder.*

(Left) *Coronal CECT in the same patient shows numerous stones ⇨ within the nondilated right & left renal collecting systems. Note that IV contrast was administered on this exam for other reasons, not the investigation of urinary tract calculi.* **(Right)** *Coronal T2 MR in the same patient shows multiple hypointense stones ⇨ in the nondilated right & left renal collecting systems.*

Transient Neonatal Renal Medullary Hyperechogenicity

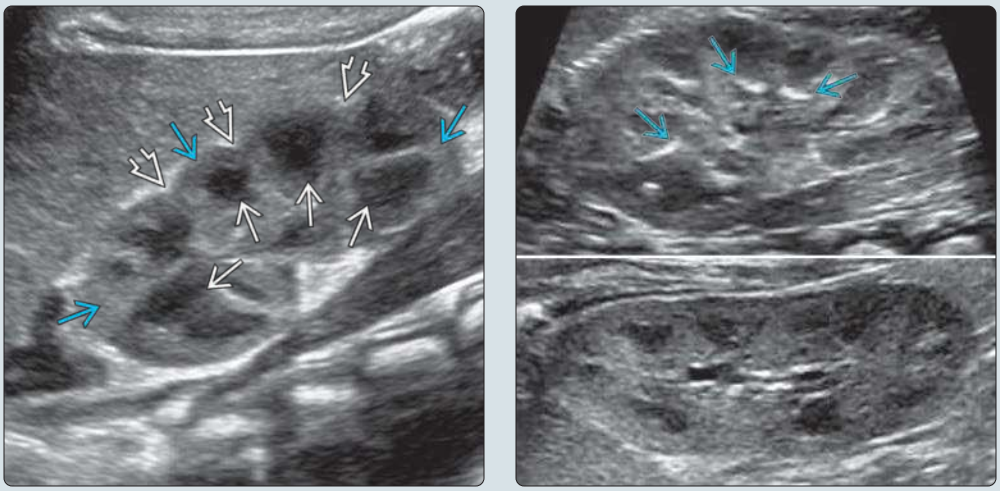
KEY FACTS

TERMINOLOGY

- Temporary sonographic appearance of hyperechoic renal medullary pyramids in some normal neonates
  - Neonatal renal pyramids are usually hypoechoic to renal cortex on US
- Etiology unclear: Not linked to ↑ concentration of normal Tamm-Horsfall glycoproteins in neonatal urine
  - Though appearance previously has been termed "Tamm-Horsfall proteinuria"
  - Therefore, recent literature uses descriptive term "transient renal medullary hyperechogenicity"

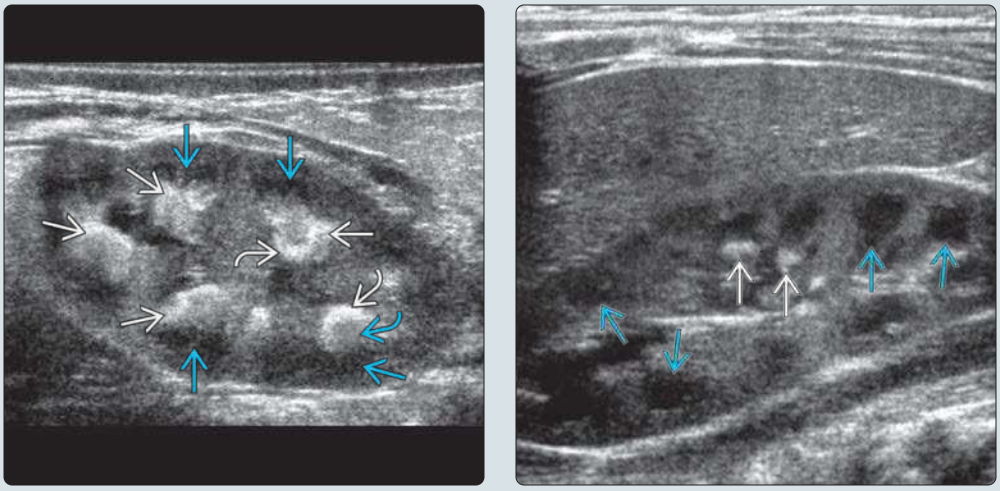
IMAGING

- Renal US shows ↑ echogenicity of medullary pyramids in neonate with normal renal function
  - Usually involves tips & central portions of pyramids
  - Bases of pyramids typically remain hypoechoic
  - Diffuse involvement of entire medullary pyramid is uncommon
  - May appear as layering gradient of ↑ echogenicity, brightest at tips of pyramids
  - Posterior acoustic shadowing is typically absent
  - Bilateral > unilateral renal involvement
  - Segmental involvement (sparing of some medullary pyramids) > diffuse (involvement of all pyramids)
  - Normal renal cortical echogenicity & size
- ↑ echogenicity of renal medullary pyramids usually resolves spontaneously by 10 days



CLINICAL ISSUES

- If renal insufficiency/failure is present, consider pathologic causes for ↑ echogenicity



DIAGNOSTIC CHECKLIST

- Normal finding up to 10th day of life; repeat US is not indicated
- If hyperechoic medullary pyramids are seen beyond 10-14 days or in setting of renal dysfunction, then another diagnosis should be considered

(Left) *Longitudinal US shows a normal right kidney in a 1-day-old girl. In the neonatal period, the medullary pyramids are normally hypoechoic compared to the renal cortex. Also note the normal fetal lobations.* **(Right)** *Longitudinal US of the left kidney in a neonate on the 1st day of life (top) shows ↑ echogenicity at the tips of multiple renal pyramids. The medullary ↑ echogenicity has resolved on the repeat US 1 month later (bottom).*

(Left) *Longitudinal US in a newborn shows ↑ echogenicity in all renal pyramids. Note the extensive involvement of individual pyramids with a gradient of echogenicity that is most pronounced at the tips & less so in the central portions. Only the bases of the pyramids have a normal hypoechoic appearance.* **(Right)** *Longitudinal US in a newborn shows discrete foci of ↑ echogenicity at the tips of 2 medullary pyramids, while other pyramids have a normal hypoechoic appearance.*

TERMINOLOGY

Synonyms

- Transient renal medullary hyperechogenicity
  - Descriptive term used in recent literature because etiology is unknown
- Tamm-Horsfall proteinuria (THP)
  - Older term devised because of theory that THP precipitates in renal tubules → transient ↑ echogenicity
  - Theory has not been substantiated

Definitions

- Temporary sonographic appearance of hyperechoic renal medullary pyramids in some normal neonates
- Etiology is unclear (not linked to THP)

IMAGING

General Features

- Best diagnostic clue
  - ↑ echogenicity of medullary pyramids in neonate with normal renal function
    - Neonatal renal medullary pyramids are usually hypoechoic relative to cortex
- Location
  - Bilateral > unilateral
  - Segmental involvement (sparing of some medullary pyramids) > diffuse (involvement of all pyramids)
- Morphology
  - Usually involves tips & central portions of pyramids
  - Typically spares bases of pyramids

Ultrasonographic Findings

- ↑ echogenicity of medullary pyramids
  - Usually involves tips & central portions of pyramids
  - Bases of pyramids typically remain hypoechoic
  - Diffuse involvement of entire medullary pyramid is uncommon
  - Discrete, hyperechoic foci may be seen with denser precipitates
  - May demonstrate layering gradient of ↑ echogenicity, brightest at tip of pyramid
  - Posterior acoustic shadowing is usually absent
- Normal renal cortical echogenicity & size
- ↑ echogenicity of pyramids usually resolves by 10 days
  - Rarely persists several days longer

Imaging Recommendations

- Best imaging tool: US
  - Commonly found incidentally on US performed for other reasons
  - Generally considered normal up to 10 days of life; repeat US is not indicated
  - Another diagnosis should be considered if
    - Hyperechoic pyramids are seen beyond 10-14 days
    - Renal dysfunction is present

DIFFERENTIAL DIAGNOSIS

Medullary Nephrocalcinosis

- Loop diuretics (e.g., furosemide)
- Distal renal tubular acidosis
- Williams syndrome: Supravalvular aortic stenosis & hypercalcemia
- Bartter syndrome: Ion transport channel mutation → ↓ Ca^{2+} resorption & hypercalciuria
- Neonatal primary hyperparathyroidism

Hypernatremic Dehydration

- Seen in some solely breastfed neonates due to poor milk production or inadequate intake
- More common in 2nd week of life

Perinatal Ischemia

- More common in premature infants

Neonatal Renal Vein Thrombus

- Pyramids can be echogenic in acute phase, ± linear echogenic striations of kidney
- Associated renal enlargement & Doppler abnormalities

PATHOLOGY

General Features

- Etiology
  - Classic theory: Reversible precipitation of THP in renal tubules → transient ↑ echogenicity of medullary pyramids seen by US in some neonates
  - Not proven: Some suggest urate crystal deposition may account for transient ↑ echogenicity
  - Resolution by ~ 10th day of life may be due to physiologic ↑ in glomerular filtration

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic
  - Renal insufficiency/failure warrants search for alternative cause of ↑ medullary echogenicity

Demographics

- Age
  - Early neonatal period
  - Full-term infants > premature infants
- Epidemiology
  - Incidence in neonates without renal impairment: 3.9–37%

Natural History & Prognosis

- Should resolve by 10th day of life
  - Rarely seen several days beyond this

Treatment

- None

Renal Vein Thrombosis

KEY FACTS

TERMINOLOGY

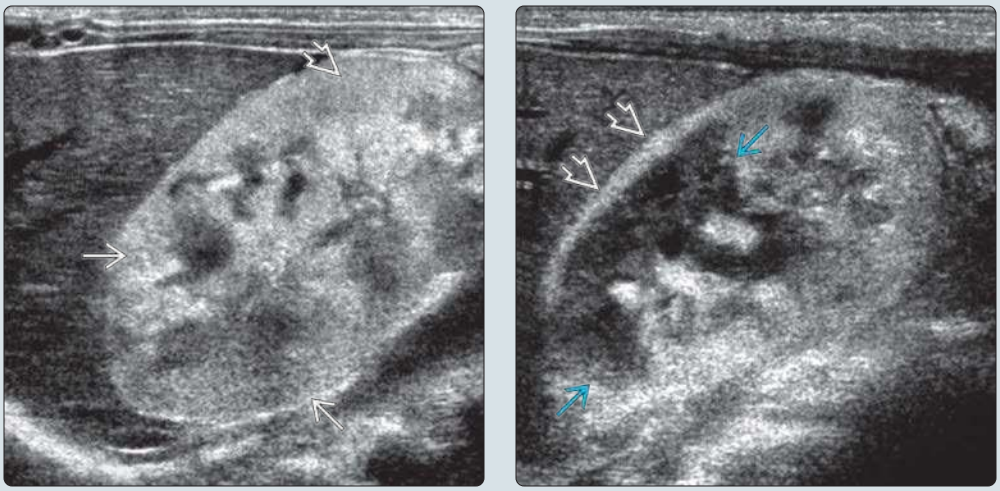
- Obstruction of renal vein(s) by thrombus

IMAGING

- Ultrasound with Doppler
  - Enlarged, echogenic kidney with ↓ corticomedullary differentiation
  - ± visualization of main renal vein thrombus
  - High-resistance renal arterial waveforms (RI > 0.9)
    - May see complete diastolic flow reversal
- CECT/MR
  - Heterogeneous or delayed renal enhancement
  - ± filling defect in renal vein, ± inferior vena cava extension
- Chronic appearance: Renal atrophy ± Ca^{2+}
- Associated adrenal hemorrhage may be present

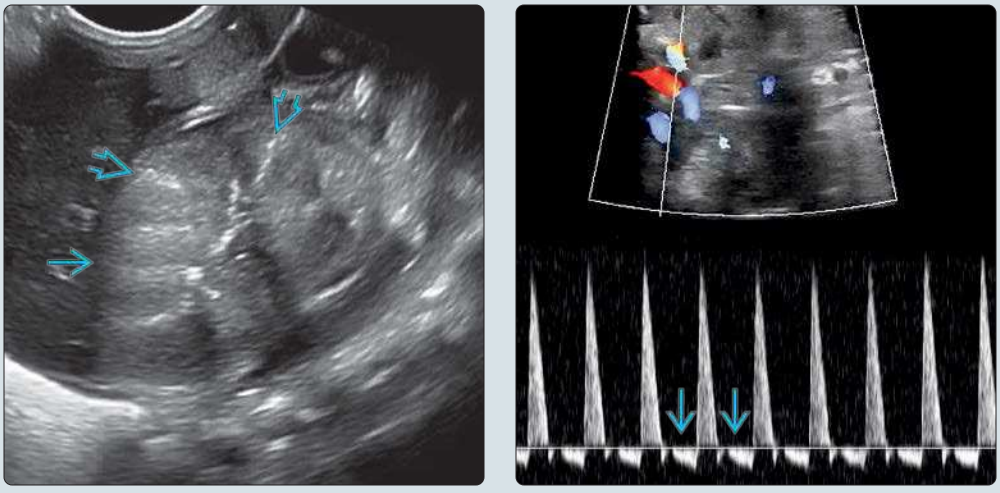
TOP DIFFERENTIAL DIAGNOSES

- Acute tubular necrosis
- Pyelonephritis
- Transient neonatal renal medullary hyperechogenicity
- Tumor thrombus



PATHOLOGY

- In neonates, thrombosis begins in small intrarenal veins → proximal extension to main renal vein
  - ↑ renal venous pressure & ↓ arterial flow
- Etiologies: Dehydration, sepsis/infection, iatrogenic



CLINICAL ISSUES

- Most commonly diagnosed in neonatal period
  - Renal dysfunction, hematuria, hypertension (HTN)
  - Classic triad: Palpable flank mass, hematuria, & thrombocytopenia in 13-22%
- Irreversible damage occurs in 70%
  - Up to 20% will have persistent HTN
- Treatment: Supportive, ± anticoagulation, rarely thrombolysis

(Left) *Longitudinal oblique US in a newborn shows an enlarged, hyperechoic right kidney with poorly defined, hypoechoic medullary pyramids in the upper pole. Corticomedullary differentiation is lost in the lower pole.* **(Right)** *Longitudinal US obtained 2 days later in the same patient shows progressive ischemia in the upper pole with a new, large, hypoechoic focus involving the medulla & cortex. A thin rim of echogenic peripheral cortex remains in this neonate with renal vein thrombosis.*

(Left) *Longitudinal US in a newborn with oliguria shows diffusely ↑ echogenicity of the right kidney with diminished corticomedullary differentiation due to renal vein thrombosis. Scattered echogenic striations are noted.* **(Right)** *Pulsed Doppler US in the same newborn with renal vein thrombosis shows a high-resistance renal arterial waveform with complete reversal of diastolic flow.*

TERMINOLOGY

Definitions

- Obstruction of renal vein(s) by thrombus

IMAGING

General Features

- Best diagnostic clue
  - Enlarged, echogenic kidney with ↓ corticomedullary differentiation
    - Cannot rely on visualization of main renal vein thrombus for diagnosis in neonates
- Location
  - Unilateral (L > R) is more common than bilateral
- Size
  - Enlarged kidney in acute stage
  - Normal size or atrophy in later stages

Ultrasonographic Findings

- Grayscale ultrasound
  - Acute phase
    - Echogenic parenchyma, predominantly cortex
      - May see echogenic striations
    - ↓ corticomedullary differentiation
    - Enlarged kidney(s)
  - Chronic phase
    - Parenchymal Ca^{2+}; renal size may be normal or atrophied
  - Other findings
    - Visualization of thrombus in main renal vein
      - May or may not be identified in neonates
    - Medullary pyramids can be hypo- or hyperechoic
      - Profoundly hypoechoic pyramids → poorer outcome
    - Associated adrenal hemorrhage may be present
- Color Doppler
  - High-resistance renal arterial waveforms (RI > 0.9) or complete reversal of diastolic flow

CT Findings

- CECT
  - Generally not indicated in neonates
  - Enlarged kidney ± perinephric stranding
  - Delayed or heterogeneous nephrogram
  - Low-attenuation thrombus within main renal vein (± inferior vena cava extension); ± collateral vessels if chronic

MR Findings

- T1WI C+
  - Delayed enhancement (most prominent in medullary pyramids)
- MRV
  - Filling defect in main renal vein (also seen on T1/T2)

Imaging Recommendations

- Best imaging tool
  - Renal US with Doppler

DIFFERENTIAL DIAGNOSIS

Acute Tubular Necrosis

- Both kidneys are typically affected; causes include shock, ischemia, infection, hemolytic-uremic syndrome

Pyelonephritis

- Patchy ↓ in perfusion & corticomedullary differentiation

Transient Neonatal Renal Medullary Hyperechogenicity

- Echogenic central renal medullary pyramids
- Normal renal size, cortical echogenicity, & vascularity

Autosomal Recessive Polycystic Kidney Disease

- Markedly enlarged & echogenic kidneys with extensive, fine striations from dilated tubules

Tumor Thrombus

- Clot continuous with renal mass (most commonly Wilms)

PATHOLOGY

General Features

- Etiology
  - In neonates, thrombosis begins in small intrarenal veins → proximal extension to main renal vein
    - ↑ renal venous pressure & ↓ arterial flow
  - Large number of potential causes dehydration, sepsis/infection, iatrogenic

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Renal dysfunction, oliguria, hypertension (HTN)
  - Classic clinical triad of palpable flank mass, hematuria, & thrombocytopenia; complete triad is seen in only 13-22%
  - ± signs of renal dysfunction

Demographics

- Age: Most commonly diagnosed in neonatal period

Natural History & Prognosis

- Irreversible damage occurs in 70%; up to 20% will have persistent HTN

Treatment

- Unilateral: Supportive care ± anticoagulation
- Bilateral &/or inferior vena cava extension: May require thrombolysis

Renal Artery Stenosis

KEY FACTS

TERMINOLOGY

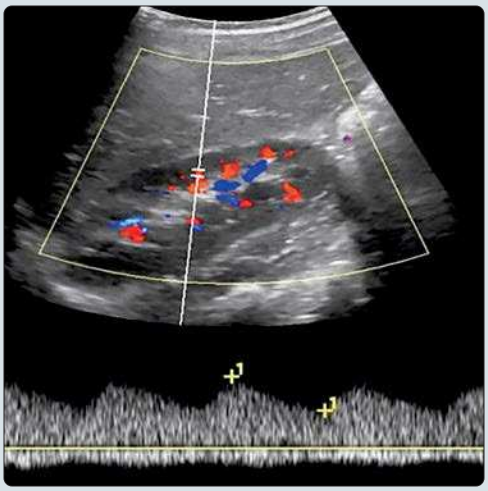
- Renovascular or renin-mediated hypertension (HTN)
  - Arterial stenosis → ↓ renal parenchymal blood flow → activation of renin-angiotensin system → HTN

IMAGING

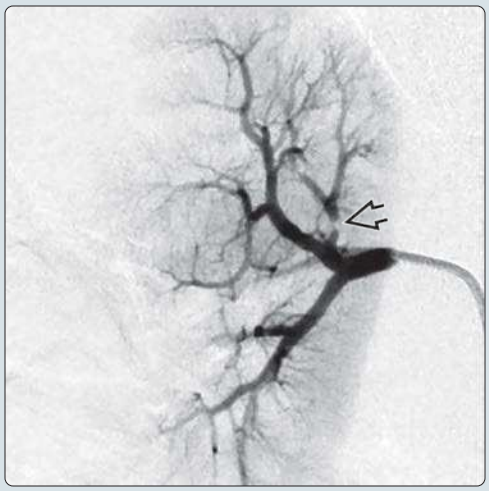
- Arterial stenoses may be extrarenal (aorta, main renal artery), intrarenal, or both
  - Intrarenal are more common in children
- Pulsed/spectral Doppler shows abnormal renal arterial waveforms
  - Distal to stenosis: Parvus et tardus, prolonged acceleration index, low resistive index (< 0.5)
  - At stenosis: ↑ peak systolic velocity
  - Evaluate aorta if waveforms are abnormal bilaterally
- CT & MR angiography
  - Focal arterial narrowing ± poststenotic dilation or aneurysm formation
  - Useful to evaluate aorta & main renal arteries; ↓ sensitivity for intrarenal abnormalities
- Digital subtraction angiography (DSA)
  - Most sensitive & specific imaging modality

TOP DIFFERENTIAL DIAGNOSES

- Reflux nephropathy
- Essential HTN
- Pheochromocytoma

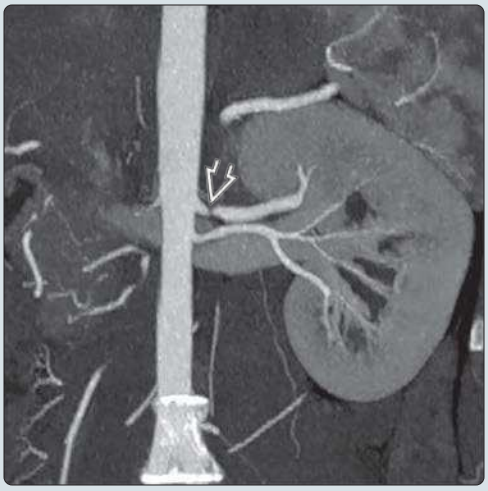


PATHOLOGY



- Common cause: Idiopathic developmental arteriopathy
  - Similar to but distinct from fibromuscular dysplasia
- Associations include neurofibromatosis type 1, Williams syndrome, tuberous sclerosis, & Marfan syndrome
- Other causes: Vasculitis, extrinsic compression, iatrogenic

CLINICAL ISSUES



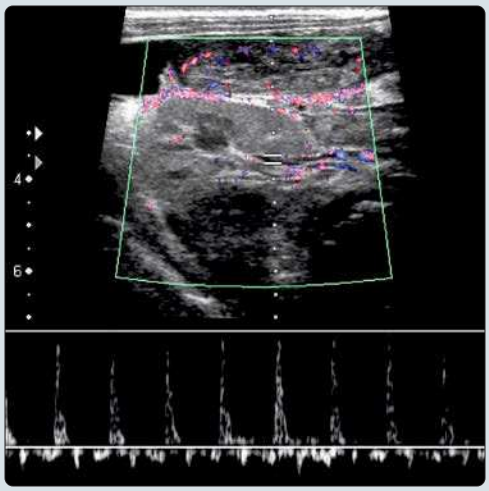
- Severe HTN refractory to multiple medications
- Endovascular or surgical treatment

(Left) *Pulsed Doppler ultrasound of the right kidney in a 7-year-old with refractory hypertension (HTN) demonstrates an abnormal, intrarenal arterial waveform with a diminished & delayed arterial upstroke (parvus et tardus) & an abnormally low resistive index (RI = 0.41).* **(Right)** *Anterior oblique digital subtraction angiogram (DSA) of the right kidney in the same patient reveals a tight stenosis of an intrarenal arterial branch.*

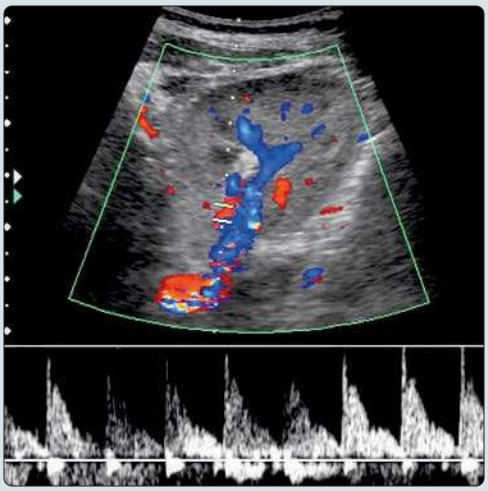
(Left) *Maximum intensity projection CTA in an 8-year-old with severe HTN shows a focal narrowing of a left upper pole accessory renal artery.* **(Right)** *Coronal 3D surface rendering of a CTA in an 11-year-old boy with HTN demonstrates ostial narrowing of both main renal arteries. There is also a stenosis of an accessory left renal artery.*

KEY FACTS

TERMINOLOGY

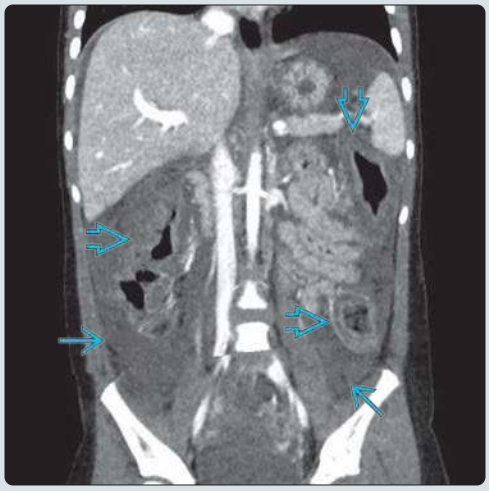


- Typical hemolytic uremic syndrome (HUS): Thrombotic microangiopathy occurring after diarrheal illness (hemorrhagic colitis) from Shiga toxin-producing bacteria (classically *Escherichia coli* O157:H7)
  - Clinical triad of hemolytic anemia, thrombocytopenia, & acute renal failure
  - Affected organ systems: Kidneys > CNS (20-50%) > gastrointestinal tract, heart, lungs
- Atypical HUS: Due to dysregulation in alternative complement pathway
  - Diarrhea is less common; higher mortality

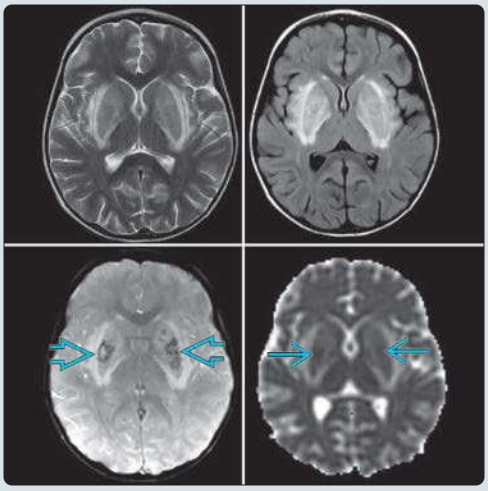


IMAGING

- Bowel: Fluid-filled loops with wall thickening
- Kidneys: ↑ renal cortical echogenicity, ↓ vascular perfusion of parenchyma early with high resistance arterial flow; perfusion improves in 2nd-4th weeks
  - Improved diastolic flow precedes urine production
- Brain: Potentially reversible, frequently symmetric lesions
  - Restricted diffusion & T2, FLAIR MR signal abnormalities
    - Deep gray nuclei, deep white matter > cortex, pons
    - Foci of T1 MR shortening due to hemorrhage, necrosis



CLINICAL ISSUES



- 1 in 100,000 children affected annually
- Most patients are 3-5 years of age
- Gastrointestinal illness precedes renal failure by 3-14 days
- With onset of HUS: Fatigue, pallor, ↓ urine output, body/extremity edema, bruising ± seizures, altered mental status, visual disturbances
- Full recovery in 70%; 1-5% mortality
- Long-term sequelae: Renal, neurologic
- Typical HUS treatment: Supportive therapy (including dialysis), packed RBCs; ± plasma exchange; no direct treatments
- Atypical HUS treatment: As above, + C5 antibody eculizumab for terminal complement blockade

(Left) *Transverse spectral Doppler US in a 15-month-old with vomiting & ↓ urine output shows an echogenic right kidney with complete reversal of diastolic flow in the main renal artery. The left main renal artery showed similar findings. Aortic waveforms were normal.* **(Right)** *Transverse spectral Doppler US in the same patient with HUS 9 days later shows improved flow in the right renal parenchyma with return of diastolic flow in the main renal artery. The patient began producing urine the following day.*

(Left) *Coronal CECT in a 3-year-old with fever & bloody diarrhea (due to Escherichia coli O157:H7) shows diffuse, marked colonic wall thickening with regions of hyper- & hypoenhancement. There is marked surrounding inflammatory change.* **(Right)** *Axial T2, FLAIR, ADC map, & SWI (clockwise from top left) MR images in the same patient after a seizure show foci of microhemorrhage & restricted diffusion in the putamen & globus pallidus, a pattern consistent with HUS. Surrounding edema extends to the insula.*

Neurogenic Bladder

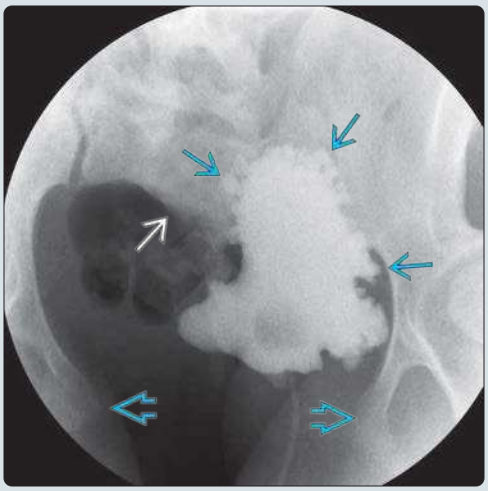
KEY FACTS

TERMINOLOGY

- Bladder dysfunction secondary to neurologic disorder

IMAGING

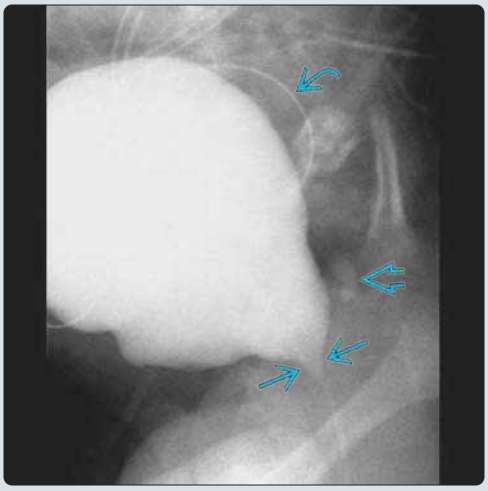
- Voiding cystourethrogram &/or US
  - Towering, contracted bladder with thickened trabeculations
  - Bladder volume is variable, ranging from small & contracted to large & atonic
  - Involuntary, uninhibited detrusor contractions
  - High filling pressure
    - Results in ↓ rate of filling or spontaneous cessation of contrast infusion
  - Voiding dysfunction: Inhibited micturition reflex
  - ↑ postvoid residual
  - Secondary bladder & upper tract abnormalities
    - Dilated upper tracts: Vesicoureteral reflux, functional obstruction, scarring



PATHOLOGY

- Classification
  - Contractile bladders (hyperreflexive detrusor)
  - Intermediate (mixed) bladders
  - Acontractile bladders (detrusor areflexia)

CLINICAL ISSUES



- Frequency, nocturia, urgency, incontinence
- Urinary tract infection, epididymitis in boys with detrusor-sphincter dyssynergia who are allowed to void
- Upper tract deterioration & chronic renal failure related to ↑ bladder pressure
- Without intervention, 50% show upper urinary tract deterioration in first 5 years of life

(Left) *Frontal voiding cystourethrogram (VCUG) in a teenage girl with a cloacal exstrophy variant & a neurogenic bladder (NGB) who catheterizes 4x/day shows a small, hypertonic bladder with trabeculation & multiple diverticula/pseudodiverticula, the so-called "Christmas tree" bladder. Note the pubic symphysis diastasis & sacral truncation of cloacal exstrophy.* **(Right)** *Transverse US of the bladder shows a trabeculated, thickened bladder wall in the same patient with cloacal exstrophy variant.*

(Left) *Oblique cystogram in a 7-day-old status post myelomeningocele (MMC) repair shows a mildly lobular, large capacity bladder with no wall thickening, an open bladder neck, left vesicoureteral reflux, & no significant bladder emptying due to an atonic detrusor, consistent with NGB. Note the ventriculoperitoneal shunt catheter.* **(Right)** *Transverse US in the same patient after MMC repair shows a large, mildly lobular bladder without significant bladder wall thickening in an atonic-type NGB.*

TERMINOLOGY

Definitions

- Neurogenic bladder (NGB): Bladder dysfunction due to neurologic disorder

IMAGING

General Features

- Best diagnostic clue
  - Small, contracted bladder with thickened trabeculations ("Christmas tree" bladder)
  - Vertical, large, smooth, borderline thick atonic bladder
  - Abnormal filling & emptying phases of modified voiding cystourethrogram (VCUG)
- Size
  - Bladder volume is variable; small & contracted to large & atonic
- Morphology
  - Taller than wide, trabeculated, thickened ± diverticula

Radiographic Findings

- Sacral anomalies, spinal dysraphism, pubic symphysis diastasis, scoliosis, obstipation
- Urinary tract calculi
- Can be normal

Fluoroscopic Findings

- VCUG
  - Noncompliant bladder
    - Involuntary, uninhibited detrusor contractions
      - Thickened, trabeculated bladder wall (hypercontractile & intermediate bladders): Grading scale of trabeculations may have clinical implications for altering therapy
    - Serrated mucosa with prominent interureteric ridge (hypercontractile bladder)
    - High filling pressure
    - Results in ↓ rate or spontaneous cessation of contrast infusion
    - Relatively low bladder capacity
    - Leakage around catheter at low volume/high pressure
  - Acontractile bladders (detrusor areflexia)
    - Little, if any, detrusor contraction
    - Relatively high bladder capacity
    - Relatively little bladder thickening
    - Bladder leaks but does not empty spontaneously
      - Large bladder residual, incomplete emptying
  - May or may not sense need to void (inhibited micturition reflex) or have physiologic urination, depending on level of lesion
  - Voiding dysfunction
    - Detrusor-sphincter dyssynergia: Seen with contractile bladders
      - Sudden opening of bladder neck at ↑ pressure
      - Reflexive contraction of external sphincter: Functional obstruction
      - Ejaculatory duct reflux → epididymitis in boys
      - Bulging of posterior urethra
    - Gradual bladder neck opening: Intermediate (mixed) bladders
      - Bladder neck is incompetent but closed on early filling
      - Opens with ↑ volume/pressure
      - Funnel-like appearance: No bulging of posterior urethra
    - Persistent bladder neck opening: Acontractile bladder
      - Incompetent, open throughout filling phase
  - Secondary bladder & upper tract abnormalities
    - Diverticula/pseudodiverticula
    - Vesicoureteral reflux (VUR) in 20-25% cases
    - Dilated upper urinary tracts
    - ↑ postvoid residual
  - Complication of VCUG in NGB
    - Autonomic dysreflexia
      - Life-threatening condition
      - Typically occurs with spinal lesions above T6
      - Sympathetic discharge in response to bladder distention or urethral catheterization
      - Severe paroxysmal hypertension, anxiety, sweating, piloerection, headaches, bradycardia
      - Treatment: Evacuate bladder & catheter, elevate head of table, check blood pressure, pharmacologic intervention if necessary

Ultrasonographic Findings

- Grayscale ultrasound
  - Small contracted/large atonic bladder; ± wall thickening; ↑ postvoid residual
  - Diverticula, pseudodiverticula
  - ± urinary tract dilation, unilateral or bilateral
  - ± VUR or functional obstruction
  - ± renal scarring

Imaging Recommendations

- Best imaging tool
  - Modified VCUG
- Protocol advice
  - VCUG: Follow-up yearly
    - ± videourodynamics (if available)
  - Renal & bladder sonography: Follow-up every 6 months

DIFFERENTIAL DIAGNOSIS

Congenital Bladder Outlet Obstruction

- Including posterior urethral valves, prune belly syndrome, urethral atresia
- Prior to ablation of valves, severity of bladder findings is dependent on VUR
  - ↑ grade of VUR → less severe bladder findings

Pelvic Mass

- ± extrinsic mass or filling defect at bladder base; may lead to degree of obstruction/voiding difficulties
  - Bladder, prostatic, ovarian, or vaginal rhabdomyosarcoma
  - Sacrococcygeal teratoma
  - Neuroblastoma
- No trabeculation; features do not change with voiding

Multiple Diverticula

- Williams syndrome
- Menkes syndrome

- Cutis laxa or Ehlers-Danlos

PATHOLOGY

General Features

- Etiology
  - Myelodysplasia (e.g., myelomeningocele)
  - Sacral agenesis
  - Cerebral palsy
  - Traumatic spinal cord lesions
- Associated abnormalities
  - Anorectal malformations
  - Caudal regression
  - Closed congenital spinal dysraphism
  - Spinal cord tethering

Staging, Grading, & Classification

- Multiple classification schemes
- Type of bladder dysfunction
  - Contractile bladders (hyperreflexive detrusor)
    - Upper motor neuron lesion
    - Uninhibited detrusor contraction, sudden bladder neck opening
    - Detrusor-sphincter dyssynergia → potential epididymitis in boys allowed to void
    - Functional obstruction; deterioration of upper tracts, especially with VUR
  - Intermediate (mixed) bladders
    - Lesions overlap neural pathways
  - Acontractile bladders (detrusor areflexia)
    - Lower motor neuron lesion
    - No detectable detrusor contractions
    - Sphincter weakness incontinence: Leakage of contrast around catheter, especially during coughing
- Bladder function
  - Inability to store urine properly
  - Inability to evacuate urine properly
- Level of neurologic disorder
  - Upper motor neuron lesion
  - Lower motor neuron lesion

CLINICAL ISSUES

Presentation

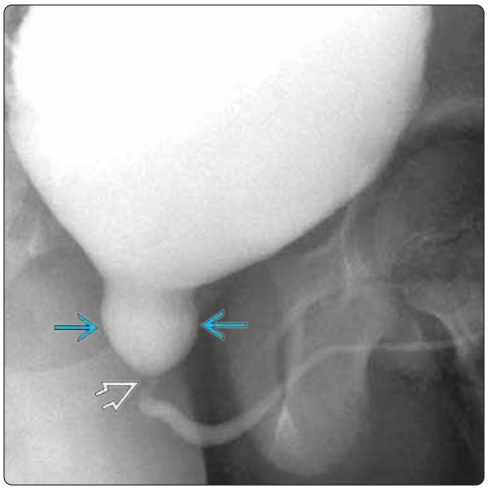
- Most common signs/symptoms
  - Failure to empty bladder
  - Frequency, nocturia, urgency, retention, incontinence
  - Urinary tract infection (UTI)
  - Bladder stones, hematuria
  - Epididymitis

Natural History & Prognosis

- Complications
  - Pyelonephritis
  - Hydronephrosis
  - Urolithiasis
  - Epididymitis
  - Sexual dysfunction
  - Autonomic dysreflexia
- Upper tract deterioration, UTI, & chronic renal failure are related to ↑ bladder pressure
  - Without bladder management, 50% develop nephropathy in first 5 years of life
  - Predictive indicators for nuclear medicine renal cortex DMSA defects &/or deterioration of renal function vary by study but often include
    - VUR
    - Trabeculations
    - Bladder wall thickness
    - High bladder-filling pressure
    - Detrusor-sphincter dyssynergia
    - Poor bladder compliance
    - High leak point pressure
    - Large postvoid residual volume

Treatment

- Treatment goals
  - Preservation of renal function
  - Avoidance of UTI, epididymitis
  - Achieve appliance-free, social continence
- Therapeutic maneuvers to achieve goals
  - Clean, intermittent catheterization
  - Medications: Antibiotics, anticholinergics, etc.
  - Surgical procedures
    - Operation for continence
    - Bladder augmentation
    - Artificial sphincters
- Hyperreflexia
  - ↑ volume: Cystoplasty, muscular or fascial slings, parasympatholytic drugs, botulinum A toxin
  - ↑ voiding: Catheter, transurethral sphincterotomy
- Hyporeflexia
  - Bladder training, intermittent catheterization, bladder neck resection/denervation, parasympathomimetic drugs



DIAGNOSTIC CHECKLIST

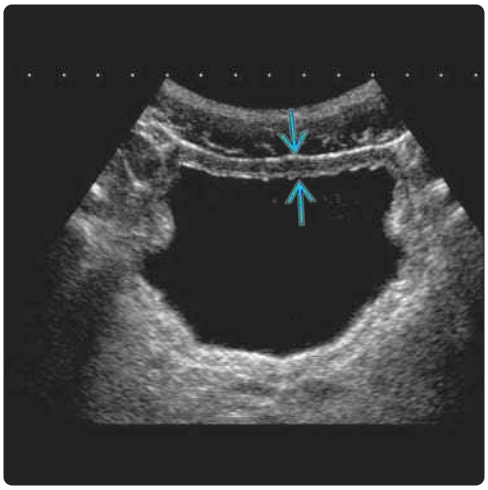


Image Interpretation Pearls

- During VCUG
  - Monitor contrast flow
  - Evaluate bladder contour, degree of trabeculations, sphincter function, bladder filling volume, VUR, & degree of emptying

(Left) *Frontal VCUG in an 11-year-old boy with NGB on intermittent catheterization shows a caliber change of the proximal urethra ➪ with dilation of the posterior urethra ⇨. Considerations include detrusor-sphincter dyssynergia & catheter-related urethral stricture.* **(Right)** *Transverse US in the same patient with NGB & VCUG findings suggestive of detrusor-sphincter dyssynergia or urethral stricture shows a diffusely thickened bladder wall ⇨, which is characteristic of NGB or bladder outlet obstruction.*

(Left) *Oblique VCUG of an infant with a history of MMC repair shows a towering bladder with wall thickening ➪, a small diverticulum at the bladder base ➪, & a lax bladder neck sphincter ⇨.* **(Right)** *Oblique VCUG obtained several years later in the same patient without appropriate follow-up shows the development of additional diverticula ➪. Also note the bulging bladder neck with contracted external sphincter ➪ on this nonvoiding image (due to detrusor-sphincter dyssynergia).*

(Left) *AP radiograph in a young adult man with a history of bladder exstrophy (suggested by pubic symphysis diastasis & a normal sacrum) who had bladder augmentation shows multiple variable-sized, lamellated bladder calculi ⇨.* **(Right)** *Oblique VCUG in an 8-month-old boy status post anorectal malformation repair shows a tall, trabeculated NGB. During voiding, there is reflux into the left ejaculatory duct ⇨ & seminal vesicle ⇨, suggesting high posterior urethral pressures & ↑ the risk of left epididymitis.*

Bladder Diverticula

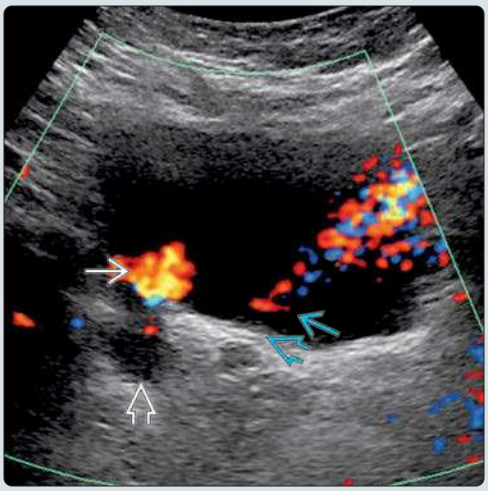
KEY FACTS

TERMINOLOGY

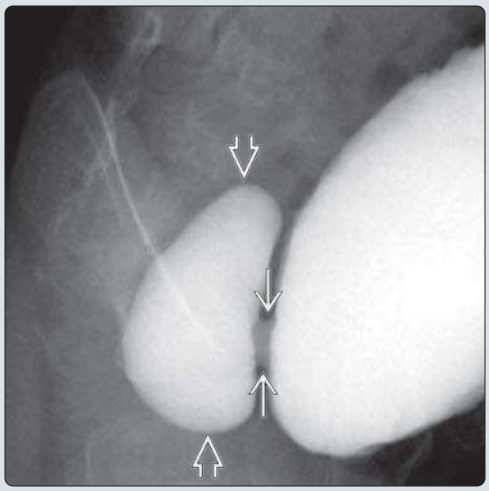
- Herniation of urinary bladder mucosa through bladder detrusor muscle
  - Primary (congenital): Poor muscular backing near ureterovesical junction (UVJ)
    - Periureteral (Hutch): Most common congenital diverticulum (90%)
  - Secondary (acquired)
    - Chronically elevated bladder pressures
    - Weak bladder wall in connective tissue disorders
    - Iatrogenic/traumatic causes (prior surgery/catheter)

IMAGING

- Best diagnostic clues
  - Round, cystic focus directly adjacent to bladder
    - Changes size with bladder filling &/or voiding
    - Anechoic on ultrasound; ± jet of urine into bladder
    - Fills with contrast on voiding cystourethrogram (VCUG)
- Diverticula with narrow neck may be small or absent during bladder filling & only seen with voiding
  - Contrast may remain after bladder emptying
- Vesicoureteral reflux (VUR) in 50%
  - Large diverticulum incorporates & distorts UVJ → VUR
- Without history of neurogenic bladder or bladder outlet obstruction, multiple diverticula should suggest syndromes
  - Williams, Menkes, Ehlers-Danlos, cutis laxa

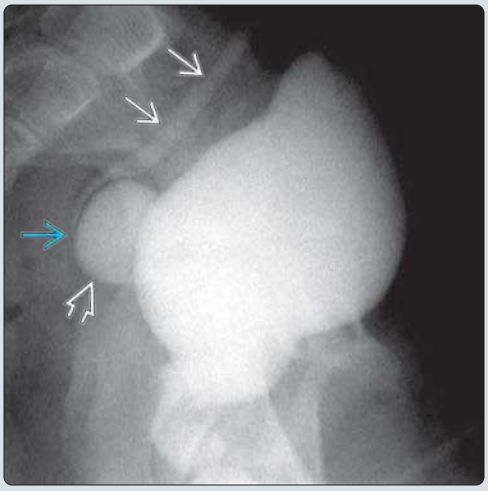


TOP DIFFERENTIAL DIAGNOSES

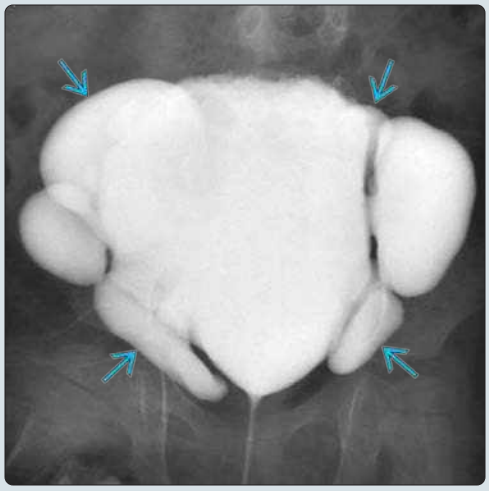


- Everting ureterocele, ureteral stump, ovarian/paraovarian cyst, gastrointestinal duplication cyst

CLINICAL ISSUES



- Asymptomatic vs. urinary tract infection, hematuria, voiding dysfunction
- Surgery for complications: Resection of diverticulum ± ureteral reimplantation



(Left) *Transverse color Doppler ultrasound of the urinary bladder shows not only a jet of urine ➡ draining from a diverticulum ➡ but also a jet of urine ⇨ emanating from the adjacent ureteral orifice ⇨ in this patient with a periureteral (Hutch) diverticulum.* **(Right)** *Oblique fluoroscopic voiding cystourethrogram (VCUG) was performed tangential to the neck ➡ of a moderate to large bladder diverticulum ➡. A projection demonstrating the neck should be acquired when a diverticulum is encountered.*

(Left) *Lateral fluoroscopic VCUG shows vesicoureteral reflux (VUR) ➡ accompanying a periureteral diverticulum. Ureter ➡ inserts directly into the diverticulum ⇨, which is important information for the urologist making management decisions.* **(Right)** *Frontal VCUG in a 3.5-year-old with Menkes disease shows multiple moderate to large diverticula ⇨ about the bladder, characteristic of this connective tissue (CT) disease. Other CT diseases with this appearance include Williams syndrome, cutis laxa, & Ehlers-Danlos syndrome.*

TERMINOLOGY

Definitions

- Herniation of urinary bladder mucosa through bladder detrusor muscle
  - Primary (congenital) due to poor muscular backing near ureterovesical junction (UVJ)
  - Secondary (acquired) due to
    - Chronically elevated bladder pressures
    - Weak bladder wall in various connective tissue disorders
    - Iatrogenic/traumatic causes (prior surgery/catheter)

IMAGING

General Features

- Best diagnostic clue
  - Focal round or ovoid outpouching of urinary bladder
- Location
  - Periureteral (Hutch): Most common primary diverticulum (90%)
  - Nonperiureteral: Usually secondary

Ultrasonographic Findings

- Grayscale ultrasound
  - Normal: Diverticulum may be decompressed & not visible
  - Focal bladder wall thickening adjacent to ureteral orifice
  - Round, anechoic structure adjacent to bladder
    - ± echogenic shadowing calculus
  - Ureteral dilation if ipsilateral vesicoureteral reflux (VUR) is present
- Color Doppler
  - Turbulence within diverticulum
  - Color jet of urine into bladder lumen
    - Especially helpful when communication with bladder is not apparent on grayscale images

Fluoroscopic Findings

- Voiding cystourethrogram
  - Outpouching of contrast at any bladder location
    - Periureteral is most common
    - Oblique images help visualize neck of diverticulum
  - Can enlarge during voiding due to ↑ bladder pressure
  - Contrast persists in diverticulum after bladder emptying
  - VUR in 50%: Larger diverticula predispose to VUR due to UVJ distortion
    - Ureter may appear to insert into diverticulum
    - Diverticula rarely obstruct ureter
  - Urethral obstruction from large diverticulum (uncommon)
  - Multiple diverticula are seen with syndromes
    - Williams, Menkes, cutis laxa, Ehlers-Danlos

Imaging Recommendations

- Protocol advice
  - Bladder sonography including kidneys
    - Scan bladder in full & postvoid states
  - Fluoroscopic VCUG
    - Be sure to image during & after voiding
      - Diverticulum may only fill during voiding
      - Document drainage pattern of diverticulum
    - Oblique images help visualize diverticulum neck & site of UVJ relative to diverticulum (if VUR occurs)

DIFFERENTIAL DIAGNOSIS

Everting Ureterocele

- Round, smooth-walled cyst within bladder at UVJ
- Everts near bladder capacity; inverts postvoid
- Duplex kidney ± obstructed upper pole, lower pole VUR

Ureteral Stump

- Often associated with ipsilateral multicystic dysplastic kidney/nephrectomy

Urachal Diverticulum

- Located at bladder dome pointing toward umbilicus

Ovarian or Paraovarian Cyst

- No communication of cyst with bladder
- Ovarian parenchyma/vascularity may surround cyst

Gastrointestinal Duplication Cyst

- Sonographic trilaminar wall may appear similar to bladder
- No communication of cyst with bladder
- Peristalsis strongly suggests duplication cyst

PATHOLOGY

General Features

- Associated abnormalities
  - Williams syndrome
  - Menkes syndrome
  - Cutis laxa
  - Ehlers-Danlos syndrome

CLINICAL ISSUES

Presentation

- Most are found incidentally (asymptomatic)
- Other cases: Urinary tract infection, hematuria, voiding dysfunction, pain

Natural History & Prognosis

- Complications determine need for operative treatment
  - Stagnant urine: Infection, hematuria, calculi
  - Deformed UVJ: VUR or obstruction
  - Urethral obstruction: Uncommon

Treatment

- Conservative: Observation ± chemoprophylaxis
- Surgery: Resection of diverticulum ± ureteral reimplant

Post-Deflux Procedure Appearance

KEY FACTS

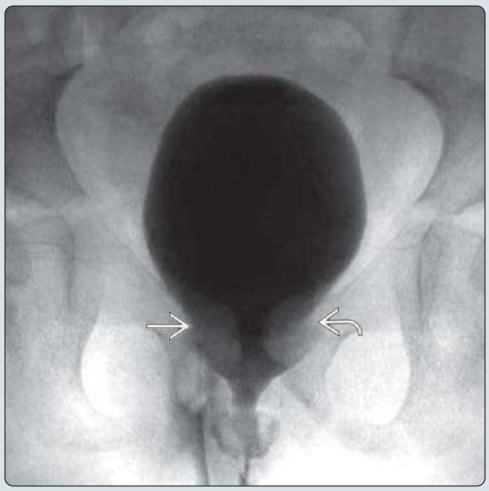
TERMINOLOGY

- Bulking agent injected near ureterovesical junction (UVJ) to prevent vesicoureteral reflux (VUR)
  - Deflux is dextranomer-hyaluronic acid copolymer
    - Biodegradable, does not migrate
  - Other brand agents: Dexell, Macroplastique, etc.
- Deflux procedure
  - Injected submucosally near UVJ
  - Techniques: STING, hydrodistention implantation technique (HIT), double HIT injections
  - Sufficient agent is used to create mass effect
  - Effectively alters angle of intramural ureter
  - Favors detrusor muscle creating effective 1-way valve

IMAGING

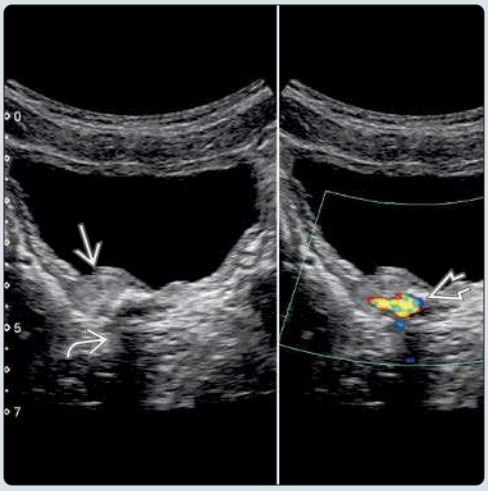
- Focal, round mass at UVJ in patient with history of antireflux procedure; uniformly echogenic on US
- Ca^{2+} can be seen months to years after injection
- Follow-up fluoroscopic VCUG or nuclear cystogram weeks to months later to assess change in VUR

TOP DIFFERENTIAL DIAGNOSES



- Urinary tract calculus
- Rhabdomyosarcoma
- Ureterocele
- Fungus ball
- Bladder clot

CLINICAL ISSUES



- Hydroureteronephrosis may be seen transiently following Deflux procedure
- Ultrasound is useful to confirm ureteral jet/patency
- Overall success rates of procedure are high
- Rare complications include obstruction, urosepsis, acute renal failure
- Recovery time is shorter than with open procedures

(Left) *Transverse US through a well-filled urinary bladder shows 2 echogenic mounds at the bladder base. The right mound is rounded, while the left is bilobed. Both represent Deflux material injected at the ureterovesical junctions (UVJ).* **(Right)** *Voiding cystourethrogram (VCUG) in the same patient following Deflux injections shows expected filling defects at the UVJ on the right & left. A VCUG or nuclear cystogram is often performed several weeks after the procedure to confirm successful treatment.*

(Left) *Split screen grayscale & color Doppler ultrasounds of a Deflux mound at the right UVJ, 5 years after injection, show irregular Ca^{2+} with shadowing & twinkle artifact.* **(Right)** *KUB radiograph in the same patient shows the irregular Ca^{2+} in the lower right pelvis that can form months to years after Deflux procedures.*

TERMINOLOGY

Definitions

- Bulking agent injected near ureterovesical junction (UVJ) to alter UVJ orientation & prevent vesicoureteral reflux (VUR)
  - Deflux (Q-Med; Uppsala, Sweden): Dextranomer-hyaluronic acid copolymer (DHA, DxHA); most commonly used in USA
    - In use clinically since 1995, FDA approved 2001
    - Relatively large particle size inhibits migration
    - Biodegradable, stable in vivo
  - Dexell (Istem Medical; Ankara, Turkey); most commonly used in Europe
    - Manufactured since 2007
    - Polycationic derivative of Dextran & cross-linked hyaluronic acid
    - Similar size & biologic profile to Deflux
  - Macroplastique (Congentix; Geleen, Netherlands)
    - FDA approved in 2006
    - Polydimethylsiloxane (solid silicone elastomer)
    - Suspended in bioexcretable polyvinylpyrrolidone gel
  - Vantris (Promedon; Cordoba, Argentina)
    - Manufactured since 2005
    - Polyacrylate-polyalcohol copolymer not biodegraded
    - Induces fibrotic response → difficult revision

IMAGING

General Features

- Best diagnostic clue
  - Focal mass at UVJ in patient with history of anti-VUR procedure
- Location
  - Periureteral at UVJ
  - Submucosal location is desired
    - Subureteral transurethral injection: STING technique initially widely used
    - Hydrodistention implantation technique [(HIT) intraluminal submucosal ureteral injection] developed
    - Double HIT (proximal & distal intraluminal submucosal injection) is now most often used
  - Intramuscular & subserosal spread is common
- Size
  - 1-2 mL per ureter
- Morphology
  - Round or ovoid
  - Bilobed appearance is common, may be due to
    - Intramuscular or subserosal spread
    - 2 injections in tandem (double HIT)
  - Can calcify after years: 2% after 4 years

Radiographic Findings

- Dystrophic calcium is occasionally seen in mound

Ultrasonographic Findings

- Round or ovoid
- Homogeneously echogenic
- Posterior shadowing if calcified, mimics UVJ stone
- Avascular on Doppler imaging; twinkle artifact if calcified

Imaging Recommendations

- Best imaging tool
  - Ultrasound encounters these "masses" most often
  - Also seen by VCUG, MR, CT, & possibly radiograph (if calcified)
  - VCUG or nuclear cystogram is performed several weeks following procedure to document success
    - ↓ in grade of VUR, even if not completely resolved, is considered procedural success

DIFFERENTIAL DIAGNOSIS

Urinary Tract Calculus

- Most are smaller, less round, & more uniformly echogenic (with posterior shadowing or twinkle artifact)
- Typically with renal colic history ± hematuria

Rhabdomyosarcoma

- More lobulated & heterogeneous than Deflux mound
- Doppler flow is expected in bladder neoplasm

Ureterocele

- Cystic protrusion of distal ureter into bladder on cross-sectional modalities

Fungus Ball

- Typically in immunocompromised patients
- Mobile & more heterogeneous on imaging

Bladder Clot

- Expect history of hematuria & mobile debris in bladder
- Doppler should not show flow in clot

Inflammatory Myofibroblastic Pseudotumor

- Nonspecific lobulated mass with internal vascularity

Fibrovascular Polyp

- Vascular pedunculated mass

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - History of Deflux procedure
- Other signs/symptoms
  - Hydronephrosis & hydroureter is seen transiently 1-6%
  - Ultrasound is useful to confirm ureteral jet/UVJ patency

Natural History & Prognosis

- Success rates
  - ~ 70-80% for VUR grades 2-3
  - ~ 50-60% for VUR grades 4-5
- Reinjection vs. reimplantation if initial injection fails
- Delayed failure rates 15-20%

Rhabdomyosarcoma, Genitourinary

KEY FACTS

TERMINOLOGY

- Malignant tumor of striated muscle originating from any pelvic organ (but paratesticular is discussed separately)

IMAGING

- Best clue: Large, heterogeneous, predominantly solid pelvic mass in child with symptoms of urinary tract obstruction
  - Variable cystic components
  - Botryoid variety resembles "bunch of grapes" with cysts protruding into lumen of vagina or urinary bladder
- May originate from bladder, vagina, cervix, uterus, pelvic side walls, prostate, & paratesticular tissues
  - May also occur in adjacent non-GU soft tissues
- Tumors spread by local extension as well as lymphatic & hematogenous routes, sending metastases to lungs, liver, & bone
  - 15-20% have metastases at diagnosis
- Work-up typically includes
  - US for initial investigation of urinary tract symptoms or palpable mass
  - CECT or MR for further tumor characterization & localization
  - Staging with chest CT & PET

PATHOLOGY

- Small round blue cell tumor of primitive muscle cells
- Major histologic types: Embryonal (majority, especially in GU sites), alveolar, & undifferentiated (adults)
- Bladder & prostate sites are unfavorable, automatically at least stage II

CLINICAL ISSUES

- Peak incidence: 2-6 years old
  - 75% < 5 years old at diagnosis
- Surgery, chemotherapy, & radiation therapy combined
- 5-year survival: Stage I (93%) vs. stage IV (~ 30%)
  - Embryonal type has better prognosis than alveolar

(Left) *AP radiograph of a 6-year-old boy shows displacement of bowel by a soft tissue mass in the pelvis, initially suspected to be due to urinary retention but not relieved by bladder catheterization.* **(Right)** *Axial CECT in the same patient with urinary retention shows a large, heterogeneously enhancing mass displacing the urinary bladder (with Foley balloon in place) anteriorly.*

(Left) *Coronal FDG PET/CT in the same patient shows predominantly peripheral uptake in the pelvic tumor but no evidence of metastatic disease. Biopsy confirmed a rhabdomyosarcoma (RMS) originating from the bladder base/prostate.* **(Right)** *Sagittal T2 FS MR in a 7-year-old boy shows a large, heterogeneous, high signal intensity RMS arising from the prostate. Note the superior displacement of the bladder & the altered course of the catheter.*

TERMINOLOGY

Abbreviations

- Rhabdomyosarcoma (RMS), genitourinary (GU)

Synonyms

- Botryoid tumor, sarcoma botryoides, embryonal RMS

Definitions

- Malignant tumor of striated muscle originating from any pelvic organ (but paratesticular site is discussed separately)

IMAGING

General Features

- Best diagnostic clue
  - Large, heterogeneous, predominantly solid pelvic mass in child with symptoms of urinary tract obstruction
- Location
  - May originate from urinary bladder, vagina, cervix, uterus, pelvic side walls, prostate, & paratesticular tissues
    - RMS may also occur in adjacent non-GU soft tissues
  - Tumors spread by local extension as well as lymphatic & hematogenous routes, sending metastases to lungs, liver, & bone
- Morphology
  - Heterogeneous, round or lobulated, solid tumor
  - Botryoid variety resembles "bunch of grapes" protruding into lumen of vagina or urinary bladder

Radiographic Findings

- Radiography
  - Soft tissue mass displacing bowel out of pelvis; can mimic distended urinary bladder

Ultrasonographic Findings

- Grayscale ultrasound
  - Round or lobulated tumor distorting &/or extending into urinary bladder
  - Mass is typically large & heterogeneous
    - Most commonly solid with variable cystic components
  - Look for evidence of urinary tract obstruction & adenopathy
- Color Doppler
  - Internal vascularity is variable in degree; presence of internal flow helps confirm solid neoplasm
  - Useful to trace displaced & compressed vessels
  - Vascular invasion is unusual

Fluoroscopic Findings

- Voiding cystourethrogram
  - Distortion of urinary bladder lumen by intrinsic or extrinsic mass
  - Filling defect may be round, lobulated, or irregular

CT Findings

- CECT
  - Heterogeneously enhancing, predominantly solid mass
  - Frequently locally invasive; look for disruption of fat planes
  - Search for adjacent adenopathy
  - Include liver due to frequency of metastatic disease

MR Findings

- Intermediate to low T1, intermediate to high T2 signal intensity
- Variable degrees of enhancement, ranging from mild & heterogeneous to intense & uniform
- DWI
  - Solid portions of tumor typically restrict diffusion
  - DWI ↑ conspicuity of all lymph nodes (normal & pathologic), helping draw attention to mildly enlarged nodes that might otherwise go unnoticed

Nuclear Medicine Findings

- Bone scan
  - Traditionally used for bony metastatic disease
- PET/CT
  - Improves staging with ↑ sensitivity for nodal spread & distant metastases
  - May improve assessment of therapeutic response

Imaging Recommendations

- Best imaging tool
  - US is typically used for initial investigation of urinary tract symptoms or palpable mass
    - Must include inferior bladder & confirm normal position of bladder
  - CECT or MR for further tumor characterization & localization
  - Staging with chest CT & PET

DIFFERENTIAL DIAGNOSIS

Ureterocele

- Cystic protrusion of distal ureter into bladder; ureteral jet &/or continuity with dilated ureter can help confirm

Bladder Hematoma/Debris

- Clinical history of instrumentation, augmentation, trauma, cystitis, or chemotherapy
- Heterogeneous mobile filling defect(s); no Doppler flow

Pelvic Neuroblastoma

- Younger age, Ca^{2+}, & encasement of vessels

Burkitt Lymphoma

- Look for bowel, splenic, & renal involvement

Ovarian Tumor

- Identifying organ of origin may be difficult
- Ovarian malignancies are often larger with higher likelihood of peritoneal spread (nodules, ascites)

Hematometrocolpos

- Markedly distended vagina posterior to bladder
- Look for layering or swirling debris on US
- Blood products are often bright on T1 MR

Sacrococcygeal Teratoma

- Heterogeneous solid &/or cystic presacral mass associated with coccyx
- Most commonly exophytic from perineum in newborn with variable size of internal components

Pelvic Inflammatory Disease/Abscess

- Complex fluid-filled mass with peripheral hyperemia, internal debris
- ± MR T2-hypointense rim; thick, irregular peripheral enhancement; central diffusion restriction of abscess

Other Solid Bladder Mass

- Inflammatory myofibroblastic tumor, plexiform neurofibromas, eosinophilic cystitis

PATHOLOGY

General Features

- Etiology
  - RMS can occur virtually anywhere in body
  - Thought to arise from primitive muscle cells
- Associated abnormalities
  - ↑ incidence of RMS in
    - Neurofibromatosis type 1
    - Li-Fraumeni syndrome
    - Rubinstein-Taybi syndrome
    - Beckwith-Wiedemann syndrome
    - *DICER1* mutation
  - Environmental factors linked to RMS
    - Parental use of marijuana & cocaine
    - In utero radiation exposure
    - Exposure to alkylating agents

Staging, Grading, & Classification

- Based on tumor invasiveness, tumor size, nodal disease, & metastases
  - Stage I* = T1 or T2; T size a or b; nodes N0, N1, or NX; M0
  - Stage II = T1 or T2; T size a; nodes N0 or NX; M0
  - Stage III = T1 or T2; T size a with nodes N1 or T size b with N0, N1, or NX; M0
  - Stage IV = T1 or T2; T size a or b; nodes N0 or N1; & M1
    - *GU site excluding bladder & prostate
      - Bladder & prostate are unfavorable sites, automatically at least stage II
    - T (tumor): T1 = confined to organ of origin; T2 = local extension
    - T size: a ≤ 5 cm diameter; b > 5 cm diameter
    - N (regional nodes): N0 = not clinically involved; N1 = involved; NX = unknown
    - M (metastases): M0 = no distant metastases; M1 = distant metastases

Gross Pathologic & Surgical Features

- Botryoid subtype has cysts of mucosanguineous fluid
  - Can have transparent, gelatinous appearance

Microscopic Features

- Small round blue cell tumor
- Rhabdomyoblasts are hallmark
  - Not always present, especially if poorly differentiated
- Histochemical markers for muscle cells are helpful: Desmin, myoglobin, actin
- Disseminated rhabdomyoblasts in bone marrow mimic leukemia
- 4 major histologic types
  - Embryonal (majority, especially in GU sites)
    - Botryoid variant of embryonal type (5%)
  - Alveolar
  - Undifferentiated (adults)

CLINICAL ISSUES

Presentation

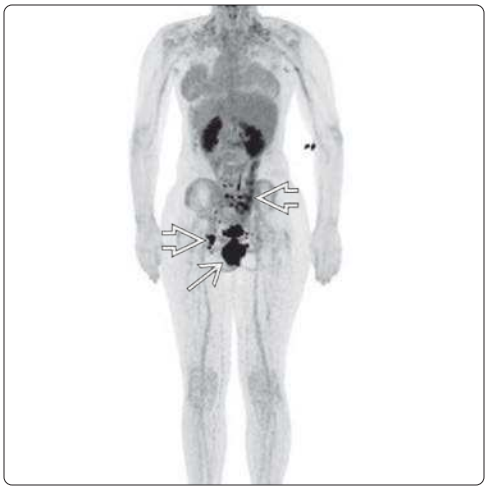
- Most common signs/symptoms
  - Large pelvic mass
  - Urinary symptoms, such as dysuria, hematuria, frequency, urinary retention
  - Pain variably present
- Other signs/symptoms
  - Vaginal discharge/bleeding or constipation

Demographics

- Age
  - Peak incidence: 2-6 years old
  - 75% < 5 years old at diagnosis
  - Paratesticular tumors are more common in adolescents
- Sex
  - M:F = 2-3:1 for GU tumors
  - M = F for head, neck, & extremity tumors
- Epidemiology
  - 250 new cases per year in USA
  - 4.5 cases per million

Natural History & Prognosis

- 5-year survival rates
  - Stage I (93%)
  - Stage II (81%)
  - Stage III (~ 50%)
  - Stage IV (~ 30%)
- Embryonal cell type has better prognosis than alveolar
- RMS of paratesticular tissues & vas deferens have best prognoses
- 15-20% have metastases at diagnosis



Treatment

- Surgery, chemotherapy, & radiation therapy
  - Initial surgery includes wide margins (when possible) & lymph node sampling
  - Pelvic exenteration-type surgeries are now rejected
    - Organ sparing surgery is now performed
    - Gonads are often moved out of radiation field temporarily
  - Secondary cancers in XRT field are not uncommon 10-20 years later

(Left) *Coronal T2 FS MR shows irregular high signal intensity mass in the left labia of this 15-year-old girl, initially treated as infection. Subsequent biopsy showed RMS. Suspicious left-sided lymph nodes are seen in the iliac chain.* **(Right)** *Posterior view 3D MIP FDG PET in the same patient shows that the primary tumor is FDG avid & that FDG-avid lymph nodes are present bilaterally in the groin & pelvis.*

(Left) *Axial T1 C+ FS MR in a 2-year-old with hematuria shows an enhancing, lobulated mass in the bladder, confirmed as RMS by biopsy. The preceding US (not shown) only visualized the superior components of this mass in a well-distended bladder, but Doppler confirmed its likely neoplastic nature.* **(Right)** *Sagittal STIR MR in a young boy shows a RMS growing up & out of the pelvis between the urinary bladder & rectum. The mass likely originated from the prostate or bladder base.*

(Left) *Longitudinal US in a 4-year-old girl shows a lobulated, heterogeneous mass distorting the anterior wall of the urinary bladder. Vascularity in the mass on color Doppler (not shown) confirmed a solid lesion.* **(Right)** *Axial CECT of the pelvis in the same patient shows the enhancing mass involving the lateral wall of the urinary bladder. Biopsy confirmed RMS.*

Neonatal Adrenal Hemorrhage

KEY FACTS

TERMINOLOGY

- Perinatal bleeding into normal adrenal gland
  - Associated with many perinatal stressors: Asphyxia, sepsis, birth trauma, coagulopathies

IMAGING

- R > L; bilateral in 5-10%
- Ultrasound: Echogenic, avascular mass replacing or expanding newborn adrenal gland
  - Appearance varies with timing of imaging
    - Acute: Hemorrhage appears echogenic & mass-like
    - Subacute: Blood products liquefy & contract, creating mixed echotexture mass
    - Chronic: Adrenal resumes normal size, ± Ca^{2+} or cyst
- CT, MR: Nonenhancing ± rim of enhancing adrenal
  - MR may show high T1 signal intensity &/or blooming on GRE, depending on age of blood products
- Radiographs (months to years later): Small unilateral or bilateral adreniform Ca^{2+}

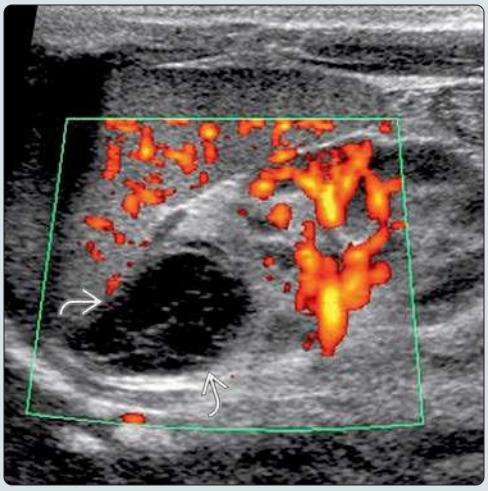
TOP DIFFERENTIAL DIAGNOSES

- Neuroblastoma
- Congenital adrenal hyperplasia
- Extralobar bronchopulmonary sequestration

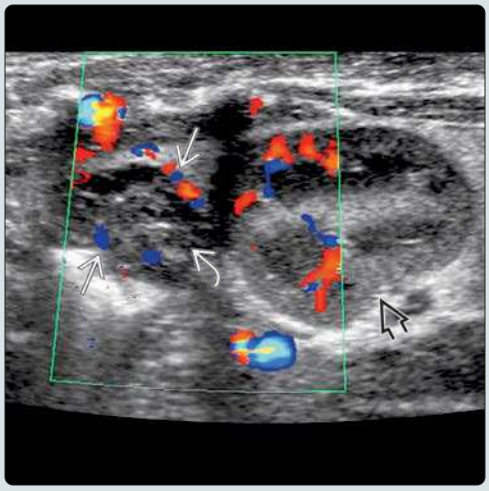
CLINICAL ISSUES

- Newborns may present with anemia, dropping hematocrit, jaundice, palpable mass, or adrenal insufficiency
  - Medical therapy for adrenal insufficiency is rarely needed

DIAGNOSTIC CHECKLIST



- In neonate: Follow-up ultrasound in 2-3 weeks to confirm expected evolution with ↓ size
  - Alternatively, determine catecholamine levels &/or characterize lesion with MR (to exclude neuroblastoma)
- In older child with incidental radiographic paraspinal Ca^{2+}
  - If morphology & extent are unclear, start with abdominal ultrasound to exclude neuroblastoma



(Left) *Longitudinal ultrasound in a 13-day-old with multiple medical problems shows a large heterogenous collection in the right adrenal with intermixed isoechoic & hypo- to anechoic regions. The adrenal is almost as large as the right kidney, which is duplicated.* **(Right)** *Transverse color Doppler ultrasound in the same patient shows mass effect from the avascular subacute adrenal hemorrhage flattening the adjacent inferior vena cava (IVC) at the level of the portal vein & hepatic artery.*

(Left) *Longitudinal oblique power Doppler ultrasound in a neonate with subacute, liquefying adrenal hemorrhage shows an absence of blood flow in the lesion with normal perfusion of the adjacent kidney & spleen.* **(Right)** *Transverse oblique color Doppler ultrasound performed 2 months later shows partial resorption of the same hematoma with improved blood flow in the adrenal gland. Mass effect on the left renal upper pole has resolved.*

TERMINOLOGY

Synonyms

- Adrenal hemorrhage, adrenal cortical hematoma

Definitions

- Perinatal bleeding into normal adrenal gland
- Associated with many perinatal stressors
  - Asphyxia, sepsis, birth trauma, coagulopathies

IMAGING

General Features

- Best diagnostic clue
  - Heterogeneous, avascular, well-defined mass replacing or expanding newborn adrenal gland
  - Bleeding seldom extends outside of adrenal
    - Case reports of concurrent scrotal hematoma
- Location
  - Suprarenal; R > L; bilateral in 5-10%

Radiographic Findings

- Radiography
  - May see Ca^{2+} months to years after hemorrhage

Ultrasonographic Findings

- Grayscale ultrasound
  - Imaging appearance varies with timing of exam
    - Acute: Hemorrhage appears echogenic & mass-like
      - Acute hemorrhage may be less echogenic in patients on anticoagulants, ECMO, etc.
    - Subacute: Blood products liquefy & contract, creating mixed echotexture mass ± internal septations
    - Chronic: Gland resumes normal size; may calcify
- Color Doppler
  - Avascular hematoma
  - Doppler is useful to assess adjacent renal veins & inferior vena cava (IVC)
    - Renal vein thrombosis is associated with adrenal hemorrhage
      - Causal relationship not established
      - Similar stressors are associated with renal vein thrombosis

CT Findings

- CECT
  - Dense (if acute) or hypodense (if subacute) mass enlarging/splaying/compressing adrenal gland
    - No enhancement of hematoma
    - Residual rim of compressed adrenal enhances
  - May see Ca^{2+} months to years after hemorrhage

MR Findings

- Variable signal intensity depending on age of blood products
  - T1 hyperintensity suggests hemorrhage
  - ± blooming of hemosiderin on GRE
  - Blood products may restrict diffusion
- Enhancing residual adrenal surrounds nonenhancing hematoma

Nuclear Medicine Findings

- MIBG or PET may show photopenic focus in adrenal
- ± nonspecific flattening of ipsilateral renal upper pole

Imaging Recommendations

- Best imaging tool
  - Ultrasound for initial diagnosis & follow-up
  - MR & MIBG are useful if lesion shows internal flow or interval ↑ in size (concerning for neuroblastoma)
    - MR documents characteristic signal intensity of aging blood products
    - MIBG shows lack of uptake
- Protocol advice
  - Doppler ultrasound confirms lack of vascular flow in mass-like hematoma

DIFFERENTIAL DIAGNOSIS

Neuroblastoma

- Most common malignancy in 1st month of life
- More likely to be cystic in neonates than older children
- Ca^{2+} in ~ 85-90% of all neuroblastomas
- May extend beyond adrenal
  - Paraspinal mass crossing midline, invading spine, encasing vessels
  - Distant metastases to liver, bone, skin
- Doppler shows internal tumor vascularity
  - Can have concurrent avascular hemorrhage
- Many cases of spontaneous regression in congenital neuroblastoma

Congenital Adrenal Hyperplasia

- Various enzyme deficiencies → lack of aldosterone & cortisol production → low cortisol triggers pituitary to secrete corticotropin → enlarged adrenal gland
- Bilateral "cerebriform" adrenal enlargement
  - Single limb thickness > 4 mm; length of gland > 20 mm
- Autosomal recessive inheritance
  - 1 in 15,000-20,000 live births
- Females: Present at birth with ambiguous genitalia
- Males: Usually present at 5-14 days of life with severe electrolyte abnormalities

Wolman Disease

- Rare autosomal recessive disorder of lipid metabolism
  - ↓ levels of lysosomal acid lipase → bilateral adrenal Ca^{2+}
- Occurs in infancy; historically fatal in most cases before 1 year of age
- Bone marrow transplant & enzyme replacement have changed prognosis
- Affected infants show signs of lipid storage in most tissues, causing
  - Hepatosplenomegaly
  - Abdominal distention
  - Vomiting
  - Steatorrhea
  - Failure to thrive
- Case reports of isolated fetal ascites in Wolman disease

Extralobar Bronchopulmonary Sequestration

- Congenital anomaly of lung formation
  - No connection to tracheobronchial tree
- May be intra- or subdiaphragmatic above kidney
- Homogeneous solid mass ± systemic vessel feeding

- Cystic components with "hybrid" CPAM lesion

Adrenal Cysts

- Well-defined, round, anechoic, avascular mass
- Associated with Beckwith-Wiedemann syndrome
  - May have hypertrophied adrenal

Lymphatic Malformation

- Multicystic congenital mass crossing soft tissue planes
- May have suprarenal components

PATHOLOGY

General Features

- Etiology
  - Several proposed mechanisms
    - Fetal compression during birth causes ↑ venous pressure & rupture of small venules
      - Does not explain in utero/fetal adrenal hemorrhages
    - Transient hypoxia or hypotension causes hemorrhage
    - Normal involution of fetal cortex & vacuolization ↑ tendency for bleeding
- Genetics
  - Not inherited
- Embryology & anatomy
  - Relative size of neonatal adrenal glands is large compared to adults
    - Fetal adrenal cortex functions in utero to produce corticosteroids
      - Quite thick at birth, creating convex borders
    - Central medullary portion of gland is brightly echogenic in comparison to cortex
    - Fetal cortex & overall size of gland ↓ after birth: Almost inapparent by 6 months

Gross Pathologic & Surgical Features

- Hemorrhage into otherwise normal adrenal
- More common on right side; up to 85% in one study
  - One theoretic risk for greater right-sided incidence: Relatively short right adrenal vein

Microscopic Features

- Ischemic necrosis, supporting theory of involuting fetal cortex as predisposing factor

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Anemia, dropping hematocrit, jaundice, adrenal insufficiency, or palpable mass in perinatal period
- Other signs/symptoms
  - Occasionally discovered incidentally during work-up of
    - Unrelated antenatal hydronephrosis
    - Unrelated abdominal pain in older child
      - Incidental paraspinal Ca^{2+} from remote hemorrhages
- Clinical profile
  - Occurs more often in full-term infants
  - Macrosomic, large for gestational age (LGA) babies
  - Perinatal asphyxia

Demographics

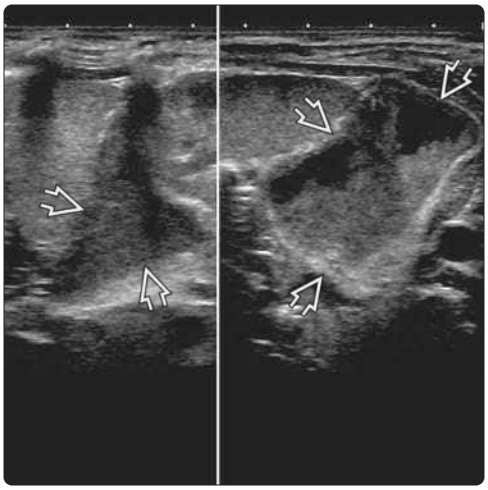
- Age
  - Newborn infants
- Epidemiology
  - 1-2 per 1,000 births

Natural History & Prognosis

- Blood products gradually retract & liquefy
- Cysts or dystrophic Ca^{2+} may develop
- Adrenal function is typically preserved
  - Especially in unilateral cases
- Involutes/resorbs in weeks to months
- Prognosis is excellent

Treatment

- Observation in most cases
- Adrenal insufficiency is extremely rare, requires damage to > 90% of adrenal tissue
  - Medical therapy may be required transiently
    - Exogenous steroid support of hypotension
- Case reports of adrenal abscess formation



DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Localized avascular suprarenal mass in neonate
  - Follow-up ultrasound in 2-3 weeks to confirm liquefaction & smaller size, **or**
  - Correlate with catecholamines, **or**
  - Evaluate with MR for solid mass (neuroblastoma)
- Incidental radiographic detection of paraspinal adrenal Ca^{2+} in older child
  - If clearly adreniform & not crossing midline, no further work-up required
  - If morphology & extent unclear, start with abdominal ultrasound to exclude neuroblastoma

(Left) *Longitudinal (left) & transverse (right) ultrasound images of the left suprarenal region in a 9-day-old infant with congenital heart disease show a mixed-echogenicity lesion with well-defined margins between the spleen & kidney.* **(Right)** *Color Doppler ultrasound in the same patient shows an absence of blood flow in the lesion, typical of adrenal hemorrhage.*

(Left) *Transverse ultrasound of the same lesion 1 week later shows progressive liquefaction, consistent with evolving hemorrhage & confirming the benign nature of the "mass."* **(Right)** *Coronal CECT in an elementary school-aged patient (who had been a premature infant) shows adreniform Ca^{2+} bilaterally, likely due to remote neonatal adrenal hemorrhages.*

(Left) *Coronal T2 FS MR in a 20-day-old with left prenatal hydronephrosis shows a heterogeneous right suprarenal mass deforming the right kidney. The mass was T1 bright with a few foci blooming on GRE (not shown). Serial ultrasound images showed progressive ↓ in size of the mass over the next 5 weeks.* **(Right)** *AP chest radiograph in a 3-year-old with cerebral palsy shows bilateral adrenal Ca^{2+}, the long-term sequela of neonatal hemorrhages due to neonatal stresses.*

Congenital Adrenal Hyperplasia

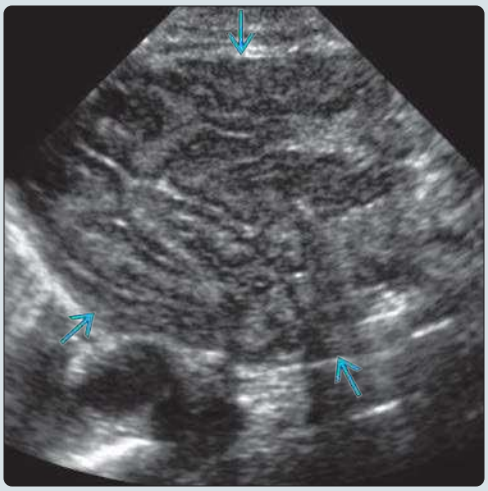
KEY FACTS

TERMINOLOGY

- Congenital adrenal hyperplasia (CAH): Inherited disorder of cortisol (± aldosterone) biosynthesis, which leads to hypertrophy of adrenal glands & excess androgen production
- Classic & nonclassic CAH, based on presentation
  - Classic: Presents as neonate with salt-wasting or virilization
  - Nonclassic: Presents as child with premature puberty or findings related to androgen production

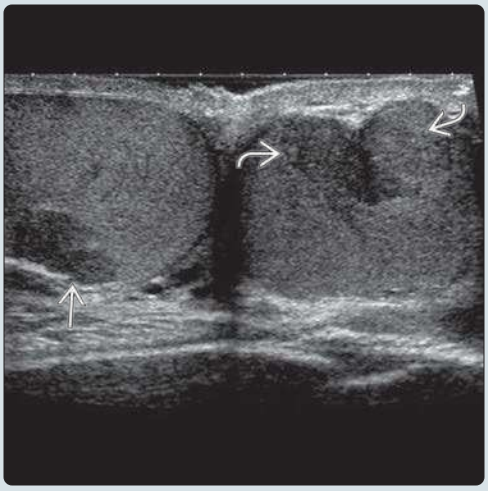
IMAGING

- Adrenal glands
  - Bilateral enlargement with cerebriform morphology
- Females
  - Ambiguous genitalia in neonates
    - US is used to identify normal female uterus
      - Excess androgen stimulation may make ovaries small & difficult to find on US
  - Polycystic appearance of ovaries in nonclassic CAH
- Males
  - Testicular adrenal rests occur in ~ 95% of adult males with CAH
    - Hypoechoic mass in each testis with ↑ vascularity, often adjacent to mediastinum testis

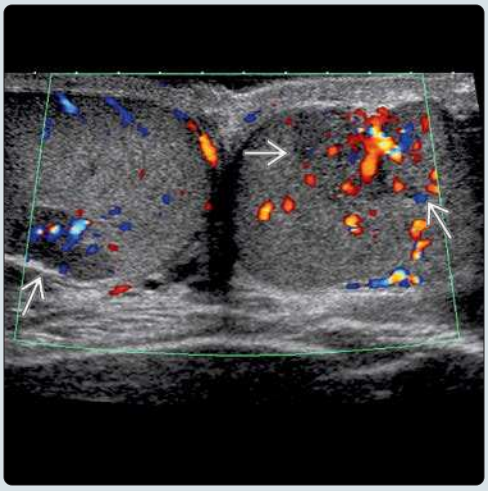


PATHOLOGY

- Caused by deficiency in 1 of 5 enzymes required to synthesize cortisol from cholesterol in adrenal cortex
  - 21-hydroxylase deficiency is most common



CLINICAL ISSUES



- Most common cause of ambiguous genitalia in females
- Males with classic CAH usually present at 5-14 days of life with acute salt-wasting crisis
- Neonatal screening panels test for severe forms of CAH
- Treated with lifelong glucocorticoids to replace cortisol & suppress androgen production

(Left) *Photograph of the perineum shows ambiguous genitalia in a genetic female (XX) with congenital adrenal hyperplasia (CAH). There is clitoromegaly & masculinization of the labioscrotal folds.* **(Right)** *Longitudinal oblique US shows a very enlarged adrenal gland with a characteristic wrinkled or cerebriform appearance. The adrenal gland has lost its normal adreniform shape but maintains corticomedullary distinction.*

(Left) *Transverse US of the scrotum in a patient with CAH shows round masses in both testes, consistent with congenital testicular adrenal rests. The lesion in the right testis is smaller & more uniformly hypoechoic compared to the lesion in the left testis.* **(Right)** *Transverse color Doppler US of the testes in the same patient shows hyperemia of the testicular adrenal rests, a typical finding in CAH. The vessels are not distorted as they pass through the lesions (as would be expected with testicular neoplasms).*

TERMINOLOGY

Abbreviations

- Congenital adrenal hyperplasia (CAH), 21-hydroxylase deficiency (21-OHD)

Definitions

- Inherited disorder of cortisol (± aldosterone) biosynthesis, which leads to hypertrophy of adrenal glands
- 2 types of CAH: Classic & nonclassic based on presentation
  - Classic CAH: Presents as neonate with salt-wasting or virilization
  - Nonclassic CAH: Presents as child with premature puberty or in adolescence/adulthood with hirsutism, irregular menses, chronic anovulation, acne, or infertility
- Classification of classic & nonclassic is artificial as disease severity is continuum determined by enzyme activity

IMAGING

General Features

- Best diagnostic clue
  - Enlarged, wrinkled appearance of adrenal glands in neonate with ambiguous genitalia
- Morphology
  - Markedly enlarged adrenal glands folded back upon themselves, giving characteristic wrinkled or cerebriform appearance

Ultrasonographic Findings

- Adrenal glands
  - Diffuse enlargement of both adrenal glands with wrinkled, cerebriform appearance
    - Single limb of adrenal gland ≥ 4 mm
    - Cerebriform appearance is caused by hypertrophied adrenal gland folding back upon itself
      - Hypoechoic cortex & hyperechoic medulla are usually maintained
      - Creates appearance similar to cerebral gyri & sulci
  - Left adrenal gland is usually larger than right
    - Potential space for right adrenal gland is smaller due to liver
  - Normal adrenal glands do not exclude CAH
  - Adrenal myelolipomas may develop in adults with CAH who have poor adherence to medical therapy
- Female reproductive organs
  - Neonatal findings
    - Classic CAH presents with ambiguous genitalia
      - Potential findings: Enlarged clitoris, partly fused labia majora with rugae, common urogenital sinus, & development of male urethra
    - US is used to identify normal female uterus
      - Excess androgen stimulation may make ovaries small & difficult to find on US
      - Hydrocolpos or hydrometrocolpos may be present
    - US confirms absence of testes in masculinized labioscrotal folds
      - Undescended testes may be present in genetic females
  - Postpubertal findings
    - Ovaries may be enlarged with polycystic appearance
    - ± ovarian adrenal rest tumors appearing as small, hypoechoic nodules
- Male reproductive organs
  - Neonatal findings
    - Normal appearance of testes at birth
    - Hyperpigmented scrotum
  - Postpubertal findings
    - Testicular adrenal rests occur in ~ 95% of adolescent & adult males with CAH
      - Ovoid hypoechoic foci within each testis; often adjacent to mediastinum testis
      - Often bilateral
      - Variable echogenicity
      - ↑ vascularity on color Doppler

Radiographic Findings

- If untreated or undertreated, can have advanced bone age

Fluoroscopic Findings

- Voiding cystourethrogram
  - High prevalence of upper tract genitourinary malformations in girls, including vesicoureteral reflux, hydronephrosis, & duplex collecting systems
- Genitography can be performed with ambiguous genitalia
  - Females with CAH & ambiguous genitalia may have common urogenital sinus
  - Genitography shows urethra, external sphincter, presence or absence of vagina, urethrovaginal confluence, & cervix

CT Findings

- Bilateral, symmetric enlargement of adrenal glands
  - Usually maintains normal adreniform shape
  - Occasionally, adrenal gland has ovoid mass-like configuration
- Adrenal myelolipomas & adenomas may occur in adults

MR Findings

- Used to identify anatomy & morphology of female reproductive organs in setting of ambiguous genitalia
- Adrenal myelolipomas & adenomas may occur in adults
- Testicular adrenal rests
  - T1: Isointense to normal testicle
  - T2: Hypointense to testicle with well-defined margins
  - T1 C+: Homogeneous enhancement with well-defined margins
- MR is used to evaluate brain during acute adrenal crisis
  - May help to detect changes related to acute encephalopathy vs. stroke
  - MR is also used to detect chronic changes, including white matter abnormalities, smaller amygdala, & temporal lobe atrophy

Imaging Recommendations

- Best imaging tool
  - US for neonates with ambiguous genitalia or salt-wasting crisis
    - US confirms cerebriform appearance of enlarged adrenal glands
    - US can confirm presence of uterus & absence of testes
  - MR can be used for problem solving & to image brain during adrenal crisis

DIFFERENTIAL DIAGNOSIS

Normal Neonatal Adrenal Gland

- Normally enlarged due to hyperplasia of adrenal cortex

Neonatal Adrenal Hemorrhage

- Variably echogenic, heterogeneous, or cystic avascular mass due to perinatal bleeding into adrenal gland from stress

Neuroblastoma

- Most common adrenal mass in children
- Well-circumscribed & confined to adrenal vs. large lobulated & invasive mass that often calcifies, encases vessels, & crosses midline
- Internal vascularity is variable

Beckwith-Wiedemann Syndrome

- Disorder characterized by omphalocele, macroglossia, & hemihypertrophy
- ± adrenal enlargement with normal configuration

Wolman Disease

- Rare, autosomal recessive lipid storage disorder
- Enlarged adrenal glands with dystrophic Ca^{2+}

Polycystic Ovary Syndrome

- Polycystic ovarian morphology with clinical & endocrinologic dysfunction
- Significant overlap in imaging findings & clinical presentation with nonclassic CAH
  - Women with nonclassic CAH have higher hydroxyprogesterone & progesterone concentrations than women with polycystic ovary syndrome (PCOS)
  - Women with PCOS may have undiagnosed CAH

PATHOLOGY

General Features

- Etiology
  - Caused by deficiency in 1 of 5 enzymes required to synthesize cortisol from cholesterol in adrenal cortex
    - Deficiency of 21-hydroxylase is most common cause of CAH
      - Accounts for > 90% of cases of CAH
      - Caused by mutation in *CYP21A2* gene
      - Aldosterone & cortisol cannot be produced
      - Adrenal gland is chronically stimulated, leading to enlargement
    - Deficiency of 11β-hydroxylase is next most common enzyme affected
- Genetics
  - Autosomal recessive disorder

Gross Pathologic & Surgical Features

- Enlarged adrenal gland appears folded on itself
- Adrenal gland weighs 2-4x more than normal
- Glands are darker than normal due to depletion of lipid-rich cells of zona fasciculata

CLINICAL ISSUES

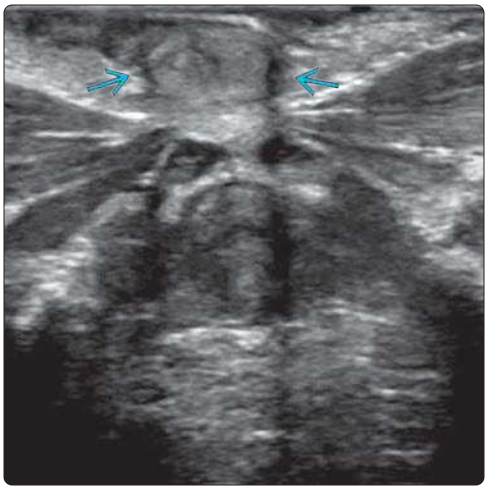
Presentation

- Most common signs/symptoms
  - CAH is part of normal neonatal screen in USA
  - 2 main types: Classic or nonclassic
  - Classic type: Presentation varies by sex
    - Females: Present at birth with ambiguous genitalia
      - Clitoromegaly, posterior fusion of labia majora, & masculinization of labioscrotal folds
      - May mimic penis with hypospadias
    - Males: Usually present at 5-14 days of life with acute salt-wasting crisis
      - Vomiting, weight loss, lethargy, severe dehydration, electrolyte imbalance, hypoglycemia, hypovolemia, & anion gap acidosis
      - May be misdiagnosed as hypertrophic pyloric stenosis
  - Nonclassic type most commonly presents with precocious puberty or hirsutism

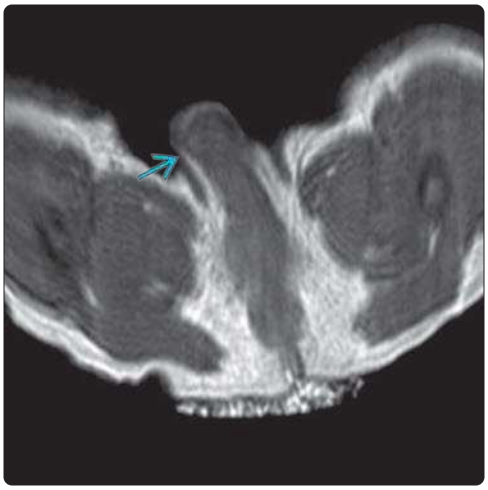
Demographics

- Epidemiology
  - Classic type occurs in 1 in 5,000-15,000 live births
    - Most common cause of ambiguous genitalia in females
  - Nonclassic type occurs in 1 in 1,000

Natural History & Prognosis



- Adrenal crisis is most common cause of early death
- Quality of life scores are ↓ compared to population
  - Major factors related to ↓ quality of life: Sexual function & ↓ fertility
- High prevalence of adrenal tumors in adults (73-83%)
  - Most common: Adenomas & myelolipomas



Treatment

- Treated with lifelong glucocorticoids to suppress secretion of corticotropin-releasing hormone + ACTH as well as to reduce androgen levels
- Patients require hydrocortisone in times of stress, such as illness or surgery
- Ongoing ethical debate regarding timing of genitoplasty in girls

(Left) *Transverse US of the labia in a newborn with ambiguous genitalia caused by CAH shows clitoromegaly.* **(Right)** *Axial T1 MR of the pelvis in the same patient shows clitoromegaly. Determining the infant's sex was not possible via imaging as gonadal structures were not visible. Ultimately, genetic testing confirmed 2 X chromosomes.*

(Left) *Color Doppler US of the left adrenal gland in a patient with CAH shows an enlarged gland with a cerebriform appearance & mild hyperemia.* **(Right)** *Lateral voiding cystourethrogram in a 1-week-old girl with CAH & ambiguous genitalia shows a genitourinary sinus with reflux of voided contrast into the vagina & uterus.*

(Left) *Axial CECT (performed after a motor vehicle accident) in a 14-year-old girl with CAH shows mild persistent enlargement & homogeneous enhancement of the bilateral adrenal glands.* **(Right)** *PA bone age radiograph of the left hand & wrist in an 8-year-old boy with CAH shows an advanced bone age of 13 years.*

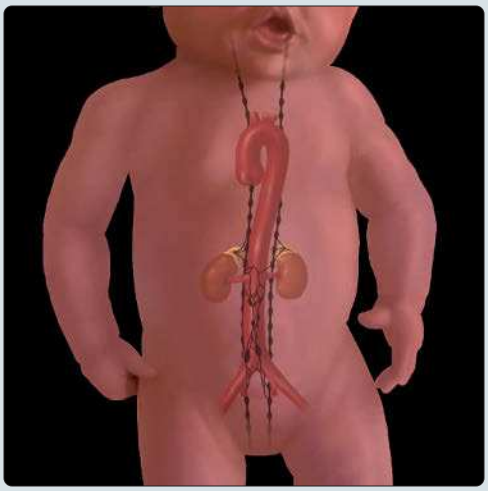
Neuroblastoma

KEY FACTS

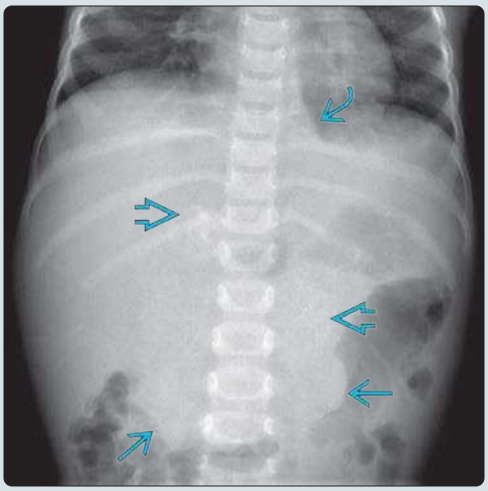
TERMINOLOGY

- Malignant tumor of sympathetic chain primitive neural crest cells
- Increasing degrees of cellular differentiation/benignity along spectrum: Neuroblastoma (malignant) → ganglioneuroblastoma → ganglioneuroma (benign)

IMAGING

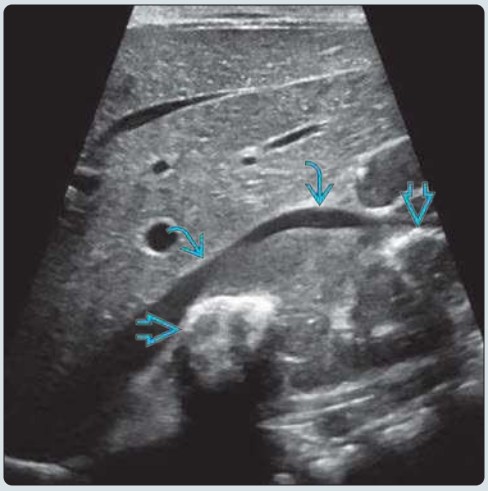


- Location
  - Adrenal (35-48%)
  - Extraadrenal retroperitoneum (18-35%)
  - Posterior mediastinum (14-20%)
  - Less common: Neck, pelvis, unknown primary
- Small round solitary mass vs. large multilobulated lesion
- Aggressive tumor with tendency to invade adjacent tissues
- Frequently engulfs & displaces adjacent vascular structures
- Ca^{2+} in up to 90% by CT
- Metastases in 50-60% at diagnosis, most commonly to bone/marrow, lymph nodes, liver, soft tissues



TOP DIFFERENTIAL DIAGNOSES

- Wilms tumor
- Neonatal adrenal hemorrhage
- Less common adrenal tumors
  - Adrenal cortical neoplasms
  - Pheochromocytoma
- Other cystic/solid suprarenal lesions



CLINICAL ISSUES

- Most common extracranial solid malignancy in children
- Median age at diagnosis: 15-19 months
- Wide variety of clinical presentations; most commonly presents as palpable abdominal mass
- Features associated with better prognosis
  - Age at diagnosis < 18 months
  - Stage 4S/MS
  - Localized tumor not involving vital structures
  - Absent *MYCN* (*N-myc*) oncogene amplification

(Left) *Graphic shows the anatomic extent of the sympathetic chain ganglia (including the adrenal glands) from the cervical region to the pelvis. Neuroblastoma (NBL) can arise anywhere along the sympathetic chain.* **(Right)** *AP radiograph in a 2-year-old with abdominal distention & pain shows displacement of bowel loops by a lobulated, partially calcified mass in the mid to upper abdomen. Note the widened left paraspinal stripe.*

(Left) *Longitudinal ultrasound in the same patient shows anterior displacement & narrowing of the inferior vena cava (IVC) by a partially calcified retroperitoneal mass.* **(Right)** *Axial CECT in the same patient shows elevation & encasement of the aorta by a large, lobulated, heterogeneous mass that crosses the midline & contains numerous calcifications, typical of NBL. The patient also had extensive bony metastases.*

TERMINOLOGY

Definitions

- Malignant tumor of sympathetic chain primitive neural crest cells
- Increasing degrees of cellular differentiation/benignity along spectrum: Neuroblastoma [(NBL), malignant] → ganglioneuroblastoma (GNBL) → ganglioneuroma [(GN), benign]

IMAGING

General Features

- Best diagnostic clue
  - Partially calcified, lobulated suprarenal/paraspinal mass in infant
- Location
  - Anywhere along sympathetic chain from neck to pelvis
    - Adrenal (35-48%)
      - 90% adrenal in prenatally detected cases
    - Extraadrenal retroperitoneum (18-35%)
    - Posterior mediastinum (14-20%)
    - Pelvis (2-5%)
    - Neck (1-5%)
    - Metastatic disease with no primary identified (1%)
  - 35% involve regional lymph nodes
  - 50% have distant metastases at diagnosis
    - May involve distant lymph nodes
- General imaging features
  - Small, round, solitary suprarenal/paraspinal mass vs. large, lobulated lesion crossing midline
  - Aggressive tumor; may invade adjacent tissues
    - Intraspinal invasion via neural foramina (~ 15%)
    - Kidney, muscle
  - Frequently engulfs & displaces adjacent vascular structures (rather than just displacing/compressing)
    - Aorta & inferior vena cava (IVC) are frequently lifted off of spine
  - Ca^{2+} in up to 90% by CT
  - Metastases in 50-60% at diagnosis, most commonly to bone/marrow, lymph nodes, liver, soft tissues
    - Liver: Well-defined focal vs. extensive, poorly defined lesions with hepatomegaly
    - Bone: Focally destructive, cortical &/or well-defined or confluent intramedullary lesions
    - Soft tissues: Cutaneous/subcutaneous lesions may be visible on physical exam & imaging

Radiographic Findings

- Often occult or subtle by radiographs
- Ca^{2+} in only 30% by radiography
- Displacement of bowel by soft tissue mass
- Widening of inferior thoracic paraspinal soft tissues
  - May be only finding of retrocrural extension of upper abdominal mass
- Subtle bony clues of soft tissue mass
  - Splaying/remodeling of adjacent ribs
  - Vertebral body scalloping, small pedicle
- Bone metastasis
  - May be extensive with little radiographic presence (especially marrow disease)
  - May be only presenting clinical/imaging finding

CT Findings

- Mass is often heterogeneous from necrosis, hemorrhage
- Ca^{2+} in up to 90% by CT

MR Findings

- Generally intermediate to high T2/intermediate to low T1 signal intensity
  - Heterogeneity from Ca^{2+}, hemorrhage, necrosis
- Variable enhancement from none to diffuse
- Typically restricts diffusion due to high cellularity
- Excellent depiction of intraspinal extension
- High sensitivity/specificity for marrow disease (but ↓ specificity posttherapy)

Ultrasonographic Findings

- Mass is often heterogeneous
  - Ca^{2+} causing echogenic foci ± posterior shadowing
- Suprarenal location displaces/distorts kidney
- Variable internal tumor vascularity on Doppler
- Vessels are often engulfed/lifted by tumor

Nuclear Medicine Findings

- MIBG scintigraphy
  - I-123 MIBG for diagnosis, staging, follow-up imaging
  - MIBG is related to norepinephrine → avid uptake in catecholamine production process
  - ↑ uptake at any site of active NBL
    - Sensitivity & specificity ~ 90% in NBL
  - Evaluates bony cortical & marrow disease
  - In MIBG-avid tumors, posttherapy evaluation is more specific than MR or FDG PET
- PET
  - 18-F FDG remains primary radiotracer
    - High sensitivity for soft tissue & bony NBL, though generally < MIBG
      - Select populations may benefit from PET, particularly non-MIBG-avid disease
  - DOTATATE
    - Somatostatin receptor analog, typically bound with Ga-68
      - May lead to targeted therapies
- Bone scan
  - Tc-99m MDP
    - Uptake in primary mass in up to 74% of cases
    - ↑ uptake in bony metastasis (cortical > marrow)
  - Limited role in current era

DIFFERENTIAL DIAGNOSIS

Wilms Tumor

- Mean age: 3 years; Ca^{2+} is uncommon
- Usually grows like ball, displacing vessels
- Arises from kidney: Claw sign of residual renal parenchyma splayed along tumor
- Lung metastases in 20%
- Invasion of renal vein + IVC

Neonatal Adrenal Hemorrhage

- Cystic &/or solid-appearing avascular suprarenal mass
- Serial US exams show gradual ↓ in size with ↑ Ca^{2+}

Less Common Adrenal Tumors

- Pheochromocytoma (uncommon in young children)
- Adrenal cortical neoplasms (usually hormonally active)

Other Cystic/Solid Suprarenal Lesions

- Congenital adrenal hyperplasia
- Extralobar bronchopulmonary sequestration
- Foregut duplication cyst
- Lymphatic malformation

PATHOLOGY

General Features

- Genetics
  - ↑ copies of *MYCN* oncogene (*MYCN* or *N-myc* amplification): Unfavorable prognosis (even stage MS)
  - *ALK* mutation/amplification: Unfavorable
  - Segmental chromosome aberrations (loss at 1p, 3p, 11q, 14q): Unfavorable
  - DNA index (measure of ploidy)
    - Diploidy or tetraploidy: Unfavorable
    - 1.26-1.76 (near triploid): Favorable
  - Only 1-2% of cases are familial, often with multiple primary tumors in infants
- Associated abnormalities
  - Neurofibromatosis type 1, Beckwith-Wiedemann syndrome, Hirschsprung disease, congenital central hypoventilation syndrome, Turner syndrome
  - Most NBL cases occur in children without associations

Staging, Grading, & Classification

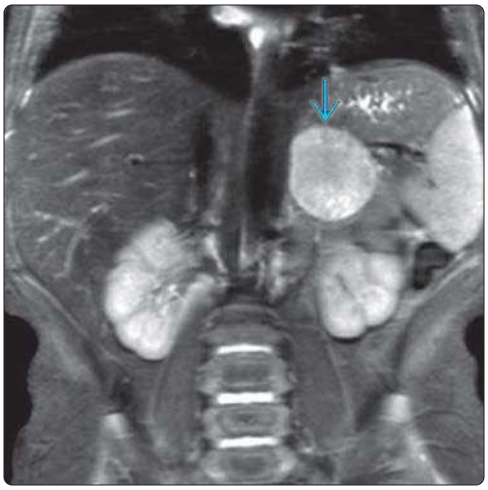
- International NBL Staging System (INSS)
  - Original 1-4S system based on resection & pathology (1988, 1993)
  - Traditionally used by Children's Oncology Group (COG) to risk stratification as low, intermediate, or high
- International NBL Risk Group Staging System (INRGSS)
  - More comprehensive, imaging-based system (2009)
  - Utilizes modifying image-defined risk factors
    - L1: Tumor in 1 body compartment, no vital structures involved
    - L2: Tumor in 2 body compartments **or** encasing/invading major structures; rarely resectable at diagnosis
    - M: Distant metastases
    - MS: Age < 18 months; metastases confined to skin, liver, bone marrow
      - Bones (including marrow) must be clear by MIBG to qualify for stage 4S/MS (with marrow disease limited to < 10% involvement by biopsy)
  - Used to stratify as very low, low, intermediate, or high risk in conjunction with age, genetics, histology
    - High risk: *MYCN* amplification, metastases if ≥ 18 months of age; additional criteria by some systems
    - "Ultra high risk": Potential, evolving category

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Painless abdominal mass
- Other signs/symptoms
  - Malaise, irritability, weight loss, limping, opsoclonus-myoclonus, Horner syndrome, cerebellar ataxia, neurologic symptoms related to compression, hypertension, watery diarrhea with hypokalemia
  - Classic presentations
    - Skin metastases: Blueberry muffin syndrome
    - Skull base metastases: "Raccoon eyes"
    - Massive liver metastases: Pepper syndrome
  - 90-95% of NBL patients have elevated levels of catecholamines/metabolites (VMA, HVA) in urine

Demographics



- Age
  - Median age at presentation: 15-19 months
  - 95% diagnosed by 7 years
  - May be diagnosed prenatally
- Epidemiology
  - Most common extracranial solid malignancy in children
    - Most common malignancy of infancy

Natural History & Prognosis

- Risk stratification: Criteria vary by cooperative groups & trials; COG version includes
  - Low risk (30% of all NBL, 70% of neonatal NBL): 5-year survival > 95% with observation (select cases) or surgery
    - Spontaneous regression most likely in
      - Infants < 6 months of age with small adrenal lesions
      - Non-*MYCN* amplified infants with localized disease or asymptomatic 4S/MS disease
  - Intermediate risk (20% of all NBL): 5-year survival > 90% with surgery + chemotherapy
  - High risk (36-50% of all NBL): 5-year survival of 30-40% with intensive multimodality therapy
    - May also use radiation therapy, myeloablative therapy with stem cell rescue, molecular inhibitors, antibodies, &/or I-131 MIBG therapy, especially for refractory/recurrent disease
- Risk stratification by INRGSS
  - Very low risk: 5-year event-free survival (5y EFS) of > 85%
  - Low risk: 75-85%
  - Intermediate risk: 50-75%
  - High risk: < 50%
  - Ultra high risk: Evolving category that typically includes
    - Anything < very good partial response to induction chemotherapy
    - 5y EFS of < 15%; death < 18 months from diagnosis

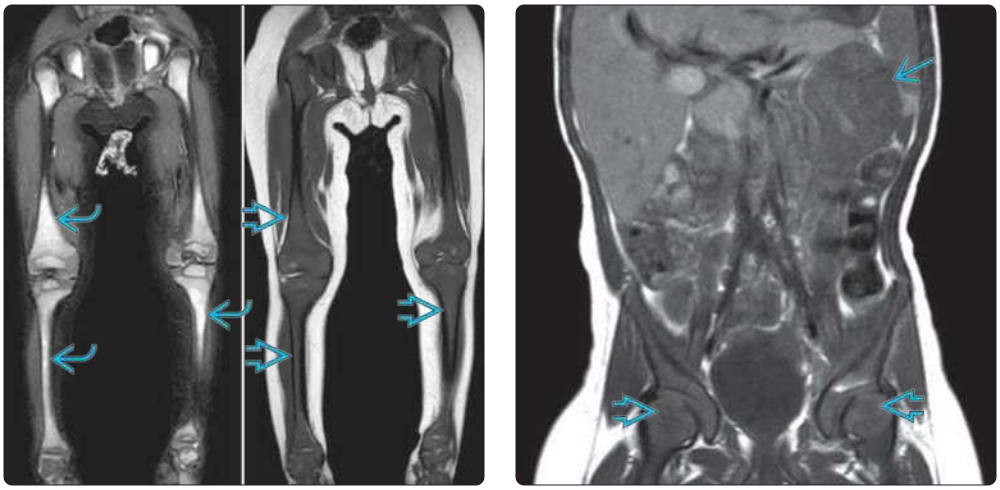
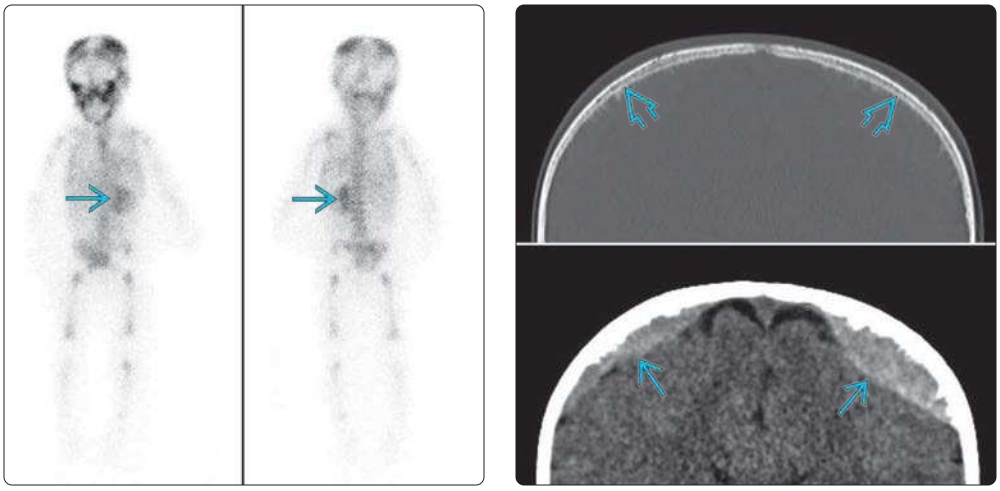
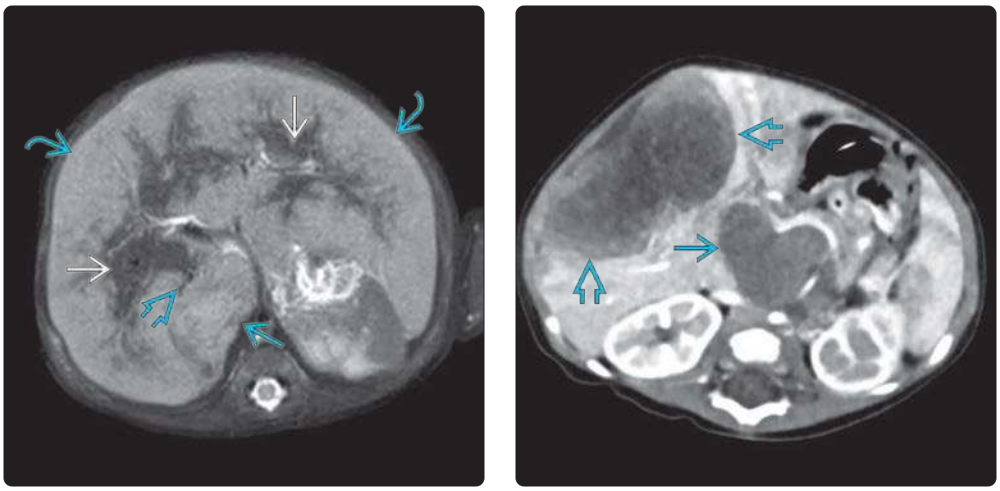
(Left) *Coronal STIR MR in a 4-month-old shows a hyperintense, round, well-circumscribed left suprarenal mass that was incidentally detected on a renal ultrasound & ultimately confirmed as NBL.* **(Right)** *Coronal STIR MR in an 11-month-old shows a mildly heterogeneous mass in the left psoas muscle, subsequently confirmed as NBL. The mass was incidentally detected as a region of heterogeneous paraspinal echogenicity on a renal ultrasound.*



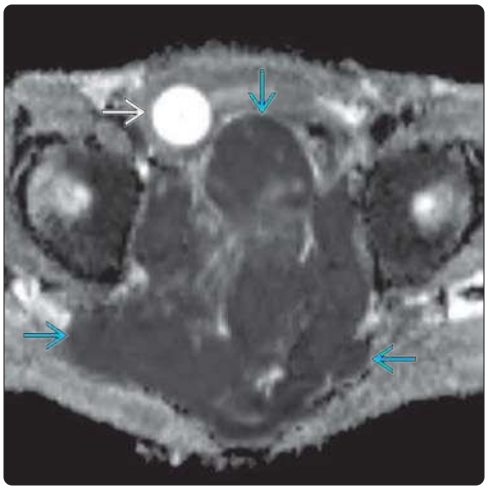
(Left) *Anterior & posterior I-123 MIBG scans in a 2-year-old NBL patient show uptake throughout the primary tumor in the right abdomen as well as numerous foci of skeletal metastases. Note that the skeleton is not normally visualized with MIBG, making all foci of bony uptake in these images consistent with metastatic disease.* **(Right)** *F-18 FDG PET & fused PET/CT images in the same patient show ↑ metabolic activity within the primary tumor as well as numerous sites of skeletal disease.*



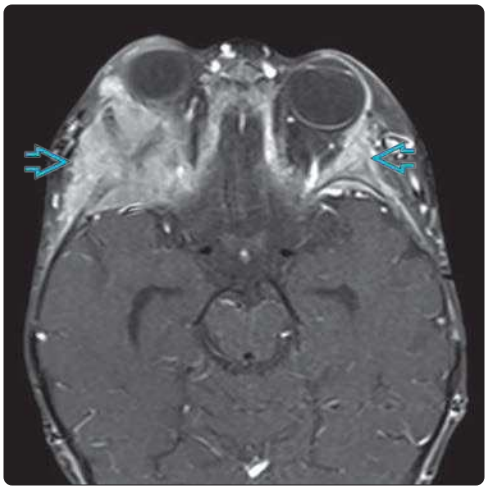
(Left) *AP radiograph in a 7-week-old with abdominal distention shows a lobulated left apical mass with marked rightward shift of the trachea. Note that no stomach bubble is seen in the upper abdomen.* **(Right)** *Sagittal SSFSE T2 MR in the same patient shows a primary cervicothoracic NBL with multilevel neuroforaminal involvement. The liver is enlarged & heterogeneous due to hyperintense metastases.*



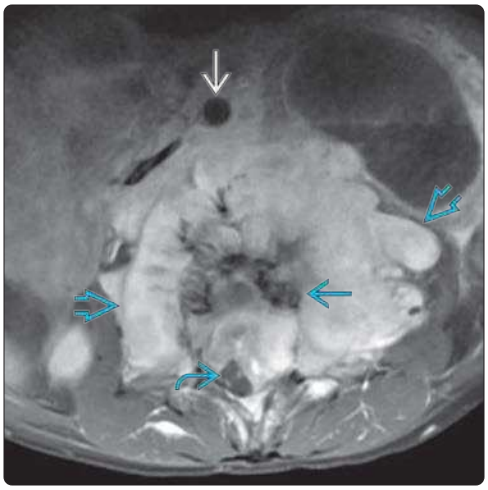
(Left) *Coronal STIR (left) & T1 (right) MR images in a 19-month-old with limping for 5 weeks show extensive confluent marrow signal abnormalities that are diffusely bright & dark, respectively.* **(Right)** *Coronal T1 MR in the same patient shows loss of the normal yellow marrow bright signal in the femoral heads due to metastases. Portions of the primary tumor are visualized in the left upper quadrant.*

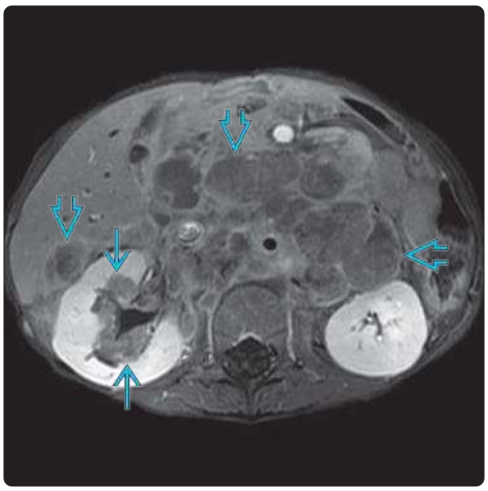


(Left) *Anterior (left) & posterior (right) I-123 MIBG images in the same patient show uptake in the primary left upper quadrant neuroblastoma. As the bones should not be visualized on an MIBG scan, the osseous activity is due to metastases, most pronounced in the skull.* **(Right)** *Coronal NECT images in the same patient in bone (top) & brain (bottom) windows show a spiculated pattern of new bone formation within the soft tissue masses. This appearance is typical of metastatic NBL in the skull.*



(Left) *Axial T2 FS MR in a newborn with abdominal distention shows a confluent rind of hyperintense tissue encasing small residual islands of normal liver parenchyma. The IVC is effaced between the liver & a right adrenal NBL that is otherwise inseparable from the liver metastases.* **(Right)** *Axial CECT in a 4-month-old with abdominal distention shows the largest of several well-circumscribed hepatic metastases from a retroperitoneal NBL.*





(Left) *Sagittal T1 C+ FS MR in a 7-year-old with back pain & urinary symptoms shows a heterogeneously enhancing presacral mass with bone involvement & intraspinal extension. The urinary bladder is anteriorly displaced & decompressed around a Foley catheter.* **(Right)** *Axial MR ADC map in the same patient at the level of the hips shows restricted diffusion throughout the NBL. The Foley catheter balloon is displaced anteriorly.*

(Left) *Axial T1 C+ FS MR in a 2-year-old with proptosis shows homogeneously enhancing soft tissue masses of the R > L greater sphenoid wings secondary to NBL metastases.* **(Right)** *Axial T1 C+ FS MR in 4-year-old with an abnormal gait shows a large, lobulated enhancing mass emanating from a permeated vertebral body, displacing the aorta & compressing the thecal sac. NBL was proven at biopsy.*

(Left) *Axial T1 C+ FS MR in a 5-year-old with constipation & weight loss shows numerous hypoenhancing retroperitoneal & peritoneal NBL nodules with invasion of the right kidney.* **(Right)** *Axial T2 FS MR in a 7-year-old with NBL shows complete replacement of the pancreatic parenchyma by confluent nodular masses. Pancreatic NBL lesions may occur from direct local invasion or distant metastases.*

Adrenocortical Carcinoma

KEY FACTS

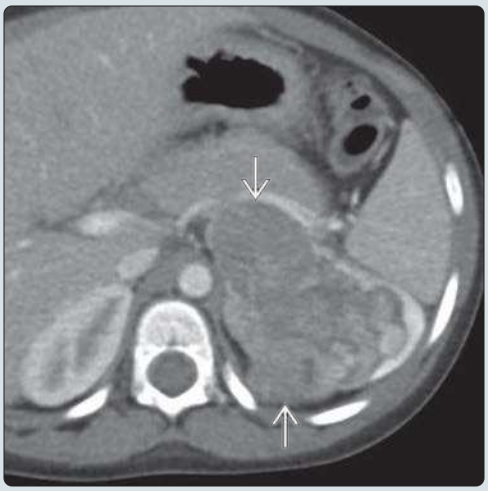
TERMINOLOGY

- Malignant adrenal cortical neoplasm

IMAGING

- Best clue: Suprarenal mass in young child with virilization or Cushing syndrome
- Average size: 7-10 cm (median: 9.5 cm)
- Well-defined mass with thin, enhancing rim
- Heterogeneous internal enhancement
- Central stellate focus: Low attenuation (CT) or high signal (T2 FS MR) without enhancement after contrast
- Ca^{2+} in ~ 70% of masses
- May invade IVC
- Sites of metastasis: Liver, lungs, lymph nodes
  - Occur in ~ 80% of patients older than 4 years of age

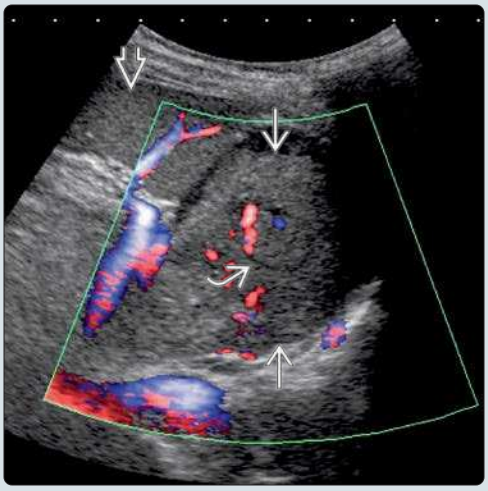
TOP DIFFERENTIAL DIAGNOSES



- Neuroblastoma
- Adrenal hemorrhage
- Adrenal adenoma
- Pheochromocytoma

PATHOLOGY

- Associated with Li-Fraumeni & Beckwith-Wiedemann syndromes
- Up to 80% have mutation of *TP53* gene
- Wienecke criteria: Best predictor of clinical outcomes in children



CLINICAL ISSUES

- Median age of 4 years; bimodal distribution in children
  - < 4 years of age vs. 2nd peak in adolescence
- Hormonally active
  - Virilization in 75-95% of patients
  - Cushing syndrome in up to 60%
- Prognosis is better than in adults
- Treatment of choice: Complete surgical excision

(Left) *Axial CECT of the abdomen shows a large mass arising from the left adrenal gland. The mass is typical of adrenocortical carcinoma (ACC) with a heterogeneous enhancement pattern & a thin rim of tissue that enhances more than the central components.* **(Right)** *Axial T2 FS MR of the abdomen in the same patient with ACC shows a heterogeneous mass that is hyperintense to the liver. The tumor has a poorly defined central stellate focus that is hyperintense to the remainder of the tumor.*

(Left) *Longitudinal color Doppler ultrasound in the same patient with ACC shows a large left suprarenal mass that is isoechoic to the adjacent spleen. There is a subtle central stellate focus that is hypoechoic compared to the remainder of the tumor.* **(Right)** *Coronal PET/CT in a toddler with virilization shows intense FDG uptake throughout the majority of a left suprarenal mass that is displacing the left kidney inferiorly. Histology confirmed an ACC.*

TERMINOLOGY

Abbreviations

- Adrenocortical carcinoma (ACC)

Definitions

- Malignant adrenal cortical neoplasm

IMAGING

General Features

- Best diagnostic clue
  - Suprarenal mass in young child with virilization or Cushing syndrome
- Location
  - Adrenal cortex
  - Metastasis to liver, lungs, lymph nodes
    - Occur in ~ 80% of patients > 4 years of age
- Size
  - At presentation: 7-10 cm (median: 9.5 cm)

CT Findings

- Well-defined mass with thin, enhancing rim
- Heterogeneous internal enhancement
  - Central stellate focus of low attenuation is common
- Ca^{2+} in ~ 70%

MR Findings

- T1WI
  - Heterogeneous mass, isointense to muscle
- T2WI FS
  - Variable signal intensity: Iso-/hyperintense to fat
  - ± central stellate focus: Hyperintense to fat
- T1WI C+
  - Heterogeneous enhancement pattern
  - Central stellate focus does not enhance

Ultrasonographic Findings

- Slightly hyperechoic suprarenal mass
- Central stellate focus is often hypoechoic
- Inferior vena cava (IVC) compression or invasion

DIFFERENTIAL DIAGNOSIS

Neuroblastoma

- Most common pediatric adrenal neoplasm
  - Arises from medulla, not cortex
- No hormonal changes
- Uptake on I-123 MIBG scans

Adrenal Hemorrhage

- Most common in neonatal age group (due to birth stress)
- No internal vascularity
- Regresses with time

Adrenal Adenoma

- Benign cortical neoplasm; uncommon in children
- Pathologic/radiologic spectrum with ACC; malignancy is favored with
  - Larger, heterogeneously enhancing tumors with Ca^{2+}
  - Distant metastases
  - FDG avidity on PET/CT

Pheochromocytoma

- Uncommon in younger children
- Typically causes hypertension
- Small, round suprarenal mass; hyperintense on T2 MR
- Uptake on I-123 MIBG scans

PATHOLOGY

General Features

- Associated abnormalities
  - Li-Fraumeni syndrome
  - Beckwith-Wiedemann syndrome
  - Other syndromes associated with ACC: Carney complex, congenital adrenal hyperplasia, McCune-Albright syndrome, & multiple endocrine neoplasia type 1

Staging, Grading, & Classification

- Various pathology-based systems for determining benignity vs. malignancy of adrenal cortical neoplasm
  - Weiss & Wienecke criteria are most commonly used
    - Wienecke criteria has shown to be better predictor of clinical outcomes in children

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Virilization occurs in 75-95%
- Other signs/symptoms
  - Cushing syndrome: ~ 60% (less common than in adults)
  - Other symptoms: Abdominal mass, hypertension

Demographics

- Epidemiology
  - 0.2% of all childhood cancers
    - 15x incidence in Southern Brazil due to higher frequency of *TP53* germline mutation
  - Median age: 4 years; bimodal distribution in children
    - < 4 years of age vs. 2nd peak in adolescence

Natural History & Prognosis

- 5-year survival rates: ~ 50%
- Factors improving prognosis
  - Age < 4 years
  - Tumor size < 10 cm
  - Tumor weight < 400 g
  - Lack of distant metastases

Treatment

- Complete surgical excision
- Chemotherapy if complete resection is not possible

Pheochromocytoma

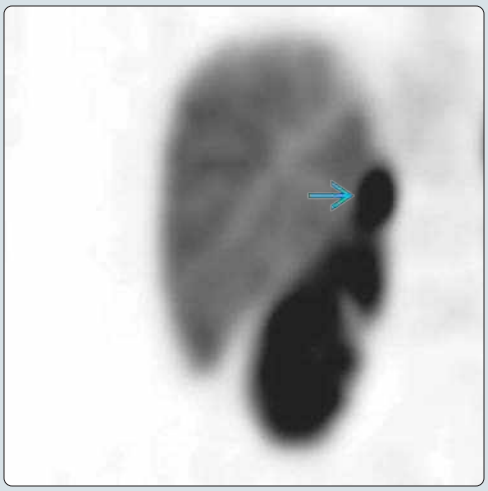
KEY FACTS

TERMINOLOGY

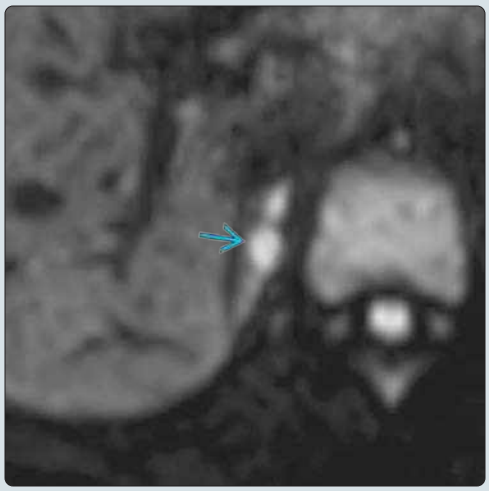
- Paraganglioma arising from catecholamine-producing chromaffin cells of adrenal medulla
- Associated with
  - Mutations in succinate dehydrogenase
  - von Hippel-Lindau syndrome
  - Multiple endocrine neoplasia syndrome type 2
  - Neurofibromatosis type 1

IMAGING

- Best diagnostic clue: Suprarenal mass in child with hypertension
- CECT: Avidly enhancing adrenal mass
- MR
  - T1: Isointense to muscle
  - T2: Mildly to moderately hyperintense vs. "light bulb bright"
  - T1 C+: Avidly enhancing mass
- MIBG: ↑ uptake in tumor

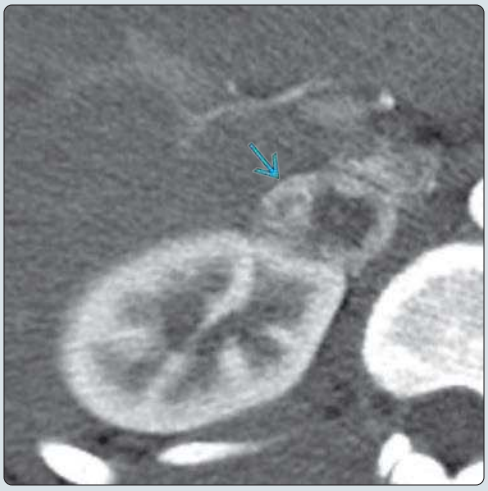


TOP DIFFERENTIAL DIAGNOSES

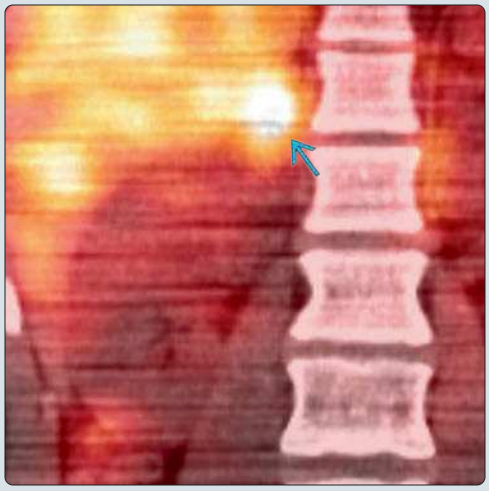


- Neuroblastoma
- Adrenocortical carcinoma
- Adrenal adenoma

CLINICAL ISSUES



- Responsible for ~ 1.5% of pediatric hypertension
  - Sustained hypertension in 63%
  - Headache, sweating, flushing, palpitations, blurred vision, syncope, panic attacks, tremor, & weight loss
- Mean age: 11-13 years
- Diagnostic test of choice: Plasma or urine metanephrine
- Bilateral tumors in 19-38% of patients
- Malignant in up to 50% of pediatric patients
  - No histologic criteria for malignancy
- Treatment: Surgical excision of primary mass
  - α- & β-blockers to block effect of catecholamines



(Left) *Coronal Ga-68 DOTATATE PET in a young adult with multiple endocrine neoplasia (MEN) 2a shows intense uptake of the radiopharmaceutical in a right adrenal pheochromocytoma. This agent is useful for neuroendocrine tumors, which generally have ↑ somatostatin receptors.* **(Right)** *Axial DWI MR in the same patient shows restricted diffusion in the small pheochromocytoma of the right adrenal gland.*

(Left) *Axial CECT in an adolescent with pheochromocytoma shows a heterogeneously enhancing mass at the inferior aspect of the right adrenal gland.* **(Right)** *Coronal fused MIBG SPECT CT in the same patient shows MIBG uptake within the right suprarenal pheochromocytoma. MIBG scans are used to identify tumors that manufacture catecholamines.*

TERMINOLOGY

Definitions

- Paraganglioma arising from catecholamine-producing chromaffin cells of adrenal medulla

Associated Syndromes

- Hereditary predisposition in up to 40%
  - Mutations in succinate dehydrogenase (SDH), von Hippel-Lindau syndrome, multiple endocrine neoplasia type 2, & neurofibromatosis type 1
- Identifiable germline mutation in 70-80% of patients

IMAGING

General Features

- Best diagnostic clue
  - Suprarenal mass in child with hypertension
- Location
  - Adrenal gland

Ultrasonographic Findings

- Suprarenal soft tissue mass
- Iso- to hypoechoic to liver

CT Findings

- CECT
  - Homogeneously enhancing adrenal mass
  - Nonionic contrast material does not incite hypertensive crisis → premedication is not required

MR Findings

- T1: Isointense to muscle
  - No signal drop on opposed-phase images
- T2: Mildly to moderately hyperintense vs. "light bulb bright"
- T1 C+: Avid enhancement, prolonged washout
  - May have salt & pepper appearance with enhancing tumor & vascular flow voids
  - Larger lesions are more likely heterogeneous

Nuclear Medicine Findings

- PET/CT
  - Useful in searching for extraadrenal tumors or metastases
  - F-18 FDG PET is less sensitive & specific than MIBG scintigraphy
  - Ga-68 DOTATATE PET/CT is more sensitive than F-18 FDG PET
    - Identifies neuroendocrine tumors with somatostatin receptors
- MIBG scintigraphy
  - I-123 is used in children
  - ↑ uptake in tumors that produce catecholamines
  - Very specific but less sensitive than CT or MR
  - Useful in searching for extraadrenal tumors or metastases

Imaging Recommendations

- Best imaging tool
  - MR due to lack of ionizing radiation
  - MIBG or whole-body MR to identify extraadrenal tumor

DIFFERENTIAL DIAGNOSIS

Neuroblastoma

- Most common adrenal tumor in children
- Median age of presentation: 15-17 months
- Often large, multilobulated mass crossing midline; displaces & encases vessels; Ca^{2+} in ~ 85-90%
- MIBG for diagnosis & staging

Adrenocortical Carcinoma

- Large, heterogeneous adrenal mass causing virilization or precocious puberty in young child; ± inferior vena cava invasion

Adrenal Adenoma

- Smaller homogeneous mass with intracellular lipid
  - Signal drop-out on opposed-phase MR imaging

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Sustained hypertension in 63%
  - Symptoms of mass effect in up to 30%
- Other signs/symptoms
  - Headache, sweating, flushing, palpitations, blurred vision, syncope, panic attacks, tremor, & weight loss
  - Paroxysmal episodes: Headaches, palpitations, diaphoresis
  - Complications: Cardiomyopathy, hypertensive crisis, cardiovascular accidents, & seizures
- Laboratory tests
  - Diagnostic test of choice: Plasma or urine metanephrine

Demographics

- Age
  - Mean age: 11-13 years
- Epidemiology
  - Most common pediatric endocrine tumor
  - Responsible for ~ 1.5% of pediatric hypertension
  - Bilateral tumors in ~ 19-38% of patients

Natural History & Prognosis

- Malignant in up to 50% of pediatric patients
- No histologic criteria for malignancy
  - Malignancy determined by local tumor invasion or metastases (bones, lungs, liver)

Treatment

- Surgical excision of primary mass
  - Pretreatment with α- & β-blockers is required to block effect of catecholamines

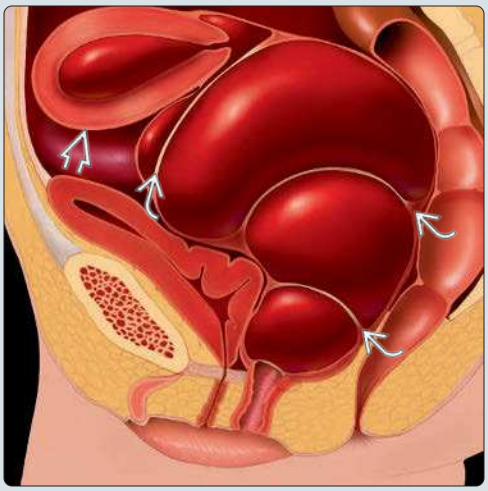
Hydrometrocolpos

KEY FACTS

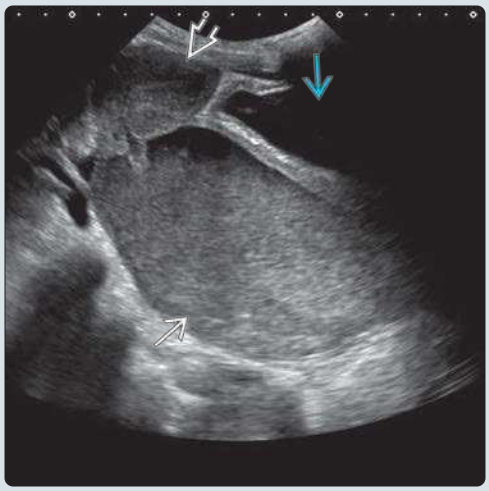
TERMINOLOGY

- Dilation of vagina ± uterus secondary to distal stenosis, atresia, transverse vaginal septum, or imperforate hymen
  - Prefix: "Hydro-" meaning fluid, "hemato-" meaning blood
  - Suffix: "-metra" meaning uterine cavity
  - Suffix: "-metrocolpos" meaning uterus & vagina

IMAGING

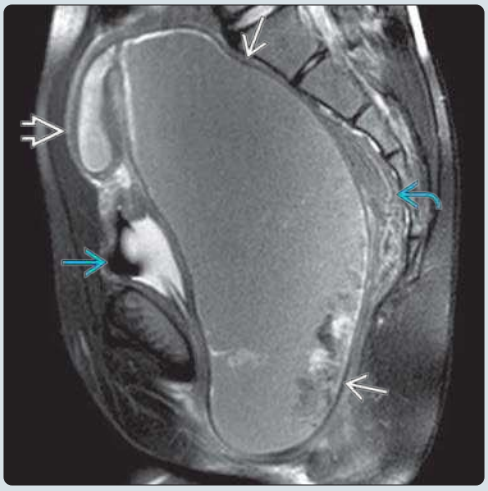


- Well-defined, cystic or debris-filled mass in female pelvis between urinary bladder & rectum
- Vertically oriented in sagittal plane, round in axial plane
- Uterus is frequently visible arising from dome of collection; may be normal or mildly distended (much less than vagina)
- US may show trilaminar appearance of vaginal wall, swirling internal debris, lack of internal vascularity
- MR often shows aging blood product signal intensities (↑ T1, ↓ T2); can help discern uterine & vaginal anomalies
- Urinary bladder or ureters may be obstructed
- Check for associated renal anomalies: Unilateral renal agenesis or secondary hydronephrosis
- Primary imaging modality for female genitourinary (GU) anomalies: US
- MR is used when uterine & complex GU anomalies cannot be clearly defined with US

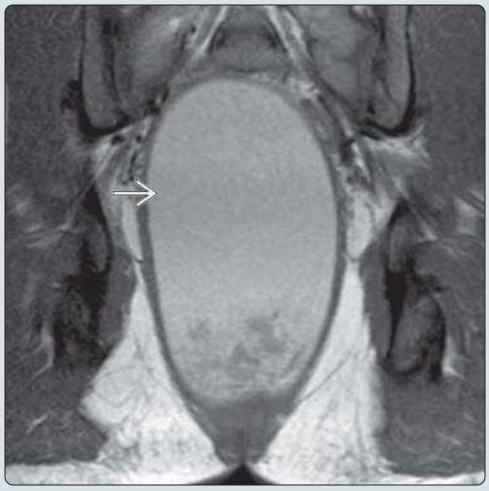


PATHOLOGY

- Imperforate hymen is more common cause of obstruction than vaginal septum
- ± associated anal, renal, vertebral, & cardiac anomalies



CLINICAL ISSUES



- Bimodal age of presentation
  - Infants (due to maternal hormonal stimulation): Pelvic mass, sepsis, or urinary tract obstruction
    - Vaginal contents are more likely mucous, fluid
  - Adolescent girls (pubertal onset): Delayed menarche, cyclic pelvic pain, mass, &/or urinary tract obstruction
    - Vaginal contents are more likely blood

(Left) *Lateral graphic shows potential levels of vaginal septa causing obstruction & hydro-/hematometrocolpos. Note that the vagina distends to a much greater degree than the uterus.* **(Right)** *Longitudinal transabdominal US through the pelvis of a 12-year-old girl with urinary retention, cramping, & no history of menses shows a large, well-marginated, heterogeneous collection posterior to the urinary bladder, suggestive of hematometrocolpos. The uterus is slightly anteflexed but not distended.*

(Left) *Sagittal T2 FS MR in the same patient shows a markedly distended vagina containing heterogeneous fluid & layering debris. The uterus projects anteriorly & is much less distended than the vagina, findings typical of hematometrocolpos. Note the mass effect on the urinary bladder & rectum.* **(Right)** *Coronal T1 MR in the same patient shows that the fluid in the vagina is predominantly hyperintense, typical of blood products. A vaginal septum was resected, relieving the obstruction.*

TERMINOLOGY

Abbreviations

- Hydrometrocolpos (HMC)

Synonyms

- Hematometrocolpos, hydrometra, hematometra

Definitions

- Dilation of vagina or vagina & uterus secondary to distal stenosis, atresia, transverse vaginal septum, or imperforate membrane
  - Prefix: "Hydro-" meaning fluid, "hemato-" meaning blood
  - Suffix: "-metra" meaning uterine cavity
  - Suffix: "-metrocolpos" meaning uterus & vagina

IMAGING

General Features

- Best diagnostic clue
  - Well-defined, cystic or debris-filled vertically oriented mass in pelvis, between bladder & rectum
  - Can cause secondary bladder outlet obstruction with hydronephrosis
- Location
  - Between bladder & rectum
- Size
  - Variable; can be very large & simulate mass or early pregnancy in teenage girls
- Morphology
  - Vertically oriented on sagittal & coronal images, round on axial images
- Classic imaging appearance: Echogenic debris filling dilated vagina & (to lesser extent) uterus, creating mass effect in pelvis
  - Vagina has elastic walls & can dilate more than uterus
- Can be associated with müllerian duct fusion anomalies, particularly uterus didelphys

Radiographic Findings

- Soft tissue mass in pelvis displacing bowel loops
- Case reports of peritoneal Ca^{2+}, presumably from debris spilling out of fallopian tubes

Ultrasonographic Findings

- Grayscale ultrasound
  - Echogenic, layering debris in large, well-defined cavity between urinary bladder & rectum
    - Distended vaginal walls may have trilaminar appearance, mimicking gut signature sign
    - Fluid in vagina will typically swirl with mild compression
  - Relatively small uterus is frequently visible arising from dome of collection
    - Look for variable uterine distention (typically much less than vagina)
    - Look for associated müllerian duct fusion anomalies
  - Urinary bladder & ureters may be dilated from secondary bladder outlet or ureteral compression
  - Also confirm presence of both kidneys, look for secondary hydronephrosis
- Color Doppler
  - Useful to confirm lack of blood flow within debris-filled cavities, as complex blood (especially acute) may appear solid on US

CT Findings

- CECT
  - Vertically elongated, fluid-filled cavity with enhancing walls originating deep in pelvis
    - Appears round on axial images
  - Displaces bladder, rectum, & small bowel
  - Enhancing uterus extends from cephalad aspect of collection
    - Scrutinize uterus for associated malformations

MR Findings

- MR findings are similar to CECT
- Aging blood components may have characteristic signal intensity (↑ T1, ↓ T2)
- Multiplanar imaging is useful to optimally profile uterine & cervical anomalies
  - Consider planes oriented to uterus

Other Modality Findings

- Percutaneous/transvaginal drainage if septic or complex care
- Rarely, hysterosalpingography or sonohysterography is performed in convalescent phase to reevaluate uterine morphology

Imaging Recommendations

- Best imaging tool
  - US is best initial imaging modality for suspected genitourinary (GU) pathology in female
  - MR is used when uterine & complex GU anomalies cannot be clearly defined with US
    - Consider delaying MR exam to convalescent phase, after fluid & debris have been drained

DIFFERENTIAL DIAGNOSIS

Perforated Appendicitis

- Poorly defined inflammatory collection of right lower quadrant
- May visualize appendiceal remnant, appendicolith

Meconium Pseudocyst

- Heterogeneous peritoneal collection (± Ca^{2+}) in newborn, typically secondary to in utero bowel perforation
- Dilated bowel is usually still present

Lymphatic Malformation

- Infiltrative multicystic mass with thin septations
- Individual compartments show varying complexity, typically due to hemorrhage

Pelvic Abscess

- Heterogeneous adnexal collection with surrounding inflammation
- Unlikely in newborn
- In adolescents, consider pelvic inflammatory disease

Fallopian Tube Torsion, Cyst, or Obstruction

- Tubular fluid collection with folds

Pelvic Rhabdomyosarcoma

- Sarcoma botryoides protrudes into vagina ("cluster of grapes")

Other Pelvic Masses

- Sacrococcygeal teratoma
- Burkitt lymphoma
- Pelvic neuroblastoma

PATHOLOGY

General Features

- Etiology
  - Embryology-anatomy: Failure of canalization with stenosis or atresia along lumen
  - In infancy, maternal hormone effects stimulate neonatal uterus & vagina
- Genetics
  - Generally sporadic; not inherited
  - McKusick-Kaufman syndrome
    - Rare multiple autosomal recessive syndrome
      - HMC
      - Postaxial polydactyly
      - Congenital heart malformation
  - Bardet-Biedl syndrome, a.k.a. Laurence-Moon syndrome
    - Also has HMC & postaxial polydactyly with retinitis pigmentosa, obesity, & learning disability becoming apparent by early school age
    - Inherited as autosomal recessive trait
- Associated abnormalities
  - Associated anal, renal, vertebral, & cardiac anomalies are most common
  - Also associated with intestinal aganglionosis, imperforate anus, urogenital sinus, cloacal anomalies
  - Can be associated with müllerian duct fusion anomalies, particularly uterus didelphys
    - Obstructed hemivagina & ipsilateral renal anomaly (OHVIRA), a.k.a. Herlyn-Werner-Wunderlich syndrome
      - Uterus didelphys, cervicovaginal obstruction, unilateral renal agenesis
  - Iatrogenic cases have been reported due to malposition of artificial urinary sphincter in prepubertal girls
- Site of obstruction can be
  - Imperforate hymen
  - Vaginal stenosis or atresia
  - Cervical stenosis or atresia
  - Mass effect from duplications of uterus & vagina (didelphys)
  - Transverse vaginal septum
    - Most common location: Between middle & upper 1/3 of vagina
    - These patients have functional uteri, though fertility can be compromised
- Secondary urinary obstruction can occur at level of
  - Urethra, ureterovesical junction, ureter

Gross Pathologic & Surgical Features

- Debris contents
  - In fetal life & infancy, contents are primarily of cervical mucus (mucocolpos or hydrocolpos)
    - Maternal estrogen stimulates cervical mucus production & causes swelling of labia minora
  - Peripubertal contents are typically blood, sloughed endometrial lining, & cervical/vaginal mucus

CLINICAL ISSUES

Presentation

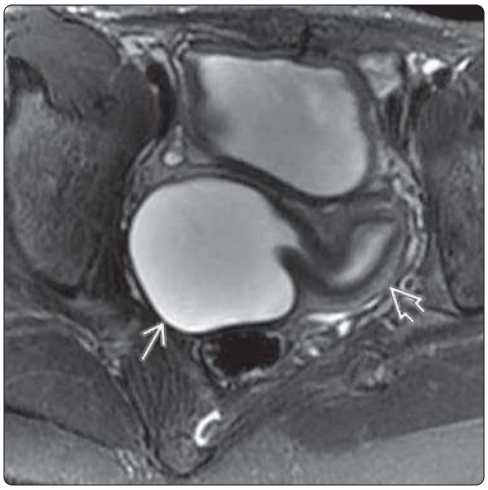
- Most common signs/symptoms
  - In infancy: Presents as pelvic mass, sepsis, or urinary tract obstruction
  - In adolescent girls: Presents as delayed menarche, cyclic pelvic pain, mass, &/or urinary tract obstruction
- Other signs/symptoms
  - Occasionally presents as prolapsing interlabial mass
  - In utero urinary tract obstruction from massive HMC can lead to fetal anuria, oligohydramnios with pulmonary hypoplasia, & renal dysplasia with renal failure in newborn
    - Intrauterine aspiration of obstructed bladder or vagina may be attempted

Demographics

- Age
  - Bimodal age presentation: Infancy or peripubertal
- Epidemiology
  - Transverse vaginal septum incidence: 1 in 80,000
  - Imperforate hymen is more common

Natural History & Prognosis

- Immediate prognosis is excellent
- Compromised fertility & endometriosis can be long-term complications



Treatment

- Typically drained with septum or stenotic segment excised from inferior approach; minimal tissue is resected
- Stenoses & focal atresias may require primary anastomosis & perioperative stenting
- Secondary hydronephrosis typically resolves spontaneously without additional intervention

(Left) *Sagittal STIR MR in a 14-year-old who had a cloacal repair in infancy shows fluid distending her tortuous neovagina &, to a lesser degree, her endometrial cavity. This was due to a stricture at the introitus.* **(Right)** *Axial T2 FS MR in a 12-year-old with pelvic pain shows a very distended vagina with high-signal fluid extending into the uterus, consistent with hydrometrocolpos.*

(Left) *Longitudinal US in a teenage girl with right lower quadrant & pelvic pain shows heterogenous material distending the vagina in layers, from anechoic anteriorly to hyperechoic posteriorly in this case of hematocolpos. The uterus is not distended.* **(Right)** *Longitudinal oblique US in a case of hematometrocolpos in a teenager with cyclic pain shows marked distention of a debris-filled vagina posterior to the bladder. Note the mildly distended uterus.*

(Left) *Coronal SSFP localizer MR in a patient who had a "vaginal collection" drained at an outside hospital shows 2 endometrial cavities draped over the bladder. A solitary left kidney is noted, a commonly associated abnormality.* **(Right)** *Axial T2 FS MR shows the paired cervices & endometrial cavities in the same patient with uterine didelphys & an obstructing septum of a hemivagina (that led to hematometrocolpos). This combination of findings is typical of Herlyn-Werner-Wunderlich syndrome.*

Müllerian Duct Anomalies

KEY FACTS

TERMINOLOGY

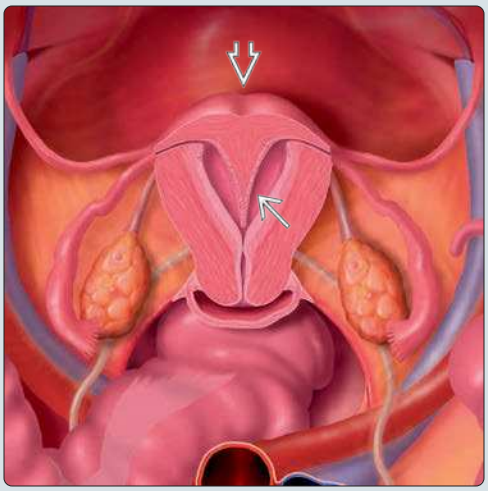
- Abnormal development, improper fusion, or failure of resorption of müllerian (paramesonephric) duct structures

IMAGING

- Abnormal contour of uterus &/or structural abnormality of endometrial cavity or vagina
- Septate uterus is most common müllerian duct anomaly (MDA): 55%
- MR is best for definitive diagnosis
- Always image kidneys to look for renal anomaly

PATHOLOGY

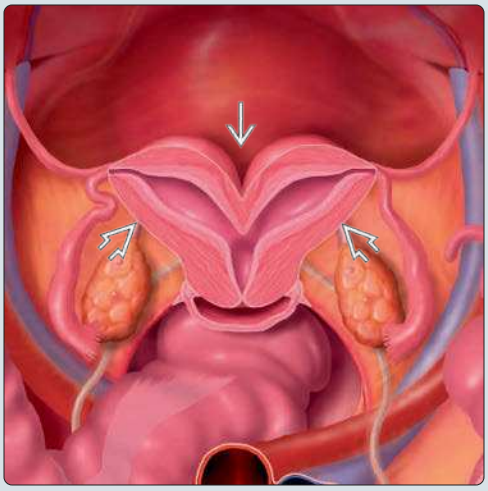
- MDAs occur in 1 of 3 phases
  - Organogenesis: Agenesis, hypoplasia, unicornuate
  - Fusion: Didelphys, bicornuate
  - Septal resorption: Septate, arcuate
- Renal anomaly is present in ~ 30%
  - Renal agenesis is most common (~ 2/3)



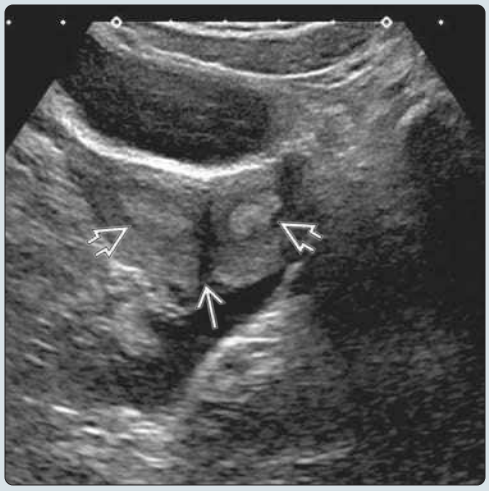
CLINICAL ISSUES

- Asymptomatic
- Symptoms may develop at menarche
  - Primary amenorrhea
  - Dysmenorrhea
  - Cyclic abdominal pain
- Incidence is estimated at 1%
- Critical to differentiate septate vs. bicornuate uterus
  - Septate is treated with hysteroscopic resection of septum
  - Bicornuate rarely requires surgery
- Treatment
  - Surgery to remove rudimentary horn, resect septum, or relieve obstruction

DIAGNOSTIC CHECKLIST



- Outer fundal contour is important for differentiating bicornuate from septate uterus



(Left) *Graphic of a septate uterus shows minimal indentation of the uterine fundus. There is myometrium in the superior aspect of the septum, though normal zonal anatomy is not present in this portion.* **(Right)** *Axial T2 MR of a septate uterus shows that the outer fundal contour is smooth, & the intercornual angle is < 75°. There is a low-signal fibrous septum extending along the length of the endometrial cavity to a single cervix.*

(Left) *Graphic of a bicornuate uterus demonstrates a deep external fundal cleft & 2 symmetric cornua that are fused inferiorly.* **(Right)** *Transverse US shows the outer contour/notch of this bicornuate uterus due to a small amount of free fluid in the pelvis. The 2 endometrial cavities are separated by myometrium.*

TERMINOLOGY

Abbreviations

- Müllerian duct anomalies (MDA)

Synonyms

- Uterine fusion anomalies
- Subtype: Obstructed hemivagina & ipsilateral renal agenesis (OHVIRA syndrome)

Definitions

- Abnormal development, improper fusion, or failure of resorption of müllerian (paramesonephric) duct structures
  - Müllerian agenesis or hypoplasia (class I in American Fertility Society classification system)
    - Complete or segmental agenesis or variable degrees of uterovaginal hypoplasia
  - Unicornuate uterus (class II)
    - Partial or complete unilateral hypoplasia
  - Uterus didelphys (class III)
    - Duplication of uterus
  - Bicornuate uterus (class IV)
    - Incomplete fusion of superior uterovaginal canal
  - Septate uterus (class V)
    - Incomplete resorption of uterine septum
  - Arcuate uterus (class VI)
    - Near-complete resorption of uterine septum

IMAGING

General Features

- Best diagnostic clue
  - Abnormal contour of uterus &/or structural abnormality of endometrial cavity or vagina
- **Müllerian agenesis or hypoplasia**
  - Mayer-Rokitansky-Kuster-Hauser syndrome
    - Aplasia of upper 2/3 of vagina
    - 90% have uterine agenesis
    - 10% have rudimentary uterus
    - Incidence of 1 in 4,500 women
    - 2nd most common cause of primary amenorrhea (gonadal dysgenesis is 1st)
  - ± hydrometrocolpos
- **Unicornuate uterus**
  - 20% of MDAs
  - Single-horned uterus
  - Asymmetric curved & elongated (banana-shaped)
  - Hypoplastic uterine horn of variable size is usually present
    - May be cavitary or noncavitary
      - Cavity may communicate with contralateral endometrium
  - ± hydrometrocolpos with obstruction
- **Uterus didelphys**
  - 5% of MDAs
  - Bilateral hemiuteri with noncommunicating endometrial cavities
  - Divergent uterine horns with deep fundal cleft
    - Each horn has normal zonal anatomy
  - 2 cervices
  - Vaginal septum is present in 75%
  - Herlyn-Werner-Wunderlich syndrome (OHVIRA): Uterus didelphys, blind hemivagina, ipsilateral renal agenesis
  - ± hematometrocolpos with obstruction
- **Bicornuate uterus**
  - 10% of MDAs
  - 2 symmetric cornua are fused inferiorly
    - Normal zonal anatomy is maintained
    - ± septum of fibrous tissue (low signal on T2)
  - External fundal cleft
    - Must be at least 1 cm in depth
      - Differentiates bicornuate from septate uterus
    - Extends to internal cervical os in complete bicornuate uterus
  - Intercornual angle is variable
    - > 105° is suggestive of bicornuate (not septate) uterus
  - Usually single cervix though variations exist
    - Bicornuate bicollis: Duplicated cervix, though there is some degree of communication between horns
  - ± hydrometrocolpos with obstruction
- **Septate uterus**
  - Most common MDA (55%)
  - Persistent uterovaginal septum of variable length
    - Septum extends into upper vagina in 25%
    - Inferior portion of septum is composed of fibrous tissue (low signal on T2)
    - Cervical duplication is rare
  - External fundal contour is usually mildly convex or flat though can be indented < 1 cm
  - Intercornual angle is variable
    - < 75° is suggestive of septate (not bicornuate) uterus
  - Overall uterine size is normal though each endometrial cavity is smaller than normal
  - ± hydrometrocolpos with obstruction
- **Arcuate uterus**
  - Mild convex indentation on fundal endometrium
  - Normal external fundal contour
  - No fibrous component
- **Vaginal septum**
  - Can be associated with any MDA
  - ± transverse or longitudinal

Ultrasonographic Findings

- Usually 1st imaging test performed, so important to recognize abnormality
- Altered uterine contour & endometrial cavity as above
- Limitations
  - Uterine characterization is limited from 2-3 months until puberty due to small size
    - Some anomalies can be seen prenatally & in neonate under influence of maternal hormones
  - Can be difficult to image outer fundal contour
    - Need transverse view of fundus in orthogonal plane
  - Demonstrating communication between endometrial cavities can also be challenging
  - 3D can be helpful
- Always image kidneys when MDA is identified

MR Findings

- T1WI
  - When obstructed, high signal intensity contents indicate hemorrhagic byproducts

- T2WI
  - Normal zonal anatomy
    - High-signal endometrium & intermediate-/high-signal myometrium
    - Junctional zone is seen as low-signal line separating endometrium & myometrium
  - Imaging parallel to long axis of uterus is best for determining uterine morphology
  - In unicornuate & uterine hypoplasia, hypoplastic uterine remnant is best seen on sagittal or axial T2
    - Usually intermediate or low signal intensity myometrium with small endometrial cavity
  - Fibrous septum is low signal intensity (septate, bicornuate)

Radiographic Findings

- Hysterosalpingography
  - Classification is based on contour/morphology of endometrial cavity or cavities
  - Outer fundal contour is not visible

Imaging Recommendations

- Best imaging tool
  - Ultrasound as initial screening exam
  - MR for definitive diagnosis
- Protocol advice
  - Image kidneys when MDA is identified on ultrasound
  - MR
    - Combination of T1/T2 for external contour & endometrial cavity
    - Image parallel to long axis of uterus for fundal contour
    - T2 is best for distinguishing zonal anatomy
    - Obtain at least 1 coronal series to cover renal fossa

DIFFERENTIAL DIAGNOSIS

Imperforate Hymen

- Not associated with MDA
- Differentiation from low transverse vaginal septum can be difficult by imaging

Cervical Stenosis

- ± inflammatory, iatrogenic, or secondary to mass effect
- Mimics MDA if obstructed & endometrium is distorted

PATHOLOGY

General Features

- Etiology
  - Müllerian duct structures
    - Fallopian tubes
    - Uterus
    - Cervix
    - Upper 2/3 of vagina
  - MDAs occur in 1 of 3 phases
    - Organogenesis: Agenesis, hypoplasia, unicornuate
    - Fusion: Didelphys, bicornuate
    - Septal resorption: Septate, arcuate
- Associated abnormalities
  - Renal anomaly is present in ~ 30%
    - Renal agenesis is most common (~ 2/3)
    - Ectopic kidney
    - Horseshoe kidney
    - Renal dysplasia
    - Duplicated collecting system

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymptomatic
  - Symptoms may develop at menarche
    - Primary amenorrhea, dysmenorrhea, cyclic abdominal pain

Demographics

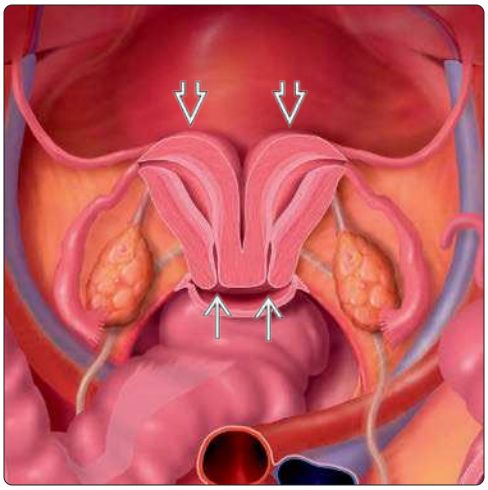
- Epidemiology
  - Incidence is estimated at 1%

Natural History & Prognosis

- Fertility issues
- Spontaneous abortions
- Ectopic pregnancy
- Endometriosis is postulated to result from retrograde menstruation

Treatment

- Septate vs. bicornuate uterus is important
  - Septate treated with hysteroscopic resection of septum
  - Bicornuate rarely requires surgery
- Medical: Suppression of menses
- Surgical
  - Removal of rudimentary horn
  - Relieve obstruction
  - Resection of uterine septum



DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Outer fundal contour is important for differentiating bicornuate from septate uterus
- Define endometrial cavity & presence of communication when there are 2 uterine horns
- 1 or 2 cervices: Complete bicornuate vs. bicornuate bicollis vs. didelphys
  - Differentiate low-signal septum extending through single cervical os from 2 separate cervices

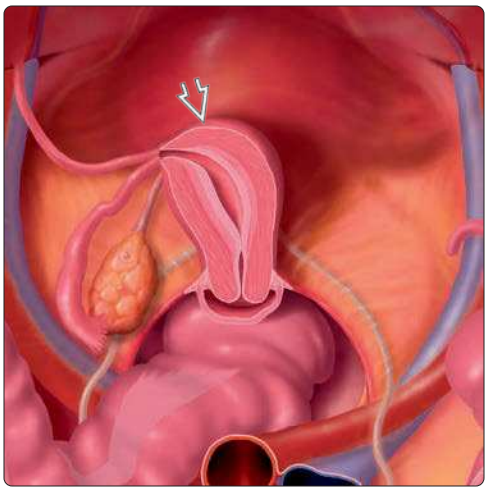
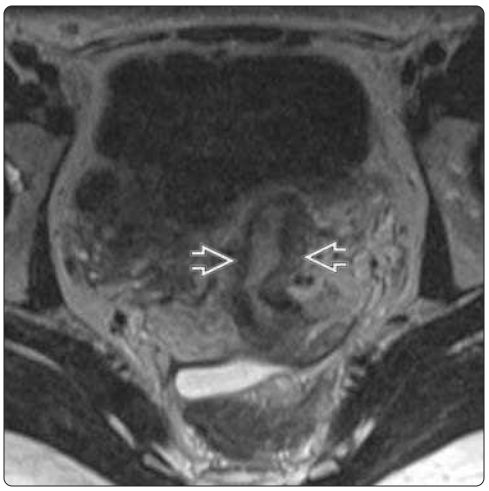
6. Jegannathan D et al: Magnetic resonance imaging of classified and unclassified Müllerian duct anomalies: comparison of the American Society for Reproductive Medicine and the European Society of Human Reproduction and Embryology classifications. SA J Radiol. 22(1):1259, 2018





(Left) *Graphic of uterus didelphys shows 2 separate uterine horns, each with normal zonal anatomy as well as 2 cervices.* **(Right)** *Coronal oblique T2 MR shows 2 separate uterine horns, 2 cervices, & a massively distended vaginal vault in this patient with hydrometrocolpos & obstructed didelphys.*

(Left) *Coronal T2 MR shows 2 uterine horns that are widely separated in the pelvis in a patient with didelphys & an anorectal malformation.* **(Right)** *Coronal oblique T2 MR shows a uterus didelphys with a 25-week fetus in the left uterine horn as compared to endometrial proliferation in the right horn. Both cervices are closed.*

(Left) *Graphic of a unicornuate uterus illustrates the typical banana shape. There is complete absence of left-sided müllerian duct structures, although this is not always the case.* **(Right)** *Axial T2 MR from an 18-year-old demonstrates a unicornuate uterus to the left of midline. A right uterine horn was present (not shown). No renal anomalies were observed.*

Ovarian Cyst

KEY FACTS

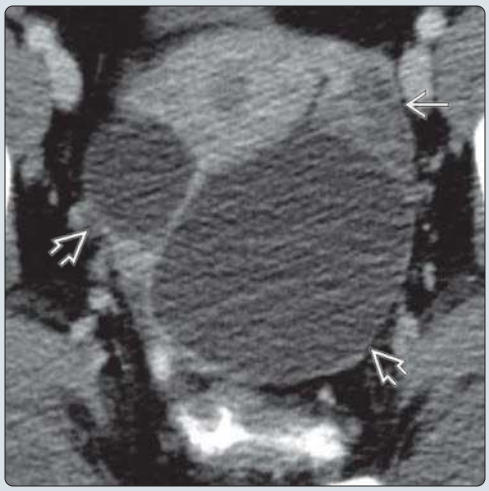
TERMINOLOGY

- Follicle: Normal physiologic cyst < 1 cm in diameter
  - Dominant follicle may measure up to 3 cm
- Functional cysts: Can measure up to 3-10 cm
  - Corpus luteal cyst: Dominant follicle after ovulation
  - Follicular cyst: Normal mature follicle fails to involute
- Hemorrhagic cyst: Hemorrhage into functional cyst

IMAGING

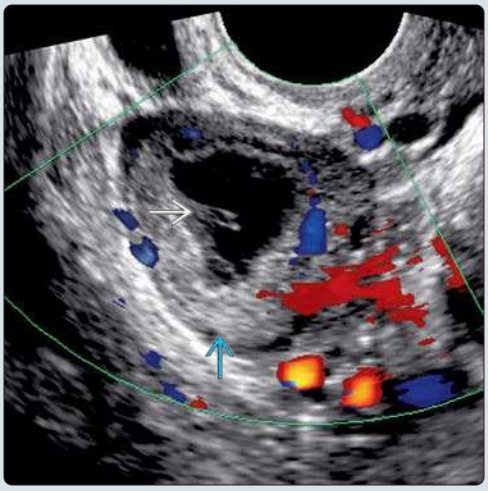
- Ultrasound is mainstay of ovarian imaging; MR in limited circumstances
- Well-marginated, round or ovoid structure within borders of ovary with no solid component
  - Thin wall (< 3 mm)
  - No internal septa, nodule, fat, Ca^{2+}, or vascularity
  - ↑ heterogeneity with hemorrhage: Internal reticulations (or lace-like pattern) of clot mixed with tiny cystic spaces vs. layering debris

CLINICAL ISSUES



- Usually asymptomatic; pain if large or complicated by rupture, hemorrhage, or torsion
- Treatment/prognosis
  - > 90% of all functional cysts resolve spontaneously
  - Cysts < 3 cm should be considered physiologic in pre- & postmenarchal children
  - Cysts up to 4-5 cm are usually monitored with surveillance ultrasound
  - Surgery vs. further imaging is considered in larger cysts due to risk of torsion or neoplasm
    - For resection, ovarian sparing approach is preferred if benign etiology is suspected

DIAGNOSTIC CHECKLIST



- With cystic ovarian lesion in child, radiologist must consider: Could this be torsion, neoplasm, or other pathology?
- Follow-up ultrasound of asymptomatic cyst in 4-6 weeks if initial study is unclear (due to size or mild complexity)

(Left) *Transverse ultrasound shows 2 well-defined, round, anechoic structures abutting the uterus, both of which have imperceptible walls & ↑ through transmission, consistent with simple cysts.* **(Right)** *Axial CECT obtained in the same patient also demonstrates typical characteristics of simple cysts. The normal-appearing left ovary lies directly adjacent to the larger cyst on this image. Both cysts resolved by the time of a follow-up ultrasound obtained several weeks later, consistent with follicular cysts.*

(Left) *Transverse endovaginal color Doppler ultrasound shows a hypoechoic structure within the right ovary that has an irregular contour, a hyperechoic rim, & a small amount of echogenic material centrally. There is mild adjacent hyperemia. The findings are characteristic of a corpus luteal cyst.* **(Right)** *Coronal CECT of the same patient on the same day shows the typical mildly thickened, irregular, hypervascular wall indicative of a corpus luteal cyst.*

TERMINOLOGY

Definitions

- Well-marginated, round or ovoid structure within or at borders of ovary; no solid component
  - No fat, Ca^{2+}, or septa
  - Thin, imperceptible wall (< 3 mm thick)
  - May appear more complex after internal hemorrhage
  - No internal vascularity on color Doppler imaging
- Definitions of different cyst types & their sizes vary
  - Follicle
    - Generally < 1 cm in diameter
    - Dominant follicle may measure up to 3 cm
  - Functional cysts
    - Corpus luteal cyst
      - After ovulation, dominant follicle becomes corpus luteal cyst
      - Usually < 3 cm, though can be much larger
    - Follicular cyst
      - Occurs when normal mature follicle fails to ovulate/involute
      - Usually 3-10 cm
  - Hemorrhagic cyst
    - Hemorrhage occurs into one of above

IMAGING

General Features

- Best diagnostic clue
  - Simple cyst: Unilocular with imperceptible wall & near water echogenicity/attenuation/signal intensity internally with no central complexity or vascularity
- Size
  - Cysts < 3 cm should be considered physiologic in pre- & postmenarchal children
  - Cysts > 4-5 cm may require additional consideration
- Morphology
  - Round or ovoid with well-defined margins

Ultrasonographic Findings

- Differentiation of follicle & functional cyst is mainly by size
- Follicles & follicular cysts without hemorrhage
  - Unilocular with smooth margin
  - No internal septations, though adjacent follicles can sometimes simulate septations
  - Anechoic with ↑ through transmission
    - May have minimal internal debris
- Corpus luteal cysts
  - Unilocular but with irregular contour
  - Range from anechoic to isoechoic
  - Wall thickness is variable due to vascularization
  - Classically have ↑ peripheral vascularity ("ring of fire")
  - Appearance can be identical to follicular cyst
- Hemorrhagic cysts
  - Contain heterogeneously echogenic debris, which becomes more hypo- or anechoic as clot lysis occurs
  - Reticular or lace-like pattern of internal echoes is classic
  - Fluid-debris level is sometimes present
  - ↑ through transmission is maintained despite echogenicity

CT Findings

- CECT
  - Hypoattenuating, well-marginated mass within ovary without enhancement
  - Ovarian stroma is usually low density, though normal tissue surrounding cyst can simulate soft tissue rim
    - Punctate hypodense follicles may be visualized in mildly enhancing ovarian parenchyma
  - Fat density or Ca^{2+} is always pathologic
  - Corpus luteal cysts
    - Unilocular
    - Thicker wall, usually 2-4 mm, often hyperenhancing & crenulated (irregular), especially if ruptured
  - Hemorrhagic cysts are more dense than simple cysts
    - Most commonly arise in follicular or corpus luteal cysts
    - Fluid-fluid level is rarely seen on CT
    - Cyst rupture can cause free peritoneal fluid, which may be hyperdense if due to hemorrhage
      - Corpus luteal cysts more commonly result in hemoperitoneum due to their vascular wall

MR Findings

- May be performed if ultrasound diagnosis is unclear
  - Accuracy for MR in characterizing sonographically indeterminate lesions ranges from 83-93%
  - Findings more indicative of neoplasm include
    - Thick, enhancing wall or septations > 3 mm
    - Enhancing mural nodule, papillary projections, or other solid components
    - Size > 5 cm
- Functional cysts: Homogeneously low T1, high T2 signal
- Hemorrhagic cyst: Typically high T1 & T2 signal
  - Fluid-debris level is sometimes seen on T2
  - No loss of high T1 signal with fat suppression
  - Hemorrhagic components may restrict diffusion
- T1 FS & in-/opposed-phase GRE sequences aid in looking for fat of dermoid
- Mild rim enhancement with hemorrhagic or corpus luteal cyst on T1 C+ FS
  - Subtracted pre- from postcontrast T1 FS images are helpful to confirm true enhancement rather than pseudoenhancement of blood products

Imaging Recommendations

- Best imaging tool
  - Ultrasound is mainstay for evaluation of ovaries
    - Characterization of cyst wall & internal components
    - Color Doppler gives additional information, especially in evaluating for presence of solid component
  - MR is considered when ultrasound is indeterminate or if neoplasm is suggested but full extent is not discernible by ultrasound
  - CT use is minimized due to radiation concerns

DIFFERENTIAL DIAGNOSIS

Dermoid/Teratoma

- 10-15% may appear as entirely cystic by imaging
- MR is much more sensitive/specific (due to fat component)

Ovarian Malignancy

- Enlarging, mildly complex cyst or higher degrees of complexity (solid nodular components, internal vascularity) should raise concern
- MR if question of hemorrhage vs. solid components

Ovarian Torsion

- Asymmetric, edematous ovarian parenchyma with peripheral follicles, ± midline/contralateral location of ovary
- ± twisted vascular pedicle (whirlpool), ↓ or absent blood flow
- Frequently associated with cysts > 5 cm

Paraovarian Cyst

- Long list of potential causes, including
  - Enteric duplication cyst
  - Peritoneal inclusion cyst
  - Lymphatic malformation
- Resected paratubal cysts recur in ~ 11% of girls

Tuboovarian Abscess

- Wide range of appearances from relatively simple-appearing cyst to complex, heterogeneous, cystic mass
- Clinical history & exam findings are crucial

Ectopic Pregnancy

- History & pregnancy test results are critical

PATHOLOGY

General Features

- Etiology
  - Infancy
    - In fetus, follicular stimulation occurs from maternal estrogen, placental hCG, & fetal gonadotropins
    - More common in maternal diabetes, toxemia, or Rh isoimmunization during pregnancy
    - Small cysts may be seen as early as 28-weeks gestation
    - Newborn estrogen & hCG levels fall but serum LH & FSH levels ↑, peaking at 3-4 months
  - Premenarchal
    - Cysts > 1 cm are least common in this age group due to low hormone levels
    - Follicle maturation occurs at low rate
  - Postmenarchal
    - Hormone levels approach adult levels & cysts become more common
    - Usually result of dysfunctional ovulation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually asymptomatic; pain if large or complicated by rupture, hemorrhage, or torsion
  - Corpus luteal cyst is more commonly symptomatic, even without significant hemorrhage

Demographics

- Epidemiology
  - Neonates: Small cysts are present in up to 98% at birth
    - ~ 20% ≥ 1 cm
  - Premenarchal: Cysts > 1 cm in 2-5%
  - Postmenarchal: Cysts are very common
    - Nonfunctional cysts & malignant ovarian neoplasms also occur at greater rate

Natural History & Prognosis

- Over 90% of all functional cysts resolve spontaneously
  - Larger cysts may take longer to resolve
  - 91-94% of pediatric ovarian cysts are benign

Treatment

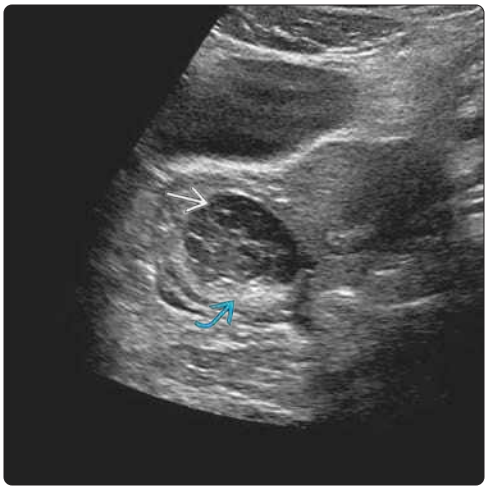
- Cysts < 4-5 cm are usually monitored with surveillance US
- Surgery is considered in larger cysts due to risk of torsion or neoplasm
  - Options include aspiration, fenestration, & resection
  - For resection, ovarian sparing approach is preferred if benign etiology suspected

DIAGNOSTIC CHECKLIST

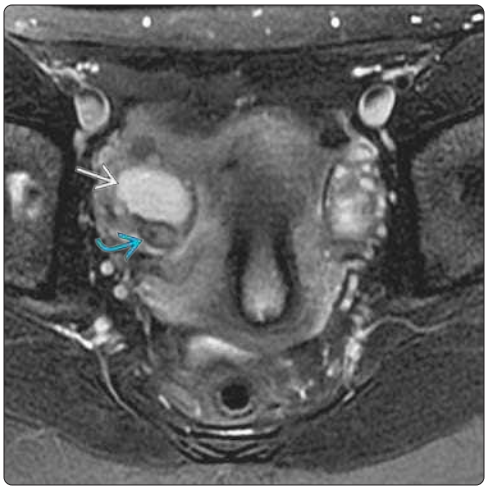
Consider

- 3 main concerns for radiologist when cystic ovarian lesion is encountered in child
  - Could this be torsed?
  - Could this be neoplastic?
  - Could this be other pathology (e.g., tuboovarian abscess, ectopic pregnancy, ruptured appendicitis, etc.)?

Image Interpretation Pearls



- Superimposed torsion is more likely with cysts > 5 cm
- Clinical judgment overrides imaging: Simple or hemorrhagic cyst with otherwise normal-appearing ovarian parenchyma (by grayscale & Doppler US) can still be torsed
  - Does not give license to use phrase "cannot rule out torsion" in every report
  - Strong clinical suspicion + any ovarian abnormality on imaging may require laparoscopy



Reporting Tips

- Close follow-up if complexity/size of asymptomatic cyst is not typical of most simple or hemorrhagic cysts
  - Repeat US in 4-6 weeks; subsequent MR &/or gynecology referral if questions persist

(Left) *Transverse ultrasound of the right ovary in a 17-year-old with pelvic pain shows a complex cystic lesion with lacy septations ➡ in the near field & more echogenic contents ⇨ dependently.* **(Right)** *Axial T2 FS MR in the same patient a few days later (imaged for persistent pain) shows liquefying cyst contents anteriorly ➡ & hemorrhagic debris dependently ⇨ in this case of a hemorrhagic ovarian cyst.*

(Left) *Transverse color Doppler ultrasound shows an irregular cystic structure containing septations ➡ within the left ovary. The ovary is surrounded by a large amount of heterogeneously echogenic material ➡, which was mobile in real time. The findings are indicative of a ruptured hemorrhagic cyst.* **(Right)** *Coronal CECT in the same patient also demonstrates the left adnexal cyst ➡ surrounded by a large volume of hemoperitoneum ➡ that extends to the subdiaphragmatic region.*

(Left) *Transvaginal ultrasound in an 18-year-old with pain shows a large simple cyst ➡ with thin wall & ↑ through transmission, volume of ~ 100 mL, stretching the ovarian tissue in the near field where 2 tiny follicles ⇨ are seen.* **(Right)** *Transverse color Doppler ultrasound in a patient with a simple cyst ➡ shows eccentric but otherwise normal-appearing ovarian tissue ➡ splayed along the cyst. Despite the unalarming sonographic appearance, the patient's symptoms warranted laparoscopy, where the ovary was found to be torsed.*

Ovarian Teratoma

KEY FACTS

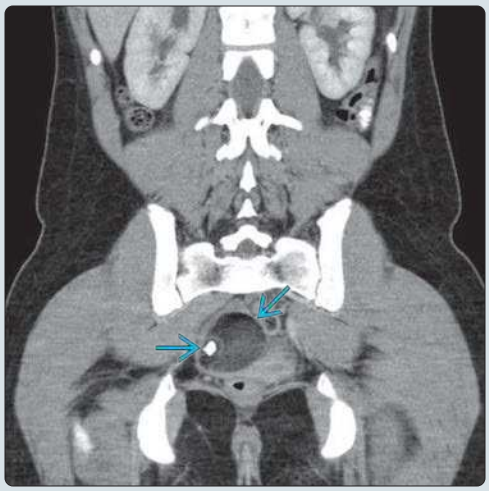
TERMINOLOGY

- Dermoid tumor, dermoid cyst, mature cystic teratoma
- Teratomas are made up of variety of parenchymal cell types from > 1 germ cell layer, usually all 3

IMAGING

- Best clue: Heterogenous pelvic mass containing Ca^{2+}, hair, fat, & cystic components
- Typically well-defined margins without surrounding inflammatory changes
- US: 1st-line modality for female pelvic pain &/or mass
  - Multiple classic signs described for teratoma
    - Dermoid plug: Echogenic nodule protruding into cyst
    - Dermoid mesh: Linear/punctate echogenic foci of hair
    - Tip of iceberg sign: Echogenic superficial interfaces obscure deeper components of mass
- Radiographs: Tooth-like Ca^{2} is strongly suggestive
- MR & CT: Best demonstrate fat, confirming teratoma

PATHOLOGY



- Complications of ovarian teratoma include
  - Ovarian torsion
  - Rupture, causing chemical peritonitis
    - May lead to severe adhesions
  - Anti-NMDA receptor encephalitis
  - Malignancy (2%)

CLINICAL ISSUES

- Teratoma is most common ovarian germ cell tumor
- Teratoma is most common ovarian neoplasm < 20 years old
  - Found in any age; mean age of presentation: 30 years
- Often incidental finding on physical exam or during imaging for unrelated symptoms
  - With torsion or rupture, acute onset of pain is typical
- Treatment: Surgical resection, ovary-sparing surgery
  - Laparoscopic surgery is preferred

(Left) *AP radiograph in a teenage girl with pelvic pain & normal menstrual cycles shows chunky Ca^{2+} in the pelvis ⇨ that are suspicious for an ovarian teratoma (or possibly appendicoliths).* **(Right)** *Coronal CECT in the same patient shows a heterogeneous mass ⇨ in the right adnexa containing Ca^{2+}, fat, fluid (not shown), & nonlayering debris. The presence of all these tissues confirms ovarian teratoma as the diagnosis.*

(Left) *Longitudinal US of the left ovary in a 14-year-old girl shows a mixed cystic & solid mass with hyperechoic foci ⇨ & curvilinear septations.* **(Right)** *Coronal SSFSE T2 MR in the same patient (performed for other medical issues) shows fat & fluid centrally ⇨ within the left ovary. The lesion was subsequently surgically shelled out of the ovary (i.e., an ovarian-sparing resection) & found to be a mature teratoma.*

TERMINOLOGY

Synonyms

- Dermoid tumor, dermoid cyst, cystic teratoma

Definitions

- Teratomas are made up of various parenchymal cell types from > 1 germ layer, usually all 3
- Teratomas generally lie in midline or paraxial & arise from totipotential cells
- Term dermoid comes from skin-like lining found in many of these tumors

IMAGING

General Features

- Best diagnostic clue
  - Heterogeneous pelvic mass containing calcium, fat, fluid, & other internal debris
  - Typically well-defined margins without surrounding inflammatory changes
- Location
  - Pelvis & lower abdomen
- Size
  - Variable, from 1-45 cm in diameter
  - Mean diameter: 6 cm
- Morphology
  - Mixed tissue types surrounded by capsule

Radiographic Findings

- May be occult
- ± Ca^{2+}; those resembling teeth or bone strongly suggest teratoma
- ± mass effect on bowel

Ultrasonographic Findings

- Grayscale ultrasound
  - Heterogeneous mass with cystic & solid components
  - Ca^{2+} may show posterior shadowing or ring-down artifact when very small
  - Fat & hair appear echogenic; hair may appear reticular
  - ± fluid-fat-debris levels &/or floating debris within cysts
  - Dermoid mesh sign: Linear & punctate hyperechoic foci (due to hair) within cystic mass
  - Dermoid plug (Rokitansky nodule): Echogenic solid focus bulging into lesion from cyst wall
  - Tip of iceberg sign: Strong echogenic interface at leading edge of teratoma blocks deeper components from view
    - May be caused by Ca^{2+}, hair, fat, etc.
- Color Doppler
  - Flow is useful in differentiating solid perfused tissue from solid avascular hair, teeth, etc.

CT Findings

- Exquisite for identifying fat & Ca^{2+}
- Otherwise heterogeneous tissue components with septations & fluid-debris levels
- Residual ovarian tissue giving rise to teratoma may be difficult to identify if tumor is large

MR Findings

- Heterogeneous signal due to mix of elements
  - Low signal intensity foci with blooming on T2* GRE suggests Ca^{2+}
  - Identification of fat is key to diagnosis
    - T1 ± FS
      - Signal loss upon FS application confirms presence of macroscopic fat (vs. other T1-bright material, such as blood, protein, etc.); may show fat-fluid level
    - In-/opposed-phase GRE sequences assess for microscopic fat
      - Signal loss on opposed-phase confirms fatty lesion

Imaging Recommendations

- Best imaging tool
  - US is primary investigative tool for female pelvic pain or palpable mass
  - MR is reserved for complex cases or patients ill-suited to sonography
  - CT is minimized due to radiation concerns
- Protocol advice
  - Scan mass in orthogonal planes looking for variable tissue & cyst contents
  - Endovaginal scanning is optimal when tolerated
  - Larger masses may require transabdominal scanning & extended field of view

DIFFERENTIAL DIAGNOSIS

Other Ovarian Neoplasms

- Benign
  - Simple/follicular cysts
  - Cystadenomas
    - Mucinous
    - Serous
  - Gonadoblastoma
- Malignant
  - Germ cell tumors
  - Sex cord-stromal tumors
  - Epithelial tumors
  - Malignant teratomas

Perforated Appendicitis With Appendicolith

- Heterogeneous collection in lower abdomen, ± Ca^{2+} & shadowing foci

Tuboovarian Abscess

- Fever, cervical tenderness, & vaginal discharge is typical

Ovarian Torsion

- May require surgical exploration to distinguish
- May coexist with ovarian teratoma

Ectopic Pregnancy

- Correlate with β-hCG

Stool Impaction

- Stool & gas in rectum can mimic tip of iceberg sign

Bladder Calculi

- Ca^{2} in pelvis could reside in urinary bladder
  - Especially in patients with Mitrofanoff, other bladder surgeries, & those performing bladder catheterization

Endometrioma

- Cyclic pain history is useful

Peritoneal Inclusion Cyst

- Lacks complex contents seen in teratomas

PATHOLOGY

General Features

- Etiology
  - Arise from primordial germ cells, which migrate during embryogenesis from yolk sac to gonads
- Associated abnormalities
  - Complications of ovarian teratoma include
    - Ovarian torsion
    - Rupture, causing chemical peritonitis
      - Severe adhesions can result from perforation of teratoma
    - Infection
    - Hemolytic anemia
    - Malignancy in ~ 2%
- 3 types of ovarian teratomas
  - Mature cystic teratoma (dermoid cyst)
  - Monodermal teratomas (struma ovarii, carcinoid tumors, & neural tumors)
  - Immature teratomas
    - Associated with growing teratoma syndrome (peritoneal recurrence)
- Teratoma distribution
  - Sacrococcygeal (57%)
  - Gonadal (29%), ovarian > testicular
  - Mediastinal > retroperitoneal > cervical > intracranial
- Cells differentiate along various germ lines, essentially recapitulating any tissue of body
- Ectoderm, mesoderm, & endodermal elements may all be present
  - Because ectodermal components tend to predominate, term dermoid cyst has been applied
  - Tissues include hair, teeth, fat, skin, muscle, & endocrine tissue

Gross Pathologic & Surgical Features

- Heterogeneous mass surrounded by well-defined capsule
- Cyst contents may be oily, milky, or have serous fluid, hair, teeth, cartilage, etc.

Microscopic Features

- Variable well-differentiated tissues, including bone, cartilage, muscle, thyroid follicles, gastrointestinal lining, respiratory epithelium, etc.
- Immature teratomas are graded from 0 to 3 based on amount of immature neural tissue found in tumor specimen
  - Higher grades are more likely to have yolk sac tumor components

CLINICAL ISSUES

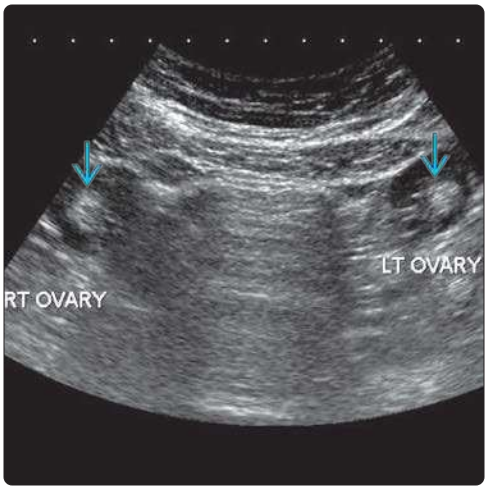
Presentation

- Most common signs/symptoms
  - Often incidental finding on physical exam or during imaging for unrelated symptoms
  - With torsion or rupture, acute onset of pain is typical
- Other signs/symptoms
  - Abdominal pain, abdominal mass, or swelling
  - Abnormal uterine bleeding
  - Urinary symptoms
  - Gastrointestinal complaints
  - Back pain is less common
  - Elevated α-fetoprotein or hCG is more likely with germ cell tumors/immature teratomas
  - Rarely associated with anti-NMDA encephalitis
  - Opsoclonus-myoclonus syndrome/ataxia association

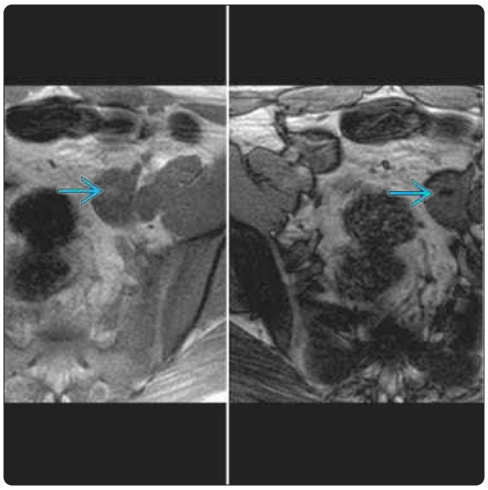
Demographics

- Age
  - Any; mean of 30 years
- Sex
  - Females only for ovarian lesions
- Epidemiology
  - Teratoma is most common ovarian germ cell tumor
  - Also most common ovarian neoplasm in patients < 20 years old
  - 10% of teratomas are diagnosed during pregnancy
  - Bilateral in up to 15%
    - Right-sided teratomas are slightly more common than left

Natural History & Prognosis



- Teratomas enlarge, spontaneously hemorrhage, or twist
- Prognosis is generally excellent following resection
  - Prognosis is poor in small minority with malignant foci
  - Malignant teratomas tend to metastasize widely
  - 5-year survival for malignant teratomas is < 30%
- Fertility issues may arise
  - When entire ovary is removed
  - When chemical peritonitis impairs ovulatory function



Treatment

- Treatment is surgical resection, ovary-sparing surgery
- Laparoscopic surgery is preferred
- Malignant teratomas are treated with surgery, hyperthermic intraperitoneal chemotherapy, neoadjuvant chemotherapy

(Left) *Tranverse US in an 11-year-old girl with anti-NMDA receptor encephalitis shows bilateral 1-cm echogenic ovarian lesions, potentially teratomas.* **(Right)** *Axial in- (left) & opposed- (right) phase T1 GRE MR images in the same patient show a left ovarian lesion containing macro- & microscopic fat with signal drop on the opposed-phase image. A similar finding was seen in the right ovary. T1 FS images (not shown) also confirmed fat in both lesions. Ovarian-sparing teratoma resection was performed bilaterally.*

(Left) *Longitudinal US of a 7 x 10 cm complex cystic mass in right pelvis of a 17-year-old girl with vague pelvic pain & fullness shows an echogenic septation & echogenic nodules in this right ovarian lesion.* **(Right)** *Axial T2 FS MR in the same patient shows dark fat within this complex ovarian mass, pathologically proven to be a mature ovarian teratoma.*

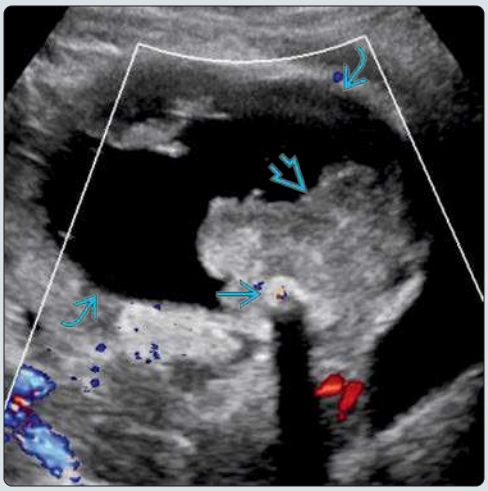
(Left) *Transverse US in a 12-year-old girl shows a complex cystic adnexal lesion with linear bright echoes, fluid, & solid components. The linear echoes corresponded to hair at gross pathology in this case of mature ovarian teratoma.* **(Right)** *Transverse oblique US in this 11-year-old scanned for incidental Ca^{2+} seen on a radiograph shows echogenic chunks of Ca^{2+} in this right ovarian teratoma. At pathology, poorly formed bone & teeth were found.*

Ovarian Malignancies of Childhood

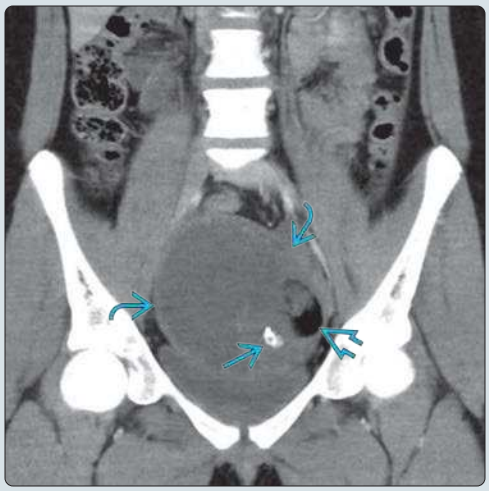
KEY FACTS

IMAGING

- **Germ cell tumors**
  - Mature ovarian teratoma: Cystic mass with fat & Ca^{2+}
  - Immature ovarian teratoma: Cannot differentiate from mature teratoma on imaging
  - Ovarian dysgerminoma: Multilobulated, solid mass with Ca^{2+}
  - Yolk sac tumor: Large, complex cystic & solid mass that extends into abdomen
  - Choriocarcinoma: Solid, hypervascular mass in female with elevated β-hCG
- **Sex cord-stromal tumors**
  - Juvenile granulosa-theca cell tumor: Large, multilocular mass with septations & solid component
  - Sertoli-Leydig cell tumor: Heterogeneous cystic & solid mass
- **Epithelial tumors**
  - Serous tumor: Homogeneous cystic mass with thin walls & no mural nodule
  - Mucinous tumor: Large, heterogeneous, multilocular cystic mass
- **Miscellaneous**
  - Small cell carcinoma of ovary, hypercalcemic type
    - May represent aggressive malignant rhabdoid tumor

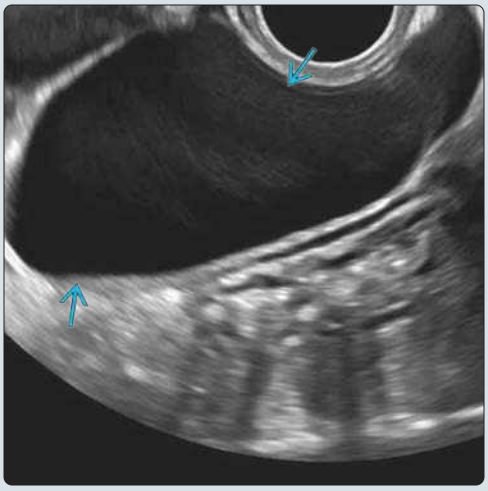


CLINICAL ISSUES

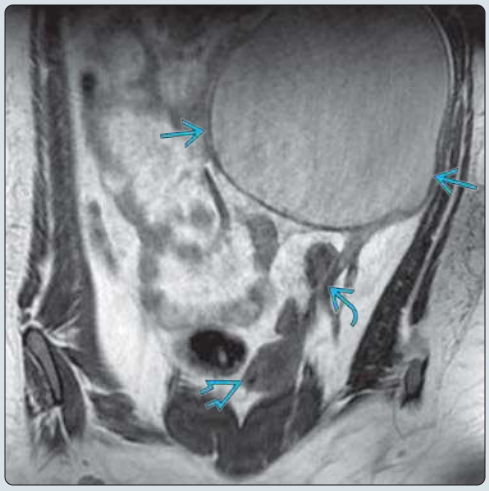


- Abdominal pain &/or distention, mass, ↓ appetite
- Hormonally active tumors
  - Juvenile granulosa-theca cell tumor: 80% present with pseudoprecocious puberty due to hyperestrogenism
  - Sertoli-Leydig cell tumor: ~ 30% virilizing
- Torsion is more likely with benign neoplasms
- Current treatment: Unilateral salpingo-oophorectomy
- Chemotherapy for stage II disease & higher

DIAGNOSTIC CHECKLIST



- Look for signs of tumor rupture/peritoneal seeding



(Left) *Longitudinal color Doppler ultrasound of the ovary in an adolescent diagnosed with an ovarian immature teratoma shows a mixed cystic & solid ovarian mass. The solid portion of the tumor contains a focus of Ca^{2+} with posterior acoustic shadowing.* **(Right)** *Coronal CECT in the same patient shows the ovarian mass containing fat & Ca^{2+}. While the findings are consistent with a teratoma, the designation of tumor maturity can only be made at histology.*

(Left) *Transverse transvaginal ultrasound of the left ovary in an adolescent diagnosed with a borderline serous cystadenoma shows a large cystic mass with no internal complexity.* **(Right)** *Coronal T2 MR in the same patient shows the large cystic left ovarian mass extending to the left upper abdomen. The mass is attached to the fallopian tube, stretching the tube & pulling the uterus to the left.*

IMAGING

General Features

- Best diagnostic clue
  - Germ cell tumors
    - Mature ovarian teratoma: Cystic mass with intratumoral fat & Ca^{2+}
    - Immature ovarian teratoma: Cannot differentiate from mature teratoma on imaging; immature teratomas tend to be larger, have smaller, speckled Ca^{2+}, & have more prominent solid components
    - Dysgerminoma: Multilobulated, solid mass with speckled Ca^{2+}
    - Yolk sac tumor: Large, complex cystic & solid mass that extends into abdomen
    - Choriocarcinoma: Solid, hypervascular mass with elevated β-hCG
  - Sex cord-stromal tumors
    - Juvenile granulosa-theca cell tumor: Large, multilocular mass with septations & solid component
    - Sertoli-Leydig cell tumor: Heterogeneous, cystic, & solid
  - Epithelial tumors
    - Serous tumor: Homogeneous cystic mass with thin walls & no mural nodule
    - Mucinous tumor: Large, heterogeneous, multilocular cystic mass
- Location
  - Most ovarian tumors are unilateral
    - Slightly more common on right
    - Bilateral tumors in 5-15%, depending on tumor type
      - More common with borderline malignant potential epithelial tumors, immature teratomas, & dysgerminomas
- Size
  - Variable; small (< 1 cm) to very large (> 20 cm)

Radiographic Findings

- Mature teratoma: May see tooth-like Ca^{2+}
- Other ovarian tumors: If large enough, tumor can cause mass effect upon bowel, displacing it superiorly & laterally

Ultrasonographic Findings

- International Ovarian Tumor Analysis (IOTA) group rules to distinguish benign from malignant ovarian tumors
  - Not validated in children
  - Factors that favor malignancy: Size > 10 cm, solid tumor, presence of ascites, ≥ 4 papillary structures, hyperemia, irregular borders
  - Factors that favor benign lesion: Unilocular cyst, solid components < 7 mm, presence of acoustic shadows, smooth borders, size < 10 cm, absent blood flow
- Germ cell tumors
  - Ovarian teratoma: Cystic mass with echogenic nodule that shadows (Rokitansky nodule)
    - May have multiple thin, echogenic bands from intratumoral hair
    - May have fat-fluid level
  - Ovarian dysgerminoma: Multilobulated mass with anechoic areas representing hemorrhage or necrosis
  - Yolk sac tumor: Large, heterogeneous mass with cystic & solid components
  - Choriocarcinoma: Mostly solid mass with cystic areas of hemorrhage or necrosis
- Sex cord-stromal tumors
  - Juvenile granulosa-theca cell tumor: Large, multilocular mass with septations & solid component
  - Sertoli-Leydig cell tumor: Heterogeneous mass with cystic & solid components
- Epithelial tumors
  - Serous: Simple cystic mass
  - Mucinous: Large cystic mass with multiple loculations

MR Findings

- Germ cell tumors
  - Mature ovarian teratoma: Intratumoral fat confirmed with fat-saturated images
  - Immature ovarian teratoma: Mass with prominent solid component, cystic areas, & intratumoral fat
  - Dysgerminoma: Multilobulated, septated mass
    - Septa are low signal intensity on all sequences but enhance intensely
  - Yolk sac tumor: Large, heterogeneous cystic & solid mass
  - Choriocarcinoma: Solid enhancing tumor with areas of hemorrhage or necrosis
- Sex cord-stromal tumors
  - Juvenile granulosa-theca cell tumor: Large, multilocular mass with septations & solid component
    - Foci of ↑ T1 signal due to intratumoral hemorrhage
    - Sponge-like appearance with solid areas interspersed with many cystic areas on T2
  - Sertoli-Leydig cell tumor: On T2, mass is predominantly low signal with scattered foci of ↑ signal
- Epithelial tumors
  - Serous: Unilocular cystic mass with homogeneous signal intensity & thin wall
  - Mucinous: Multilocular cystic mass with locules containing fluid of differing signal intensity
- Small cell carcinoma
  - Solid & enhancing mass with cystic or hemorrhagic foci

CT Findings

- MR is preferred to CT for evaluation of ovarian mass
- CT findings similar to MR findings
- CT is more likely to visualize Ca^{2+}
  - Mature ovarian teratoma: Cystic mass + fat & Ca^{2+}
  - Immature ovarian teratoma: Ca^{2+} can be scattered rather than confined to mural nodules
  - Dysgerminoma: May have speckled Ca^{2+}

Imaging Recommendations

- Best imaging tool
  - Ultrasound: 1st-line imaging modality
  - MR for further characterization & localization
    - DWI & T1 C+ FS images can help detect peritoneal tumor deposits
    - ADC values overlap in benign & malignant pediatric ovarian tumors

Tumor Markers Associated With Pediatric Ovarian Tumors

Tumor Markers	Tumor Type
Alpha feto-protein (AFP)	Yolk sac tumor Immature teratoma Embryonal carcinoma Mixed germ cell tumor Sertoli-Leydig cell tumor
Beta-human chorionic gonadotropin (ß -hCG)	Choriocarcinoma Embryonal carcinoma Dysgerminoma
Lactate dehydrogenase (LDH)	Dysgerminoma
CA-125	Epithelial tumors
Inhibin A	Juvenile granulosa cell tumor
Calcium	Sex cord stromal tumor Small cell carcinoma

DIFFERENTIAL DIAGNOSIS

Functional Cyst

- Occurs during follicular phase of menstrual cycle
- Simple ovarian cyst (usually < 3 cm) that resolves over time

Hemorrhagic Cyst

- Variable internal complexity depending on age of blood products
  - Layering debris, lace-like septations, retracting clot
- No internal vascularity

Ovarian Torsion

- Presentation: Acute pain & asymmetric ↑ in ovarian size
- Torsion may occur secondary to mass acting as lead point
  - Tumor is present in 26% of cases of torsion
  - Best suggested by size of lesion & new onset pain

PATHOLOGY

Microscopic Features

- Epithelial serous & mucinous tumors can be differentiated into benign, borderline, & malignant, depending on histology
- Small cell carcinoma of ovary, hypercalcemic type, likely represents malignant rhabdoid tumor

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Abdominal pain &/or distention
- Other signs/symptoms
  - Palpable mass, fever, ↓ appetite
  - Torsion is uncommon presentation for ovarian malignancy
    - Torsion is more likely with benign neoplasms
    - Tumor is present in 26% of cases of torsion; only 3.5% of these tumors are malignant
  - Teratomas may present with N-Methyl-D-aspartic acid or N-Methyl-D-aspartate (NMDA) encephalitis
  - Hormonally active tumors
    - Juvenile granulosa-theca cell tumor
      - 80% present with pseudoprecocious puberty due to hyperestrogenism
    - Sertoli-Leydig cell tumor: ~ 30% virilizing; associated with *DICER1* mutation

Demographics

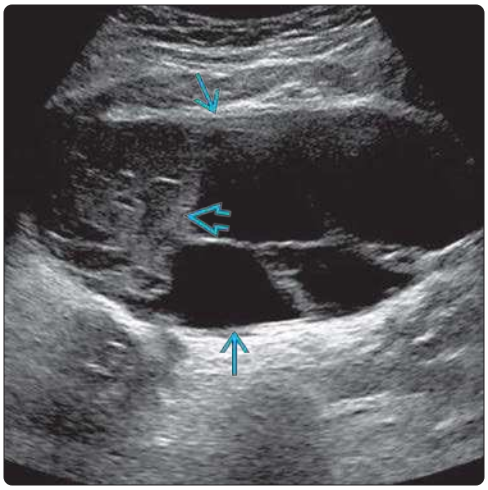
- Epidemiology
  - Incidence of ovarian masses in childhood: 2.6 cases per 100,000 girls per year
  - 16-55% malignant; account for < 3% of all pediatric cancers

Natural History & Prognosis

- Most tumors are FIGO stage I at diagnosis
- Different tumors have different markers (see Table)

Treatment

- Current treatment: Fertility-sparing surgery if possible
- Chemotherapy for stage II disease & higher



DIAGNOSTIC CHECKLIST

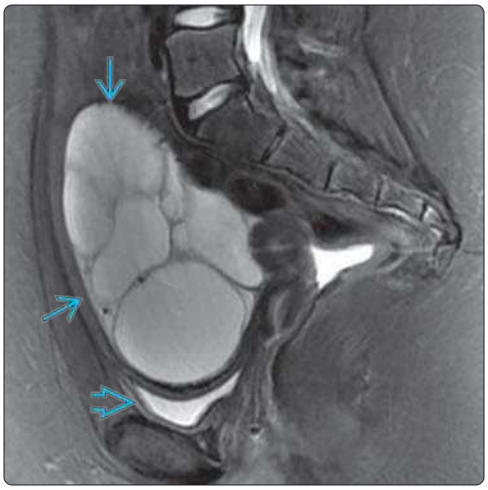


Image Interpretation Pearls

- Fat-containing ovarian mass: Teratoma
- Other ovarian masses are often diagnosed at resection
  - More important to suggest neoplasm & evaluate for complication than name specific tumor type
- Complications include
  - Ovarian torsion (typically in benign lesions)
  - Tumor rupture/peritoneal seeding
    - Irregular or discontinuous tumor margins
    - Ascites ± dependently layering debris
    - Smooth or nodular peritoneal thickening
    - Nodularity & abnormal enhancement of omentum
  - Distant metastases

(Left) *Longitudinal ultrasound of the ovary in an adolescent diagnosed with a granulosa cell tumor shows a mixed cystic & solid mass. The cystic component has multiple septations. A solid component is present in the superior aspect of the mass.* **(Right)** *Sagittal T2 FS MR in the same patient shows the multiseptated granulosa cell tumor superior to the urinary bladder.*

(Left) *Sagittal T1 C+ FS MR in the same patient shows the multiseptated ovarian mass superior to the bladder. The wall & septations of the mass enhance.* **(Right)** *Coronal CECT in an adolescent diagnosed with a metastatic ovarian germ cell tumor shows a large mass extending to the midabdomen. The mass has multiple aggressive features, including septations or nodularity & large internal tumor vessels. A large peritoneal deposit is also present.*

(Left) *Transverse color Doppler ultrasound of the pelvis in an adolescent diagnosed with a small cell ovarian carcinoma shows a mostly solid mass of the left ovary.* **(Right)** *Sagittal T1 C+ FS MR performed in the same patient shows the large ovarian mass. The superior aspect of the mass does not enhance. The inferior aspect of the mass is connected to the fallopian tube. Note the ascites superior to the urinary bladder.*

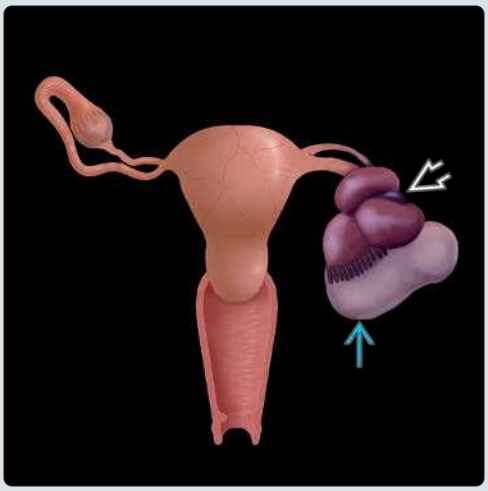
Ovarian Torsion

KEY FACTS

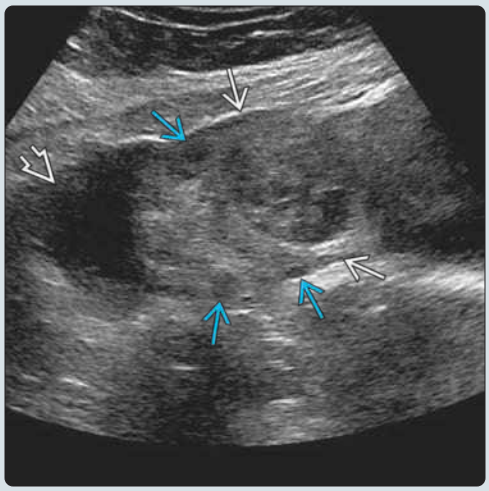
TERMINOLOGY

- Definition: Twisting of vascular pedicle of ovary, fallopian tube, or both → venous obstruction → edema → arterial compromise → ischemia → hemorrhagic infarction

IMAGING

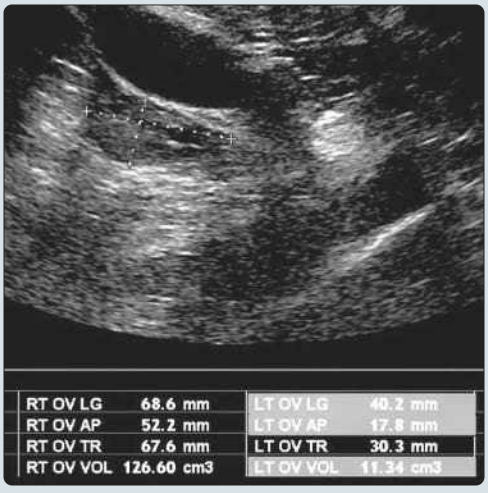


- Unilaterally enlarged ovary
  - Ovarian volume > 100 mL is highly suggestive of torsion
  - Ovarian volume < 20 mL in postpubertal patient was never torsed in one series
  - Ratio of abnormal to normal ovarian volumes ≥ 5:1 strongly correlated with torsion in same series
- Scattered mostly peripheral follicles, often 8-12 mm
- Torsed ovary is often displaced to midline
  - May extend into abdomen or contralateral pelvis
- Sonographic whirlpool sign of twisted vascular pedicle
- Variable patterns of Doppler flow within twisted ovary ranging from normal to completely absent
- Pelvic free fluid or hemoperitoneum
- Hemorrhagic cyst in fetal/neonatal ovary suggests torsion

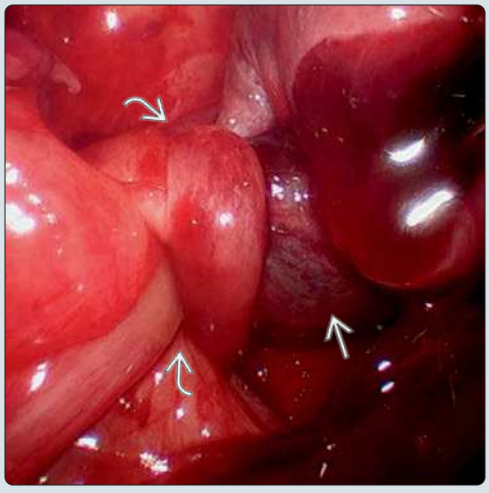


CLINICAL ISSUES

- Urgent surgical detorsion
  - Conservation of ovarian tissue if not frankly necrotic
  - > 90% salvage rate of ovarian function
- Variable rates of retorsion; oophoropexy is controversial



DIAGNOSTIC CHECKLIST



- Painful midline pelvic mass may represent torsed ovary if both normal ovaries are not confidently visualized
- Doppler exam of ovarian parenchyma may be normal despite true adnexal torsion → grayscale findings & high clinical suspicion are more predictive
- Presence of underlying ovarian cyst/mass can create diagnostic dilemma
  - Experienced clinical evaluation is key in these cases
- Normal symmetric grayscale & Doppler appearance of ovaries makes ovarian torsion highly unlikely

(Left) *Graphic shows torsion of the ovarian vascular pedicle & fallopian tube, which results in ischemia of the ovary & distention of the distal segment of the fallopian tube.* **(Right)** *Transverse pelvic ultrasound for acute pain in a 13-year-old girl shows a large 6- to 7-cm heterogeneous mass with adjacent free fluid. A few cysts are present at the outer margin of the mass. No normal right ovary was visualized.*

(Left) *Comparison ultrasound of the left adnexa in the same patient shows the normal left ovary between the cursors, with a volume of 11 mL. The painful right-sided mass (her right ovary) was over 10x as large & was torsed 3x at laparoscopy.* **(Right)** *Intraoperative photograph during laparoscopy shows the typical twisting & spiral appearance of adnexal-supporting structures. The darker structure deep to the twisted tissue is the torsed ovary.*

TERMINOLOGY

Synonyms

- Adnexal torsion, twisted ovary

Definitions

- Twisting of vascular pedicle of ovary, fallopian tube, or both → venous obstruction → edema → arterial compromise → ischemia → hemorrhagic infarction

IMAGING

General Features

- Best diagnostic clue
  - Unilateral ovarian enlargement with scattered peripheral follicles ± discrete cyst or tumor in setting of acute pain
  - Painful midline pelvic mass with failure to identify ipsilateral normal ovary is also very suspicious
  - Doppler exam is not sensitive for ovarian torsion
    - Abnormal flow can be useful adjunct to grayscale
- Location
  - Ovaries usually lie on either side of uterus; torsed ovary is often displaced to midline
    - May extend into abdomen or contralateral pelvis
  - Right ovary is affected slightly more often than left
- Size
  - Twisted adnexa: 7- to 200-mL volume (mean of 24 mL in recent series); rarely > 2,000 mL
  - Twisted ovary is generally > 2x size of contralateral ovary
    - Can be much larger, especially with underlying mass

Ultrasonographic Findings

- Grayscale ultrasound
  - Unilateral ovarian enlargement
    - Ovarian volume > 100 mL suggests torsion
    - Ovarian volume < 20 mL in postpubertal patient was never torsed in one series
      - Ratio of abnormal to normal ovarian volumes ≥ 5:1 strongly correlated with torsion in same series
      - Median torsed to normal ovarian volume ratio of 12:1 in another series
  - Scattered, predominantly peripheral follicles of 8-12 mm in enlarged ovary
    - Moderately sensitive, highly specific for torsion in adolescents
      - Different than numerous "string of pearls" peripheral follicles bilaterally in polycystic ovarian syndrome patient without pain
    - ± fluid-debris levels in follicles; variable size of follicles
    - Follicular ring sign: ↑ echogenicity surrounding follicles in torsion (38%)
  - Variable ovarian parenchymal echotexture depending on presence of
    - Edema vs. hemorrhage/infarction
    - Underlying cystic or solid mass
      - Consider normal vs. abnormal appearance of residual ovary surrounding lesion
  - Failure to confidently visualize bilateral normally positioned ovaries
  - Fallopian tube thickening > 10 mm
  - Pelvic free fluid or hemoperitoneum
  - In neonate, hemorrhagic cyst also suggests torsion
    - Fluid-debris level, retracting clot, lace-like contents
- Color Doppler
  - Sonographic whirlpool sign of twisted vascular pedicle
    - Round, swirling bull's-eye or target appearance of hyper- & hypoechoic rings or stripes ± Doppler flow
    - May only be achieved with endovaginal scanning
  - Variable patterns of flow within twisted ovary ranging from normal to completely absent
    - View any asymmetry in flow with suspicion

MR Findings

- Tubal thickening, enlargement of ovarian stroma
- Scattered T2-hyperintense peripheral follicles
- ± T2 hyperintensity of ovarian stroma
- ± foci of T1 hyperintensity from hemorrhage
- ↓ or absent enhancement of ovarian parenchyma
- Surrounding soft tissue edema & fluid
- Whirlpool sign of twisted vessels & adnexal supporting structures

CT Findings

- Not recommended for evaluation of ovarian torsion but may be 1st modality obtained for other clinical suspicions
- Bland, rounded, soft tissue density mass ± cyst
  - Smooth thickening of wall suggests torsion
- Uterine deviation toward twisted adnexa
- Tubal thickening (> 10 mm) + surrounding edema/fluid
- Ascites, which may be hemorrhagic

Imaging Recommendations

- Best imaging tool
  - Ultrasound: Grayscale findings are more reliable (92% sensitive, 96% specific) than Doppler (50% sensitive)
    - Doppler exam of ovary may be normal despite true adnexal torsion
  - MR offers greater sensitivity & specificity but delays surgical treatment as secondary exam
  - Overall sensitivity: 79-92% for ultrasound; > 95% for MR, 42% for CT
- Protocol advice
  - Endovaginal scanning in patients who are sexually active
  - Transabdominal scanning via well-distended urinary bladder in patients who are not sexually active
    - May need to fill bladder via Foley if patient is vomiting & dehydrated

DIFFERENTIAL DIAGNOSIS

Appendicitis

- Noncompressible, thick-walled, blind-ending tubular structure in right lower quadrant originating from cecum & measuring > 6 mm in diameter with surrounding fat induration; more difficult to define with perforation

Ovarian Cyst

- Simple or hemorrhagic cyst may cause pain without torsion
  - In fetus/neonate, hemorrhagic cyst should suggest torsed ovary
- Avascular internally by Doppler
- Hemorrhagic cyst has reticular septations, debris, nodular clot
- Cyst > 5 cm is more likely to be associated with torsion

Isolated Fallopian Tube Torsion

- Dilated fluid-filled tube or paraovarian cystic mass, often with normal adjacent ovary

Pelvic Inflammatory Disease

- Complex tuboovarian fluid collection in setting of cervical tenderness, discharge, & generalized pain is typical of pelvic inflammatory disease

Ovarian Tumor

- Discrete heterogeneous cystic &/or solid mass
- Painful rarely from rupture or necrosis vs. superimposed torsion (always painful)

Ectopic Pregnancy

- Cystic tubal mass ± yolk sac, extrauterine embryonic cardiac activity, surrounding hyperemia, free fluid
- Serum β-hCG result is crucial

Distal Ureteral Calculus

- Echogenic stone ± Doppler twinkle artifact, posterior acoustic shadowing, thick-walled hydroureter, abnormal ureteral jet, variable hydronephrosis

PATHOLOGY

General Features

- Etiology
  - Usually spontaneous twist of ovary & fallopian tube
    - Torsion of normal adnexal structures is more common in children than adults
  - Developmental abnormalities of fallopian tubes or mesosalpinx (such as excessively long tube or absent mesosalpinx) can precipitate torsion
  - Intrinsic ovarian or tubal disease, tumors, cysts, trauma, or recent surgery also predispose to torsion
    - ~ 50% of pediatric cases have dominant cyst or tumor
      - Torsion is most likely if mass > 5 cm

Microscopic Features

- Peripheral cysts reflect ovarian congestion & transudation of fluid into follicles

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute, severe unilateral lower abdominal/pelvic pain, constant or intermittent
  - Nausea & vomiting (often synchronous with pain)
- Other signs/symptoms
  - Low-grade fever
  - Tender palpable mass
  - Incarcerated inguinal hernia

Demographics

- Age
  - Mean: 10-11 years
  - 50% of cases occur in premenarchal girls
    - Tend to have delayed diagnosis & longer duration of ovarian ischemia
  - ~ 10% occur in perinatal period
- Epidemiology
  - Annual incidence: 1 in 20,000 females ages 1-20 years

Natural History & Prognosis

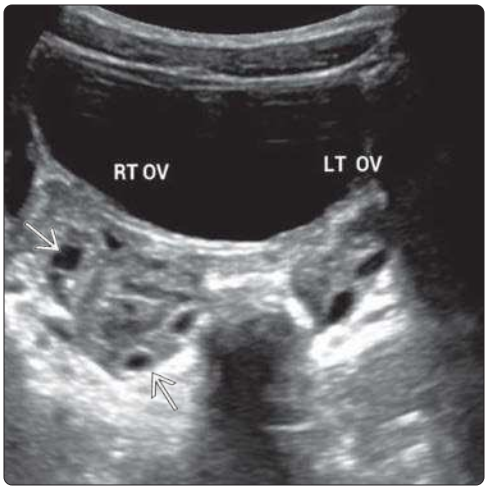
- Infarction → nonfunctioning ovary → infertility risk
- Risk of autoamputation of infarcted ovary → mobile calcified ovary
- Variable retorsion rate after detorsion
  - Higher retorsion rate in prepubertal girls
- Asynchronous bilateral ovarian torsion in 5-10%

Treatment

- Urgent surgical detorsion
  - Conservation of ovarian tissue
    - Oophorectomy is now uncommon, even if necrotic-appearing
  - Oophoropexy (to prevent retorsion) is controversial
- Salvage rates are better for ovarian than testicular torsion
  - > 90% salvage rate for ovarian function
  - Length of symptoms prior to surgery does not always predict viability
  - Appearance at surgery is also not predictive of salvage
- Aspiration ± biopsy vs. resection of cyst or solid lesion

DIAGNOSTIC CHECKLIST

Consider



- Painful midline pelvic mass may represent torsed ovary if 2 normal ovaries are not confidently visualized

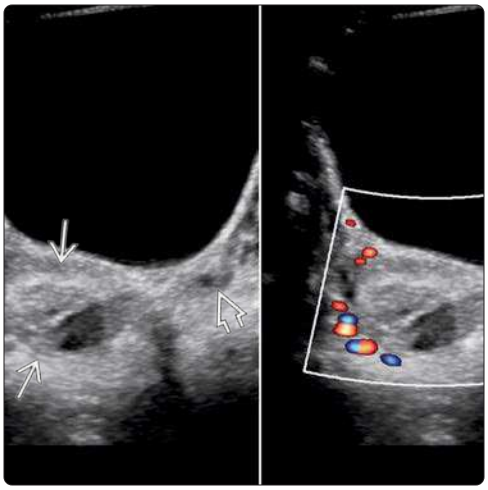


Image Interpretation Pearls

- Documenting normal arterial & venous flow in adnexa does not exclude torsion
  - Grayscale findings & high clinical suspicion are more predictive
- Presence of underlying ovarian cyst/mass can create diagnostic dilemma
  - Hemorrhagic cyst may be painful in absence of torsion despite causing overall ↑ ovarian volume
  - However, cyst/mass also predisposes to torsion & may obscure other classic imaging findings of torsion
  - Experienced clinical evaluation is key in these cases
- Completely normal & symmetric grayscale & Doppler appearance of ovaries makes ovarian torsion highly unlikely

(Left) *Transverse ultrasound in a 6-year-old premenarchal girl shows an enlarged right ovary with peripheral cysts. The right ovarian volume was 4.5x the left ovarian volume in this case of surgically confirmed right ovarian torsion.* **(Right)** *Transverse grayscale & color Doppler ultrasound images show an asymmetrically enlarged & heterogeneous right ovary in this 11-year-old premenarchal girl with a volume of 22 mL (compared to 4 mL on the left side) in another case of ovarian torsion.*

(Left) *Midline longitudinal ultrasound in a 7-year-old girl with acute pain shows a round, solid mass posterior to the uterus. No normal right ovary was identified.* **(Right)** *Transverse color Doppler ultrasound in the same patient shows numerous small peripheral follicles & minimal blood flow within this displaced edematous right ovary. Ovarian torsion was confirmed at surgery.*

(Left) *Transverse ultrasound in an adolescent girl shows a large, heterogenous, complex cystic lesion in the right ovary with shadowing Ca^{2+} corresponding to her point of maximal pain. A mature teratoma with torsion was found at surgery.* **(Right)** *Sagittal T2 FS MR in a 12-year-old girl with pain & a reported "uterine mass" shows an enlarged, displaced, low signal intensity ovary with peripheral follicles & surrounding soft tissue edema, consistent with torsion.*

Ectopic Ovary

KEY FACTS

TERMINOLOGY

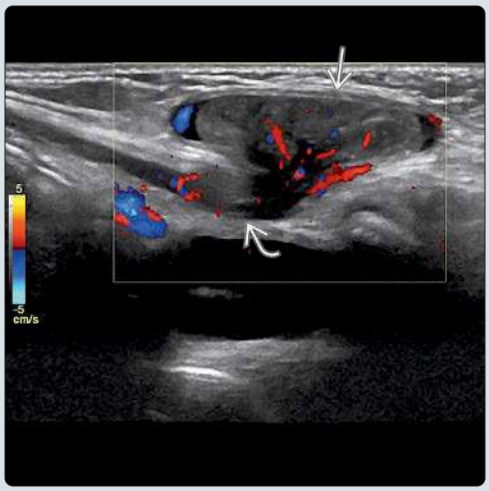
- Ectopic ovary: Abnormally located ovary
  - Inguinal ovarian hernia (95%): Presents as labial mass
    - Canal of Nuck hernia
  - Intraabdominal ectopia may be incidental or iatrogenic
  - Retroperitoneal location is extremely rare

IMAGING

- Labial/groin soft tissue mass with numerous follicles
  - R > L (60% vs. 30%); 10% bilateral
- US is study of choice for palpable inguinal mass (± specific suspicion for ovarian herniation)
  - Use highest frequency transducer available
  - Step-off pad improves visualization of superficial structures (including herniated ovarian follicles)

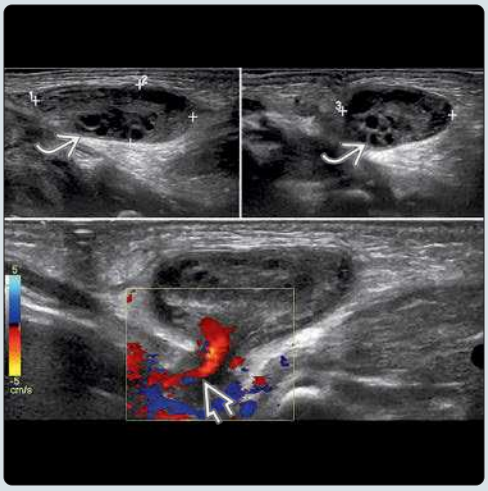
TOP DIFFERENTIAL DIAGNOSES

- Abscess
- Inguinal lymphadenopathy
- Bowel-containing inguinal hernia
- Mesothelial cyst of round ligament
- Ovarian torsion

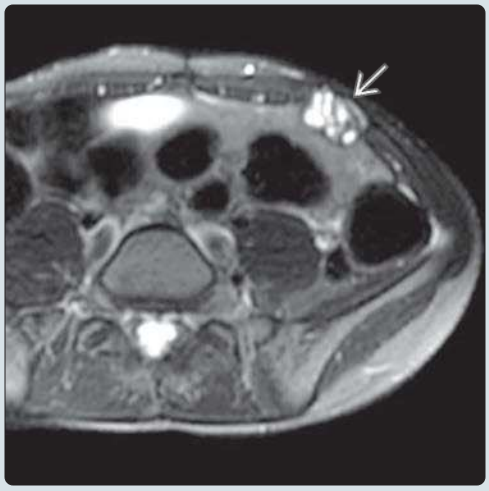


PATHOLOGY

- Canal of Nuck is analogous to processus vaginalis in boys
  - May remain patent in up to 10% of term newborns
- Up to 20% with ovarian herniation also have herniation of salpinx, urinary bladder, bowel, &/or uterus
- ~ 20% of herniated ovaries develop strangulation or torsion
- Small association of ovarian herniation with müllerian anomalies



CLINICAL ISSUES



- Inguinal ovarian hernia should be top consideration in any newborn/infant girl with labial or groin mass
- Little morbidity without superimposed strangulation/torsion

(Left) *Clinical photograph shows an 8-month-old girl with a new, nonpainful right inguinal mass due to herniation of the right ovary through the canal of Nuck. Note the relative concavity on the normal, contralateral side.* **(Right)** *Longitudinal color Doppler US of the right groin in the same patient shows a normal-appearing ovary in the superficial soft tissues. Note the adnexal vessels extending through the canal of Nuck. Transverse US (not shown) better demonstrated anechoic follicles, confirming that this was the ovary.*

(Left) *Longitudinal (top left) & transverse (top right) US images of a palpable labial mass in a newborn show a normal-appearing ovary (calipers) with numerous anechoic follicles. Oblique longitudinal color Doppler US (bottom) better shows the adnexal vessels of the herniated ovary extending though the canal of Nuck.* **(Right)** *Axial T2 FS MR in a 12-year-old girl with several prior surgeries for an anorectal malformation shows an ectopic left ovary positioned in a prior ostomy site.*

TERMINOLOGY

Definitions

- Ectopic ovary: Abnormally located ovary
  - Inguinal ovarian hernia (95%): Presents as labial mass
  - Intraabdominal ectopia: Incidental or iatrogenic
    - Nonstandard ovarian location is common & usually incidental (due to long ovarian ligaments)
    - Nonpelvic location is sometimes seen after numerous or complex abdominopelvic surgeries
    - Ovarian transposition is sometimes performed to preserve fertility prior to radiation therapy
  - Retroperitoneal location is extremely rare

IMAGING

General Features

- Best diagnostic clue
  - Oval soft tissue mass with numerous follicles in unexpected location for ovary
- Location
  - Inguinal, groin, or labial mass (95%)
    - R > L (60% vs. 30%); 10% bilateral
- Size
  - Ovarian size remains normal for age (0.5-3.0 cm)

Ultrasonographic Findings

- Grayscale ultrasound
  - Typical ovarian morphology: Oval soft tissue mass with multiple round anechoic follicles scattered throughout
- Color Doppler
  - Look for ↓, absent, or otherwise abnormal blood flow as sign of ovarian torsion/strangulation
    - Grayscale findings are actually more sensitive

MR Findings

- T2-bright follicles are easily recognized on MR

Imaging Recommendations

- Protocol advice
  - Newborn or infant with groin or labial mass
    - US: Use highest frequency transducer available
    - Step-off pad further ↑ visualization of superficial structures (such as herniated ovarian follicles)
- Suspected intraabdominal ovary in older child
  - Multiplanar T2 MR through pelvis
  - Preceding ovarian stimulation aids identification

DIFFERENTIAL DIAGNOSIS

Abscess

- Complex fluid collection without internal blood flow
- Look for other signs of inflammation/infection: Cellulitis, erythema, exquisite pain, fever, etc.

Lymphadenopathy

- Usually multiple hypoechoic ovoid/reniform masses
- Look for hilar vessels & echogenic fatty hilum
  - May be absent with necrosis or infiltration

Bowel-Containing Inguinal Hernia

- Most common labial mass, often easily reducible
- Look for classic bowel wall US signature & peristalsis

Mesothelial Cyst of Round Ligament

- Benign cyst of round ligament within inguinal canal
- Simple, unilocular cystic mass; may be complex if infected
- Rare; analogous to hydrocele of spermatic cord in boys

Ovarian Torsion

- Swollen, torsed ovary (without herniation) may be displaced to midline or contralateral pelvis
- Failure to visualize 2 normal ovaries in patient with pain & "pelvic mass" → torsion until proven otherwise

PATHOLOGY

General Features

- Canal of Nuck is analogous to processus vaginalis in boys
  - Evagination of parietal peritoneum into inguinal canal
  - Normally loses connection with peritoneal cavity but may remain patent in up to 10% of term newborns
  - Up to 20% with ovarian herniation also have herniation of salpinx, urinary bladder, bowel, &/or uterus

Gross Pathologic & Surgical Features

- Small association with müllerian anomalies
- ~ 20% of herniated ovaries are strangulated or torsed

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Painless, palpable, mobile mass in groin or labia majora
  - Pain & vomiting are common with superimposed strangulation or torsion

Natural History & Prognosis

- Good prognosis with little morbidity if not strangulated

Treatment

- Relatively urgent reduction, hernia repair, & oophoropexy
- Emergent reduction for ovarian strangulation/torsion

DIAGNOSTIC CHECKLIST

Consider

- Always consider ectopic ovary in girls with labial/groin mass
- ~ 10% of term newborns have metachronous hernias

Image Interpretation Pearls

- Look for rare associated müllerian duct anomalies (solitary or pelvic kidney, uterine anomalies, etc.)

Epididymoorchitis

KEY FACTS

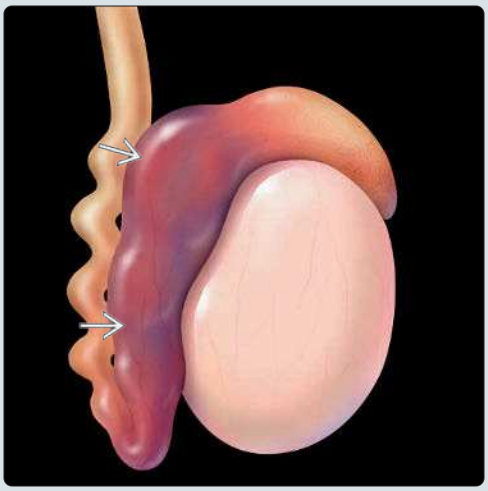
TERMINOLOGY

- Infectious inflammation of epididymis, testicle, or both
- Orchitis alone is much less common than epididymoorchitis

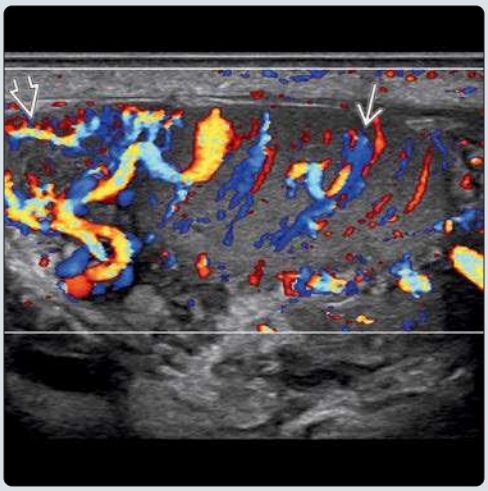
IMAGING

- Enlargement of affected tissues (i.e., testicle, epididymis, or both) with accompanying ↑ blood flow
  - ↑ blood flow is best demonstrated on transverse side-by-side comparison view
  - Arterial waveforms typically remain low resistance
- Echotexture may be ↑ or ↓, often heterogeneous
- Reactive hydrocele
- Scrotal wall is also thickened

TOP DIFFERENTIAL DIAGNOSES



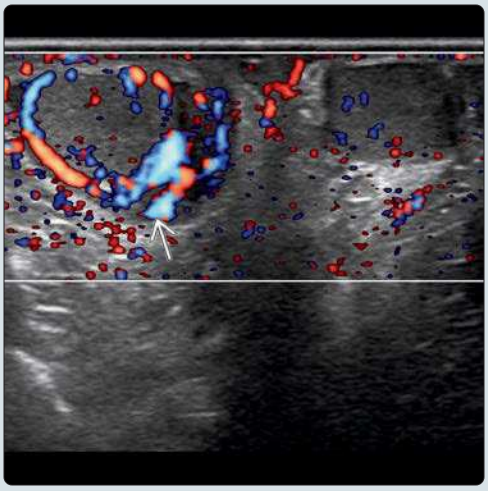
- Torsion of appendage testis/epididymis
- Testicular torsion
- Scrotal cellulitis
- Hernia



PATHOLOGY

- Bacterial infections may be due to ascending infection (in sexually active adolescents), direct seeding of infected urine with genitourinary (GU) anomalies (especially in young children), or hematogenous seeding
- Can also be viral (typically mumps) or posttraumatic
- Some cases of epididymitis are likely due to unrecognized appendage torsion

CLINICAL ISSUES



- Gradual onset of painful scrotum, swelling, erythema ± dysuria, enuresis, frequency
  - Prehn sign: Elevation of affected hemiscrotum relieves pain of epididymitis & exacerbates pain of torsion
- Primary therapy: Antibiotics
- Bedrest, scrotal support & elevation, ice packs, antiinflammatory agents, & analgesics are also used
- Consider work-up for GU anomalies in younger children & recurrent cases

(Left) *Graphic shows epididymitis with an inflamed, hyperemic epididymal body ➔ draped over a normal-appearing testicle. In epididymoorchitis, the testicle would also be inflamed.* **(Right)** *Longitudinal oblique color Doppler US shows marked hyperemia of the left testis ➔ & epididymis ➔ in a teenager with acute pain, consistent with epididymoorchitis.*

(Left) *Transverse grayscale US in a 5-year-old boy with acute right scrotal swelling shows asymmetric enlargement & heterogeneous echotexture of the epididymis ➔. The testicle has ➔ normal echotexture but was larger than the contralateral side. A small, simple hydrocele ➔ is also present.* **(Right)** *Color Doppler US in the same patient shows marked hyperemia ➔ of the right epididymis, testicle, & surrounding scrotal tissues, consistent with epididymoorchitis.*

TERMINOLOGY

Synonyms

- Acute scrotum, epididymitis, orchitis, mumps

Definitions

- Infectious inflammation of epididymis, testicle, or both
- Orchitis alone is much less common than epididymoorchitis

IMAGING

General Features

- Best diagnostic clue
  - Enlargement of affected tissues (i.e., testicle, epididymis, or both)
  - Accompanying ↑ blood flow
  - Small reactive hydrocele
- Location
  - Entire hemiscrotum may show inflammatory changes
  - Acute epididymitis is bilateral in 5-10% of patients

Ultrasonographic Findings

- Grayscale ultrasound
  - Inflamed organs typically show ↑ size when compared to asymptomatic side
  - Echotexture may be ↑ or ↓ from normal, often heterogeneous
  - Reactive hydrocele is common
  - Scrotal wall is also thickened
- Color Doppler
  - Hyperemia of involved tissues
    - Flow in testis typically remains low resistance
  - ↑ blood flow is often best demonstrated on transverse side-by-side comparison view
  - Testicular blood flow can sometimes be difficult to demonstrate in very young males
    - Flow is easy to see in cases of epididymoorchitis
- Power Doppler
  - Doppler flow dramatically ↑

Fluoroscopic Findings

- Voiding cystourethrogram
  - May be performed in infants & nonsexually active boys to exclude underlying genitourinary (GU) anomaly
    - Ectopic ureter, vesicoureteral reflux
    - Urethral abnormality with reflux into vas deferens
    - Voiding dysfunction/high-pressure voiding pattern
  - Trend toward less imaging work-up with presumed viral etiology

Nuclear Medicine Findings

- Nuclear scintigraphy
  - Historical interest only (now replaced by US)
  - Radiotracer of choice: Tc-99m pertechnetate
  - Scan shows hyperemia with ↑ radiotracer accumulation & enlargement; occasional cold rim of large hydrocele

MR Findings

- MR urography if complex GU anomalies are suspected & not fully elucidated by US & VCUG

Radiographic Findings

- No role for radiography except in cases of penetrating injury or suspected foreign body

Imaging Recommendations

- Best imaging tool
  - Ultrasound with Doppler
- Protocol advice
  - High-frequency linear transducer is best
  - Supporting scrotum on towel(s) may be helpful

DIFFERENTIAL DIAGNOSIS

Torsion of Appendage Testis

- Nodular hypo- or hyperechoic avascular mass adjacent to testis with surrounding hyperemia
- Likely is most common cause of acute scrotum in childhood
  - Some cases of epididymal hyperemia are likely reactive from unrecognized appendage torsion

Testicular Torsion

- Unilateral testicular blood flow is diminished or absent (on side of pain)
- May see twist or knot of spermatic cord above testis
- Surgical emergency
- Note that intermittent torsion may show hyperemia; look for other clues, including
  - Abnormal lie of testis
  - Hydrocele completely surrounding testis (suggesting bell-clapper deformity)
  - High-resistance arterial waveforms in setting of "improved pain"

Traumatic Rupture of Testicle

- Focal parenchymal heterogeneity with contour deformity & interruption of echogenic tunica albuginea
- History is typically obvious

Scrotal Cellulitis

- Generalized wall thickening & hyperemia
- Normal testicle & epididymis
- May be infectious, allergic, related to insect bite, or Henoch-Schönlein purpura

Scrotal Hernia

- Herniated abdominal contents are continuous with peritoneal cavity through inguinal canal
- Look for bowel wall signature & peristalsis
- Herniated bowel displaces normal testis & epididymis
  - May cause ↓ blood flow of ipsilateral testis in young infants

Leukemia

- Unilateral or bilateral enlargement
- Parenchyma may be hypoechoic diffusely with palisading vessels

PATHOLOGY

General Features

- Etiology
  - Ascending GU tract infection in sexually active adolescents

- In males 14-35 years of age, disease is most frequently caused by *Neisseria gonorrhoeae* & *Chlamydia trachomatis*
- Retrograde passage of infected urine from prostatic urethra to epididymis via ejaculatory ducts & vas deferens
- Bacterial seeding may also occur
  - Directly in cases with GU anomaly
  - Hematogenously in cases without demonstrable anomaly
- Most often caused by *Staphylococcus aureus*, *Escherichia coli*, or viruses, especially mumps
  - Mumps orchitis often has fever, malaise, & myalgia
  - Parotiditis precedes onset of orchitis by 3-5 days
  - Subclinical infections occur in 30-40% of patients
  - Outbreaks of mumps have been reported in school age children, despite mumps, measles, & rubella (MMR) vaccination
  - Mumps epididymoorchitis most often has focal swelling of epididymal head with head:tail ratio > 2
  - Mumps orchitis is typically unilateral & seen in only 1/3 of all mumps cases
- Associated abnormalities
  - When seen in infants & young children, search for predisposing GU anomaly
    - Ectopic ureter
    - Ectopic vas deferens
    - Prostatic utricle
    - Urethral duplication
    - Posterior urethral valves
    - Urethrorectal fistula
    - Detrusor sphincter dyssynergia
    - Vesicoureteral reflux
    - Neurogenic bladder
    - Anorectal malformation

CLINICAL ISSUES

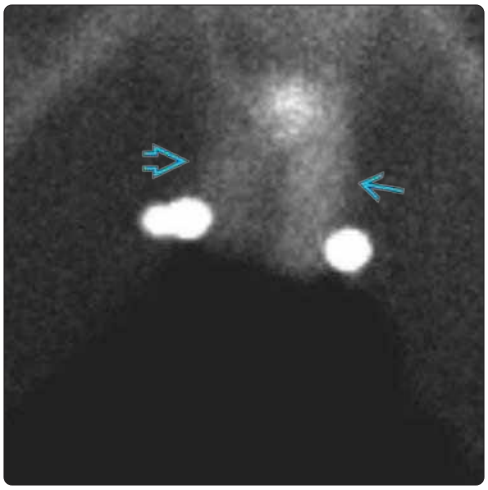
Presentation

- Most common signs/symptoms
  - Gradual onset of painful scrotum, swelling, erythema
  - Systemic symptoms of fever, nausea, vomiting
  - Urinary symptoms of dysuria, enuresis, frequency
- Other signs/symptoms
  - Prehn sign: Elevation of affected hemiscrotum relieves pain of epididymitis & exacerbates pain of torsion
  - Instrumentation & indwelling catheters are common risk factors for acute epididymitis
  - Association with clean intermittent catheterization
  - Urethritis or prostatitis can also coexist

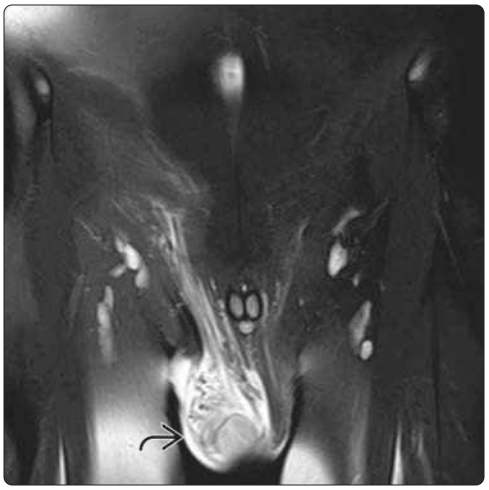
Demographics

- Age
  - Adolescents beginning sexual activity
  - In infants & children, consider work-up for underlying urinary tract anomalies
- Sex
  - Males
- Ethnicity
  - No ethnic or racial predilection
- Epidemiology
  - MMR vaccine has reduced incidence of mumps orchitis
  - 1 in 1,000 men are affected yearly; frequency in pediatric patients is lower
  - Torsion of testicular/epididymal appendage is more common than epididymoorchitis or testicular torsion
    - Some cases of epididymitis are likely due to unrecognized appendage torsion

Natural History & Prognosis



- Prognosis is generally excellent
- Can lead to abscess if not treated
- Can recur in ~ 25%
  - Recurrent episodes can lead to long-term fertility problems
- Term "chronic epididymitis" refers to patients with symptoms lasting ≥ 6 months
- Reports of secondary thrombosis of pampiniform plexus



Treatment

- Antibiotics are mainstay of therapy
  - Antibiotics are reserved for culture positive cases; otherwise, viral etiology is presumed
  - Bedrest, scrotal support & elevation, ice packs, antiinflammatory agents, & analgesics are also used
  - Follow-up scans to exclude abscess if not improving
- Work-up for GU anomalies in younger children & recurrent cases
- Surgical exploration is only performed
  - If testicular torsion cannot be ruled out
  - If complications occur from acute epididymitis & orchitis
    - Abscess, pyocele, testicular infarction

(Left) *Anterior 5-minute image from a Tc-99m pertechnetate scan in a 17-year-old with left scrotal pain demonstrates ↑ radiotracer uptake at the left testicle compared to the right, which can be seen with epididymoorchitis.* **(Right)** *Coronal T2 FS MR in a 12-year-old with 1 week of right hip pain shows marked high signal intensity throughout the right hemiscrotum, suspicious for epididymoorchitis or subacute torsion given the duration of his symptoms.*

(Left) *Transverse side-by-side US performed following the MR shows an enlarged right testicle, enlarged heterogeneous epididymis, hydrocele, & right-sided scrotal wall thickening.* **(Right)** *Transverse side-by-side color Doppler US in the same patient shows hyperemia in all of the right-sided scrotal structures compared to the left, confirming right epididymoorchitis. There was no evidence of testicular torsion.*

(Left) *Transverse US in a 6-year-old boy who had marked scrotal swelling on the left shows a hydrocele, enlarged heterogeneous epididymis, & scrotal wall thickening.* **(Right)** *Transverse side-by-side color Doppler US in the same patient shows marked hyperemia of all the left-sided scrotal contents, consistent with epididymoorchitis.*

Testicular Torsion

KEY FACTS

TERMINOLOGY

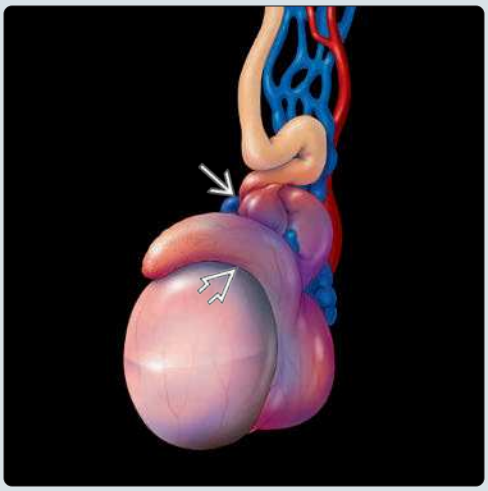
- Spontaneous or traumatic twisting of testis & spermatic cord within scrotum → vascular occlusion/infarction

IMAGING

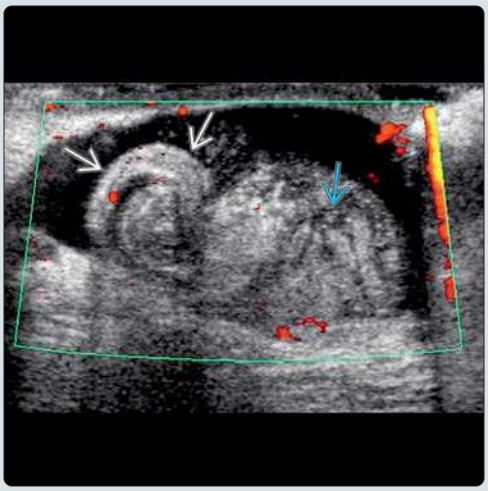
- ↓ or absent blood flow in testicle on Doppler US
  - Transverse side-by-side comparison image of asymptomatic & symptomatic testicles is very helpful
- "Spiral" twist of spermatic cord just above testis
- ± abnormal lie of testicle within scrotal sac
- Enlarged testis ± altered echotexture
- May see hyperemia after detorsion

TOP DIFFERENTIAL DIAGNOSES

- Epididymoorchitis or orchitis
- Torsion of testicular or epididymal appendage
- Testicular trauma
- Hernia complications

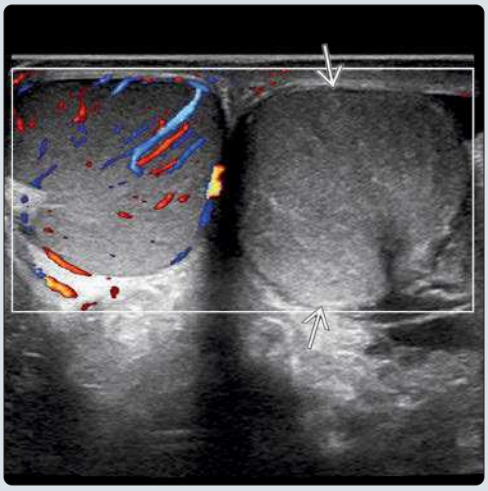


PATHOLOGY

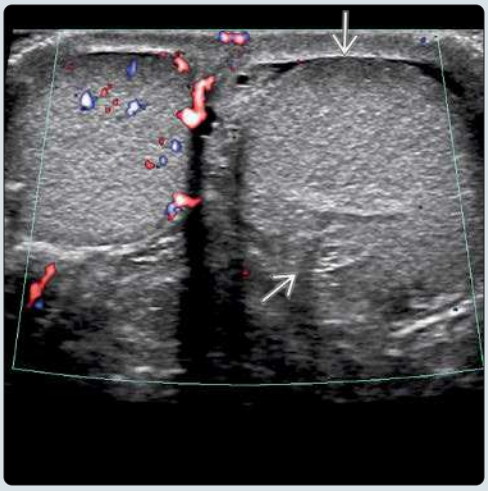


- Intravaginal torsion of spermatic cord
  - Abnormally high attachment of tunica vaginalis → bell clapper deformity
- Extravaginal torsion of spermatic cord
  - Occurs proximal to attachments of tunica vaginalis
  - More common in neonates; rarely salvageable

CLINICAL ISSUES



- Presents with acute scrotal &/or inguinal pain
- Surgical emergency to prevent testicular infarction
- Surgical exploration with detorsion & bilateral orchiopexy if testicle is viable
  - Nonviable testicle is usually removed
- Salvage rates
  - 80-100% within 6 hours of pain onset
  - Virtually 0% after 12 hours of pain onset



(Left) *Anatomic drawing of testicular torsion shows a twisted cord (resembling a snail shell) & an enlarged epididymis.* **(Right)** *Longitudinal power Doppler US at the inguinal-scrotal junction shows a twisted spermatic cord ("cord knot") surrounded by a hydrocele in a teenager with several hours of left-sided scrotal pain. The epididymis is enlarged & heterogeneous, & no flow was seen in the testicle (not shown), consistent with torsion.*

(Left) *Transverse side-by-side US of the testes in a 3-year-old with scrotal pain & swelling shows a mildly enlarged left testis with no color Doppler flow & a small hydrocele. Left testicular torsion was found at surgery.* **(Right)** *Transverse side-by-side view of the scrotum in a teenager awakened from sleep by left-sided pain shows a mildly enlarged & avascular left testis, confirmed as torsion at surgery.*

TERMINOLOGY

Synonyms

- Torsion, late or "missed" torsion, acute scrotum

Definitions

- Spontaneous or traumatic twisting of testis & spermatic cord within scrotum → vascular occlusion/infarction
- Testicle twists medially in 2/3 of cases, so manual detorsion laterally is more likely to be effective
  - Direction of manual detorsion is described as "opening book"

IMAGING

General Features

- Best diagnostic clue
  - ↓ or absent blood flow in testicle on color Doppler US
    - Easiest to appreciate when compared side by side to normal flow in asymptomatic testicle
- Location
  - Unilateral in 95% of patients
  - Caution: Undescended testes can also torse!
    - Look for avascular inguinal testis & empty hemiscrotum
- Size
  - Normal testicular volume
    - 1 mL in newborn
    - 15-20 mL in postpubertal males
  - Volume may ↑ in torsion depending on severity & length of ischemia

Ultrasonographic Findings

- Grayscale ultrasound
  - Testicular parenchyma may be normal early
    - Gradual development of hypoechoic &/or heterogeneous testicular parenchyma
    - Intratesticular necrosis, hemorrhage, or fragmentation is seen with delayed diagnosis
  - Enlarged testicle & epididymis
    - Remote torsion shows small testicle ± Ca^{2+}
  - Testicle may lie in abnormal plane
  - Spiral, whirlpool, or knot twist of spermatic cord just above testicle (below inguinal canal)
    - Snail shell-shaped mass measuring 11-33 mm
  - Reactive or secondary hydrocele
  - Scrotal wall thickening
- Color Doppler
  - Absent or ↓ blood flow throughout testicle
    - Compare side by side with asymptomatic testicle
    - Small percentage of patients with early or partial torsion have normal exam
  - ± high-resistance residual flow in partially or intermittently torsed testicle
  - Peripheral capsular & scrotal wall hyperemia
  - Hyperemia may be seen in testicle after detorsion
- Microvascular Doppler imaging is helpful in neonates & prepubertal testes
- Sensitivity of 86%, specificity of 100%, accuracy of 97% in diagnosis of testicular torsion when presence of intratesticular flow is sole criterion for diagnosis
- Contrast-enhanced ultrasound is seldom indicated

Nuclear Medicine Findings

- Tc-99m pertechnetate: Sensitivity 80-90%
  - Technique
    - Dynamic flow imaging at 2- to 5-second intervals for 1 minute (vascular phase)
    - 5-minute intervals for tissue phase
    - Pinhole collimation is useful, especially in young patients
    - Penis should be positioned out of field of view, usually secured to anterior abdominal wall
    - Scrotum is supported symmetrically on towels
  - "Cold" spot of torsed testicle with surrounding hyperemia

Imaging Recommendations

- Best imaging tool
  - US with high-frequency linear transducer & color Doppler
- Protocol advice
  - Power Doppler with comparison to contralateral normal testis
    - Particularly helpful in neonates & young boys
  - Transverse superior to inferior sweep of spermatic cord from distal inguinal canal through testis will help demonstrate "cord knot"

DIFFERENTIAL DIAGNOSIS

Epididymoorchitis or Orchitis

- Enlarged hypoechoic epididymis with ↑ flow on color Doppler
- Swollen heterogeneous epididymis may mimic cord knot of torsion

Torsion of Testicular or Epididymal Appendage

- Look for round, devascularized, enlarged, heterogeneous appendix with surrounding hyperemia

Inguinal Hernia

- Incarcerated/strangulated hernia can mimic testicular torsion
- Can cause ↓ blood flow in testis in neonate/infant

Testicular Trauma

- Hematocele, irregular contours, heterogeneous parenchymal echogenicity, ± interruption of echogenic capsule

Testicular Tumor

- Focal intratesticular mass with abnormal flow

PATHOLOGY

General Features

- Etiology
  - Most occur spontaneously; occasionally due to trauma
- Embryology/anatomy
  - Intravaginal torsion of spermatic cord
    - Abnormally high attachment of tunica vaginalis → bell clapper deformity
      - Testicle rotates freely within scrotum → spermatic cord twists → venous flow occludes → arterial flow occludes

- Bell clapper deformity is present in 12% of male population at autopsy
  - Much higher than testicular torsion
- Extravaginal torsion of spermatic cord
  - Occurs proximal to attachments of tunica vaginalis
  - More common in neonates
  - Accounts for only 5% of all cases of testicular torsion
  - Bilateral in 20%

Staging, Grading, & Classification

- Previously classified as acute, subacute, or delayed based on duration of symptoms
  - Duration of symptoms is not always predictive of salvage rate, especially in partial or intermittent torsion

Gross Pathologic & Surgical Features

- Purple, edematous, ischemic testicle; may rapidly reperfuse when manually untwisted
- Varying degrees of ischemic necrosis & fibrosis depending on duration of symptoms

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute scrotal &/or inguinal pain; occasionally referred pain in abdomen
  - Swollen erythematous hemiscrotum without recognized trauma
  - Physical exam findings highly predictive of testicular torsion include
    - Elevation of affected testicle
    - Transverse position of testicle
    - Anterior rotation of epididymis
    - Absence of cremasteric reflex
    - Pain relief with successful manual detorsion
    - TWIST score 0-6
  - In neonates, purple discoloration of swollen scrotum may indicate extravaginal testicular torsion
    - More common in high birth weight babies
    - Can be confused with scrotal hematoma due to birth trauma
- Other signs/symptoms
  - Nausea & vomiting
  - Incomplete/intermittent torsion may be tolerated for long periods
  - Almost 1/2 of patients have history of similar symptoms previously that resolved spontaneously
    - Indicates spontaneous torsion & detorsion

Demographics

- Age
  - Bimodal peak: Teenagers during puberty vs. neonates
- Sex
  - Males only
- Epidemiology
  - Epididymoorchitis & torsion of testicular appendage > testicular torsion
  - 4.5/100,000 males < 25 years of age per year

Natural History & Prognosis

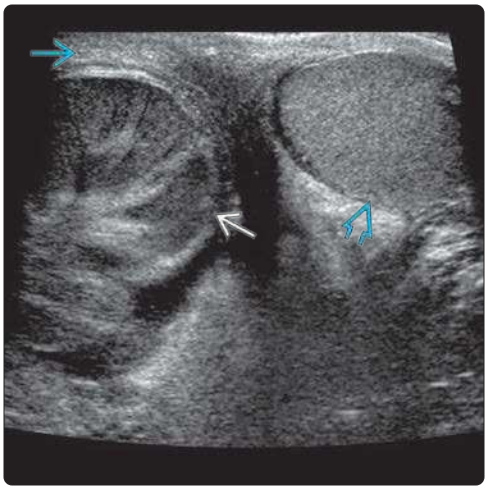
- Surgical emergency: Testicular infarction if not treated promptly
- Testicular viability depends on
  - Degree of torsion: > 540° twist is worse
  - Duration of symptoms & time to surgical intervention
    - ~ 1/3 of testes are not salvageable at operation
- Unilateral testicular loss typically does not lead to infertility problems

Treatment

- Surgical exploration + detorsion + bilateral orchiopexy if testicle is viable
  - Nonviable testicle is usually removed (due to antisperm antibody theory)
  - Higher risk of subsequent torsion on contralateral side justifies contralateral pexy
- Salvage rates
  - 80-100% within 6 hours of pain onset
  - Virtually 0% after 12 hours
  - Only 9% salvage rate in neonates
- Neonatal torsion: Asynchronous contralateral torsion in 5%; prompt surgery & orchiopexy are recommended
- Bilateral pexy is advocated in children with intermittent scrotal pain
  - Risk of testicular loss approaches 80% in patients with intermittent torsion
- Orchiopexy does not 100% guarantee against future torsion
  - Case reports of torsion postpexy → twisted hammock appearance
- Antioxidant medications, heparin, & steroids are being tested to ↓ ischemia-reperfusion injury

DIAGNOSTIC CHECKLIST

Consider



- Early/partial/intermittent torsion may not show complete absence of flow

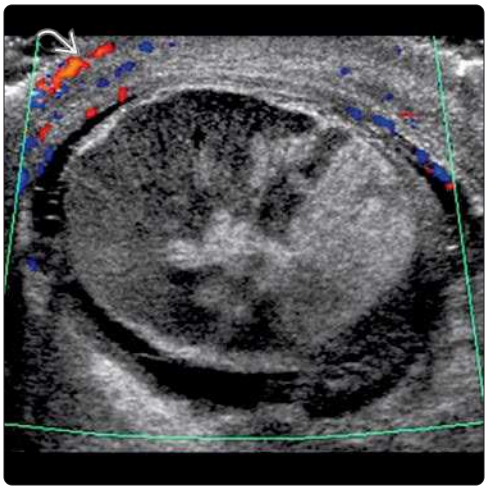


Image Interpretation Pearls

- Heterogeneity of avascular testicular parenchyma on US ↓ likelihood of salvageability

(Left) *Transverse US in a 13-year-old boy with 2 weeks of waxing & waning pain in the right scrotum shows an enlarged right testis ➡ with heterogeneous echotexture. There is also a small right hydrocele with scrotal wall thickening ⇨. The left testis has a normal homogeneous echotexture ⇨.* **(Right)** *Transverse color Doppler US of the symptomatic right testicle shows absent blood flow within the testicle, confirming subacute testicular torsion. Note the mild hyperemia ➡ in the thickened scrotal wall.*

(Left) *Transverse power Doppler US in a 14-year-old boy with acute left-sided pain shows absent blood flow in the left testicle ➡, consistent with testicular torsion. After the patient repositioned his scrotal contents on the exam cushions, he exclaimed that he felt much better.* **(Right)** *Repeat power Doppler US in the same patient shows hyperemia in the previously avascular symptomatic testicle, indicating spontaneous/manual detorsion. This testicle remains at risk for retorsion & requires orchiopexy.*

(Left) *Longitudinal color Doppler US in a teenage boy with several hours of right-sided pain & swelling shows a large hydrocele with mobile debris ➡ & an avascular enlarged right testis ➡. Note the enlarged epididymis ➡.* **(Right)** *Transverse color Doppler US of both testes in the same teenager shows a complex hydrocele ➡, avascular right testis ➡, hyperemia of the thickened scrotal wall ⇨, & blood flow in the left testicle ⇨. At surgery, the right testis was necrotic & could not be salvaged.*

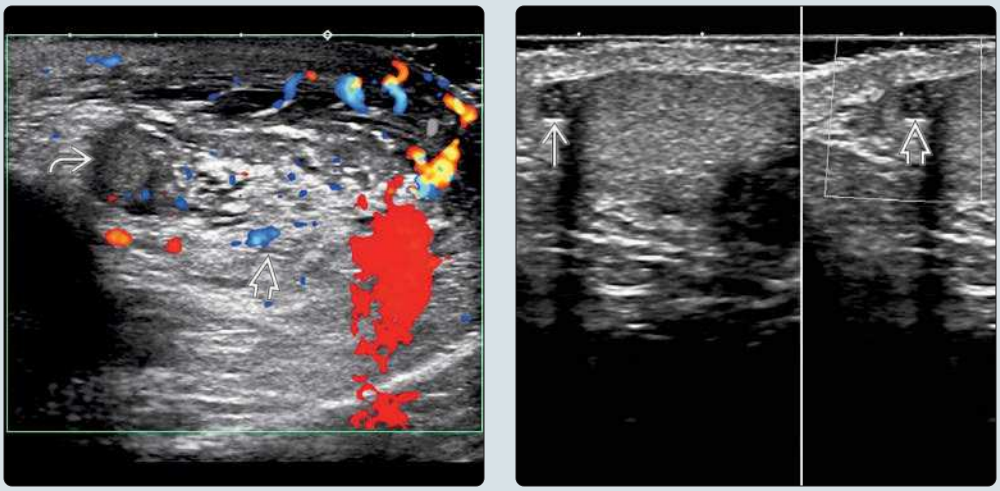
Torsion of Testicular Appendage

KEY FACTS

TERMINOLOGY

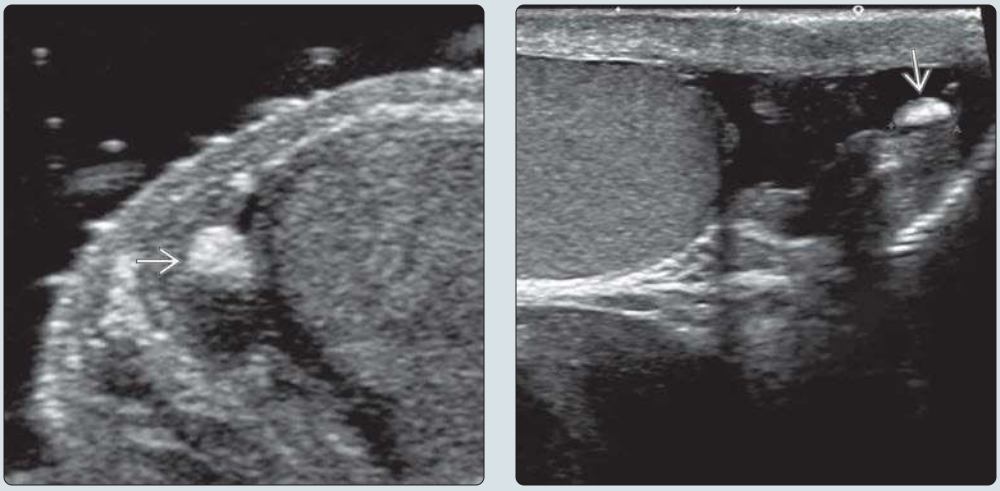
- Synonyms: Twisted appendage, torsed appendix testis, torsion of appendix epididymis, appendiceal torsion
- Definitions
  - Spontaneous twisting of pedunculated vestigial remnant along testicle or epididymis, causing ischemia & pain
  - Acute scrotal pain in children: Torsed appendage is most common (62%)
    - Testicular torsion 25%, epididymoorchitis 10%, trauma 2%

IMAGING



- Ultrasound with Doppler: Best imaging modality
- Appendage size is best indicator of torsion (> 5-6 mm acutely)
- Spherical shape suggests swelling (normally vermiform)
- Duration of symptoms determines echogenicity
  - < 24 hours: Hypoechoic with salt & pepper pattern
  - > 24 hours: Hypo-, iso-, or hyperechoic
- Classically ↓ or absent internal vascularity of torsed appendix with periappendiceal hyperemia
- Reactive hydrocele & scrotal wall edema are common

TOP DIFFERENTIAL DIAGNOSES



- Testicular torsion
- Epididymoorchitis or orchitis
- Isolated scrotal wall edema
- Inguinal hernia complications
- Testicular or paratesticular tumor
- Testicular trauma

CLINICAL ISSUES

- Acute scrotal pain, swelling
- ± small, tender, mobile lump at upper pole of testis
- ± blue dot sign of ischemic appendage seen through scrotal wall in minority of patients (< 30%)
- 80% of cases are 7-14 years old; mean age: 9 years
- Self-limited illness, excellent prognosis

(Left) *Longitudinal color Doppler US in 7-year-old with scrotal pain & swelling shows lack of blood flow in a small round nodule ➪ adjacent to an inflamed epididymis ➪. Testicular blood flow (not shown) was normal. The findings are consistent with a torsed appendage.* **(Right)** *Longitudinal US images of epididymis in a 6-year-old show a hypoechoic nodule ➪ (superior to the testis) that is avascular ➪ on Doppler. This was the point of maximal discomfort & likely represented a torsed appendage.*

(Left) *Oblique scrotal US shows an echogenic appendage ➪ in a patient with a subacute history of pain. The ↑ echogenicity may reflect acute hemorrhage vs. more chronic fibrotic change or Ca^{2+} in a torsed appendage.* **(Right)** *Longitudinal US shows a hyperechoic ovoid focus ➪ surrounded by a small hydrocele, consistent with a partially calcified, chronically torsed appendage. At this point in time, the patient was asymptomatic.*

TERMINOLOGY

Synonyms

- Twisted appendage, torsed appendix testis, torsion of appendix epididymis, appendiceal torsion

Definitions

- Spontaneous twisting of pedunculated vestigial remnant along testicle or epididymis, causing ischemia & pain
- Most common etiology of acute scrotal pain in children
  - Incidence > > epididymoorchitis & testicular torsion

IMAGING

General Features

- Best diagnostic clue
  - Enlarged, spherical, hypoechoic, avascular nodule along testis or epididymis at site of patient pain + hyperemia of surrounding tissues
    - Reactive hydrocele is very common
- Location
  - Most common appendage to twist: Testicular remnant of paramesonephric (müllerian) duct
    - Located between superior pole of testis & epididymis
  - Appendix epididymis is remnant of mesonephric (wolffian) duct
    - Most often seen projecting from head of epididymis
  - Other minor appendages of testicle & epididymis have variable locations & may also twist
  - Can be difficult to differentiate testicular vs. epididymal appendage (not clinically relevant)
- Size
  - Appendage > 5.6 mm in size: Diagnostic of acute torsion
    - Enlarged appendage sensitivity of 68.2% & specificity of 100%
    - Normal appendix is usually tubular, pedunculated, & ≤ 4 mm
  - Chronically torsed appendage is also small
- Morphology
  - Spherical shape & enlargement are most reliable indicators of appendiceal torsion
  - Echotexture is not predictive of torsion, but ↑ echotexture is associated with longer chronicity

Ultrasonographic Findings

- Grayscale ultrasound
  - Appendix size is best indicator of torsion (> 5-6 mm acutely)
  - Spherical shape suggests swelling (normally vermiform)
  - Duration of symptoms determines echogenicity
    - < 24 hours: Hypoechoic with salt & pepper pattern
      - Echogenic dots & septa
    - > 24 hours: Hypo-, iso-, or hyperechoic
  - Reactive hydrocele
  - Scrotal wall edema
  - Epididymal head enlargement
- Color Doppler
  - Classically ↓ or absent internal vascularity of torsed appendix with periappendiceal hyperemia
    - Findings can be variable
  - Testicular blood flow may be normal or ↑
- Power Doppler
  - Useful in younger, uncooperative patients
    - Sensitive for low flow; no directional information
- Contrast-enhanced ultrasound
  - May be useful in equivocal exams but delays surgery if there is testicular torsion

MR Findings

- Reserved for complex cases or to clarify abnormal anatomy

Nuclear Medicine Findings

- Tc-99m pertechnetate scan
  - Historic interest only: Replaced by ultrasound
  - Normal testicular uptake, excluding diagnosis of testicular torsion
  - May show focal ↑ or ↓ uptake in region of superior testicle at site of twisted appendix
    - Focal "hot" spot is equivalent to blue dot sign seen on physical exam
  - Technique is same as scan for testicular torsion
    - Pinhole or low-energy, high-resolution collimator
    - Scrotum supported on towels; penis secured up & out of field of view
    - Dynamic acquisition during blood flow or perfusion phase
    - Static delayed imaging ± markers

Imaging Recommendations

- Best imaging tool
  - Ultrasound with Doppler
    - More sensitive & specific for diagnosing appendage torsion than
      - Clinical signs alone
      - Imaging in other causes of acute scrotal pain (i.e., testicular torsion or epididymoorchitis)
- Protocol advice
  - High-frequency linear transducer
  - Thick layer of ultrasound gel ↓ discomfort during scan
  - Support scrotum on towels
  - Compare with asymptomatic side

DIFFERENTIAL DIAGNOSIS

Testicular Torsion

- Abnormal Doppler (absent, diminished, or high-resistance flow) in painful testis compared to asymptomatic side
- Whirlpool or knot sign of twisted spermatic cord above testis
- Normal grayscale appearance of testicular parenchyma early with subsequent changes of frank infarction

Epididymoorchitis/Orchitis

- Hyperemia & enlargement of affected side ± tissue heterogeneity
- Global tenderness on physical exam

Isolated Scrotal Wall Edema

- Thickening, heterogeneity, & hyperemia of scrotal wall
- May be isolated & self-limited or due to cellulitis, insect bite, allergic reaction, or Henoch-Schönlein purpura

Inguinal Hernia Complications

- Normal peristalsing bowel vs. abnormal, thick-walled ischemic bowel tracking from peritoneal cavity through inguinal canal into scrotum
- Pressure effects may cause testicular ischemia in young infants

Testicular or Paratesticular Tumor

- Distortion of normal sonographic anatomy by focal intratesticular or paratesticular mass
- Scrotal tumors range from small & homogeneous to large & heterogeneous
- Usually manifest with gradual swelling or palpable mass, not pain

Testicular Trauma

- Hematocele, altered testicular echotexture, irregular testicular contour with capsular disruption
- History of trauma is usually known

PATHOLOGY

General Features

- Etiology
  - Spontaneous twisting of appendage is most common; occasionally associated with trauma or tumor
  - Rising levels of estrogen & androgens early in puberty may account for appendiceal enlargement & predisposition to appendiceal torsion in this age group
    - Testicular appendage contains variable numbers of both androgen & estrogen receptors
  - Metachronous contralateral testicular appendage torsion is reported in < 5%
- Associated abnormalities
  - Rare case reports of tumors arising in scrotal appendages
    - Appendix testis contains müllerian epithelium
    - May produce epithelial tumors similar to those occurring in female genital tract
  - Paratesticular tumors (e.g., rhabdomyosarcoma) are likely arise from stromal tissues rather than appendages

Microscopic Features

- Variable degrees of interstitial edema, hemorrhage, & necrosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute scrotal pain & swelling
  - ± small, tender, mobile lump at upper pole of testis
  - ± blue dot sign of ischemic appendage seen through scrotal wall in minority of patients (< 30%)
- Other signs/symptoms
  - Metachronous & bilaterally synchronous cases of appendiceal torsion are rarely reported

Demographics

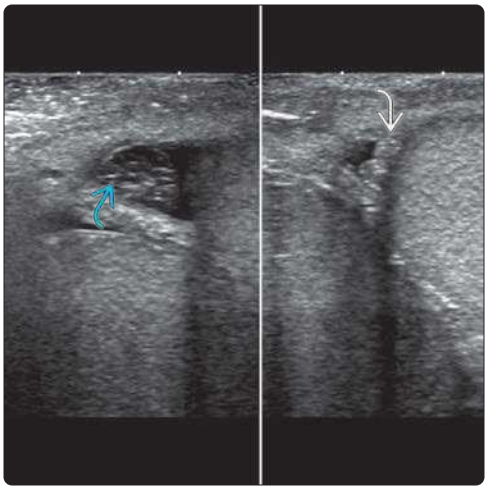
- Age
  - 80% of cases occur between ages 7-14 years
  - Mean age: 9 years
    - Mean age of 14 years for testicular torsion & epididymoorchitis
- Sex
  - Males only
- Epidemiology
  - Most common cause of acute scrotal pain in children
    - Torsion of testicular or epididymal appendage: 62%
    - Testicular/spermatic cord torsion: 25%
    - Epididymoorchitis: 10%
    - Trauma: 2%
  - Incidence of 1 in 2,000 males

Natural History & Prognosis

- Self-limited illness, excellent prognosis
- Pain usually resolves within 1 week
- Consider repeat imaging if symptoms persist
  - Rare reports of secondary infection in infarcted, necrotic tissue

Treatment

- Analgesics & antiinflammatory agents for symptom relief
  - Antibiotics are not indicated in routine cases
- Reports of manual detorsion with ultrasound guidance
  - Reduction by pulling or squeezing appendage
  - Success if pain relieved, appendix size ↓, Doppler flow restored
- Resection of torsed appendage if scrotum is explored due to concern for testicular/spermatic cord torsion
  - Surgery is not indicated if torsed appendix diagnosis is clear



DIAGNOSTIC CHECKLIST

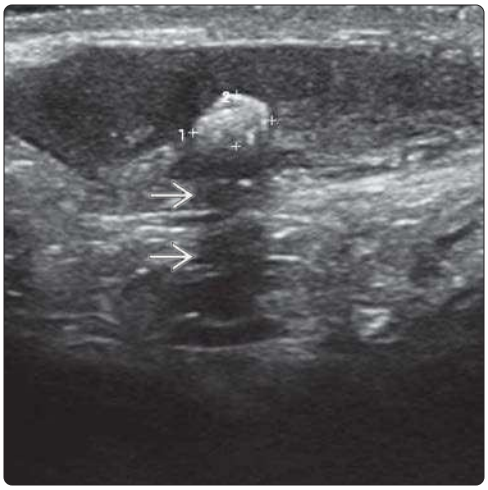


Image Interpretation Pearls

- Can be difficult to distinguish from epididymitis if no discrete nodule is visualized
  - Appendage torsion is more common, especially in prepubertal population
  - Treatment for both entities is nonsurgical

(Left) *Transverse US views of the scrotum show asymmetric size & shape of small appendages along the testes. The right appendage is enlarged, ovoid, & hypoechoic compared to the isoechoic & vermiform left appendage. Pain at this site on the right confirmed acute torsion of the appendage.* **(Right)** *Longitudinal US in the lateral aspect of the scrotum shows a hyperechoic nodule between cursors with posterior shadowing, consistent with a calcified, autoamputated remotely torsed appendage.*

(Left) *Longitudinal color Doppler US in a 12-year-old boy with acute right-sided scrotal pain shows an ovoid, heterogeneously hypoechoic, avascular nodule along the superior pole of the testis, consistent with a torsed appendage.* **(Right)** *Longitudinal color Doppler US of the scrotum in a 15-year-old boy with acute left-sided scrotal pain shows a small discrete avascular nodule at the lower pole of the left testis. There is surrounding hyperemia & an adjacent hydrocele, consistent with appendage torsion.*

(Left) *Longitudinal color Doppler US in a 5-year-old boy with scrotal pain shows a round, heterogeneously hypoechoic nodule along the superior pole of the testicle. Note the internal salt & pepper appearance with surrounding hyperemia but no internal vascularity, consistent with a torsed appendage.* **(Right)** *Coronal localization PET/CT shows a tiny Ca^{2+} in the right scrotum in this teenage boy having oncologic imaging. The Ca^{2+} is most likely due to the remote torsion of a testicular appendage.*

Paratesticular Rhabdomyosarcoma

KEY FACTS

TERMINOLOGY

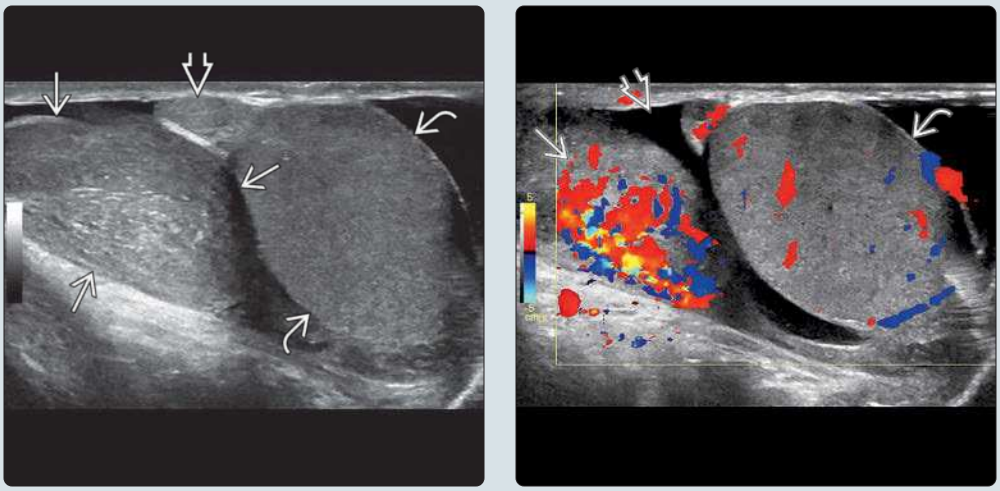
- Malignant solid tumor of mesenchymal origin; arises from skeletal muscle precursors
- Paratesticular rhabdomyosarcoma (PT-RMS) refers only to intrascrotal rhabdomyosarcoma (RMS), not other genitourinary sites

IMAGING

- Large, lobulated paratesticular mass with variable echogenicity; often heterogeneous & hypervascular compared to testis
  - Usually arises in epididymis; may arise from or invade tunica, testis, or spermatic cord
  - Can be ill defined or well defined; may encase testicle
- Look for retroperitoneal adenopathy

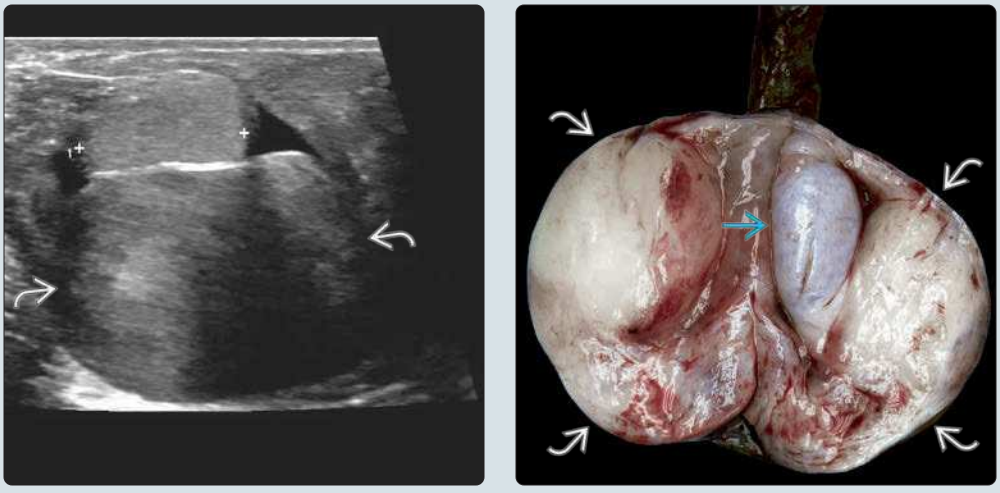
TOP DIFFERENTIAL DIAGNOSES

- Epididymitis: Usually painful swelling; no discrete mass
- Inguinal hernia: Peristalsing bowel loop in inguinal canal
- Hematoma: Avascular, associated with trauma
- Lipoma: Usually homogeneously hyperechoic
- Polyorchidism: Identical appearance to testis
- Testicular adrenal rests: Multiple, bilateral, intratesticular



PATHOLOGY

- Most PT-RMS are embryonal RMS subtypes
- Most cases are sporadic; ↑ risk with *TP53* mutations, *DICER1* mutations, RASopathies



CLINICAL ISSUES

- Gradual, painless scrotal swelling, ± palpable mass
- 2 age peaks: < 5 years vs. 2nd decade
- Most common extratesticular solid mass in boys
- PT-RMS accounts for ~ 5% of childhood RMS but has much better prognosis than other forms of genitourinary RMS
  - > 90% survival rate for localized (nonmetastatic) PT-RMS
  - Age < 1 or > 10 years, tumor size ≥ 5 cm, & lymph node involvement portend worse prognosis

(Left) *Longitudinal oblique US through the left hemiscrotum shows a slightly heterogeneous & hyperechoic paratesticular soft tissue mass. Note the normal testis & epididymis.* **(Right)** *Color Doppler US in the same patient reveals markedly ↑ blood flow within the mass compared to the testis. Also note the small hydrocele. This mass was a localized paratesticular rhabdomyosarcoma (PT-RMS).*

(Left) *Scrotal US in a 5-year-old with 1 week of right scrotal swelling shows a large, slightly heterogeneous paratesticular mass, ultimately proven to be a PT-RMS. Real-time imaging showed the mass to almost completely surround the testis (shown with calipers).* **(Right)** *Gross pathologic bivalved specimen in the same patient status post orchiectomy shows a large, bland, tan-white PT-RMS almost completely surrounding, but not invading, the testis.*

TERMINOLOGY

Abbreviations

- Paratesticular rhabdomyosarcoma (PT-RMS)

Definitions

- Malignant solid tumor of mesenchymal origin arising from skeletal muscle precursors

IMAGING

General Features

- Best diagnostic clue
  - Large, vascular paratesticular soft tissue mass
- Location
  - PT-RMS refers only to intrascrotal RMS; other genitourinary locations of RMS are considered separately
  - Usually arises within epididymis but can occur within testicular tunica, testis, or spermatic cord
- Morphology
  - Can be ill defined or well defined, may encase testicle, & may invade tunica or testis itself

Ultrasonographic Findings

- Lobulated paratesticular mass with variable echogenicity, often heterogeneous
- Doppler shows ↑ blood flow compared to testes
- May have associated hydrocele

CT Findings

- Chest/abdomen/pelvis CT used to evaluate for lung metastases & retroperitoneal lymphadenopathy (LAD)
- PET/CT improves sensitivity for nodal disease

MR Findings

- Generally not indicated for PT-RMS (vs. RMS) but may be used to evaluate retroperitoneal LAD

DIFFERENTIAL DIAGNOSIS

Epididymitis

- Enlarged, hypervascular epididymis; no distinct mass
- History usually involves painful scrotal swelling

Inguinal Hernia

- Peristalsing bowel loops, omental fat
- Continuity with peritoneal cavity through inguinal canal

Lipoma

- Most common benign paratesticular neoplasm
- Usually within spermatic cord; homogeneously hyperechoic on US & of fat attenuation/signal on CT/MR

Adenomatoid Tumor

- Most common benign tumor of epididymis
- Usually affects young adult men aged 20-30 years
- Typically well-circumscribed, round to oval, homogeneous mass with variable echogenicity

Polyorchidism

- Well-defined mass resembling normal testicle
- Ipsilateral testis is often small, may be contiguous
- Identical appearance to testis on all imaging modalities

Testicular Adrenal Rest Tumors

- Multiple, bilateral (usually peripheral) intratesticular masses with ↑ vascularity; typically hypoechoic
  - Intermixed with echogenic mediastinum testis
- Adrenal rests are trapped in developing fetal testis
  - 10-15% of newborns; < 1% of adults
  - Enlarge if exposed to ↑ ACTH; otherwise, regress

Splenogonadal Fusion

- Extremely rare, almost always left sided; occurs in association with limb deficiency & micrognathia
- May be in continuity with spleen (through inguinal canal)
- Splenic scintigraphy can be diagnostic

PATHOLOGY

General Features

- Etiology
  - Primitive skeletal muscle precursors within testes, epididymis, & spermatic cord
- Associated abnormalities
  - Most cases are sporadic
  - Several genetic diseases have predisposition for RMS

Staging, Grading, & Classification

- RMS consists of 6 histologic subtypes; most PT-RMS are of embryonal subtypes
- Staging is complex: PT-RMS is stratified into 1 of 4 risk groups based on TNM stage, histologic subtype, extent of postoperative residual tumor, & age at diagnosis

Gross Pathologic & Surgical Features

- Tumor spreads mostly by lymphatics → retroperitoneal LAD
- Hematogenous spread is less common: Liver, lungs, & bones
- Direct invasion of tunica or testicle is rare

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Gradual, painless scrotal swelling, ± palpable mass

Demographics

- 2 age peaks: < 5 years vs. 2nd decade

Natural History & Prognosis

- Most common extratesticular solid mass in boys
- PT-RMS accounts for ~ 5% of childhood RMS but has much better prognosis than other forms of genitourinary RMS
  - > 90% survival rate for localized (nonmetastatic) PT-RMS
  - Age < 1 or > 10 years, tumor size ≥ 5 cm, & lymph node involvement portend worse prognosis

Treatment

- Multimodal treatment based on local control & assessment of any distant involvement: Radical orchiectomy, chemotherapy, ± radiation

SELECTED REFERENCES

1. Rogers TN et al: Surgical management of paratesticular rhabdomyosarcoma: a consensus opinion from the Children's Oncology Group, European Paediatric Soft Tissue Aarcoma Study Group, and the Cooperative Weichteilsarkom Studiengruppe. Pediatr Blood Cancer. 68(4):e28938, 2021

Testicular Tumors

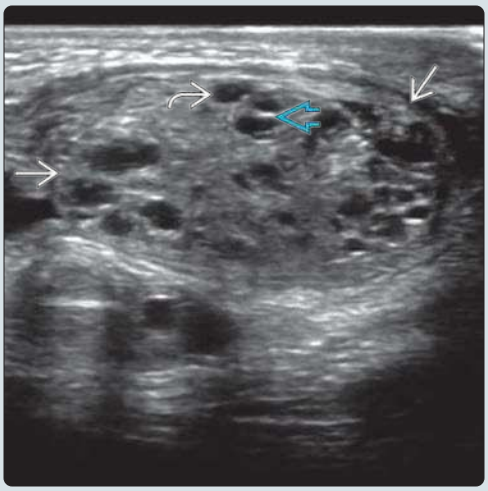
KEY FACTS

TERMINOLOGY

- Testicular neoplasms: Germ cell vs. nongerm cell tumors
  - Germ cell tumors: ~ 2/3 of pediatric tumors
  - Nongerm cell tumors: ~ 1/3 of pediatric tumors
  - Lymphoma & leukemia can also involve testes

IMAGING

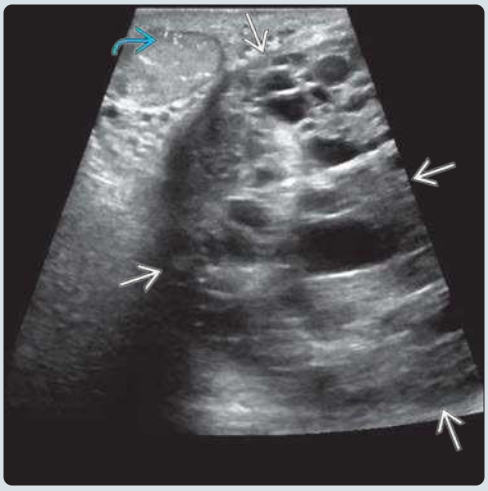
- Intratesticular mass of variable echogenicity & vascularity
- Vary widely in size, from imperceptible to testis-replacing
- Teratomas characteristically have extremely complex appearance with cystic areas, Ca^{2+}, solid components, & punctate or linear echogenic hairs
- Epidermoids (true cysts, not neoplasms) appear solid, targetoid, or "onion skin" from laminations of keratinizing stratified squamous epithelium
- Regressed MGCTs may appear as subtle architectural distortion with ill-defined microcalcification
- Sex cord-stromal tumors are often small & well defined



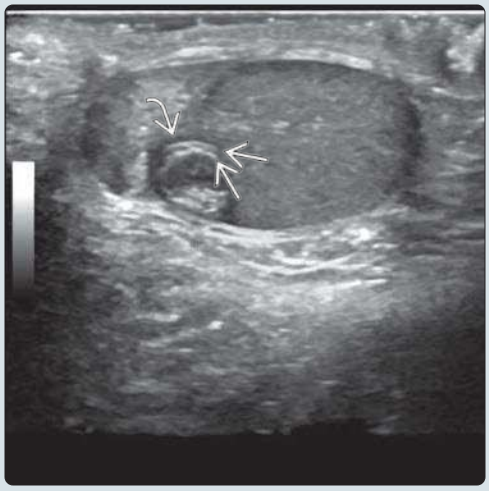
CLINICAL ISSUES

- Presentations: Asymptomatic or painless mass
- ↑ risk with microlithiasis or cryptorchidism
- Most prepubertal intratesticular masses are benign (teratoma, epidermoid), though YSTs are 2nd most common tumor
  - YSTs: 90% have ↑ AFP, used as tumor marker
- Most postpubertal intratesticular masses are malignant: Embryonal carcinoma & MGCT most common
- Standard of care: Orchiectomy; testis-sparing enucleation is increasingly performed in newborns & prepubertal boys without ↑ AFP; ± adjuvant chemotherapy depending on tumor type & stage

DIAGNOSTIC CHECKLIST



- Use high-frequency linear-array US transducer
  - With other diagnostic considerations (e.g., hematoma, focal orchitis), short-term follow-up can help clarify
- MR for problem-solving or questionable masses



(Left) *Longitudinal US of a juvenile granulosa cell tumor in a newborn with firm testicular enlargement shows a heterogeneous mass replacing the testis. There are numerous hypoechoic foci separated by thin septations, a classic appearance for this rare tumor.* **(Right)** *Gross pathologic photograph status post orchiectomy in the same patient shows complete replacement of the testis by a gray-white tumor with scattered cystic spaces & foci of hemorrhagic staining.*

(Left) *Transverse US shows a large left-sided testicular teratoma in a 15-year-old with 12 months of painless scrotal swelling. The 8-cm partially cystic mass is quite heterogeneous & complex, as is typical of this common pediatric testicular tumor. Note right-sided microlithiasis.* **(Right)** *Longitudinal US shows an intratesticular epidermoid incidentally discovered in a child with contralateral epididymitis; note its multilaminated onion skin appearance, a classic finding in epidermoids.*

TERMINOLOGY

Synonyms

- Yolk sac tumor (YST): Endodermal sinus tumor, orchioblastoma
- Teratoma: Differentiated or mature teratoma, undifferentiated or immature teratoma
- Mixed germ cell tumor (MGCT): Polyembryoma
- Leydig cell tumor: Interstitial cell tumor
- Sertoli cell tumor: Androblastoma

Definitions

- Primary testicular tumors: Germ cell tumors (GCTs) vs. non-GCTs
- GCTs: ~ 2/3 of pediatric testicular tumors
  - YST: Histologically recapitulates yolk sac, allantois, & extraembryonic mesenchyme
  - Teratoma: Contains elements of all 3 germinal layers (endoderm, mesoderm, & ectoderm)
    - Mature contains only well-differentiated tissues; immature adds fetal elements
    - Epidermoids: Monodermal cysts (not neoplasms) filled with keratinizing stratified squamous epithelium
  - Embryonal carcinoma: Malignant tumor of anaplastic undifferentiated cells similar to those seen in very early embryo
  - Choriocarcinoma: Rare, highly malignant tumor composed of placenta-like tissues
  - Mixed GCTs: Malignant tumor of 2 or more germ cell types
  - Seminoma: Malignant tumor of germ cell origin lacking any embryonic elements
- Non-GCTs: ~ 1/3 of pediatric testicular tumors
  - Leydig cell tumors: Recapitulate normal development of Leydig cells (stromal cells that produce androgens)
  - Sertoli cell tumors: Recapitulate normal development of Sertoli cells (sex cord cells that support spermatogonial stem cells)
  - Juvenile granulosa cell tumors: Extremely rare stromal tumor that resembles ovarian graafian follicles
- Lymphoma & leukemia can also involve testes

IMAGING

General Features

- Best diagnostic clue
  - Intratesticular mass ± internal vascularity
- Morphology
  - Epidermoids, YSTs, & sex cord-stromal tumors tend to be well defined; others tend to be ill-defined

Ultrasonographic Findings

- Nonspecific appearance for most testicular masses, necessitating surgery
  - Most nonseminomatous GCTs have variable echogenicity
    - ± hypo-, iso-, or hyperechoic; homogeneous vs. heterogeneous
    - Commonly have cystic areas from necrosis & echogenic areas from Ca^{2+}, fibrosis, or hemorrhage
    - More aggressive tumors (especially embryonal carcinoma) may invade tunica albuginea
    - YSTs are often well defined; may simply enlarge testis without discernible mass
  - Teratomas characteristically have extremely complex appearance with cystic areas, Ca^{2+}, solid components, & punctate or linear echogenic hairs
  - Epidermoids (true cyst, not neoplasm) appear solid, targetoid, or "onion skin" from laminations of keratinizing stratified squamous epithelium
  - Regressed MGCTs may appear as subtle architectural distortion with ill-defined microcalcification
  - Seminomas are usually hypoechoic, homogeneous, well-defined intratesticular masses with lobulated margins
  - Sex cord/stromal tumors may be small & well defined
    - Most (2/3) juvenile granulosa cell tumors are multicystic, multiseptated; remaining 1/3 appear solid
    - Leydig cell tumors are usually small (< 1-cm diameter) & very well defined; markedly hypervascular on color Doppler & contrast-enhanced US; stiffer than surrounding parenchyma by elastography

MR Findings

- Nonseminomatous GCTs are usually heterogeneous, T1 iso- or hyperintense, T2 hypointense
- Regressed MGCTs have ill-defined areas of low T2 signal or architectural distortion without visible mass
- Seminomas are usually homogeneous, T1 isointense, & T2 hypointense
- Look for pelvic & retroperitoneal adenopathy

Imaging Recommendations

- Best imaging tool
  - US ~ 100% sensitive; MR for problem-solving
  - Chest (CT) + abdomen & pelvis (CT or MR) screening for metastases, depending on tumor type
- Protocol advice
  - US: Supine positioning with warm folded towel between thighs to support scrotum; use highest frequency linear-array transducer available; color Doppler setting should be sensitive to low-velocity flow
  - MR: Large field-of-view (FOV) axial T2 FS & DWI from kidneys through pelvis; small FOV high-resolution T2 FS images in 3 planes + axial GRE & T1 FS pre- & post gadolinium of scrotum

DIFFERENTIAL DIAGNOSIS

Hematoma

- History is crucial, but trauma does not exclude hemorrhage of preexisting neoplasm
- Can be multifocal & any size; color Doppler demonstrates no internal vascularity
- Hyperacute/acute → isoechoic to parenchyma; chronic → becomes hypoechoic/anechoic; 24-hour repeat US can be useful to document evolution

Focal Orchitis

- Presents with acute scrotal pain & swelling; concomitant epididymitis is common
- Altered echotexture, swelling, hypervascularity
- Appearance improves with short-term follow-up

Epidermoid Cyst

- Ectodermal inclusion cyst; most common benign intratesticular mass
- Laminated, concentric rings of low & high echogenicity or signal, a.k.a. onion skin pattern; no blood flow
- Surgeon may remove by enucleation, not orchiectomy

Testicular Adrenal Rest Tumors

- Adrenal rests (not neoplasm) trapped in developing fetal testis, found in 10-15% of newborns
- Enlarge if exposed to ↑ adrenocorticotrophic hormone; otherwise, regress; seen in < 1% of adults
- Multiple bilateral intratesticular nodules; usually near mediastinum or peripheral
- Usually hypoechoic but may be hyperechoic; may have homogeneous or heterogenous echogenicity
- Characteristic low T2 signal; hypo- or isointense on T1
- Variable vascularity (often hypervascular) but do not distort vessels passing through lesion

Dilated Rete Testes

- Benign dilation of tubules near mediastinum, rare in boys
- Often bilateral; associated with spermatoceles; geographic margins, no mass effect

Segmental Infarction

- Uncommon, may see in sickle cell disease
- Wedge-shaped hypoechogenicity with absent or diminished flow; MR may show hemorrhagic signal around avascular region

PATHOLOGY

Staging, Grading, & Classification

- No universal staging system for pediatric testicular tumors
- Children's Oncology Group stages GCTs
  - Stage I: Limited to testis; complete resection, normal tumor markers
  - Stage II: Invasion of scrotum or spermatic cord, incomplete resection (microscopically), persistent elevation of tumor markers
  - Stage III: Incomplete resection (macroscopically); retroperitoneal lymph node involvement but no visceral or extraabdominal metastases
  - Stage IV: Distant metastases

CLINICAL ISSUES

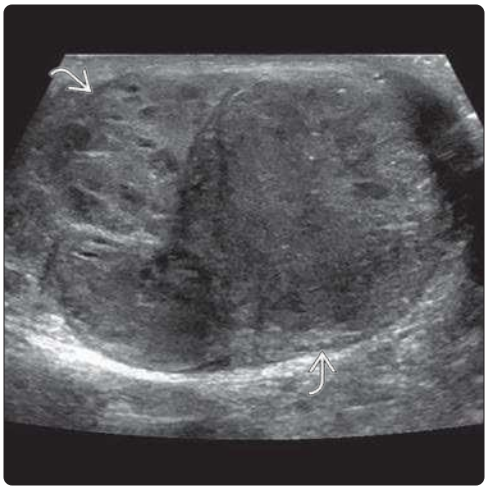
Presentation

- Most common signs/symptoms
  - Asymptomatic; painless (rarely painful) testicular mass; mild discomfort or pain in abdomen, groin, or testicle; perceived scrotal heaviness
- Other signs/symptoms
  - YST: 90% have ↑ α-fetoprotein, used as tumor marker
  - Choriocarcinoma: Most have ↑ β-hCG; diagnosis is usually due to result of hematogenous metastasis
  - Sertoli cell tumors: Painless mass in infants; may have gynecomastia
  - Leydig cell tumors: Boys aged 5-10 years; may elaborate testosterone or have ↑ estrogen & estradiol levels → precocious puberty or gynecomastia
  - Juvenile granulosa cell tumors: Most frequent congenital testicular neoplasm

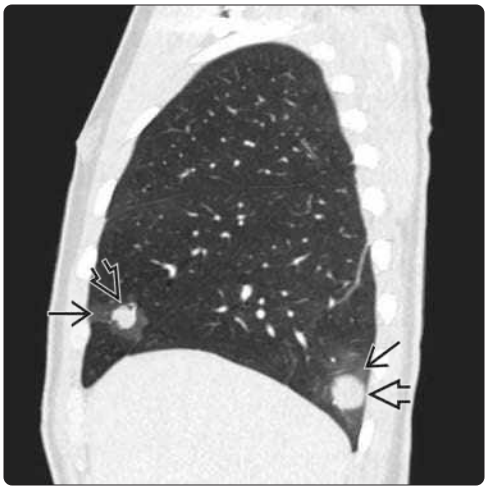
Demographics

- Represent 1-2% of childhood solid tumors
- ~ 1 per 100,000 boys; most common malignancy in postpubertal young men (15-34)
- 2 age peaks: First 2 years of life & late adolescence
  - Most prepubertal masses are benign (teratoma, epidermoid), though YSTs are 2nd most common tumor
    - YST: Most common pure GCT
    - Teratoma: Increasingly reported as most common prepubertal tumor; most present in 1st year of life
      - Prognosis depends on age rather than presence of mature or immature histologic features
  - Most postpubertal masses are malignant: Embryonal carcinoma & MGCT are most common
    - Embryonal carcinoma: Very rare prior to puberty
    - Seminoma: Extremely rare prior to puberty; usually men
- 10% are associated with cryptorchidism
  - If orchiopexy occurs before puberty → relative risk is 2x that of general population
  - If orchiopexy after puberty → relative risk is 5x that of general population
- ↑ risk in patients with microlithiasis

Natural History & Prognosis



- YST: Most in infants are stage I → orchiectomy only, > 80% are disease free at 6 years; recurrence has excellent response to platinum therapy
- Teratoma: Age predicts prognosis → benign in prepubertal testes, even if immature; 1/3 are malignant in postpubertal teratomas, even if mature
- Choriocarcinoma: Seen in older adolescents & young men, usually with advanced disease
- Juvenile granulosa cell tumors: Benign & hormonally inactive; 20% are associated with Y-chromosomal &/or urogenital abnormalities



Treatment

- Standard of care: Orchiectomy; testis-sparing enucleation may be performed in newborns & prepubertal boys without ↑ AFP
- YST & teratomas in prepubertal boys may need no further treatment beyond orchiectomy

(Left) *Longitudinal US in a 17-year-old boy who presented with chronic fatigue & a large, firm testicular mass shows a lobulated, complex, & heterogeneous lesion replacing the right testis. Blood tests revealed anemia & elevated levels of LDH & β-hCG. Metastatic choriocarcinoma was ultimately diagnosed.* **(Right)** *Sagittal lung CECT in the same patient with choriocarcinoma demonstrates well-defined pulmonary metastases with surrounding areas of ground-glass attenuation due to hemorrhage.*

(Left) *Transverse US in an infant with nonpainful testicular swelling shows a well-defined, complex testicular mass. Note the echogenic, solid component surrounded by fluid. A mature teratoma was found at resection.* **(Right)** *Longitudinal grayscale & color Doppler US images in a 7-year-old with precocious puberty, ↑ testosterone, & a bone age 8 standard deviations above the mean show a well-defined, hypoechoic testicular mass with marked hypervascularity, ultimately proven to be a Leydig cell tumor.*

(Left) *Transverse grayscale US (top) shows asymmetric enlargement of the left testis due to leukemic infiltration. Color Doppler US (bottom) shows marked asymmetric hyperemia of left testis compared to the normal right side, a common finding in leukemic infiltration.* **(Right)** *Coronal STIR MR in a teenager with a thigh hematoma shows 2 incidental hypointense masses in the left testis. Note the normal homogeneously hyperintense appearance of the right testis. Seminoma was found at biopsy.*

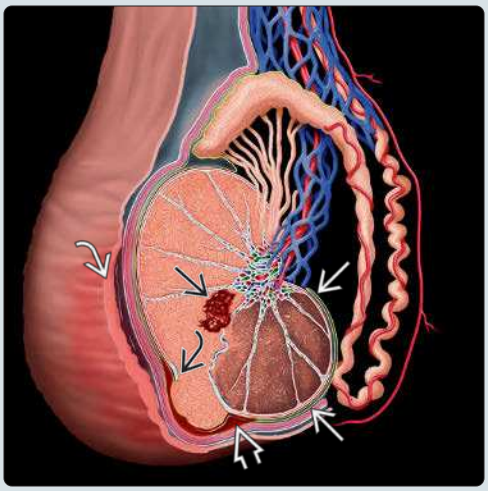
Testicular Trauma

KEY FACTS

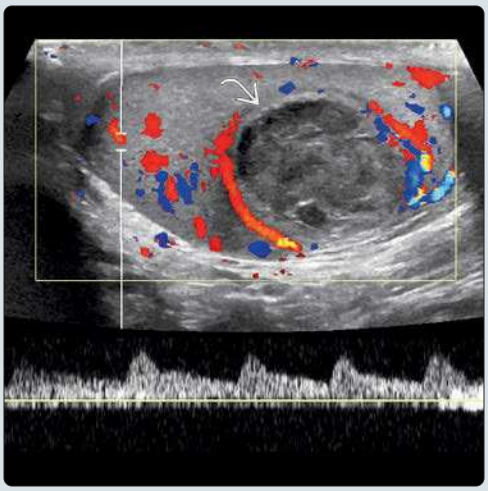
TERMINOLOGY

- Hydrocele: Simple fluid between layers of tunica vaginalis
- Hematocele: Blood between tunica vaginalis layers
- Hematoma: Contained collection of blood products within testis, epididymis, or scrotal wall; may involve ≥ 1 site
- Testicular fracture: Disruption of testicular parenchyma
- Testicular rupture: Disruption of tunica albuginea, often with extrusion of testicular parenchyma
- Devascularization: Vascular pedicle injury causing absent or diminished blood flow without true torsion (twisting)
- Traumatic epididymitis: Epididymal contusion causing inflammation, enlargement, & hypervascularity
- Traumatic testicular ectopia: Traumatic dislocation of testis into inguinal canal, abdominal cavity, or perineum

IMAGING

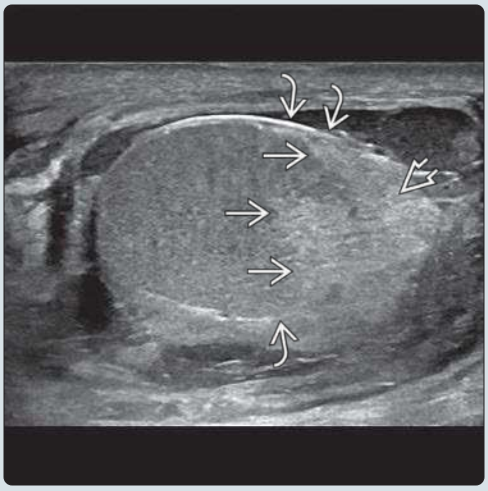


- Look for alteration of normal testicular echotexture, disruption of tunica albuginea, absent or diminished blood flow, complex hydrocele, &/or scrotal wall thickening

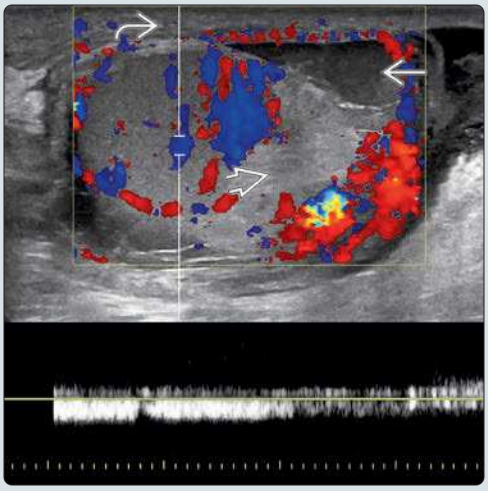


TOP DIFFERENTIAL DIAGNOSES

- Infectious epididymitis
  - Epididymal enlargement, heterogeneity, & hyperemia
  - Imaging is indistinguishable from trauma without history
- Testicular torsion
  - No blood flow to testis; twisting of spermatic cord
  - May occur spontaneously or after minor trauma
- Torsion of testicular appendage
  - Leading cause of acute scrotum in boys
  - Enlarged, spherical, echogenic, pedunculated remnant of tissue, ± periappendiceal hyperemia, reactive hydrocele
- Neoplasm
  - Rare, but 10-15% are found during US for scrotal trauma
  - Intratesticular mass with vascular flow (vs. testicular hematoma, which will not have blood flow)



CLINICAL ISSUES



- Testicular fracture/rupture → urologic emergencies → prompt treatment reduces infection, atrophy, necrosis

(Left) *Graphic shows various manifestations of scrotal trauma, including a scrotal wall hematoma, rupture of the tunica albuginea, segmental testicular infarction, parenchymal hematoma, & a small hematocele.* **(Right)** *US in a teenager with hemophilia A who hit a tree while skiing shows a well-defined, heterogeneous, avascular intratesticular hematoma, which was smaller on follow-up US (not shown). Note that a neoplasm would have internal blood flow & would not be smaller on follow-up.*

(Left) *US in an 11-year-old who was kneed during a basketball game shows a sharp, jagged demarcation through the parenchyma, representing a testicular fracture & hyperechogenicity in the lower pole due to segmental infarction. Tunica albuginea is interrupted.* **(Right)** *Doppler US in the same boy shows no vascularity in lower testis due to segmental infarction (with reactive hypervascularity of adjacent parenchyma). Note the surrounding hematocele & adjacent scrotal wall edema.*

TERMINOLOGY

Definitions

- Hydrocele: Simple fluid between layers of tunica vaginalis
- Hematocele: Blood products between layers of tunica vaginalis
- Hematoma: Contained collection of blood products within testis, epididymis, or scrotal wall; can be multifocal
- Testicular fracture: Disruption of testicular parenchyma
- Testicular rupture: Disruption of tunica albuginea, often with extrusion of testicular parenchyma
- Devascularization: Vascular pedicle injury causing absent or diminished blood flow without true torsion (twisting)
- Traumatic epididymitis: Epididymal contusion causing inflammation, enlargement, & hypervascularity
- Traumatic testicular ectopia: Traumatic dislocation of testis into inguinal canal, abdominal cavity, or perineum

IMAGING

Ultrasonographic Findings

- Hydrocele, hematocele, epididymitis, scrotal hematoma
  - Echogenic/complex fluid of hematocele is most common finding (after hydrocele)
- Fracture: Hypoechoic line through testicular parenchyma with focally altered echotexture ± disruption of echogenic tunica albuginea
  - Testicular parenchyma may extrude through tunica (resulting in contour deformity)
- Hematoma
  - Scrotal: Echogenic thickening of scrotal wall ± focal areas of complex fluid
  - Epididymal: Mixed echogenicity, nonvascular mass
  - Testicular: Mixed echogenicity, nonvascular mass
- Devascularization: Absent/diminished testicular blood flow
- Testicular dislocation: Rare; consider if testis not in scrotum
- If available, contrast-enhanced ultrasound improves delineation of testicular fractures; also has ↑ sensitivity for devascularization & hematomas

Imaging Recommendations

- Best imaging tool: Grayscale & color Doppler ultrasound with highest frequency (10- to 14-MHz) linear-array transducer available
  - Sensitivity & specificity > 95%
  - Compare echotexture, size, & vascularity of testis to asymptomatic side in transverse side-by-side view

DIFFERENTIAL DIAGNOSIS

Infectious Epididymitis

- Epididymal enlargement, heterogeneity, & hyperemia
- Indistinguishable from traumatic cause without history

Testicular Torsion

- Absent or diminished vascularity in testis
- Look for twisting of spermatic cord just above testicle
- May occur spontaneously or after minor trauma

Torsion of Testicular Appendage

- Echogenic or salt & pepper appearance of enlarged nodular tissue along margin of testis, usually with periappendiceal hyperemia
- May cause reactive hydrocele & scrotal wall thickening
- Leading cause of acute scrotum in boys

Neoplasm

- Intratesticular mass with internal vascular flow
- 10-15% are found during ultrasound for trauma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Intense scrotal pain in setting of recent trauma
  - Ecchymosis, swelling, skin abrasion, or laceration

Natural History & Prognosis

- Possible complications: Infarction, infection, atrophy, ↓ sex hormones & spermatogenesis, infertility

Treatment

- Physical exam has poor correlation to degree of injury; therefore, ultrasound is important to guide management (conservative vs. surgical repair or debridement)
- Fracture & rupture = urologic emergency
- Salvage rate for rupture: 90% → 45% after 72 hours
- Testis can usually be repaired to avoid orchiectomy
- Large hematocele or hematoma may require evacuation

DIAGNOSTIC CHECKLIST

Consider

- Ultrasound helps exclude testicular fracture or rupture (injuries which usually require urgent surgery)
- In cases of penetrating trauma, ultrasound may be limited by air artifact but can be helpful to identify possible foreign body

Image Interpretation Pearls

- Testicular rupture may violate tunica vasculosa → high rate of devascularization
- Do not confuse testicular hematoma with neoplasm; do remember that hemorrhagic neoplasms can cause false-positive ultrasound for trauma
- Hematoceles have high association with rupture (but lack of hematocele does not rule out testicular rupture or fracture)
- Testicular dislocation is extremely rare, but do not assume cryptorchism in cases of trauma with missing testicle

Reporting Tips

- Patients with large, expanding hematocele may need surgery secondary to pain or possible compromise to testis
- Large hematomas may need follow-up to exclude superinfection or testicular necrosis

Ectopic Testicle

KEY FACTS

TERMINOLOGY

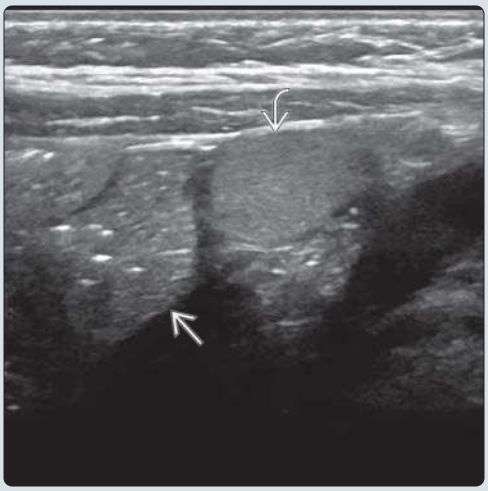
- Undescended testis (UDT): Found along normal pathway of descent but outside scrotum
- Ectopic testis: Found outside normal pathway of descent
  - Very rare, < 5% of boys worked up for UDT
- Testicular retraction: Physiologic, reducible retraction of testis out of scrotum due to hyperactive cremasteric reflex
- Ascending testis: Nonphysiologic, nonreducible retraction of testis out of scrotum (acquired UDT)

IMAGING

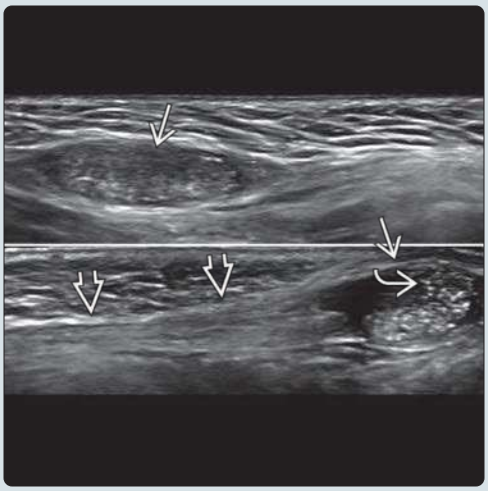
- Many pediatric urologists prefer to skip imaging for UDT
- UDT: Empty hemiscrotum, ± testis along pathway of descent; no history of testis having been within scrotum
- Ectopic testes: Empty hemiscrotum & testis abnormally located in perineum, femoral canal, superficial inguinal pouch, suprapubic area, or contralateral hemiscrotum

TOP DIFFERENTIAL DIAGNOSES

- Inguinal lymphadenopathy
- Female with congenital adrenal hyperplasia



PATHOLOGY



- Pathogenesis of testicular ectopia & UDT is influenced by hormonal, genetic, environmental, & anatomic factors
- UDT: Testis is intrinsically abnormal with altered spermatogenesis
- Ectopic: Testis is normally developed with normal spermatogenesis (if treated)

CLINICAL ISSUES

- UDT: Most spontaneously descend in 1st year of life; testis will not descend after 12 months; ↑ risk of infertility, testicular tumors, torsion, inguinal hernia if not treated
- Ectopic: ↑ risk of trauma, ± altered spermatogenesis
- Testicular retraction is very common in 1st decade but may herald ascending testis (↑ risk of infertility, trauma, tumor)

(Left) *RLQ US in an infant with cryptorchidism shows a normal-appearing testis next to bowel in the abdomen. Testes located outside the normal pathway of descent are termed ectopic testes.* **(Right)** *Trans (top) & long (bottom) US in a boy with cryptorchidism show the right testis in the inguinal canal. Normal spermatic cord course implies that it followed a normal pathway of descent. Unlike ectopic testes, undescended testes (UDTs) are intrinsically abnormal & have a higher rate of microlithiasis.*

(Left) *Oblique US of the left perineum in a 1-week-old with a persistent bulge lateral to the inguinoscrotal crease shows an otherwise normal testis within the perineal subcutaneous fat. Note adductor muscles deep to the testis. Treatment in such cases is elective orchiopexy.* **(Right)** *Coronal STIR MR in a toddler shows a retracted testis next to inguinal lymph nodes. The spermatic cord & epididymis help distinguish the testis from lymph nodes, which have vessels entering at the hilum.*

TERMINOLOGY

Synonyms

- Undescended testis (UDT), cryptorchidism

Definitions

- UDT: Along normal route of descent but outside scrotum
- Ectopic testis: Outside normal pathway of descent
- Testicular retraction: Physiologic, reducible retraction of testis out of scrotum due to hyperactive cremasteric reflex
- Ascending testis: Nonphysiologic, nonreducible retraction of testis out of scrotum (acquired UDT)

IMAGING

General Features

- UDT: Empty hemiscrotum with testis along pathway of descent in 80% (or not found); no history of testis ever in scrotum
  - Differentiation of UDT from testicular retraction & ascending testis is based on history & physical exam
- Ectopic testes: Empty hemiscrotum with testis abnormally located in perineum, femoral canal, superficial inguinal pouch, suprapubic area, or contralateral hemiscrotum

Ultrasonographic Findings

- Ectopic testis is usually normal-appearing; UDTs may be normal or small with hydrocele ± microlithiasis

CT Findings

- Testicular retraction is often noted on CT as 1 or both testes "riding high" in inguinal canal(s)

MR Findings

- Useful problem-solving tool for ambiguous genitalia or ectopic testes; no added value for UDT

Points to Consider

- Many pediatric urologists prefer to skip imaging for UDT

DIFFERENTIAL DIAGNOSIS

Lymphadenopathy

- Look for typical hilar fat & vessels + classic reniform shape
- Lymph nodes will be lateral to inguinal canal

Female With Congenital Adrenal Hyperplasia

- Ambiguous external genitalia with normal ovaries & uterus
- Abnormal electrolytes & endocrinologic studies

PATHOLOGY

General Features

- Pathogenesis of testicular ectopia & UDT is multifactorial
  - Hormonal factors (hypothalamic-pituitary dysfunction, low androgens) & genetics play major role in UDT
  - Environmental & anatomic factors (short vas deferens, ventral wall defects, etc.) play role in ectopia & UDT
- Associated abnormalities
  - Boys with UDT have higher rates of inguinal hernia, other GU abnormalities, & endocrine abnormalities
  - Prader-Willi syndrome, Kallmann syndrome, pituitary hypoplasia, ventral wall defects → high rates of UDT

Staging, Grading, & Classification

- Testicular ectopia can be congenital or posttraumatic
  - Congenital: Femoral canal, base of penis, or perineum
    - Crossed testicular ectopia: Rare anomaly of aberrant migration into opposite hemiscrotum
      - a.k.a. transverse testicular ectopia
  - Posttraumatic: Dislocation into inguinal canal, abdominal cavity, or perineum
- UDT: Classified based on location
  - 80% are superficial & palpable (upper scrotum, superficial inguinal pouch, or inguinal canal)
  - 20% are not palpable (intraabdominal)

Gross Pathologic & Surgical Features

- UDT: Testis is intrinsically abnormal with altered spermatogenesis; ↑ risk of inguinal hernia, testicular neoplasm, torsion, & infertility
- Ectopic: Testis is normally developed with normal spermatogenesis (if treated); no ↑ risk of inguinal hernia, testicular neoplasm, torsion, or infertility

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - UDT: Empty hemiscrotum, ± palpable testis along pathway of descent; right 50%, left 30%, bilateral 20%
  - Ectopic testes: Unilateral empty scrotal sac & palpable mass in location characteristic for ectopic testis

Demographics

- UDT is most common gonadal abnormality in boys; incidence is 30% if preterm, 5% if term, & 1% by 1 year
- Ectopic testis is very rare (< 5% of boys worked up for UDT)

Natural History & Prognosis

- UDT: Most spontaneously descend in 1st year of life; testis will not descend after 12 months; ↑ risk of infertility, testicular tumors, torsion, inguinal hernia if not treated
- Ectopic: ↑ risk of trauma ± altered spermatogenesis
- Testicular retraction is very common in 1st decade but may herald ascending testis (↑ risk of infertility, trauma, tumor)

Treatment

- Orchiopexy by 1 or 2 years of age; reduces (but does not remove) risk of testicular cancer

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Make sure inguinal "mass" is not actually testicle prior to biopsy of "enlarged node"

Variations of Hydroceles

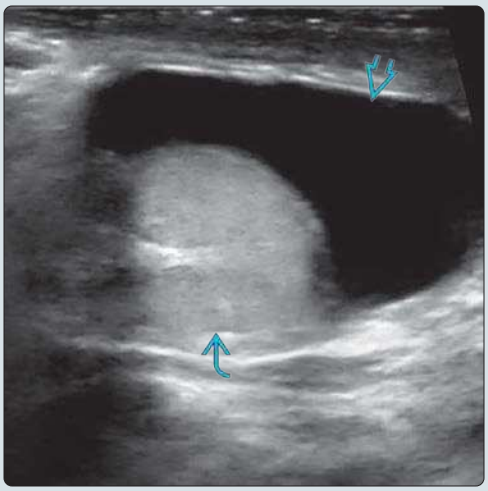
KEY FACTS

TERMINOLOGY

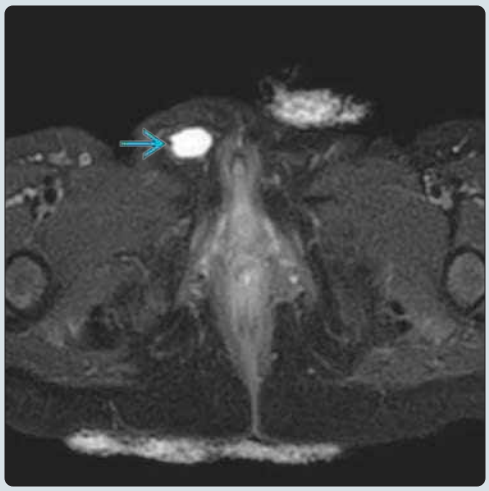
- Hydrocele: Abnormal fluid in scrotal tunica vaginalis &/or spermatic cord/inguinal canal
- Communicating hydrocele: Fluid connects freely between scrotum & peritoneal cavity via patent processus vaginalis
- Noncommunicating hydrocele: No connection between scrotum & peritoneal cavity
  - Implies closed processus vaginalis
- Encysted hydrocele: Loculated fluid in inguinal canal with no connection to scrotum or peritoneal cavity
- Funicular hydrocele: Fluid in inguinal canal with connection to peritoneal cavity (via open internal ring)
- Abdominoscrotal hydrocele: Loculated, dumbbell-shaped fluid collection with abdominal & scrotal components
- Hydrocele of canal of Nuck: Females only → localized fluid collection in groin &/or labia majora
- Complex hydrocele: Complicated fluid, which may be due to blood (hematocele) or pus (pyocele)

IMAGING

- Simple, anechoic fluid surrounding testicle
  - Sparing of "bare area": Site of testicular attachment to epididymis; lacks tunica vaginalis
- ± connection to inguinal canal & peritoneal cavity
- ± mild debris or thin septations

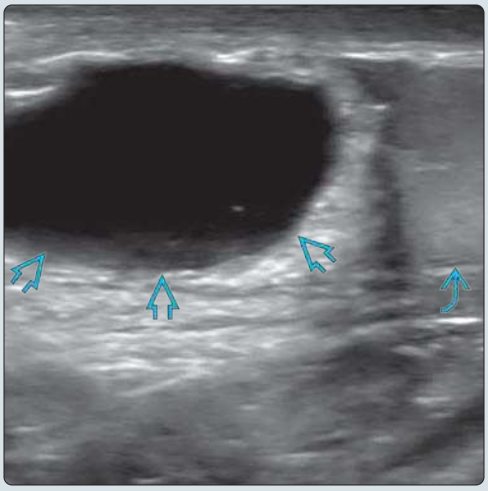


TOP DIFFERENTIAL DIAGNOSES

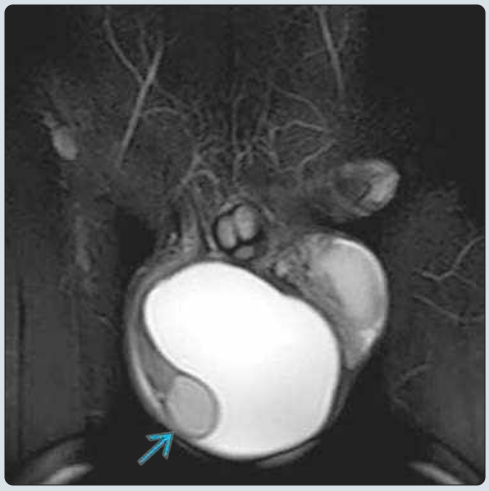


- Indirect inguinal hernia
- Paratesticular rhabdomyosarcoma
- Lymphatic malformation
- Enlarged lymph nodes

CLINICAL ISSUES



- Most common < 1 year of age
  - ↑ incidence in premature infants & children with peritoneal dialysis, ventriculoperitoneal shunts, or ascites
- Patent processus vaginalis often spontaneously closes ≤ 2 years of age; surgery is often required > 2 years



(Left) *Transverse ultrasound in an 18-month-old boy with scrotal swelling demonstrates simple fluid isolated to the tunica vaginalis surrounding the left testicle, consistent with a noncommunicating hydrocele.* **(Right)** *Axial T2 FS MR in a 3-year-old girl undergoing pelvic MR for early-onset inflammatory bowel disease shows well-circumscribed fluid in the right labia majora, consistent with a canal of Nuck hydrocele.*

(Left) *Longitudinal ultrasound of the left inguinal canal in a 5-year-old boy with groin swelling shows fluid in the inguinal canal above the left testicle. The fluid ↑ when the patient was upright, indicating a connection to the peritoneal cavity (i.e., a funicular hydrocele of the spermatic cord).* **(Right)** *Coronal T2 FS MR in 12-year-old boy with a history of hernia & hydrocele repair shows a large amount of simple fluid surrounding the right testicle, consistent with a recurrent noncommunicating hydrocele.*

TERMINOLOGY

Definitions

- Hydrocele: Abnormal fluid in scrotal tunica vaginalis &/or spermatic cord/inguinal canal
- Communicating hydrocele: Fluid connects freely between scrotum & peritoneal cavity via patent processus vaginalis
- Noncommunicating hydrocele: No connection between scrotum & peritoneal cavity
  - Implies closed processus vaginalis
- Encysted hydrocele: Loculated fluid in inguinal canal with no connection to scrotum or peritoneal cavity
- Funicular hydrocele: Fluid in inguinal canal with connection to peritoneal cavity (via open internal ring)
- Abdominoscrotal hydrocele: Loculated, dumbbell-shaped fluid collection with abdominal & scrotal components
  - More frequent in adolescents & adults
- Hydrocele of canal of Nuck: Females only → localized fluid collection in groin &/or labia majora
- Complex hydrocele: Complicated fluid, which may be due to blood (hematocele) or pus (pyocele)
  - Older children, usually with history of trauma, infection, testicular torsion, or malignancy

IMAGING

General Features

- Best diagnostic clue
  - US showing simple fluid around testicle with extension into inguinal canal
- Size
  - Variable size; can be quite large
  - Canal of Nuck hydroceles tend to be smaller (< 3 cm)

Ultrasonographic Findings

- Grayscale ultrasound
  - Simple, anechoic fluid surrounding testicle
    - Except for "bare area" (site of testicular attachment to epididymis; lacks tunica vaginalis)
  - ± connection to inguinal canal & peritoneal cavity
  - ± mild debris or thin septations
  - Hydrocele may deform or resolve with compression

MR Findings

- T2WI
  - High fluid signal surrounding testes
  - May extend into inguinal canal
  - Canal of Nuck hydrocele: High-signal fluid collection in inguinal canal & labia majora

Imaging Recommendations

- Best imaging tool
  - Grayscale ultrasound
- Protocol advice
  - Must image inguinal canal to determine communication with peritoneal cavity
  - Consider imaging with different positions (upright, supine) & Valsalva maneuver

DIFFERENTIAL DIAGNOSIS

Indirect Inguinal Hernia

- Dynamic protrusion of bowel &/or echogenic mesenteric fat into inguinal canal ± scrotum

Paratesticular Rhabdomyosarcoma

- Solid, heterogeneous, extratesticular malignant mass with variable internal vascularity

Lymphatic Malformation

- Multicystic slow-flow vascular malformation infiltrating different tissue compartments
- Rarely isolated to scrotum (though scrotum is often involved by more extensive lymphatic malformations)

Enlarged Lymph Nodes

- Inguinal adenopathy is common; usually benign, reactive
  - Enlarged, reactive nodes with normal architecture
  - Necrotic/suppurative adenitis with cellulitis → abscess
  - Malignant infiltration with loss of architecture, round morphology, & distorted internal vascularity

PATHOLOGY

General Features

- Etiology
  - Failure of involution of normal developmental peritoneal fold extending into scrotum during testicular descent → patent processus vaginalis
  - Occurs at labia majora in girls along round ligament

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Scrotal or inguinal swelling, typically painless
  - May change with position & Valsalva (if communicating)

Demographics

- More common in infants
- Boys > > girls
- ↑ incidence in premature babies & children with peritoneal dialysis, ventriculoperitoneal shunts, or ascites

Natural History & Prognosis

- Patent processus vaginalis often spontaneously closes ≤ 2 years of age → observation considered
- > 2 years of age, spontaneous resolution is unlikely → surgery usually required
  - Closure of patent processus vaginalis + opening or drainage of hydrocele sac

Musculoskeletal Imaging Modalities

Radiography

Although there have been great advances in imaging technology, radiography remains the most important imaging test in most circumstances of suspected musculoskeletal pathology. With appropriate techniques, the associated radiation exposure is usually minimal, & radiography is less expensive than other more advanced imaging studies. Most cases of trauma require radiographs & no other imaging. With suspicion of nonaccidental trauma (or an underlying skeletal dysplasia), a full skeletal survey should be performed.

Computed Tomography

CT is fast but utilizes ionizing radiation & must be employed judiciously. It allows multiplanar assessments & provides better soft tissue contrast than radiographs. Cortical bone detail is excellent by CT, though marrow evaluation is limited. CT is helpful in the detection & characterization of specific fractures that are intraarticular or complex, or for fractures that are often subtle but risk significant consequences if the diagnosis is delayed. Additional CT indications include the evaluations of osteoid osteoma, sequestra of osteomyelitis, tarsal coalitions, & union of complicated fractures.

Ultrasound

Ultrasonography uses no radiation, is relatively inexpensive, requires no sedation, & provides excellent superficial spatial resolution. It also enables dynamic assessments, differentiates cystic vs. solid masses, & characterizes vascular flow. Specific indications include the evaluations of developmental dysplasia of infant hips, retained nonradiopaque foreign bodies, soft tissue masses & fluid collections, & tendon injuries.

Magnetic Resonance

MR imaging uses no ionizing radiation; however, it is costly, has a relatively long exam time, & may require sedation & IV contrast agents. MR provides excellent soft tissue contrast & is multiplanar. When there is a high suspicion of pathology at a targeted musculoskeletal site, MR is the primary tool for investigation. Such indications include joint trauma, infection, soft tissue masses, & bone tumors. Other indications are stress injuries, physeal osseous bridges, & myopathy/myositis. Whole-body MR imaging has seen increased use in the last decade for several indications, including detecting occult or multifocal infection & screening for childhood malignancies in the setting of a tumor predisposition syndrome.

Nuclear Medicine

In isolation, nuclear medicine scans have excellent sensitivity (but low specificity) for whole-body screening of bone pathology. Traditional bone scan indications include the detection of osteomyelitis, metastatic disease, nonaccidental trauma, stress fracture, spondylolysis, osteoid osteoma, & osteonecrosis, though MR imaging has replaced many of these routine uses. Sensitivity can be ↑ by using bone scan SPECT, & excellent anatomic localization is achieved in combination with bone CT (e.g., for the detection of spondylolysis). FDG PET indications are most commonly centered on cancer staging.

Congenital Abnormalities

These abnormalities are typically discovered prenatally, at birth, or within the 1st few months of life. The diagnosis of such entities mainly relies on radiographs.

Proximal focal femoral deficiency (PFFD) is a malformation in which complete growth & development of the upper femur fails to occur. The Aitken classification, from class A (the least severe form with a short femur & common subtrochanteric varus deformity) to class D (in which both the femoral head & acetabulum are absent with a short, distal femoral segment), guides treatment in PFFD. However, classification can be difficult with radiographs at an early age (due to unossified segments).

Tarsal coalition is the congenital or acquired fusion of 2 or more tarsal bones & is most commonly found at the calcaneonavicular or talocalcaneal levels.

Congenital tibial dysplasia is a congenital pseudoarthrosis with anterolateral tibial bowing or fracture. Seventy percent of patients will eventually be diagnosed with neurofibromatosis type 1 (NF1).

Congenital tibial bowing is otherwise typically convex posteromedially & due to in utero positioning. It tends to resolve.

Other malformations include syndactyly, radial clubhand, radioulnar synostosis, arthrogryposis, & amniotic band syndrome.

Trauma

Pediatric fractures may be complete (i.e., all the way through the bone from one surface to the opposite surface) or incomplete. The elastic properties of the developing pediatric skeleton ↑ the potential for incomplete fractures, including plastic deformation (bowing), buckle, or greenstick fractures. It is important to obtain orthogonal views for a complete evaluation of the fracture. When describing the fracture, remember to include the location, extension, translation, & angulation.

Salter-Harris Classification

Approximately 1 in 5 pediatric fractures involves an adjacent growth plate.

In a type I fracture, the fracture is purely through the growth plate or physis (e.g., slipped capital femoral epiphysis).

In a type II fracture [the most common type of Salter-Harris (SH) fracture], the physeal fracture extends through a portion of the metaphysis.

In a type III fracture, the physeal fracture extends through the epiphysis (e.g., juvenile Tillaux fracture).

In a type IV fracture, the fracture extends across the physis & involves both the epiphysis & metaphysis (e.g., triplane & lateral condylar fractures).

In a type V fracture, there is a crush injury of the physis. This is rarely seen in actual practice.

Common Elbow Fractures

The supracondylar fracture is the most common pediatric elbow fracture, most frequently occurring at 5-7 years of age. An elbow effusion may suggest an occult, nondisplaced supracondylar fracture.

The medial epicondyle avulsion comprises 10% of elbow fractures in pediatrics. The avulsed fragment may become entrapped in the elbow joint.

The lateral condylar fracture is typically a SH type IV fracture with the distal component extending through the unossified distal humeral cartilage.

The radial neck fracture accounts for 5% of pediatric elbow fractures with an average age of 10 years. Ninety percent are SH type II fractures.

Important Ankle Fractures

The juvenile Tillaux fracture is a SH type III fracture through the anterolateral distal tibial epiphysis. Mortise or oblique imaging views are helpful, but bone CT with coronal & sagittal reformation helps determine the degree of articular displacement & required therapy (e.g., when there is > 2 mm of articular surface displacement, operative treatment is employed).

The triplane fracture is typically a SH type IV fracture in 3 planes (transverse physeal, sagittal epiphyseal, & coronal metadiaphyseal planes). Bone CT has similar implications as for the juvenile Tillaux fracture.

Common Soft Tissue Masses

The underlying diagnosis of some soft tissue masses can be suspected by clinical exam, such as lipomas (which are superficial & doughy by palpation) & ganglion cysts (which transilluminate & lie near a joint or tendon). Others warrant further evaluation by US &/or MR. US is excellent for characterizing the internal vascularity of a lesion & assessing any dynamic properties, such as compressibility & mobility. MR is particularly helpful in determining the deep extent of a lesion & recognizing characteristic features that may elude US (including the presence of fat, layering blood products, & surrounding muscle edema). Firm, round, solid masses are particularly concerning for malignancy & almost always require biopsy. Nonspecific but small & entirely superficial lesions on US may be considered for excision without MR.

The ganglion cyst is a homogeneously hyperintense round or lobulated mass with minimal peripheral enhancement on MR; it communicates with an adjacent tendon or joint space.

A lipoma follows fat signal on all MR sequences & has thin septations with no significant enhancement. Other fat-containing lesions in the 1st decade of life include lipoblastoma, fibrous hamartoma of infancy, involuted infantile hemangioma, & lipofibromatosis.

Vascular malformations are congenital anomalies that are present at birth but may not manifest until later in life. Slow-flow venous or lymphatic malformations are usually soft/compressible & may show layering fluid-fluid levels of stagnant blood products. Venous lesions will show gradual, patchy to diffuse enhancement (& may contain hard, painful phleboliths), while lymphatic malformations will only show rim or septal enhancement. Fast-flow arteriovenous malformations show a tangle of vascular flow voids with minimal soft tissue mass.

An infantile hemangioma is a benign neoplasm that is typically small or absent at birth with rapid growth over the 1st few months of life before involuting over months to years. On MR, this lobulated lesion is typically subcutaneous & shows hyperintense T2 signal, vascular flow voids, & intense contrast enhancement. On Doppler US, there are > 5 vessels/cm^2 in the lesion with numerous low-resistance arterial waveforms.

Fat-shearing injuries most commonly follow blunt trauma (though the patient may not remember the traumatic event) & typically manifest as a subcutaneous, elongated fluid collection with angular peripheral margins (± central fat globules).

Plexiform neurofibromas are found in NF1 & may show a target or bag-of-worms appearance. There is concern for a malignant peripheral nerve sheath tumor when the mass shows disproportionate enlargement, loses the target sign, invades the surrounding structures, or becomes painful.

Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma in children. Embryonal RMS accounts for 60-70% of childhood RMS & typically occurs in the GU tract & head/neck (but may occur in the extremities). Alveolar RMS occurs in adolescents, most commonly in the extremities, trunk, & perianal/perirectal area.

Synovial sarcoma is the 2nd most common soft tissue sarcoma of childhood. It most commonly presents at 15-35 years of age. There is Ca^{2+} in 1/3 of cases, & the lesion often occurs near a joint. The lesion may be small & indolent-appearing on MR, potentially mimicking a cyst.

Desmoid-type fibromatosis varies in appearance depending on the amount of intralesional collagen vs. cellularity. The mass may erode or scallop the adjacent bone. It is often infiltrating & slow growing with a high rate of local recurrence.

Focal Bone Lesions

In the evaluation of extremity bone tumors, begin the exam with T1 & STIR MR joint-to-joint imaging to exclude skip metastases of the marrow. Smaller field-of-view images targeted at the main tumor can then be obtained with dedicated surface coils.

Osteosarcoma is the most common malignant primary bone tumor in children & young adults. The bimodal age distribution is 10-30 years followed by > 60 years. It classically shows aggressive destruction + new osteoid formation with 55-80% occurring around the knee. It is typically metaphyseal (90%).

Ewing sarcoma is the 2nd most common primary bone malignancy in children. The typical age range is 5-25 years. It has an aggressive appearance that is permeative or moth eaten, though sclerosis (in the bone) may occur in up to 25%. Its aggressive periosteal reaction may include Codman triangles, a spiculated (i.e., sunburst or hair standing on end) appearance, or a lamellated onion-skin appearance. There is often a disproportionately larger soft tissue mass than the amount of bone destruction.

Langerhans cell histiocytosis has a variable radiographic appearance. It occurs between 0-30 years of age with a peak at 5-10 years. It is classically a lucent, round or geographic, punched-out lesion with a narrow zone of transition. Enhancing tissue usually fills the defect on MR but does not substantially extend beyond the bone.

Infection

The absence of radiographic findings early does not exclude osteomyelitis. It typically shows periosteal reaction &/or bony destruction with an aggressive look after 7-10 days. In subacute osteomyelitis, an intraosseous Brodie abscess may show the penumbra sign with a high T1 signal rim marginating a more hypointense center.

The abscess ends across the proximal tibial physis* ➡.

Primary and Secondary Growth Centers

KEY FACTS

TERMINOLOGY

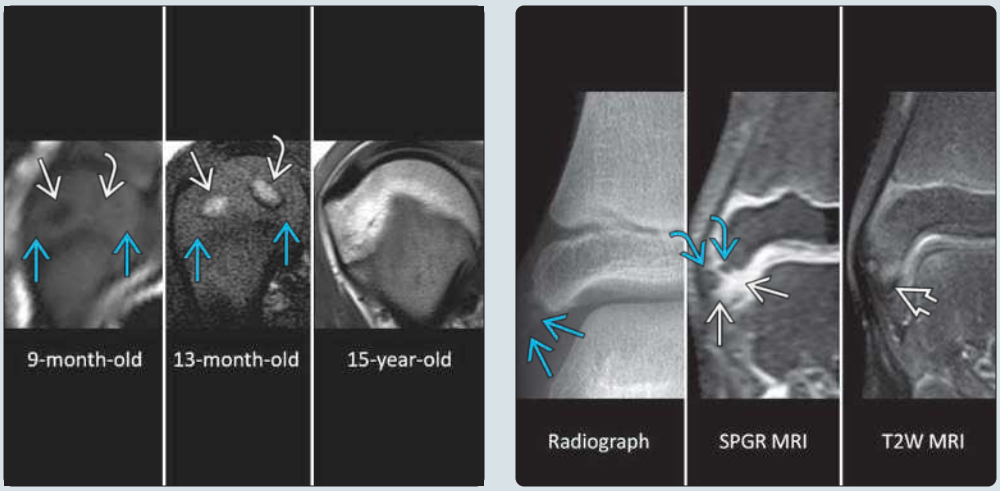
- Primary (1°) growth center = 1° ossification center
- Secondary (2°) growth center = 2° ossification center
- Endochondral ossification: Bone formation on preexisting cartilage model at 1° & 2° growth centers
- 1° growth centers: Where majority of ossification occurs
  - Predominately at long bone physes in childhood
- 2° growth centers: Ossification centers that do not significantly contribute to longitudinal growth
  - Surrounded by growth plate & unossified cartilage
  - Found at articulations of long bones (epiphyses) & epiphyseal equivalents (e.g., apophyses)

IMAGING

- Radiographs: Multiple &/or irregular growth centers are normal at some locations but can mimic pathology
  - Upper extremity: Trochlea, pisiform
  - Lower extremity: Femoral condyles, tibial tubercle, medial malleolus, calcaneal apophysis
- MR: Normal ossification centers do not show abnormal edema/fluid signal

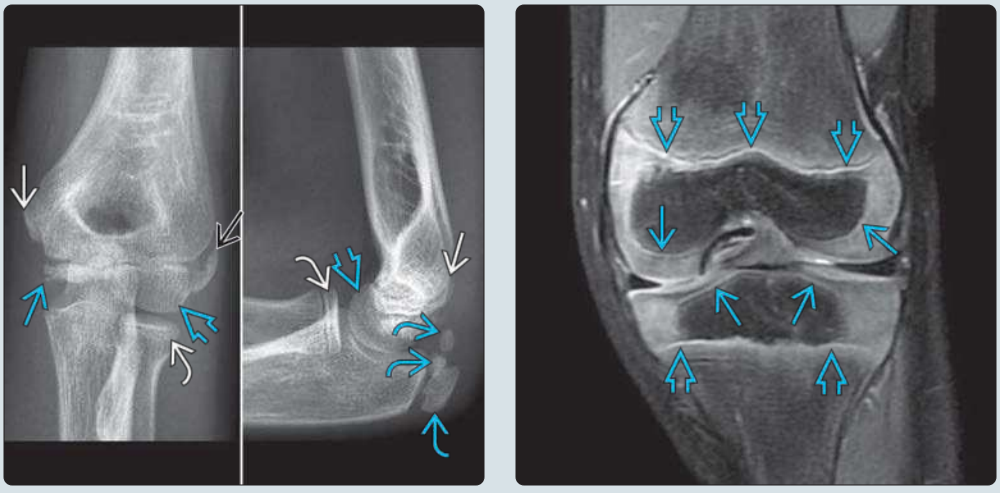
TOP DIFFERENTIAL DIAGNOSES

- Osteochondroses
- Osteochondritis dissecans
- Osteomyelitis
- Osteonecrosis



CLINICAL ISSUES

- 1° & 2° growth centers are normally asymptomatic
- Pathology can occur at growth centers (e.g., acute/chronic trauma, infection, & osteonecrosis)



DIAGNOSTIC CHECKLIST

- Familiarity with normal sites of irregular or multiple ossification centers prevents mistaking them for pathology
- Comparison with contralateral side or prior studies of similar-aged children can be helpful
- MR is useful in difficult cases

(Left) *Coronal T1 MR shows changes of the humerus at 3 ages. The 2° growth centers of the epiphysis & greater tuberosity are low to intermediate signal (red marrow) at 9 months & ↑ signal (yellow marrow) at 13 months. Epiphyseal cartilage surrounds these centers. The centers are fused in the 15 year old.* **(Right)** *Radiograph shows multiple medial malleolar ossification centers. These are low signal on the SPGR MR within bright epiphyseal cartilage. T2 MR shows no edema.*

(Left) *Note the elbow 2° growth centers: Capitellum, radial head, internal (medial) epicondyle, trochlea, olecranon, & external (lateral) epicondyle. The trochlear irregular ossification & the multiple olecranon growth centers are normal findings.* **(Right)** *Coronal T2 FS MR in a 3 year old shows hyperintense lines along the metaphyses of the tibia & femur representing the 1° physes. The hyperintense lines surrounding the 2° ossification centers represent the 2° physes.*

TERMINOLOGY

Synonyms

- Primary (1°) growth (ossification) center
- Secondary (2°) growth (ossification) center

Definitions

- Endochondral ossification: Bone formation of preexisting cartilage model at 1° & 2° growth centers
  - Occurs at limbs, pelvis, vertebral column, & portions of clavicles, scapulae, skull base
- Intramembranous ossification: Bone formation from mesenchymal cells without prior cartilage model
  - Occurs at cranial vault, facial bones, & portions of clavicles, scapulae
- 1° growth centers: Provide majority of ossification
  - Form in central diaphyses of tubular bones in utero
    - Ossification proceeds outward (proximal & distal)
    - 1° growth plates (physes) form at leading edge(s) of expanding 1° ossification centers
  - Predominately found at tubular bone physes in childhood
  - Account for majority of longitudinal growth
- 2° growth centers: Do not significantly contribute to longitudinal growth
  - Surrounded by 2° growth plate & unossified cartilage
  - Found at articulations of long bones (epiphyses) & epiphyseal equivalents (e.g., apophyses)

IMAGING

General Features

- Location
  - Skull base: 1° growth centers develop ~ 12-17 weeks
  - Vertebrae: 1° growth centers are present at birth, 2° growth centers form in C2-L1 after birth
  - Elbow: Order of appearance of 2° growth centers is remembered by acronym **CRITOE**: **C**apitellum → **r**adial epiphysis → **i**nternal (medial) epicondyle → **t**rochlea → **o**lecranon → **e**xternal (lateral) epicondyle
  - Hand/wrist: Growth centers of carpals & 2° growth centers of phalanges form after birth
  - Pelvis: 2° growth centers form in teens, most fuse in 20s
  - Femur: 2° growth centers form in utero & in childhood
  - Tibia: 2° growth centers form at birth & in childhood
  - Fibula: 2° growth centers form throughout childhood
  - Foot: Growth centers of tarsals form before & after birth, 2° growth centers of phalanges form after birth
- Morphology
  - Multiple &/or irregular growth centers at some locations
  - Upper extremity
    - Trochlea of distal humerus: Irregular ossification
    - Pisiform: Irregular ossification
  - Lower extremity
    - Proximal femoral epiphyses: Mild irregularity < 3 years
    - Femoral condyles: Irregular ossification medially & posteriorly
      - Radiographically difficult to distinguish from osteochondritis dissecans (OCD)
      - Irregular ossification typically occurs in younger patients posteriorly & not in intercondylar region
    - Tibial tubercle: Multiple irregular centers
    - Medial malleolus: Multiple irregular centers
    - Calcaneal apophysis: Multiple irregular centers
    - Apophysis of 5th metatarsal base: Lateral & longitudinally oriented

Radiographic Findings

- Irregular growth centers can mimic pathology
- Unossified cartilage of 2° centers may mimic abnormal fluid on radiographs

MR Findings

- Helpful in difficult cases to distinguish irregular ossification & pathologic processes
- Normal development will show multiple &/or irregular dark ossification centers in normal bright surrounding cartilage without abnormal edema/fluid signal
  - Best for cartilage: PD FS or T2* GRE
  - Best for fluid: T2 FS or STIR

DIFFERENTIAL DIAGNOSIS

Osteochondroses

- Poorly defined group of painful growth disturbances (usually due to repetitive microtrauma &/or avascular necrosis) that occur at epiphyses & apophyses

Osteochondritis Dissecans

- Overuse injury in femoral condyles, talus, & capitellum

Osteomyelitis

- Can involve epiphysis: May be 1° site in infants vs. spread from metaphysis or joint in any child
- Typical signs & symptoms of infection

Osteonecrosis

- May see in sickle cell & steroid use or 1° idiopathic hip disease

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 1° & 2° growth centers are normal part of endochondral ossification & are asymptomatic
  - Growth center pathology can occur (e.g., acute/chronic trauma, infection, osteochondroses, & osteonecrosis)

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Familiarity with common sites of normal variant irregular ossification prevents mistaking multiple/irregular growth centers with pathology
- Comparison with contralateral side (in limited circumstances), prior studies of similar-aged children, & reference texts can be helpful
- MR may be useful in difficult cases

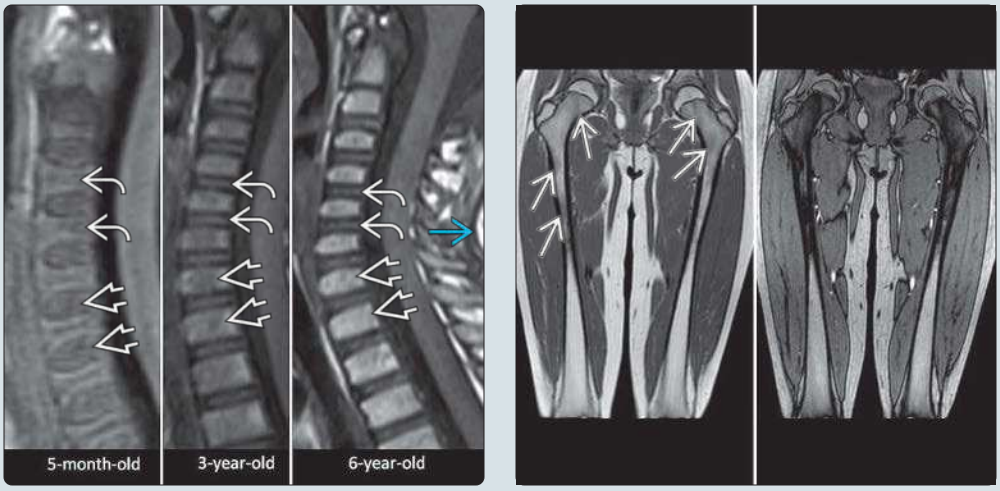
Red to Yellow Marrow Conversion

KEY FACTS



IMAGING

- At birth, red marrow is present throughout entire skeleton
- Conversion of hematopoietic red to fatty yellow marrow begins shortly after birth & follows predictable pattern
  - Appendicular before axial skeleton
  - Distal before proximal extremities (e.g., phalanges of fingers begin conversion before humeri)
  - Within individual long bones
    - Epiphyses convert 1st: Within 6 months of appearance, epiphyseal ossification center should contain almost entirely yellow marrow
    - Central diaphyses next, spreading toward metaphyses
    - Metaphyseal red marrow often persists in adults
      - Typically flame-shaped or poorly defined
  - Conversion of red to yellow marrow is typically symmetric (i.e., similar appearance of R vs. L extremities)
- By 12-24 months, most appendicular marrow is approaching MR signal intensity of subcutaneous fat on spin-echo T1 (i.e., concordance of signal intensities)
  - Diffuse or multifocal discordance after this age (especially on spin-echo T1) implies pathology
- Variability exists among individuals as to exact timeframe
- Some degree of red marrow often persists in spine & pelvis
- On spin-echo T1 MR (best marrow sequence): Red marrow shows low to intermediate signal intensity
  - Typically iso- or slightly hyperintense as compared to muscle & intervertebral discs
- In- & opposed-phase T1 MR
  - Normal red marrow drops signal intensity on opposed-phase images compared to in-phase images
    - Due to water & fat protons in same voxel
  - Infiltrating processes (such as leukemia & metastases) generally do not drop signal on opposed-phase images
- Reconversion of yellow to red marrow (from variety of causes) occurs in reverse order from initial conversion

(Left) *Coronal T1 MR shows femurs in normal children of various ages. Initially, low signal intensity red marrow is seen diffusely. In infancy, yellow marrow appears 1st in the epiphyses & central diaphysis, progressing to the metaphyses, but metaphyseal foci of red marrow persist.* **(Right)** *Corresponding coronal STIR MRs show homogeneous low signal intensity early. Later, epiphyseal & diaphyseal yellow marrow are of lower signal intensity than metaphyseal red marrow.*

(Left) *Sagittal T1 MRs show the cervical spine at various ages. The signal intensity of vertebral body marrow, as compared to the intervertebral discs, is initially hypointense, gradually becoming iso- & hyperintense. In the 6 year old, the marrow signal is slightly < subcutaneous fat.* **(Right)** *Coronal T1 GRE MRs in a 9-year-old with residual red marrow show ill-defined foci of intermediate signal in the proximal femurs on the in-phase (L) image, which drop signal on the opposed-phase (R) image.*

TERMINOLOGY

Synonyms

- Red (hematopoietic) marrow, yellow (fatty) marrow

Definitions

- At birth, red marrow is present throughout entire skeleton
- Conversion to yellow marrow begins shortly after birth
- Reconversion from yellow to red marrow occurs secondary to variety of causes & must be distinguished from pathologic marrow infiltration

IMAGING

General Features

- Best diagnostic clue
  - In predictable pattern, appendicular skeleton converts from red to yellow marrow before axial skeleton
  - Conversion of red to yellow marrow is typically symmetric (i.e., R vs. L)
  - By 12-24 months, most appendicular marrow is generally approaching signal intensity of subcutaneous fat on T1-weighted spin-echo MR pulse sequences
    - On FS T2 or STIR MR, epiphyseal yellow marrow has greatest concordance with subcutaneous fat
  - Regions of red marrow often persist in spine, pelvis, & long bone metaphyses of normal adults
- Location
  - Appendicular skeleton conversion
    - Begins in bones of distal extremities (i.e., phalanges of fingers & toes) & progresses proximally
    - Within individual long bones
      - Epiphyses convert 1st: Within 6 months of appearance, epiphyseal ossification center should contain almost entirely yellow marrow
      - Central diaphyseal conversion occurs next, spreading proximally & distally toward metaphyses
      - Residual red marrow often persists in adult metaphyses, particularly proximal femurs & humeri
  - Spine: Marrow signal intensity of vertebral bodies changes on spin-echo T1-weighted MR by approximate ages
    - 0-1 year: Hypointense to intervertebral disc
    - 1-5 years: Iso- to mildly hyperintense to disc
    - > 5 years: Hyperintense to disc, hypointense to subcutaneous fat
  - Reconversion of yellow to red marrow generally occurs in reverse order as compared to initial conversion
    - Axial → appendicular skeleton
    - Proximal → distal extremities
    - Long bone metaphyses → diaphyses → epiphyses

MR Findings

- T1 MR (spin-echo)
  - Yellow marrow shows ↑ signal intensity
  - Red marrow shows ↓ to intermediate signal intensity
    - Mildly ↑ compared to muscle & intervertebral discs
    - Neonatal red marrow may be isointense or ↓ in signal intensity compared to muscle & discs
- T1 in-phase (IP) & opposed-phase (OP)
  - Red marrow drops signal on OP images due to water & fat protons in same voxel
  - Helps distinguish red marrow from infiltrating processes (such as leukemia & metastases), which generally do not drop signal on OP
  - Red marrow typically shows
    - ≥ 20% drop in signal on OP at 1.5T
    - ≥ 25% drop in signal on OP at 3T
- T2 FS & STIR
  - Yellow marrow shows ↓ signal intensity, most pronounced in epiphyses
  - Red marrow generally shows signal intensity similar to or mildly ↑ compared to skeletal muscle

DIFFERENTIAL DIAGNOSIS

Residual Red Marrow or Red Marrow Reconversion

- Iso- to mildly hyperintense on T1 MR compared to skeletal muscle & intervertebral discs
- Drops signal on OP MRs
- In long bones, normal residual red marrow is often flame-shaped in metaphyses

Systemic Marrow Infiltrating Processes

- Primarily leukemia or metastases
- Diffuse confluent or multifocal well-defined marrow lesions ± cortical destruction, periosteal reaction
- Iso- to hypointense to skeletal muscle & intervertebral discs on T1; usually hyperintense on T2 FS/STIR MR
- Typically drops < 20% of signal at 1.5T (< 25% at 3T) on OP

Marrow Deposition Diseases

- Gaucher disease: Most common lysosomal storage disease
  - Distribution & signal intensity can be similar to red marrow reconversion
  - Other imaging findings are typically present: Endosteal scalloping, Erlenmeyer flask deformities (undertubulation), bone infarcts, hepatosplenomegaly
- Iron deposition disease: ↓ signal intensity on all sequences

PATHOLOGY

General Features

- Differences in fat & water content account for imaging appearances of red & yellow marrow
- Red marrow ~ 40% adipocytes, 60% hematopoietic cells
- Yellow marrow ~ 95% adipocytes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Conversion of red to yellow marrow is asymptomatic normal physiologic process
  - Physiologic stresses, disease processes, & medications may cause reconversion to red marrow

Normal Musculoskeletal Developmental Variants Confused With Disease

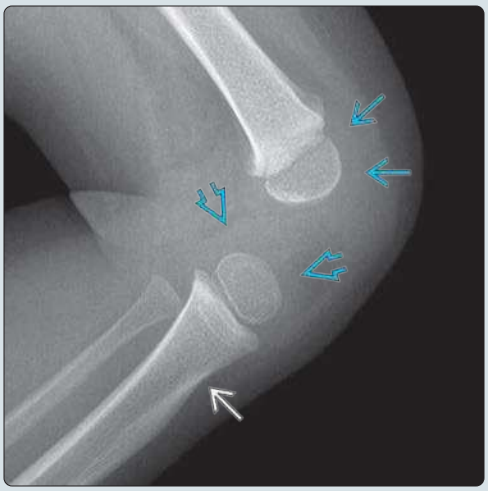
KEY FACTS

IMAGING

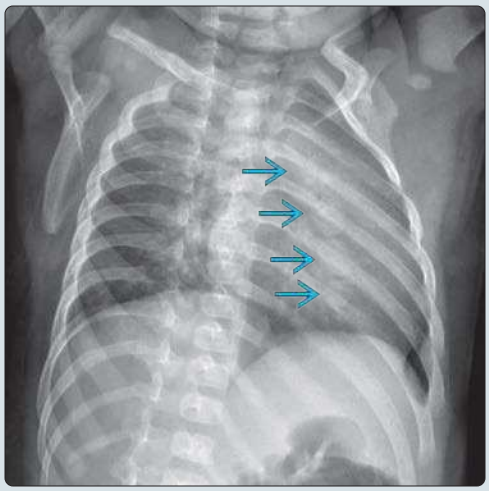
- Growing skeleton demonstrates range of normal age-related radiographic appearances due to
  - Abundant radiolucent growth cartilages
  - Gradual endochondral ossification of such cartilages
- Normal developmental variants have
  - Typical orientation, site, & patient age
  - No overlying swelling or point tenderness
    - May be clouded by isolated soft tissue injury
- MR is useful when source of symptoms is unclear (i.e., is fragmented growth center incidental normal variant or pathologic due to fracture, infarction, or infection)
  - Marrow edema on T2 FS/STIR MR favors pathology
  - ± soft tissue edema &/or joint effusion

TOP DIFFERENTIAL DIAGNOSES

- Physeal fractures
- Incomplete fractures
- Remote trauma
- Child abuse
- Ligamentous disruption
- Avascular necrosis



CLINICAL ISSUES



- Usually asymptomatic; come to attention incidentally by radiographs (often with history of regional trauma)

DIAGNOSTIC CHECKLIST

- If unclear whether or not bony appearance is abnormal vs. incidental normal developmental variant in regionally symptomatic child
  - Review prior radiographs
  - Discuss with referring clinician regarding exact site of symptoms (including point tenderness)
  - Consider
    - Contralateral radiographs of asymptomatic side
    - Splinting with follow-up radiographs in 10-14 days to assess for healing changes

(Left) *Lateral knee radiograph in a 2-year-old shows a normal anterior tibial metadiaphyseal concavity at the site of the unossified tibial tubercle. Transversely oriented fractures may be seen at this level but show focal buckling or cortical interruption. Also note the unossified cartilages of the femoral & tibial epiphyses.* **(Right)** *Oblique rib radiograph from a skeletal survey in a 3-month-old shows multiple sternal ossification centers overlapping the left posterior ribs, which can mimic the bulbous callous of healing rib fractures.*

(Left) *Lateral radiograph in a 2-year-old girl shows poorly defined sclerosis in the posterior talus, a commonly seen normal finding in this age group.* **(Right)** *AP internal rotation radiograph of the right shoulder in a 15-year-old boy shows an unfused acromion ossification center. The sloped proximal humeral physis is viewed at different heights anteriorly & posteriorly (a common fracture mimic).*

TERMINOLOGY

Definitions

- Skeletally immature patients have numerous radiolucent growth centers composed of cartilage
  - Primary physis: Site of majority of longitudinal growth; lies between epiphysis & metaphysis
  - Secondary physis: Surrounds secondary ossification center (SOC) in epiphysis or equivalent bone
    - Interface where cartilaginous precursor is transformed into bone from central to peripheral
    - Process is uniform in some centers (capitellum, femoral head), nonuniform in others (fragmented trochlea, irregular medial femoral condyle)
  - Apophysis: Nonarticular SOC with muscle/tendon attachment (ischial & tibial tuberosities)
  - Zone of provisional calcification (ZPC): Thin, radiodense line at interface of physeal growth cartilage & newly mineralized bone
- Accessory ossification centers: Separate small rounded ossicles vs. SOCs in same unossified cartilage as adjacent epiphysis (or equivalent bone)
- Pseudoepiphysis: False appearance of growth centers at distal 1st & proximal 2nd-5th metatarsals & metacarpals
- Physiologic periosteal reaction (PPR): Smooth, solid, new bone being symmetrically & rapidly laid down along entire lengths of long bone diaphyses in infants

IMAGING

General Features

- Best diagnostic clue
  - No overlying swelling or point tenderness
    - May be clouded by isolated soft tissue injury
  - Orientation, site, & patient age are typical for specific variant
- Morphology
  - SOCs are widely spaced at carpals & tarsals before maturity (due to remaining unossified cartilage)
  - Some long bones (radius, ulna) have normal mild degrees of generalized curvature

Radiographic Findings

- Growth cartilages are normally lucent
- Bony metaphyseal & epiphyseal margins are often undulating; may be irregular in some instances
- Lack of interrupted cortex or ZPC
- No soft tissue edema (unless isolated soft tissue injury)
- PPR: Smooth, solid periosteal reaction along shafts of certain long bones (humeri, femurs, tibias)
  - Typical age: 1-6 months
  - Most commonly symmetric

MR Findings

- Useful when source of symptoms is unclear (i.e., is fragmented growth center incidental normal variant or pathologic, such as fractured, infarcted, or infected)
- Marrow edema on T2 FS/STIR MR favors pathology
  - ± soft tissue edema, joint effusion

DIFFERENTIAL DIAGNOSIS

Physeal Fractures

- Soft tissue edema ± physeal widening & displaced metaphyseal or epiphyseal fragment

Incomplete Fractures

- Buckle fractures: Abnormal focal cortical bump or angulation
- Plastic/bowing deformities: ↑ curvature

Remote Trauma

- Sclerotic margins; soft tissue edema is absent
- Differentiation from normal variant is not always possible

Child Abuse

- Subtle metaphyseal corner fracture in infant may lead to extensive periosteal reaction
- Typically unilateral/asymmetric

Ligamentous Disruption

- ↑ separation of bones with overlying soft tissue edema
- Stress views can be helpful

Avascular Necrosis

- Sclerosis, fragmentation, &/or collapse of SOC
- In otherwise healthy child, certain sites & ages are typical (such as Legg-Calvé-Perthes at hip)

CLINICAL ISSUES

Presentation

- Normal variants are usually asymptomatic; come to attention incidentally on imaging (often with history of regional trauma)

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- If unclear whether or not bony appearance is abnormal vs. incidental normal developmental variant in regionally symptomatic child, then
  - Review prior radiographs
  - Discuss with referring clinician regarding exact site of symptoms (including point tenderness)
- Consider
  - Contralateral radiographs of asymptomatic side
  - Splinting + follow-up radiographs in 10-14 days to assess for healing changes

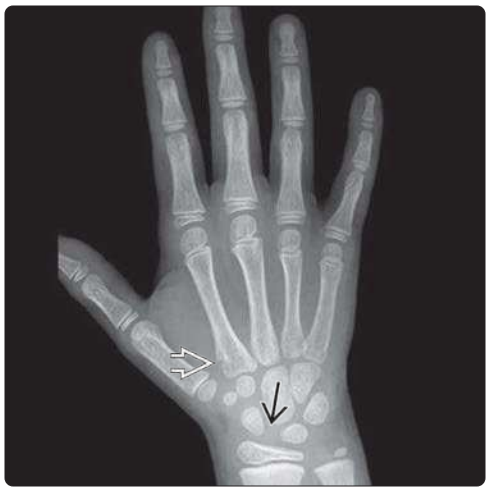
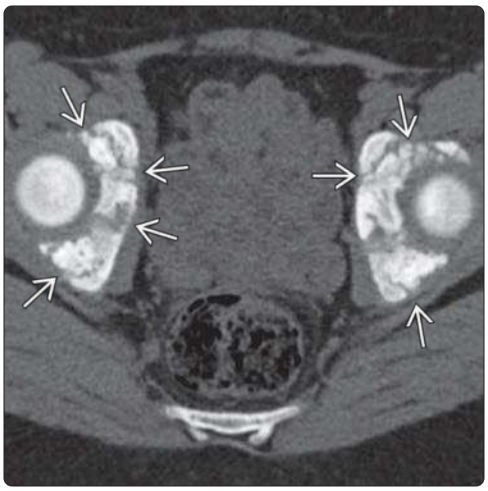
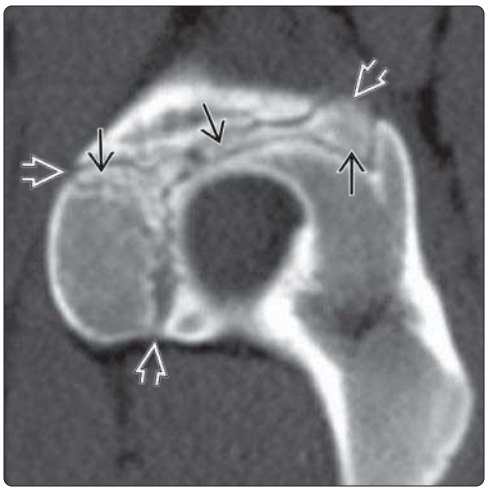
(Left) *AP radiograph of a 7-year-old patient shows a normal location for step-off at the lateral physeal margin of the proximal radial metaphysis. Note the smooth radial metaphyseal neck laterally (which is a common site for Salter-Harris II injuries).* **(Right)** *Lateral elbow radiograph in a 4-year-old girl shows the commonly seen normal step-off at the anterior & lateral physeal margin of the proximal radial metaphysis.*



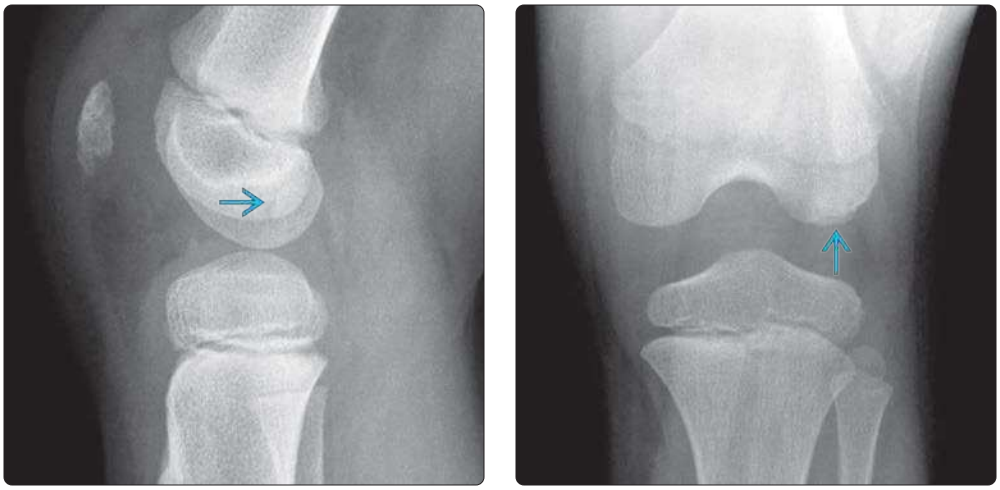
(Left) *Oblique radiograph of the elbow in an 8-year-old girl shows fragmentation of the trochlear ossification center, a normal finding.* **(Right)** *AP radiograph in a 12-year-old patient shows the normal ossification centers about the elbow. The lateral or external epicondyle may be fragmented, the radial head may be sclerotic, & the trochlea may be irregular, sclerotic, &/or fragmented.*

(Left) *AP left forearm & oblique right hand radiographs in a 3-month-old with a femur fracture show a normal variant appearance of the distal ulnar metaphyses mimicking "fraying & cupping." As the remaining growth centers show normal zones of provisional calcification, underlying rickets is excluded.* **(Right)** *PA radiograph of a 7-year-old girl shows false widening of the scapholunate interval due to incomplete carpal ossification in this age. Note the pseudoepiphysis at the 2nd metacarpal.*

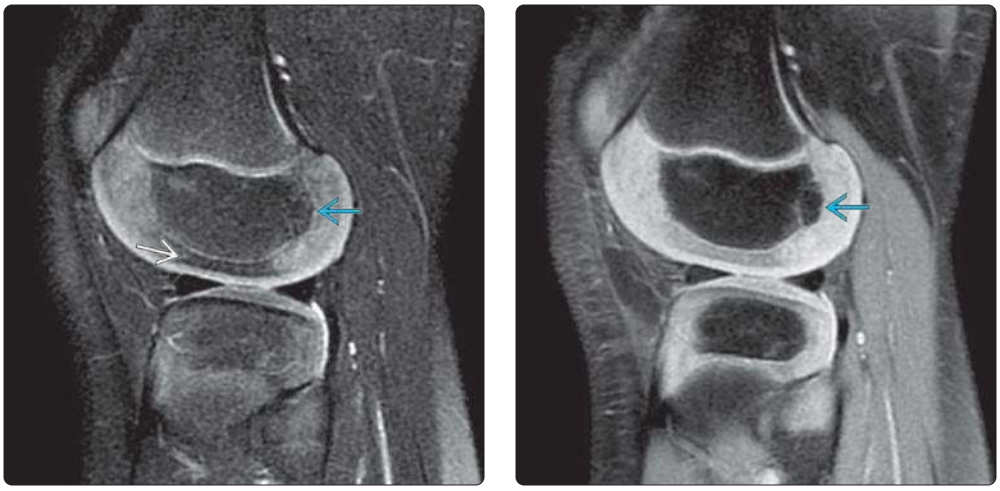




(Left) *AP radiograph in a 3-year-old with pain after a fall shows irregular peripheral margins ⇨ to the distal femoral secondary ossification center, a common normal variant in young children.* **(Right)** *AP femur radiographs in a 1-month-old patient show thin, smooth, solid periosteal reaction along the lateral aspects of the femoral diaphyses bilaterally ➡, typical of physiologic periosteal reaction.*



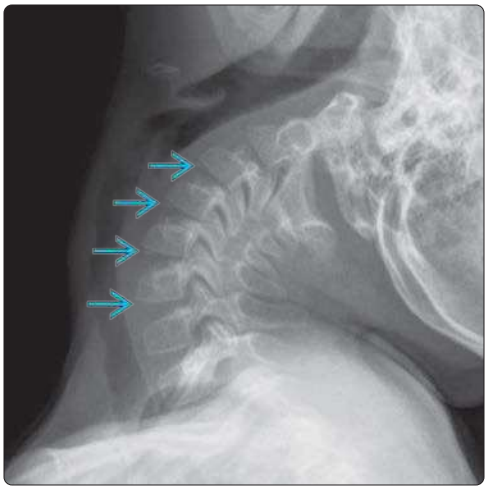
(Left) *AP (left) & lateral (right) radiographs show a typical location & configuration of avulsive irregularity of the posteromedial distal femur. A well-defined sclerotic margin ⇨ is often present with mild medial ➡ & posterior ⇨ irregularity being less frequent. Any lesion at this location appearing more aggressive than this should get further work-up.* **(Right)** *AP foot radiograph in a 2-year-old boy shows normal metaphyseal undulation ➡ at the base of the 1st metatarsal as well as the distal 2nd & 3rd metatarsals.*



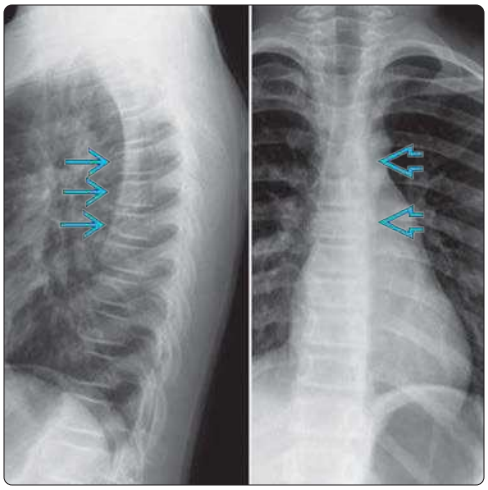
(Left) *Axial NECT in a 7-year-old patient shows multiple ossification centers within the triradiate cartilages of the medial acetabula bilaterally ➡.* **(Right)** *Sagittal NECT of the same patient more clearly displays the arrangement of the accessory ossification centers ⇨ within the triradiate cartilage ➡ of the medial acetabular wall.*

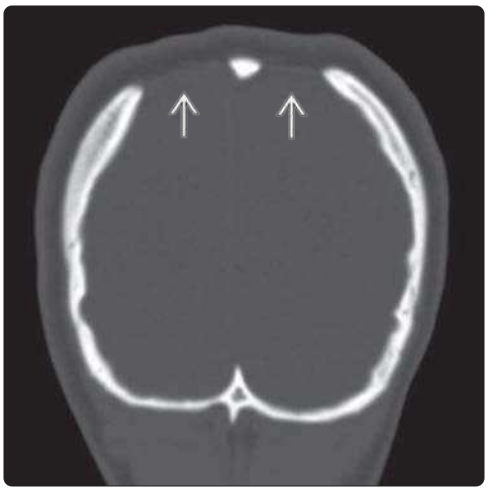
(Left) *Lateral radiograph in a 6-year-old patient with knee pain shows an irregular lucency in the posterior lateral femoral condyle*, **(Right)** *Tunnel view of the same knee shows the irregularity/fragmentation of the posterior non-weight-bearing aspect of the lateral femoral condyle, a common location for developmental irregular ossification. This is in contrast to osteochondritis dissecans (OCD), which more classically affects the lateral & central aspects of the medial femoral condyle.*

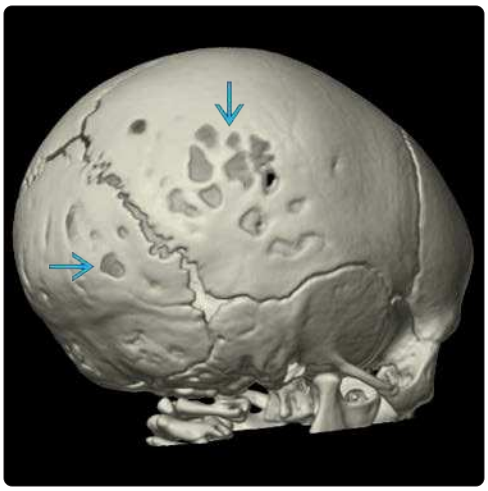
(Left) *Sagittal T2 FS MR in the same patient shows minimal ossific fragmentation posteriorly without adjacent marrow edema, cystic change, cartilage fissuring, or secondary growth plate interruption to suggest a true OCD lesion. Also note the normal dark signal of the weight-bearing unossified femoral condyle due to water displacement in the cartilage.* **(Right)** *Sagittal PD FS MR in the same patient shows the ossific "puzzle piece" fragmentation of the posterior lateral femoral condyle, a normal variant.*



(Left) *AP ankle radiograph in a 9-year-old boy shows an ovoid ossification center with sclerotic margins at the medial malleolus. This is a very common location for accessory ossification centers (which may be fragmented).* **(Right)** *Lateral radiograph of the calcaneus in a 10-year-old patient shows a normal fragmented & sclerotic appearance of the calcaneal apophysis. Patients may have symptoms related to recurrent traction here (Sever disease), but this entity is not diagnosed by bony radiographic changes.*







(Left) *AP radiograph of the pelvis in a 14-year-old boy with a coccygeal injury shows a mixed lucent & sclerotic expansile lesion at the right ischiopubic synchondrosis. This is a recognized & typically asymptomatic normal variant occurring in some patients around puberty.* **(Right)** *AP radiograph of the lower extremities in a child with genu varum shows physiologic bowing of the tibias & femurs. Note that there is only mild medial downsloping of the proximal tibial metaphyses without fragmentation (in contrast to Blount disease).*

(Left) *Lateral cervical spine extension radiograph in a 6-year-old without trauma shows normal mild anterior wedging of vertebral bodies due to incomplete ossification. Note the small ring apophyses.* **(Right)** *Chest radiographs in a 10-year-old with chest pain but no trauma show very mild gradual anterior wedging of several midthoracic vertebral bodies without focal concavity. The vertebral body heights are maintained from left to right on the AP view. This normal wedging can be difficult to separate from traumatic compression.*

(Left) *Coronal NECT in an 11-year-old with a history of headaches shows a typical location & symmetric morphology of giant parietal foramina, an appearance which was stable from a CT scan 2 years prior. Note the smoothly tapered bony margins without permeation or periosteal reaction.* **(Right)** *3D NECT shows apparent lytic skull lesions at sites of normal bone thinning (confirmed to be intact on source images) in the parietal & occipital bones, due to normal convolutional markings in an infant.*

Distal Femoral Avulsive Irregularity

KEY FACTS

TERMINOLOGY

- Common pediatric finding at posterior, medial distal femoral metaphysis: Cortical defect deep to medial gastrocnemius or adductor magnus attachments
  - Likely due to chronic avulsive forces
  - Typically incidental lesion; no treatment needed
- Synonyms
  - Avulsive cortical irregularity or tug lesion
  - Cortical desmoid: Misnomer as biology & histology differ from true desmoid tumors (which are locally aggressive benign neoplasms)

IMAGING

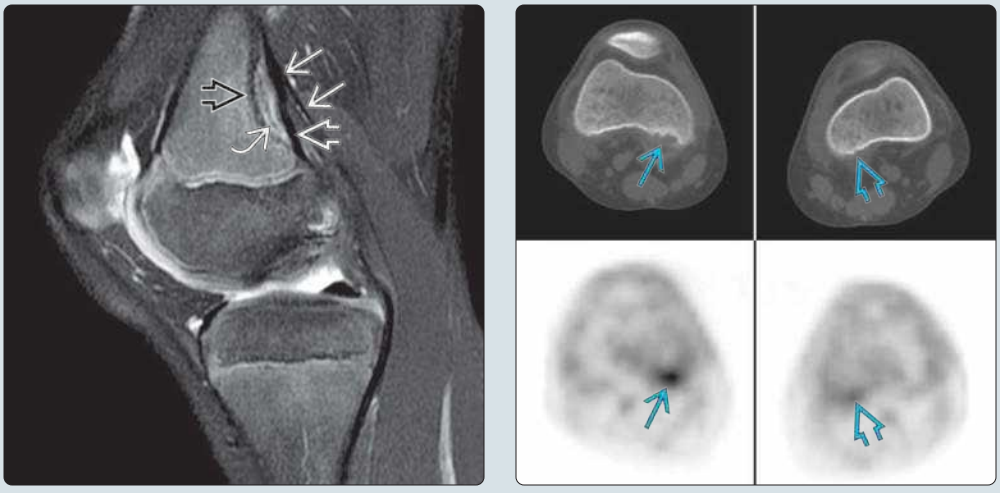
- Lucent focus of cortical interruption/irregularity at posterior, medial distal femoral metaphysis
- Deep margin is commonly concave ± sclerosis
- May have adjacent cortical thickening
- Frontal view may show well-defined round/ovoid lucent focus with sclerotic rim or mild medial cortical irregularity
- Bilateral: 25-100%

TOP DIFFERENTIAL DIAGNOSES

- Osteosarcoma
- Osteomyelitis
- Langerhans cell histiocytosis
- Fibroxanthoma
- Periosteal/juxtacortical chondroma
- Osteoid osteoma
- Metastases

PATHOLOGY

- Benign, self-limited reactive process (not neoplasm)
- Needle biopsy may lead to inappropriate treatment
  - "Do not touch" lesion



DIAGNOSTIC CHECKLIST

- Location of this entity is very typical
- More aggressive entities also occur here
  - Get MR or contralateral radiographs if unclear

(Left) *AP radiograph from a 10-year-old boy shows a common appearance of distal femoral avulsive irregularity (DFAI) in the medial distal femoral metaphysis: it is well circumscribed, ovoid, & centrally lucent with mildly sclerotic margins.* **(Right)** *Lateral radiograph in the same patient shows a scalloped appearance of the posterior distal femoral cortex at the site of the lesion. There is no periosteal reaction.*

(Left) *Sagittal T2 FS MR through the same lesion shows heterogeneous signal intensity centrally. There is typical, concave low signal intensity at the sclerotic deep margin. The overlying periosteum (which is normally thickened at this level) is intact deep to the medial gastrocnemius muscle attachment.* **(Right)** *Axial CT (top) & FDG PET (bottom) images in a teenager with a known chest wall Ewing sarcoma (not shown) demonstrate ↑ metabolic activity at bilateral foci of DFAI, R > L.*

TERMINOLOGY

Synonyms

- Benign cortical irregularity of distal femur
- Avulsive cortical irregularity or tug lesion
- Cortical desmoid: Misnomer as biology & histology differ from true desmoid tumors (which are locally aggressive benign neoplasms)

Definitions

- Irregularity of posterior, medial distal femoral metaphyseal cortex deep to attachments of gastrocnemius muscle medial head or adductor magnus aponeurosis
- Benign self-limited lesion likely due to chronic avulsion

IMAGING

General Features

- Best diagnostic clue
  - Typically incidental radiographic finding at classic location without soft tissue mass or symptoms
- Location
  - Bilateral: 25-100%
  - Other chronic stress-related irregularities
    - Deltoid insertion on lateral humerus
    - Pectoralis major insertion on medial humerus
- Morphology
  - Round vs. elongated with femoral long axis
  - May appear as
    - Scalloped, concave, saucer-shaped cortical defect with well-defined border
    - Bulging, convex cortical lesion with irregular surface
    - Divergent lesion splitting cortex

Radiographic Findings

- Lateral view (key to visualization)
  - Lucent focus of cortical interruption/irregularity
    - Deep margin is commonly concave ± sclerosis
    - Solid periosteal reaction or cortical thickening may abut lesion
    - Lesion may contain bony spicules
- Frontal view may show round or ovoid lucent focus with sclerotic rim &/or subtle medial cortical irregularity
- Important negative findings
  - No associated soft tissue abnormality
  - No aggressive periosteal reaction

MR Findings

- Interruption of contiguous smooth cortex by intermediate T1/heterogeneous T2 signal intensity lesion
- Thin, concave, T1-/T2-hypointense deep rim
- Lesion may enhance on T1 C+ sequences
- Overlying periosteum is intact
- ± mild adjacent marrow edema (more likely if symptomatic)
- No overlying soft tissue mass

Nuclear Medicine Findings

- Bone scan
  - Healing lesions show mildly ↑ uptake
  - Inactive lesions show no uptake
- PET/CT
  - ↑ metabolic activity; accompanying CT is diagnostic

DIFFERENTIAL DIAGNOSIS

Osteosarcoma

- Destructive bone lesion most commonly arising from intramedullary distal femoral metadiaphysis
- Aggressive features are rule, not exception

Osteomyelitis

- Overlying soft tissue edema early
- Radiographic bone changes in 10-14 days
  - Lucent cortical destruction/permeation

Langerhans Cell Histiocytosis

- Flat bones > metaphyseal/diaphyseal long bones
- Classically: Geographic lytic lesion
- Sclerotic margins with healing

Fibroxanthoma/Nonossifying Fibroma

- Overlaps distal femoral avulsive irregularity in some cases
- Eccentric multilobulated lucent metaphyseal/metadiaphyseal lesion
- Thin sclerotic margin; narrow zone of transition

Periosteal/Juxtacortical Chondroma

- Uncommon benign surface lesion with scalloping & buttressing of cortex ± chondroid matrix

Bone Metastases

- Neuroblastoma & leukemia are most common < 10 years
- Lucent metaphyseal bands vs. poorly defined lesions with permeative destruction & aggressive periosteal reaction

Osteoid Osteoma

- Small lucent, highly vascular nidus ± central Ca^{2+}
- Adjacent periosteal reaction, cortical thickening, soft tissue & marrow edema

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually asymptomatic; local pain is uncommon

Demographics

- Age: 3-17 years; most common: 10-15 years
- Sex: M > F = 1.4-3:1

Treatment

- None if asymptomatic
- With localizing symptoms & no other etiologies, conservative therapy may relieve repetitive stress injury
- Avoid unnecessary biopsy

VACTERL Association

KEY FACTS

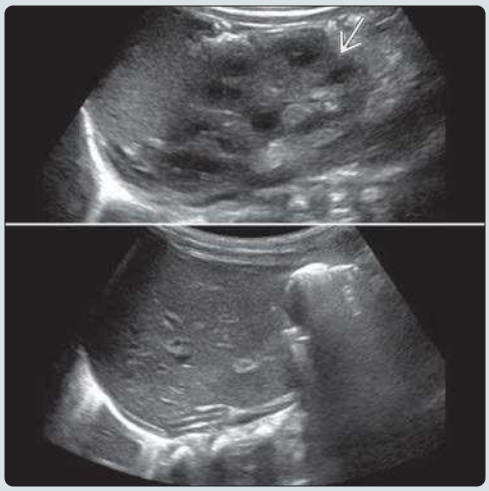
TERMINOLOGY

- Nonrandom association of anomalies involving multiple organ systems (except brain); causative gene is unknown
  - **V**ertebral/vascular
  - **A**nal atresia/auricular
  - **C**ardiac
  - **T**racheoesophageal fistula
  - **E**sophageal atresia
  - **R**enal/radial/rib
  - **L**imb
- VACTERL association is typically diagnosed when ≥ 3 malformations are present

IMAGING

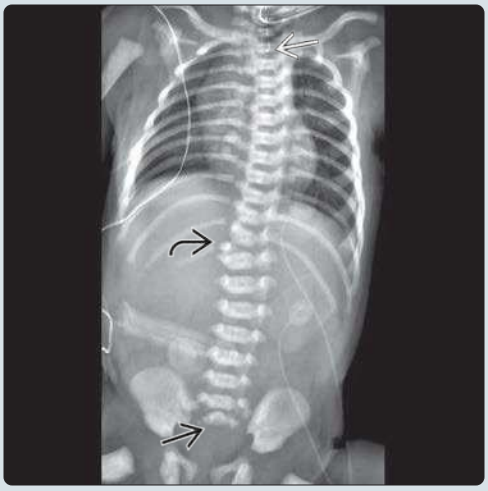
- Actively seek other features of VACTERL association when 1-2 components are present
- Initial imaging in suspected cases: Radiographs & US
  - Radiographs: Spine & limbs (if limb anomaly is present on physical exam)
  - US: Head, spine, renal/bladder, echocardiography
- Further imaging depends on initial imaging & clinical exam findings

CLINICAL ISSUES

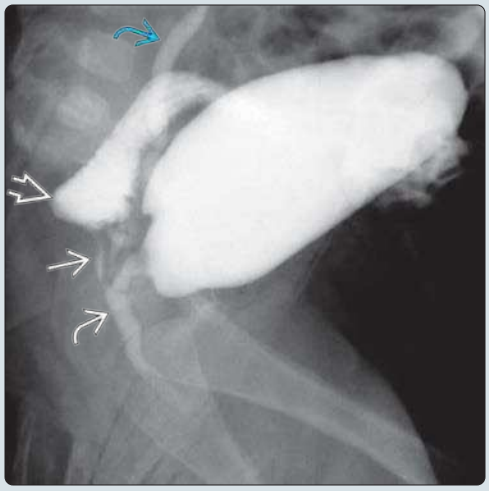


- Incidence of VACTERL association: 1/10,000 to 40,000 liveborn infants
- Children with VACTERL: 72% have 3 anomalies, 24% have 4 anomalies, 8% have 5 anomalies
- Frequency of anomalies in VACTERL
  - Cardiac: 40-80%
  - Renal: 50-80%
  - Anal: 55-90%
  - Tracheoesophageal: 50-80%
  - Vertebral: 60-80%
  - Limb: 40-50%

DIAGNOSTIC CHECKLIST



- Consider VACTERL in child with vertebral & other anomalies



(Left) *AP radiograph in a newborn shows vertebral segmentation anomalies. The nasogastric tube (NGT) could not be advanced beyond the upper esophagus due to esophageal atresia (EA) [with the bowel gas indicating an associated tracheoesophageal fistula (TEF)]. Mild central pulmonary vascular congestion is secondary to a VSD. There is partial sacral agenesis in this child with an ARM.* **(Right)** *Longitudinal US of the left (top) & right (bottom) renal fossae in the same patient show a solitary left kidney.*

(Left) *AP radiograph in a newborn shows vertebral segmentation anomalies & partial agenesis of the sacrum. The NGT could not be passed beyond the upper esophagus due to EA (with the lack of abdominal gas indicating the absence of a TEF).* **(Right)** *Lateral view from a VCUG in the same child shows a rectourethral fistula from the rectal pouch to the posterior urethra. Left vesicoureteral reflux is also seen in this child with an ARM.*

TERMINOLOGY

Synonyms

- VATER, VACTER, VACTEL association, TREACLE, ARTICLE, ARTICLE V, axial mesodermal dysplasia spectrum

Definitions

- Nonrandom association of anomalies involving multiple organ systems (except brain)
  - **V**ertebral/vascular
  - **A**nal atresia/auricular
  - **C**ardiac
  - **T**racheoesophageal fistula (TEF)
  - **E**sophageal atresia (EA)
  - **R**enal/radial/rib
  - **L**imb
- VACTERL association is typically diagnosed when ≥ 3 malformations are present
  - Clubfoot & hip dysplasia are excluded if no other limb anomalies are present
- No clinical or laboratory evidence of alternative diagnosis

IMAGING

General Features

- Best diagnostic clue
  - Vertebral anomalies in presence of other malformations

Radiographic Findings

- Radiography
  - Axial skeleton
    - Vertebral anomalies
      - Cleft, block, butterfly vertebrae; hemivertebrae; hypersegmentation; vertebral bars; caudal regression
      - Secondary scoliosis, kyphosis
    - Other spine issues: Cord tethering (8-78%)
    - Ribs: Fused, bifid, hypoplastic, supernumerary/cervical
  - Limbs or extremities
    - Radial ray: Dysplastic or absent radius, radioulnar synostosis, thumb hypoplasia, radial polydactyly, absent scaphoid, radial artery hypoplasia
    - Hands: Polydactyly (20%) is most common; syndactyly
    - Reduction deformities (34%): Aplasia/hypoplasia of humerus, radius, femur, tibia, or fibula
  - Head & neck
    - Choanal atresia, cleft lip/palate, auricular defects
  - Chest
    - Congenital heart disease: Ventricular septal defect (VSD) (30%); patent ductus arteriosus (PDA) (26%); atrial septal defect (ASD) (20%)
    - EA/TEF
    - Lung agenesis, horseshoe lung (posterior lung fusion), ectopic bronchus
  - Abdomen & pelvis
    - Imperforate anus ± fistula
    - Microgastria, duodenal atresia, malrotation, Meckel diverticulum

Ultrasonographic Findings

- Renal/bladder US to evaluate for renal/GU anomalies
  - Renal agenesis is most common (bilateral in ~ 13%); multicystic dysplasia, horseshoe kidney, ectopia, hydronephrosis
  - Persistent urachus; cryptorchidism
- Neonatal head US to evaluate for findings suggestive of other diagnoses (e.g., hydrocephalus)
- Spinal US to evaluate for tethered cord
- Prenatal detection rates of VACTERL anomalies
  - Renal malformations: 45%; TEF: 44%; cardiac malformations: 20%; vertebral: 13%; limb: 11%

Imaging Recommendations

- Actively seek other features of VACTERL when 1-2 components are present
- Multidisciplinary group suggests specific work-up for VACTERL in
  - All infants with 2 features of VACTERL association
  - All infants with TEF/EA
  - All infants with anorectal malformation (ARM)
- Radiographs & US are used initially for imaging in suspected cases
  - Radiographs: Spine & limbs (if limb anomaly is present on physical exam)
  - US: Head, spine, renal/bladder, echocardiography
  - Additional & advanced imaging depend on radiographic & clinical exam findings

DIFFERENTIAL DIAGNOSIS

Alagille Syndrome

- Butterfly vertebra & cardiac anomalies ± renal anomalies
- Differs from VACTERL: Bile duct paucity/cholestasis, ophthalmologic anomalies, neurologic anomalies, characteristic facies, *JAG1* mutations in > 90%

CHARGE Syndrome

- Cardiac malformations, GU anomalies ± TEF
- Differs from VACTERL: Coloboma, cranial nerve dysfunction, characteristic facial features, *CHD7* mutations in > 50%

Currarino Syndrome

- Partial sacral agenesis, presacral mass, & ARM
- Differs from VACTERL: Presacral mass, *MNX1* mutations

Fanconi Anemia

- Radial deficiency & many other features of VACTERL
- Differs from VACTERL: Pancytopenia, pigmentation anomalies

Holt-Oram Syndrome (Heart-Hand Syndrome)

- Cardiac conduction defect ± ASD/VSD; thumb, wrist, & forearm abnormalities
- Differs from VACTERL: Heterozygous mutations in *TBX5* gene

Oculoauriculovertebral Syndrome (Goldenhar Syndrome)

- Vertebral, cardiac, limb, & urogenital anomalies
- Differs from VACTERL: Ear anomalies, hemifacial microsomia

Thrombocytopenia/Absent Radius Syndrome

- Normal thumb

- Differs from VACTERL: Thrombocytopenia

VACTERL-H (VACTERL + Hydrocephalus)

- Severe intellectual disability; poor prognosis
- Differs from VACTERL: Hydrocephalus, various known mutations

22q11.2 Deletion Syndrome (DiGeorge/Velocardiofacial Syndrome)

- Cardiac malformations, renal anomalies
- Differs from VACTERL: Hypocalcemia, immune dysfunction, characteristic facial features, deletion of 1 copy of chromosome 22q11.2

PATHOLOGY

General Features

- Etiology
  - Classified as association due to no unifying causative gene identified
    - Association: Grouping of anomalies more frequently than expected by chance
  - Exact etiology unknown
  - Various overlapping theories for etiology of VACTERL
    - Malformations occur during blastogenesis → developmental field defect → polytopic anomalies affecting multiple organ systems
    - Undiscovered genetic & epigenetic causes
    - Nongenetic factors have been implicated in playing role in VACTERL (e.g., maternal diabetes mellitus, alcohol or antiepileptic use, assisted reproductive techniques, & in utero hypoxia)
- Genetics
  - *SHH* mutations are theorized based on animal models
    - Not established in humans
  - Associated with trisomies 13 & 18, cri du chat syndrome, Fanconi anemia
- Associated abnormalities
  - Cleft palate: 18%
  - Neural tube defect: 10%
  - Diaphragmatic hernia: 8%
  - Omphalocele: 6%
  - Exstrophy of cloaca
  - Congenital pulmonary airway malformation
  - Sirenomelia

Staging, Grading, & Classification

- No definitive consensus of criteria for VACTERL
  - Most require ≥ 3 components for diagnosis
- Some researchers/clinicians believe "core" features, such as TEF or ARMs, should be present for diagnosis
- Other etiologies in differential should be excluded based on clinical & laboratory work-up

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Neonatal: Depends on anomaly constellation
- Other signs/symptoms
  - Prenatal imaging
    - Polyhydramnios (EA), kyphoscoliosis, absent radius, cardiac &/or renal anomalies, single umbilical artery
  - Prematurity: ~ 1/3
  - Stillborn: 12%

Demographics

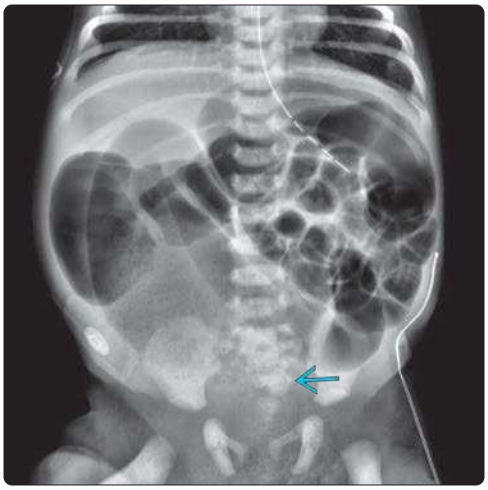
- Epidemiology
  - 1/10,000 to 40,000 liveborn infants
  - Frequency of anomalies in VACTERL
    - Cardiac: 40-80%
    - Renal: 50-80%
    - Anal: 55-90%
    - Tracheoesophageal: 50-80%
    - Vertebral: 60-80%
    - Limb: 40-50%
  - Concurrence of 2 specific VACTERL anomalies is 11x more frequent than expected by chance
    - Probably belongs to VACTERL continuum
  - Concurrence of ≥ 3 specific VACTERL anomalies is 95x more frequent than expected by chance
  - Children with VACTERL: 72% have 3 anomalies, 24% have 4 anomalies, 8% have 5 anomalies
    - Most common 3-anomaly combinations: Cardiac-renal-limb & cardiac-renal-anal
    - Most common 5-anomaly combination: Cardiac-renal-limb-anal-tracheoesophageal

Natural History & Prognosis

- Mortality (not due to any specific defect)
  - 28% neonatal mortality
  - 48% mortality in 1st year
- Intelligence is usually normal

Treatment

- If prenatal diagnosis: Delivery at tertiary care facility



DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Consider VACTERL in child with vertebral & other anomalies

(Left) *AP abdominal radiograph in a newborn boy with an ARM shows diffusely dilated bowel loops, consistent with a distal bowel obstruction. The sacrum has an anomalous morphology, nearly scimitar.* **(Right)** *Transverse US of the right renal fossa in the same patient shows a cross-fused ectopic left kidney, which is inferior to & fused to the inferior pole of the normally positioned right kidney.*

(Left) *Sagittal US of the pelvis in the same boy shows the blind-ending distal rectum, consistent with an ARM. The urinary bladder is seen anteriorly & echogenic sacral vertebral bodies are seen posteriorly.* **(Right)** *Lateral fluoroscopy of the pelvis from a distal colostogram in the same boy with an ARM shows a long rectoperineal fistula extending from the distal rectal pouch to the perineum.*

(Left) *Sagittal T2 (left) & T1 MR images in a 3-month-old boy with VACTERL show partial agenesis of the sacrum. There is a low-lying conus with an associated syrinx & a terminal lipoma. The decompressed blind-ending rectum does not extend to the perineum, consistent with this child's known ARM.* **(Right)** *3D surface-rendered CT in the same patient at 10 years of age shows multiple vertebral anomalies & partial sacral agenesis.*

Polydactyly

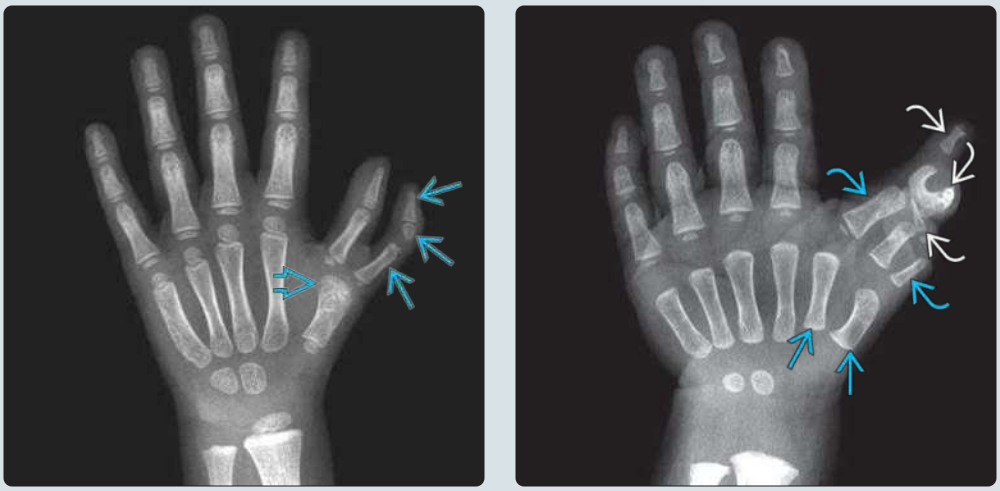
KEY FACTS

TERMINOLOGY

- Polydactyly: Extra digits of hands or feet
  - Description of individual bones: Bifid (distal cleft) vs. duplication (complete distal to proximal cleft)
  - Preaxial: Radial side of hand, tibial side of foot
  - Post axial: Ulnar side of hand, fibular side of foot
  - Central (mesoaxial): Involves central digits
  - Mirror-image polydactyly: Central thumb/great toe-like digit with variable duplication of 2nd-5th digits
- Syndactyly: Fusion of digits
  - Simple (soft tissue fusion) vs. complex (osseous fusion)
  - Complete (entire digit) vs. incomplete (spares distal digit)
- Polysyndactyly: Polydactyly + syndactyly (soft tissue ± osseous fusion of digits)

IMAGING

- Radiographs of affected hand/foot are done primarily to detect skeletal elements within extra digit(s)
- Extra digit can range from small, entirely soft tissue skin tag → rudimentary digit with hypoplastic bones → fully developed extra digit
- Affected phalanges & metacarpals/metatarsals may be bifurcated or duplicated
- Skeletal survey is indicated if syndromic association is suspected



PATHOLOGY

- Most cases are sporadic & isolated
- However, ~ 300 syndromes are associated with polydactyly (e.g., trisomies, Meckel-Gruber, VACTERL, Ellis-van Creveld)

DIAGNOSTIC CHECKLIST

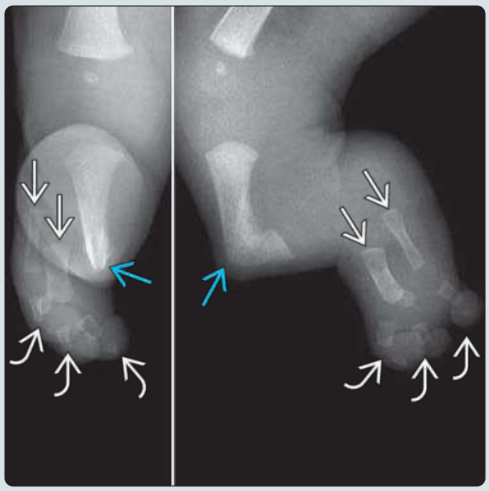
- If found on prenatal US/MR, search for other anomalies
- Description of each digital anomaly should include
  - Degree of bifurcation/duplication of each phalanx
  - Morphology of metacarpal/metatarsal (e.g., duplicated, bifurcated Y or T shape, broadening of head)
  - Any associated soft tissue (± osseous) syndactyly

(Left) *PA radiograph shows the left hand in a 2-year-old girl with preaxial polydactyly. The duplicated thumb is triphalangeal ⇨ (Wassel type VII). The distal end of the 1st metacarpal is broad ⇨ but not duplicated.* **(Right)** *PA radiograph of the left hand in a girl with multiple limb anomalies shows a complex, preaxial polydactyly with 2 metacarpals ⇨, 3 proximal phalanges ⇨, & a complex array of middle & distal phalanges ⇨ with soft tissue & osseous fusion.*

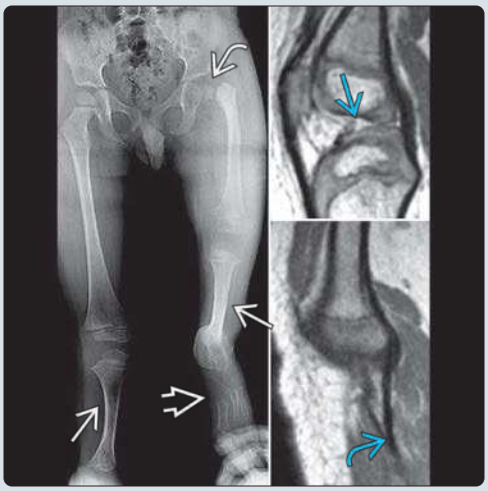
(Left) *AP radiograph of both feet in a 2-year-old girl shows bilateral, postaxial polydactyly (type B) with duplication of the 5th middle & distal phalanges ⇨.* **(Right)** *PA radiograph in a 1-year-old with a complex, central polysyndactyly shows a ring finger proximal phalanx deformity/shortening ⇨ with bifurcation of the middle & distal phalanges ⇨. There is also ring/middle finger soft tissue syndactyly & a supernumerary bone ⇨ between the 3rd & 4th metacarpals.*

KEY FACTS

TERMINOLOGY

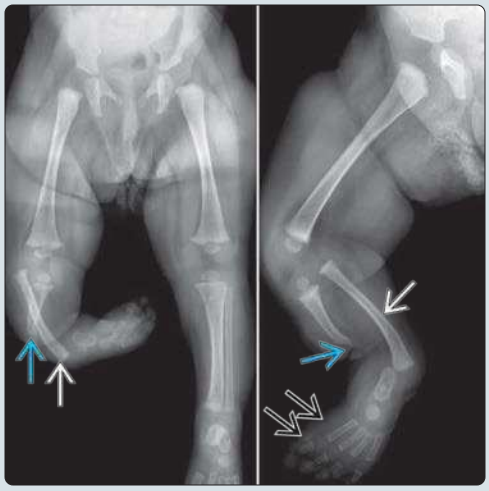


- Hemimelia: Absence of all or portion of distal limb
  - Transverse hemimelia: Defects of both tibia & fibula
  - Paraxial hemimelia: Defect of only tibia (preaxial) or fibula (post axial)
  - Terminal hemimelia: Foot bones absent to some degree
  - Intercalary hemimelia: Foot spared



IMAGING

- Radiographs remain primary imaging modality for detection & characterization of hemimelia
- Both lower extremities should be imaged from hips to feet with AP & lateral views to characterize
  - Specific hemimelia defects
  - Associated limb shortening/limb length discrepancy
  - Other lower extremity bony anomalies
- US & MR more accurately define extent of
  - Cartilaginous anlage of unossified bone
  - Presence/absence of patella & quadriceps



DIAGNOSTIC CHECKLIST

- Differentiating fibular from tibial hemimelia
  - Fibular hemimelia associations
    - Tibial bowing (typically with anteromedial apex); tibia remains centered on femur
    - Absent lateral digits
    - Valgus foot deformity
  - Tibial hemimelia associations
    - ↑ fibular width; fibula overrides distal femur
    - Absent medial digits
    - Varus foot deformity
- Report details should include descriptions of
  - Complete vs. partial absence of each leg bone
    - Approximate fraction & position of affected segment
  - Specifics of foot involvement
    - Be aware of radiographically limited tarsal assessment in young children due to ossification timing
  - Associated lower extremity anomalies

(Left) *Frontal (left) & lateral (right) radiographs in a 2-week-old show absence of the fibula with anteromedial tibial bowing. Also note the foot deformity with only 2 metatarsals & 3 digits.* **(Right)** *AP radiograph (left) in a 4-year-old shows bilateral fibular hemimelia with associated left proximal focal femoral deficiency, shortening of the left lower extremity, & left foot anomalies. Sagittal PD MR images of the left knee (right) show absence of the ACL & an elongated conjoined tendon.*

(Left) *Frontal (left) & lateral (right) radiographs in a 3-month-old with partial tibial hemimelia show absence of the distal right tibia. The right fibula is thickened. There is an associated preaxial foot anomaly with absence of a normal 1st metatarsal & great toe.* **(Right)** *Frontal (left) & lateral (right) radiographs of the left leg in a 1-year-old with tibial hemimelia show complete absence of the tibia. The left fibula is intact but thickened. An associated foot anomaly is partially visualized.*

Tibial Bowing

KEY FACTS

TERMINOLOGY

- Tibial bowing: Typically unilateral, congenital or infantile diaphyseal deformity characterized by direction of apex
  - Posteromedial: Physiologic bowing frequently secondary to intrauterine positioning
  - Anteromedial: Associated with fibular hemimelia
  - Anterolateral: Associated with neurofibromatosis type 1
    - May develop fractures (secondary to osseous dysplasia) & pseudoarthrosis (secondary to abnormal cellular healing)

IMAGING

- Frontal & lateral leg radiographs are necessary to characterize apex of deformity
  - If tibial bowing is present, evaluate for
    - Cortical thickening or thinning
    - Fracture or pseudarthrosis
    - Underlying lesion or abnormal mineralization
    - Fibular hemimelia
    - Associated knee, ankle, & foot deformities
- Standing leg length radiograph
  - Characterizes limb length discrepancy
- Additional radiographs to evaluate for associated anomalies
  - Foot radiographs
    - Posteromedial bowing: Calcaneovalgus
    - Anteromedial bowing with fibular hemimelia: Absent rays, talipes equinovalgus, tarsal coalitions
- Advanced imaging may be used to evaluate associated conditions affecting management
  - Knee MR in fibular hemimelia may show congenital ligamentous & meniscal abnormalities

DIAGNOSTIC CHECKLIST

- Depending on apex direction/type, tibial bowing should prompt search for associated anomalies
  - Affects local diagnosis, prognosis, & therapy
  - May impart underlying systemic diagnosis

(Left) *Frontal radiograph (left) in a 1-year-old shows right medial tibial bowing ⇨ & shortening of the right tibia & fibula with a limb length discrepancy. The lateral radiograph (right) shows posterior tibial bowing ➡ & suggestion of a foot deformity (though weight-bearing views are required to adequately assess disorders of foot alignment).* **(Right)** *Frontal (left) & lateral (right) radiographs in an 8-month-old with fibular hemimelia show anteromedial tibial bowing ⇨ associated with absence of the fibula ➡.*

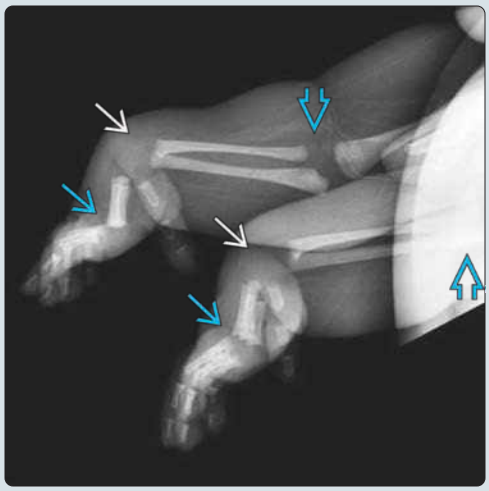
(Left) *AP radiographs in a 6-year-old girl with neurofibromatosis type 1 (NF1) show lateral bowing of the tibias ⇨. Additionally, an early, incomplete fracture line is present in the medial aspect of the mid to distal left tibial diaphysis ➡.* **(Right)** *Lateral radiographs of the legs in the same patient confirm bilateral anterolateral bowing ⇨, which is characteristic of NF1. The fracture ➡ is due to associated osseous dysplasia & may go on to form a pseudarthrosis because of abnormal cellular healing in NF1.*

KEY FACTS

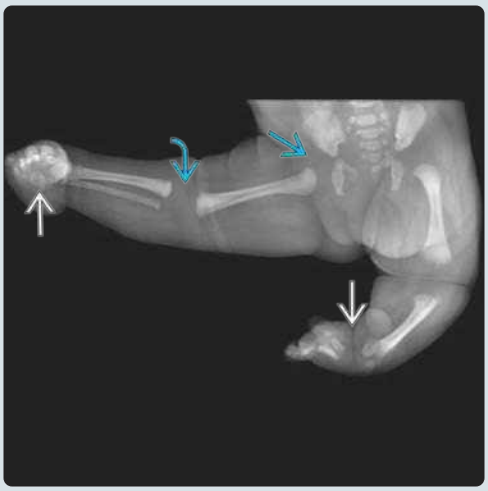
TERMINOLOGY

- Arthrogryposis multiplex congenita (AMC): Descriptive term for infant born with ≥ 2 joint contractures
  - **Not** specific diagnosis (> 300 underlying causes)

IMAGING

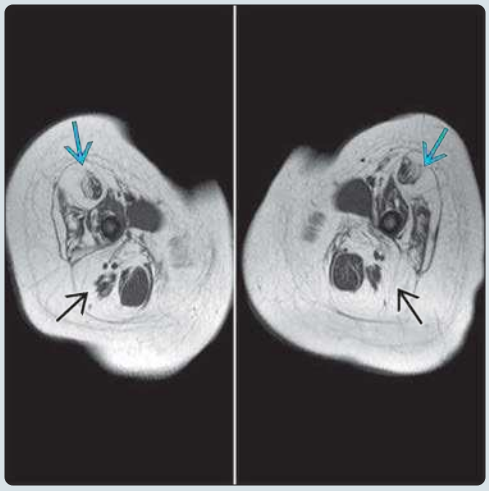


- Radiographs of affected limbs are typically performed
  - Static/fixed abnormal deviations/orientations of joints
    - Positioning for standard views is difficult
  - Gracile & osteoporotic bones with muscle wasting
  - Foot radiographs should simulate weight-bearing to accurately diagnose associated alignment disorders
- MR
  - Brain/spine evaluation if neurologic exam is abnormal
  - Extremities show ↓ muscle bulk with fatty replacement in many conditions
  - May aid in preoperative assessment of joints (e.g., soft tissue bands, abnormalities of unossified cartilage)

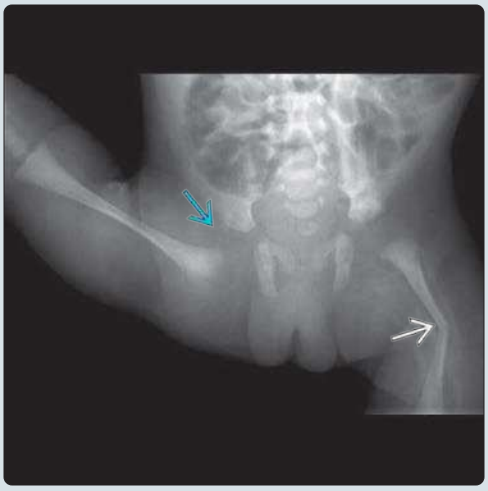


PATHOLOGY

- Broad categories of AMC etiologies
  - Neurologic (70-80%): Various CNS/PNS anomalies
    - Forebrain malformations, spinal muscular atrophy
  - Primary myopathies (~ 20%)
    - Amyoplasia (most common cause of AMC overall)
    - Distal arthrogryposis, congenital muscular dystrophies
  - Connective tissue disorders
    - Skeletal dysplasias, multiple pterygium syndromes
  - Maternal exposures: Teratogens, infections
  - Intrauterine compression: Oligohydramnios, multiple gestations, uterine anomalies



CLINICAL ISSUES



- Perinatal fractures are common in AMC
- Initial treatment of contractures is typically nonoperative: Passive manipulation & serial casting
- Operative treatments: Soft tissue release, tendon transfer, various osteotomies

(Left) *Lateral radiograph of both arms in a newborn with arthrogryposis multiplex congenita (AMC) due to amyoplasia shows persistent extension at the elbows with the forearms held straight out from the body. The wrists show hyperflexion with hyperextension at the MCP joints. **(Right)** Lower extremity radiograph in the same patient shows right hip flexion & right knee hyperextension. Bilateral talipes equinovarus deformities are incompletely evaluated on this non-weight-bearing exam.*

(Left) *Axial T1 MR in a 5-month-old with AMC due to amyoplasia shows severe loss of muscle bulk of the bilateral quadriceps & hamstring muscles with associated fatty replacement. Fatty & fibrous replacement of muscles is typical of amyoplasia. **(Right)** Frontal radiograph of the pelvis in a newborn with AMC shows right hip hyperflexion. Both femurs are gracile (overtubulated) with muscle wasting of the bilateral thighs. There is a fracture of the left femoral diaphysis. Perinatal fractures are common in infants with AMC.*

Clubfoot

KEY FACTS

TERMINOLOGY

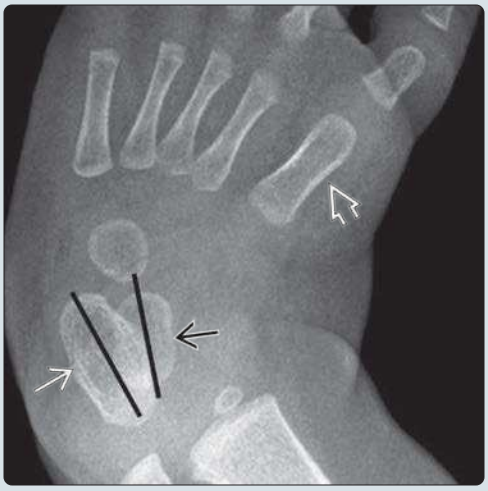
- Synonym: Talipes equinovarus
- **C**avus, forefoot **a**dductus, hindfoot **v**arus & **e**quinus (CAVE)
- Plantarflexion of calcaneus relative to tibia (equinus) + hindfoot inversion (varus) + forefoot adduction (varus)

IMAGING

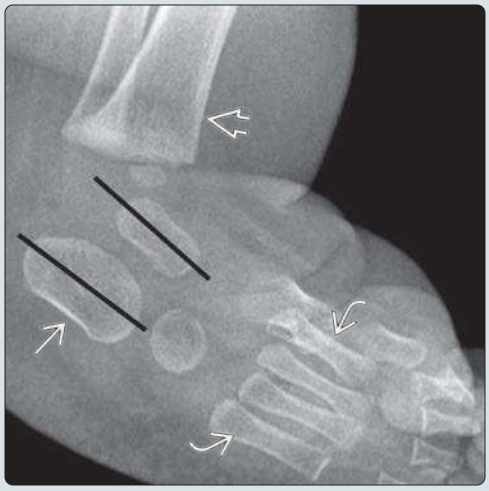
- Talus: Lateral rotation within ankle joint
  - Talus is point of reference for hindfoot
- Calcaneus: Relative medial rotation + equinus
- Navicular: Medial subluxation on talus
- Cuboid: Medial subluxation on calcaneus
- Metatarsals: Inverted, appears parallel on lateral view
- AP view: "Laterally pointing" hindfoot + adducted forefoot
  - Long axis of talus is very lateral to 1st metatarsal
  - Long axis of calcaneus is lateral to 5th metatarsal
- Measure on weight-bearing views (may be simulated)
  - ↑ tibiocalcaneal angle on lateral view (> 90° = calcaneal equinus)
  - ↓ talocalcaneal angle on lateral & AP views (hindfoot varus)
  - ↑ talus-1st metatarsal angle (forefoot varus)
- Frequently detected on 2nd-trimester ultrasound
- Prenatal MR performed for other abnormalities (e.g., myelomeningocele) may detect clubfoot

PATHOLOGY

- Isolated, idiopathic, & congenital form is most common
- Additional anomalies in 24-50%
  - Myelomeningocele, arthrogryposis, myotonic dystrophy
  - Various syndromes (trisomies 18, 21)
- Association with intrauterine "packing disorders" (e.g., oligohydramnios, twinning)



CLINICAL ISSUES



- 50% are bilateral
- Treatment is primarily conservative with manipulation & casting; selective use of surgery

(Left) *Oblique graphic shows a clubfoot deformity with equinus, inversion, & forefoot adduction.* **(Right)** *Sagittal US through the lower leg of a 27-weeks-gestational age fetus with amniotic band syndrome shows abnormal positioning of the foot relative to the foreleg with the tibia, fibula, & all metatarsals visible in their long axes on a single image. This finding is consistent with clubfoot.*

(Left) *AP radiograph in a 9-month-old with clubfoot shows hindfoot varus with a reduced talocalcaneal angle (black lines). There is varus angulation of the forefoot with the long axis of the talus far lateral to the 1st metatarsal & the long axis of the calcaneus lateral to the 5th metatarsal.* **(Right)** *Lateral view shows hindfoot varus with a reduced talocalcaneal angle (black lines). The angle between the long axes of the tibia & calcaneus is > 90° (hindfoot equinus). The inverted metatarsals appear parallel.*

TERMINOLOGY

Abbreviations

- **C**avus, forefoot **a**dductus, hindfoot **v**arus, hindfoot **e**quinus (CAVE)

Synonyms

- Talipes equinovarus

Definitions

- Plantarflexion of calcaneus relative to tibia (equinus) + hindfoot inversion (varus) + forefoot adduction (varus)

IMAGING

General Features

- Best diagnostic clue
  - AP view: Hindfoot "points lateral" + adducted forefoot
    - Long axis of talus is very lateral to 1st metatarsal; long axis of calcaneus is lateral to 5th metatarsal

Radiographic Findings

- Measure on weight-bearing views (may be simulated)
- ↑ tibiocalcaneal angle (calcaneal equinus)
  - Lateral view: Normal 70-90°; > 90° in clubfoot
- ↓ talocalcaneal angle (hindfoot varus)
  - AP view: Normal 20-40°; ~ 0-10° in clubfoot
  - Lateral view: Normal 35-50°; ~ 10-20° in clubfoot
- ↑ talus-1st metatarsal angle (forefoot varus)
  - AP view: Normal 0-15°; ~ 20-40° in clubfoot
- Talus: Lateral rotation within ankle joint
  - Talus is point of reference for hindfoot
- Calcaneus: Relative medial rotation + equinus
- Navicular: Medial subluxation on talus
- Cuboid: Medial subluxation on calcaneus
- Metatarsals: Inverted, appearing parallel on lateral view

MR Findings

- Prenatal MR can detect clubfoot

Ultrasonographic Findings

- Prenatal
  - Affected foot is short, plantarflexed, bent medially
- Post natal
  - Dynamic visualization of unossified cartilage
  - Serial US to evaluate treatment response

DIFFERENTIAL DIAGNOSIS

Metatarsus Adductus

- Forefoot varus without other findings of clubfoot

Congenital Vertical Talus

- Talar plantarflexion with relative dorsal displacement of navicular + hindfoot equinus

Rocker-Bottom Foot

- Foot is foreshortened & convex ("Persian slipper")
- May be associated with clubfoot repair

Amniotic Band Syndrome

- Ranges from extremity ring constrictions (edema → fracture → amputation) to major craniofacial & visceral defects

Vertical Calcaneus in Myelodysplasia

- Imbalance of ankle/foot dorsi/plantar flexion → vertical calcaneal rotation

PATHOLOGY

General Features

- Etiology
  - Isolated: Idiopathic congenital is most common form
  - Additional anomalies: 24-50%
    - Neuromuscular etiologies: Myelomeningocele, arthrogryposis, myotonic dystrophy
    - Numerous syndromic associations
  - Intrauterine factors with ↑ risk: Intrauterine growth restriction, twinning, oligohydramnios, amniotic bands, 1st-trimester amniocentesis
  - Acquired/postnatal onset is seen in cerebral palsy (> 5 years)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hindfoot: Varus & equinus
  - Forefoot: Adduction
  - Stiffness: Ankle & foot
  - 50% are bilateral

Demographics

- Age: Most commonly congenital
- Sex: M:F = 2.5:1

Natural History & Prognosis

- Untreated → lateral weight-bearing → ↑ equinus & inversion → ↑ lateral column growth → ↑ deformity/stiffness

Treatment

- Goals: ↑ mobility, ↓ pain, ↓ stiffness
  - Nonsurgical: Birth to 12 months (better if earlier)
    - Ponseti method: Serial casting ± Achilles tenotomy
  - Surgery: Not primary therapy
    - Used in treatment-resistant cases & to correct posttreatment deformities

Discoid Meniscus

KEY FACTS

IMAGING

- Modality of choice: MR
  - Sagittal images with confirmation on coronal data sets
    - Sagittal: Evaluate periphery
      - Complete "bow ties" on ≥ 3 consecutive images (with 4- to 5-mm slices) are suggestive
    - Coronal: Central images are key
      - > 50% coverage of unilateral tibial plateau
      - > 13- to 14-mm transverse width
      - ≥ 2 mm in height > medial meniscus
  - Frequent linear or amorphous ↑ intrameniscal signal (intermediate to hyperintense on PD, T2, or T2* GRE) in slab-like meniscus
    - Difficult to determine if intrameniscal signal indicates tear, vascularity, mucoid degeneration, or cyst

PATHOLOGY

- Watanabe classification
  - Complete discoid meniscus: Stable
    - Extends into intercondylar notch on coronal images
  - Incomplete: Stable
    - No extension into intercondylar notch
  - Wrisberg ligament type: Unstable, hypermobile
    - Lacks posterior meniscal attachments

CLINICAL ISSUES

- Most commonly asymptomatic in children
  - Symptoms may not develop until adolescence or later
  - Snapping knee syndrome: Wrisberg type
    - < 10 years old
    - Snaps in flexion & extension
  - Symptomatic in older children from tears or unstable variant: Locking, pain, clicking
- Treatment
  - Asymptomatic: Typically observe, no surgical treatment
  - Symptomatic: Saucerization & repair
    - Arthroscopic goal: Width of peripheral rim remaining at 5-8 mm

(Left) *Graphic shows a discoid lateral meniscus with minimal resorption of the central portion & > 50% coverage of the lateral tibial plateau surface.* **(Right)** *AP standing radiograph in a child with knee popping/clicking shows widening of the lateral joint compartment. There is cupping of the lateral tibial plateau. This appearance proved to be a discoid lateral meniscus on MR & subsequent arthroscopy.*

(Left) *Coronal T2 FS MR in an 8-year-old with knee pain & popping after playing basketball shows a complete discoid lateral meniscus. Note the slab-like appearance with the lack of tapering of the inner margin of the lateral meniscus compared to the normal tapering of the medial meniscus.* **(Right)** *Sagittal T2 FS MR in the same child shows the slab-like appearance of the discoid lateral meniscus. Note the internally ↑ signal intensity in the meniscus on both images.*

TERMINOLOGY

Definitions

- Large, congenitally dysplastic meniscus with loss of normal semilunar shape

IMAGING

General Features

- Best diagnostic clue
  - Continuity of anterior & posterior horns on ≥ 3 consecutive MR sagittal images (with 4- to 5-mm slices)
    - Central meniscal portion covers > 50% of articular surface of lateral tibial plateau
    - Loss of normal semilunar morphology
- Location
  - Lateral > > medial discoid meniscus
  - Bilateral: 20-50%
- Size
  - ≥ 2 mm in craniocaudal height > medial meniscus
  - > 13-14 mm in transverse dimension on central coronal cross section (for both partial & complete discoid meniscus)
    - Normal: 5-13 mm from capsular margin to free edge on central coronal image
  - Ratio of minimal meniscal width to maximal tibial width of ≥ 20% on coronal image
- Morphology
  - Large slab/pancake-like complete discoid meniscus
  - Partial discoid meniscus tapers centrally

Radiographic Findings

- Discoid lateral meniscus
  - Normal radiographs in most
  - Widened lateral joint space (best on weight-bearing view)
  - High fibular head
  - Hypoplastic or squared femoral condyle
    - Condylar cutoff sign: ↓ prominence of lateral condyle adjacent to intercondylar notch on tunnel view (with complete discoid meniscus)
  - Hypoplastic lateral tibial spine
  - Cupping of lateral tibial plateau

MR Findings

- Continuous body with continuity of anterior & posterior horns ("bow ties") on ≥ 3 consecutive sagittal images (with 4- to 5-mm thick slices)
- Transverse meniscal dimension ("width") > 13-14 mm in cross section on central coronal image
  - Normal hypointense meniscus: 5-13 mm from capsular margin to free edge on central coronal image
- Complete discoid meniscus has pancake-like appearance (does not taper medially)
  - Hypointense, slab-like meniscus
  - Extending from intercondylar notch to periphery of compartment
- Partial discoid meniscus: Tapers centrally but too wide & tall peripherally
  - ≥ 2 mm in craniocaudal height > medial meniscus
- Frequent linear or amorphous ↑ intrameniscal signal (intermediate to hyperintense on PD, T2, or T2* GRE)
  - Difficult to determine if intrameniscal signal indicates tear, vascularity, mucoid degeneration, or cyst
    - Within substance of meniscus (intrameniscal tear) vs. extending to articular surface (tear)
      - Extensive signal abnormality may reflect tear
    - Discoid menisci are prone to more complex tears
- Prominent ligament of Wrisberg
- May see cord-like intermeniscal ligament
- MR arthrography may have role in distinguishing articular surface meniscal tear from intrameniscal tear
  - If contrast extends into meniscus: Articular surface tear
  - If contrast does not enter meniscus: Intrameniscal tear, cyst, or degeneration
- Advanced cartilage techniques (e.g., T2 mapping) can look at articular cartilage degeneration before/after discoid meniscus repair

Ultrasonographic Findings

- New literature supporting sonographic criteria for diagnosis of discoid meniscus
  - Anterior & posterior meniscus angles, meniscal body angle

Imaging Recommendations

- Best imaging tool
  - MR is modality of choice
  - MR sagittal images are suggestive with confirmation on coronal data sets
    - Coronal images are most accurate

DIFFERENTIAL DIAGNOSIS

Vacuum Phenomenon

- ↓ signal intensity in joint between weight-bearing surfaces
- Rarely homogeneous like discoid meniscus

Flipped Meniscus

- Abnormal morphology to "donor site" of torn meniscus
  - Portions of meniscus are missing, allowing distinction from discoid meniscus
  - < 2 "bow ties" on consecutive sagittal images (4- to 5-mm slices)
- Displaced meniscal fragment may be found in various locations
  - May lie along other portions of meniscus, creating abnormally thick/tall appearance focally

Bucket-Handle Tear

- Longitudinal vertical peripheral tear with displacement of meniscal fragment into intercondylar notch
  - Displaced fragment remains continuous with nondisplaced torn meniscus at anterior & posterior horns
- Double posterior cruciate ligament (PCL) sign
  - Displaced meniscal fragment anterior to PCL creates appearance of 2 PCLs
- Foreshortened, truncated, & abnormal-sized meniscus on sagittal images
  - < 2 "bow ties" on consecutive sagittal images (4- to 5-mm slices)

Osteochondritis Dissecans/Osteochondral Lesion

- Focal ovoid irregularity/defect of subchondral femoral condyle

- ± fissuring with fluid undercutting lesion, cystic change, surrounding marrow edema
- ± detached osteochondral fragment in joint space
- Most common at lateral aspect of medial femoral condyle
- May be due to acute trauma or repetitive microtrauma

PATHOLOGY

General Features

- Etiology
  - Failure of fetal discoid meniscal form to involute
    - Derived from mesenchyme that is initially disc-shaped then forms semilunar shape

Staging, Grading, & Classification

- Watanabe classification
  - Complete discoid meniscus (type 1)
    - Stable
    - Covers > 80% of unilateral tibial plateau on coronal image
    - Extending into intercondylar notch on coronal images (fills entire lateral compartment)
  - Incomplete (type 2)
    - Stable
    - Covers ≤ 80% of unilateral tibial plateau on coronal image
    - Does not extend into intercondylar notch on coronal images
  - Wrisberg type (type 3)
    - Unstable
    - Least common
    - Lacks posterior meniscal attachments
    - Hypermobile, can extend into intercondylar notch with knee extension

Gross Pathologic & Surgical Features

- Pancake-like or large, otherwise normal-appearing meniscus in lateral > > medial compartment
- Wrisberg-type discoid meniscus lacks posterior meniscotibial attachment
- More prone to tears
  - Due to meniscal thickness & mechanical relationships
  - Most common: Horizontal cleavage tear
- Peripheral rim instability patterns
  - 28% of discoid lateral meniscus patients at arthroscopy → requires repair
  - Most commonly involves anterior 1/3 of meniscus

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Often asymptomatic in children (most common), especially < 10 years of age
  - Snapping knee syndrome may be seen < 10 years
    - Snap in flexion & extension due to displacing meniscus
      - Wrisberg type
    - Virtually pathognomic for discoid lateral meniscus
  - Symptomatic in older children from tears or unstable variant
    - Patients often present with pain, clicking, & snapping
    - Locking is common in children
    - Recurrence of knee "giving way"
    - Lateral joint line tenderness
    - Effusion
- Other signs/symptoms
  - McMurray & Apley grinding test may have pain & audible snap or click

Treatment

- Asymptomatic: Debatable, but most observe without surgical treatment
- Symptomatic: Arthroscopic partial central meniscectomy (i.e., saucerization)
  - Stabilization to capsule if unstable
  - Repair tear if present
- Attempt to leave peripheral rim width of 5-8 mm
- Case reports of meniscal regrowth after repair

DIAGNOSTIC CHECKLIST

Consider

- Displaced meniscal tear may cause same symptoms

Image Interpretation Pearls

- Sagittal images: ≥ 3 consecutive images show "bow tie" configuration → think discoid meniscus
- Coronal images: Slab-like shape with meniscus not tapering centrally toward intercondylar notch
- Meniscus displacement & deformation → ↑ risk of tear
  - True tears of discoid meniscus may be difficult to diagnose on MR

(Left) *Sagittal PD MR of the knee in a 9-year-old with a Wrisberg variant of a discoid meniscus shows anterior buckling of the meniscus. At arthroscopy, no posterior capsular attachment of the discoid lateral meniscus was found.* **(Right)** *Sagittal T2 FS MR shows hyperintense signal within the anterior & posterior horns of this discoid lateral meniscus. The meniscus was found to be degenerated & torn at arthroscopy.*

(Left) *Tunnel radiograph of the knee shows a normal prominence of the medial margin of the lateral femoral condyle adjacent to the intercondylar notch in a patient without a discoid meniscus.* **(Right)** *Tunnel radiograph in a 9-year-old with a discoid lateral meniscus shows ↓ prominence of the lateral femoral condyle, the positive cutoff sign. This child had undergone a discoid lateral meniscus repair on the contralateral knee in the past.*

(Left) *Coronal T2 FS MR of the left knee in the same patient shows a complete discoid lateral meniscus. Note the slab-like appearance of the meniscus covering the entire lateral tibial plateau with the lack of tapering of the meniscal inner margin (as compared to the normal tapering of the medial meniscus).* **(Right)** *Sagittal T2 FS MR in a 3-year-old with pain, clicking, & popping shows enlargement of a discoid lateral meniscus with internal hyperintense signal. A radial tear was found at arthroscopy.*

Physeal Fractures

KEY FACTS

TERMINOLOGY

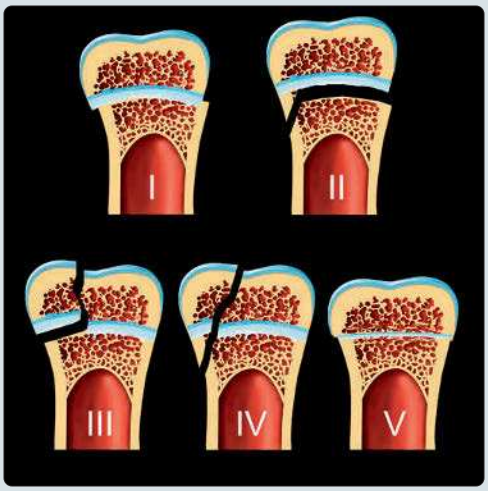
- Fracture of immature skeleton involving cartilaginous primary growth plate (physis)

IMAGING

- Most are detected & managed by radiographs alone
  - Widening or interruption of normally uniform, undulating lucent physis
  - Translation &/or angulation of bony fragment adjacent to physis with overlying soft tissue swelling
  - Persistent physeal widening > 3 mm post reduction suggests tissue entrapment requiring open reduction
- CT: Helps evaluate comminution, displacement, articular surface step-off, loose intraarticular fragment(s)
- MR: Can detect nondisplaced fractures, assess cartilaginous & soft tissue injury or entrapment

TOP DIFFERENTIAL DIAGNOSES

- Incomplete fracture
- Chronic physeal stress injury
- Rickets
- Osteomyelitis



CLINICAL ISSUES

- Peak age: 11-12 years
- 6-30% of childhood fractures involve physis
- Overall complication rate: ~ 14% (but varies by site)
  - Premature physeal closure with limb shortening or angulation
    - Growth disturbance risk is highest in distal femur, tibia
  - Joint incongruity due to intraarticular extension → degenerative arthritis
  - Osteomyelitis (particularly with nailbed injury)

DIAGNOSTIC CHECKLIST

- Always evaluate involved growth plate for premature closure on follow-up studies

(Left) *Graphic shows the relationship of the epiphyseal, physeal, & metaphyseal components of the 5 classic Salter-Harris (SH) fractures. (SH V is a crush injury to the physis, quite uncommon.)* **(Right)** *Lateral (left) & PA (right) radiographs in a 9-year-old show an SH II fracture of the distal radius with ~ 60% dorsal translation of the epiphyseal & metaphyseal fracture fragments with ~ 45° apex volar angulation. Note the uncovering of the volar metaphysis. Also note the nondisplaced ulnar styloid fracture.*

(Left) *Frontal radiograph of the right knee in a 13-year-old boy with a knee injury shows a very subtle SH IV fracture with a lateral metaphyseal component, mild widening of the lateral physis, & a more central fracture line extending through the epiphysis to the intercondylar notch.* **(Right)** *Coronal T1 MR in the same child better shows the metaphyseal & epiphyseal components of the fracture.*

TERMINOLOGY

Synonyms

- Salter-Harris (SH) fractures 1-5 (I-V)

Definitions

- Fracture of immature skeleton involving cartilaginous primary growth plate (physis)

IMAGING

General Features

- Best diagnostic clue
  - Widening or interruption of normally uniform, undulating lucent physis
  - Translation/angulation of bony fragment adjacent to physis with overlying soft tissue swelling
- Location
  - Upper extremity
    - Distal radius: 28-50%
    - Phalanges: 26%
    - Distal humerus: 7-17%
    - Proximal radius: 5%
    - Distal ulna: 5%
    - Metacarpals: 4%
    - Proximal humerus: 2%
  - Lower extremity
    - Distal tibia: 9-11%
    - Phalanges: 7%
    - Distal fibula: 3%
    - Metatarsals: 1%
    - Proximal tibia: 1%
    - Distal femur: 1-5%

Radiographic Findings

- Upon presentation
  - Partial or complete physeal widening with metaphyseal &/or epiphyseal fracture lines
  - Varying degrees of translation &/or angulation of distal fragments
    - Thurstan Holland fragment: Metaphyseal fragment (often triangular) separated from parent bone by SH II or IV fractures
      - Remains attached to physis & travels with displaced epiphysis
      - Quite variable in size
  - Overlying soft tissue edema
- Immediately after reduction
  - Persistent physeal widening > 3 mm suggests entrapment requiring open reduction
    - Overlying periosteum is most common
    - Adjacent ligament or tendon
    - Bony fragment from comminution
- Long-term follow-up
  - Evaluate affected physis for premature closure

CT Findings

- Bone CT
  - Helps evaluate comminution, displacement, articular surface step-off, loose intraarticular fragment(s)
    - ≥ 2-mm articular surface gap or step-off generally requires open reduction + internal fixation

MR Findings

- T1WI
  - Low signal intensity fracture line
- T2WI FS
  - High signal intensity fracture line due to fluid
  - Surrounding marrow & soft tissue edema
  - Elevation of loose metadiaphyseal periosteum by subperiosteal hemorrhage
  - Low signal intensity periosteum, ligament, or tendon is rarely entrapped in fracture
- STIR
  - Similar to T2 FS (both are fluid-sensitive sequences)
- T2* GRE
  - Cartilage-sensitive sequence
  - Most useful in chronic setting to detect growth arrest (physeal bar/bridge) due to prior injury
- MR may alter clinical management in acute setting by
  - Detecting nondisplaced fractures
  - Visualizing fracture relationship to radiolucent cartilage (changing fracture classification)
  - Visualizing entrapped structures (requiring open reduction)
  - Visualizing adjacent neurovascular injury
- MR can alter clinical management of long-term complications by
  - Detecting & quantifying bone bridges
  - Detecting degenerative changes

Ultrasonographic Findings

- Useful in neonates/infants/toddlers with limited ossification of epiphyses
- May visualize displacement of cartilaginous epiphyses, physeal &/or cortical interruption, &/or subperiosteal fluid
- Sonographic comparison of contralateral side is helpful

Imaging Recommendations

- Best imaging tool
  - Typically detected & managed by radiographs alone
  - CT & MR have limited indications
- Protocol advice
  - Opposite side comparison radiographs may help (particularly for SH I)
  - Fluid-sensitive sequences are critical if MR is requested

DIFFERENTIAL DIAGNOSIS

Incomplete Fracture

- Cortical buckle deformity of metadiaphysis shows no fracture line extension to physis

Chronic Physeal Stress Injury

- Partially or completely widened physis mimics nondisplaced SH I fracture
  - Interruption of endochondral ossification results in persistence of growth cartilage without fracture
- Metaphyseal irregularity & sclerosis
- Chronic pain in adolescent high-level athletes

Epiphysiodesis

- Extremity may show physeal widening & irregularity after drilling

- Sometimes performed to halt growth in setting of growth arrest of contralateral long bone from remote insult (therefore preventing limb length discrepancy)

Rickets

- Variety of metabolic abnormalities can inhibit endochondral ossification with physeal widening
- Multiple physes are symmetrically involved
- Classic rickets has metaphyseal fraying, cupping, widening, & loss of zone of provisional calcification (ZPC)

Osteomyelitis

- Commonly affects metaphysis in children
- Soft tissue abnormalities precede bony radiographic findings
  - Permeative lytic bone destruction &/or periosteal reaction after 10 days
  - May cause physeal widening
- Pathologic fracture may result

PATHOLOGY

General Features

- Etiology
  - Structure of normal physis
    - Germinal zone (closest to epiphysis): Small active chondrocytes emerge from resting chondrocytes
    - Proliferative zone: Chondrocytes rapidly dividing; arranged in columns
    - Hypertrophic zone: Chondrocytes undergo hypertrophy; arranged in columns
    - ZPC (closest to metaphysis): Chondrocytes undergo apoptosis, cartilage matrix calcifies, osteoblasts form osteoid
- Associated abnormalities
  - ± injuries of neurovascular bundle, ligaments, cartilage, other bones
    - Depends on mechanism, fracture location, fracture type, & degree of displacement

Staging, Grading, & Classification

- Type I (~ 8.5%): Involves only physis
- Type II (~ 73%): Involves physis & metaphysis
- Type III (~ 6.5%): Involves physis & epiphysis
- Type IV (~ 12%): Involves physis, metaphysis, & epiphysis
- Type V (< 1%): Crush fracture involving physis
  - Usually recognized when cone epiphyses or partial physeal arrest becomes apparent later
- Types VI-IX, as described by Ogden 1981
  - Infrequently used classification

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, swelling, point tenderness, limited range of motion, inability to bear weight

Demographics

- Peak age: 11-12 years
- Sex: Skeletal maturity occurs earlier in girls than in boys
  - Mean age of physeal injuries is 1-2 years earlier in girls
- Epidemiology: Up to 30% of childhood fractures involve physis; likely underestimated if based only on initial exam

Natural History & Prognosis

- Overall complication rate ~ 15%
  - Premature physeal closure with limb shortening or angulation
    - Much more common in lower than upper extremities (regardless of SH type)
      - 40-90% of distal femur, 25% of proximal tibia, 5-50% of distal tibia physeal fractures
      - 5-7% of distal radial physeal fractures
    - 2x as likely in displaced vs. nondisplaced fractures
  - Joint incongruity due to articular surface involvement → degenerative arthritis
    - Up to 29% of SH III or IV ankle injuries
  - Osteomyelitis with adjacent nailbed trauma ("stubbed toe osteomyelitis") or penetrating injury

Treatment

- Closed reduction & casting for low SH categories (unless unstable post reduction)
  - < 2-mm displacement → ↓ risk of growth arrest
  - Follow-up at 5-7 days to ensure stability
- Open reduction & internal fixation is often required with higher categories (due to articular surface involvement)
- Subsequent bone bridges → angular deformities or limb length discrepancies → bone bridge resection vs. contralateral epiphysiodesis

DIAGNOSTIC CHECKLIST

Consider

- Always evaluate involved growth plate for premature closure on follow-up studies
  - Follow-up of physeal injuries is prolonged due to risk of growth disturbances

Reporting Tips

- Include type, direction, & magnitude of displacement
  - Translation (including shortening & distraction), angulation, & rotation
- Presence of physeal &/or articular extension

(Left) *Lateral radiograph in a 15-year-old with pain from a gymnastics injury shows widening of the posterior physis of the proximal tibia.* **(Right)** *Sagittal T2 FS MR in the same patient shows low signal intensity periosteum trapped in the widened physis. The metaphyseal components of an SH II fracture are present anteriorly. Subsequent growth arrest is more likely when periosteal entrapment occurs.*

(Left) *Frontal radiograph in a 12-year-old girl with a right wrist injury shows an acute SH II fracture of the distal radius.* **(Right)** *Frontal radiograph in the same girl 2 years later shows the development of a distal radial physeal bridge. The growth arrest in the radius has lead to ulnar positive variance with associated ulnocarpal impaction, evidenced by the sclerosis in the proximal lunate. MR (not shown) confirmed lunate marrow edema with cartilage & TFCC injury.*

(Left) *Coronal T2 FS MR in a 12-year-old shows an SH III fracture of the distal femur with vertical intraarticular epiphyseal & horizontal medial physeal components. These fractures can be radiographically occult.* **(Right)** *PA radiograph of the hand in a 10-year-old shows slightly ↑ angulation of the ulnar-sided cortex of the middle finger proximal phalanx. A metaphyseal fragment confirms an SH II fracture.*

Apophyseal Injuries

KEY FACTS

TERMINOLOGY

- Apophysis: Nonarticular secondary center of ossification that serves as attachment site for muscle or tendon
  - Considered epiphyseal equivalent
- Acute injury: Avulsion fracture of osseous &/or cartilaginous apophysis through subjacent physis
- Chronic injury: Repetitive submaximal tensile forces (avulsive microtrauma) exceed rate of repair, leading to local growth plate disturbance (± symptoms)

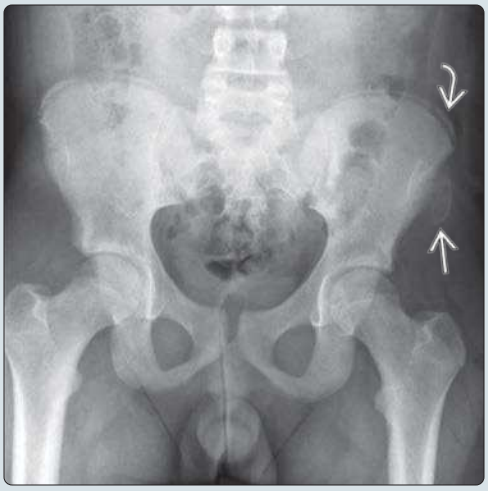
IMAGING

- Acute injury: Displaced apophyseal ossification center
- Chronic injury: Soft tissue swelling with ossific irregularity at tendon attachment site
- Radiographs are usually diagnostic of acute avulsion
- Further imaging may be required if fragment is nondisplaced, ossification center is not yet present, or chronic apophysitis is suspected
  - MR is more sensitive & specific than US

TOP DIFFERENTIAL DIAGNOSES

- Osteomyelitis
- Ewing sarcoma
- Muscle injury
- Stress injury of bone

CLINICAL ISSUES



- Acute injury: Sudden onset of pain with sensation of pop & instant ↓ in muscle function during athletic activity
- Chronic injury: Insidious onset of pain & swelling without specific event or associated bruising
- Majority of acute pelvic avulsions occur from ages 12-18 years; mean of 13.8-15.2 years
  - Most occur during kicking, sprinting, or jumping
  - AIIS, ASIS, ischial tuberosity > iliac crest, pubic symphysis
- Conservative (nonsurgical) therapy: Highly successful
  - Complications (nonunion, heterotopic ossification, chronic pain) are uncommon
- Surgical fixation is reserved for displacement > 1.5-2.0 cm

(Left) *Frog leg lateral radiograph in a 13-year-old girl with acute onset of left hip pain & sensation of a pop during cheerleading shows displaced bony fragments adjacent to the left ischial tuberosity.* **(Right)** *Coronal T2 FS MR in the same patient shows the attachments of the hamstring tendons to the displaced curvilinear osteocartilaginous apophysis at the ischial tuberosity. Fluid undercuts the displaced fragment, typical of an acute avulsion injury.*

(Left) *AP radiograph in a 16-year-old boy with a history of pain & a pop while kicking a ball shows an inferiorly displaced bony fragment that was avulsed from the anterior superior iliac spine (ASIS). The lateral left iliac wing apophysis also shows fragmentation & growth plate widening, suggesting an additional avulsion component.* **(Right)** *AP radiograph in the same patient 3 months later shows progressive healing at the site of injury with callus now seen between the fragment & underlying iliac bone .*

TERMINOLOGY

Synonyms

- Acute injury: Avulsion fracture
- Chronic injury: Apophysitis, physeal stress fracture, osteochondrosis, various eponyms specific to site

Definitions

- Apophysis: Nonarticular secondary center of ossification that serves as attachment site for muscle or tendon
  - Contributes to bony shape but not length
  - Considered epiphyseal equivalent
- Acute injury: Avulsion fracture of osseous &/or cartilaginous apophysis through subjacent physis
- Chronic injury: Repetitive submaximal tensile forces (avulsive microtrauma) exceed rate of repair, leading to local growth plate disturbance (± symptoms)

IMAGING

General Features

- Best diagnostic clue
  - Acute injury: Displaced apophyseal ossification center
  - Chronic injury: Soft tissue swelling with ossific irregularity at tendon attachment site
- Location
  - Acute avulsion injury
    - Pelvis/hips: High concentration of muscle attachments
      - Ischial tuberosity (hamstrings: Biceps femoris, semimembranosus, semitendinosus)
      - Anterior inferior iliac spine (AIIS) (rectus femoris)
      - Anterior superior iliac spine (ASIS) (sartorius)
      - Iliac crest (tensor fascia lata, abdominal wall muscles)
      - Pubic symphysis (adductors)
      - Greater trochanter (gluteus medius & minimus)
      - Lesser trochanter (iliopsoas)
    - Tibial tubercle (patellar tendon)
    - Medial epicondyle of humerus (flexor group & ulnar collateral ligament)
  - Chronic stress injury
    - Tibial tuberosity: Osgood-Schlatter disease
    - Humeral medial epicondyle: Little Leaguer's elbow
    - Iliac crest
    - Calcaneal apophysis: Sever disease

Radiographic Findings

- Acute avulsion injury
  - Displacement of apophyseal ossification center
    - Tangential view: Crescentic, triangular, or irregular bone fragment
    - En face view: Poorly defined or ovoid fragment
  - Moderate to marked soft tissue edema
    - May be only sign if ossification has not yet developed in apophysis
    - May be occult at pelvis due to overlapping structures
- Healed/remote acute avulsion fracture
  - Bony remodeling from prior injury that may result in apparent expansion/overgrowth
  - Heterotopic ossification of soft tissues may develop at site of prior injury
- Chronic stress injury
  - Ossific irregularity or fragmentation at site of tendon attachment
  - Underlying physeal widening (lengthening) without true fragment displacement
  - Mild overlying soft tissue swelling

MR Findings

- T1WI
  - Dark signal intensity of marrow & soft tissue edema
  - ± bright fatty marrow in avulsed bone
- T2WI FS
  - Long TE ↓ conspicuity of cartilage, especially unossified epiphyseal cartilage (appears dark)
  - Acute injury
    - Bright fluid deep to displaced apophysis
    - Dark tendon remains attached to osteocartilaginous fragment
    - Bright marrow edema of apophysis & adjacent metaphyseal equivalent donor site
    - Moderate/marked surrounding soft tissue edema
      - Fluid &/or hemorrhage at avulsion site
      - Muscle edema from strain ± laxity
  - Chronic injury
    - Mild edema of nondisplaced apophysis & metaphysis
    - Mild ↑ signal, widening (lengthening), & irregularity of physis without discrete fluid
- PD/intermediate FS
  - Bright cartilage fragment
    - Short TE improves cartilage visualization
- GRE FS
  - Bright cartilage fragment, dark bone fragment

Ultrasonographic Findings

- Grayscale ultrasound
  - Distortion of normal soft tissue planes & osteocartilaginous interfaces
    - Comparison to contralateral normal side is key
  - Acute injury: Displaced osteocartilaginous fragment attached to muscle/tendon
    - Hypoechoic cartilage surrounding hyperechoic, shadowing ossification center
    - Dynamic maneuvers can move fragment
  - Chronic: Soft tissue edema, tendon thickening, bony fragmentation

Imaging Recommendations

- Best imaging tool
  - Radiographs are usually diagnostic of acute avulsion
  - MR is useful in some settings
    - Acute injury: Nondisplaced fragment or purely cartilaginous fragment (prior to ossification)
    - Chronic apophysitis
- Protocol advice
  - T2 FS or STIR MR: Best for marrow & soft tissue edema
  - PD FS or GRE FS MR: Best for cartilaginous fragments

DIFFERENTIAL DIAGNOSIS

Osteomyelitis

- Pelvic bones adjacent to growth cartilages (i.e., metaphyseal equivalents) are frequently involved

- Marrow & soft tissue edema ± fluid collections

Ewing Sarcoma

- Often involves entire pelvic bone with permeation, expansion, aggressive periosteal reaction, & (sometimes large) soft tissue mass

Muscle Injury

- Musculotendinous junction becomes weak link of musculoskeletal system after physeal closure
- Edema, fluid, interruption of muscle fibers ± tendon; muscle retraction if tear is complete

Stress Injury of Bone

- Solid periosteal reaction ± linear sclerosis or lucency (often perpendicular to bone long axis)
- Dark T1 MR signal fracture line precedes radiographic findings
- Surrounding marrow & soft tissue edema on T2 FS MR

PATHOLOGY

General Features

- Etiology
  - Osteochondral junction: Weakest point of immature musculoskeletal system
  - ↑ muscle strength of adolescence causes ↑ forces on relatively weak sites of muscle/tendon attachments
  - Acute apophyseal avulsions: Essentially Salter-Harris growth plate fractures
  - Chronic injury (apophysitis): Repetitive submaximal tensile stresses exceed rate of bone repair
    - Physeal widening (lengthening) due to impaired endochondral ossification or chondrocyte hypertrophy
    - Chronic stress injury may weaken physis & predispose to acute avulsion

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute: Sudden onset of pain with sensation of pop & instant ↓ of muscle function during athletic activity
  - Chronic: Insidious onset of pain & swelling without specific event or associated bruising

Demographics

- Age
  - Acute pelvic avulsions: Majority occur from ages 12-18 years; mean of 13.8-15.2 years
    - Ossification centers about pelvis appear around ages 12-14 years, fuse by 25 years
    - Sites of radiographically diagnosed injuries correlate with timing of ossification center appearance
      - Older patients (Risser 4): Iliac crest, ASIS avulsions
      - Younger patients (Risser 0): AIIS, ischial tuberosity avulsions
  - Medial epicondyle avulsions: 9-14 years
  - Tibial tubercle avulsions: 13-16 years
- Sex
  - M:F = 3:1
- Epidemiology
  - Acute
    - Most pelvic avulsions occur with kicking or sprinting
      - Soccer, gymnastics, rugby, track & field
      - AIIS, ASIS, ischial tuberosity > iliac crest, pubic symphysis
      - Multiple fractures in 6% of cases
    - Tibial tubercle avulsions are common in basketball & American football
    - Medial epicondyle avulsions are common with throwing or dislocation
  - Chronic
    - Little Leaguer's elbow: Valgus stress of overhead throwing
    - Osgood-Schlatter disease: Repetitive traction of jumping
    - Sever disease: Traction by Achilles tendon

Natural History & Prognosis

- Complications are uncommon
  - Nonunion: Much more likely if displacement is > 2 cm
  - Chronic pain
    - Most common with AIIS avulsions
      - Concomitant or subsequent labral injury
      - Exuberant heterotopic ossification
    - Sciatic nerve irritation or entrapment from displaced ischial tuberosity avulsions
  - Not at risk for clinically significant growth arrest (unlike long bone physeal injuries)

Treatment

- Most therapy is conservative (nonsurgical) & highly successful
  - Initial rest followed by physical therapy
- Surgical fixation is reserved for higher grade injuries
  - More likely if displacement > 1.5-2.0 cm

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Check pelvic apophyses closely in teenager with acute hip pain & pop during activity
- Radiographs may be negative initially in younger patients who have not yet ossified their apophyses

(Left) *Oblique radiograph in a 7-year-old boy after a fall shows medial translation & fragmentation of the medial epicondyle apophysis with marked overlying soft tissue swelling.* **(Right)** *AP radiograph of a 12-year-old patient with hip pain shows mild lateral displacement of an avulsed anterior inferior iliac spine (AIIS) ossification center at the attachment of the rectus femoris muscle.*

(Left) *Axial T2 FS MR in a 14-year-old boy who felt a pop while running shows a displaced apophyseal fragment due to sartorius avulsion of the left ASIS. The right ASIS shows chronic physeal stress injury with growth plate widening.* **(Right)** *Sagittal T2 FS MR in the same patient shows cartilaginous apophyseal avulsion at the sartorius attachment to the left ASIS. This fracture was radiographically occult.*

(Left) *AP radiograph in a 14-year-old patient who felt a pop while swimming shows avulsion of the unfused right lesser trochanter. This fracture does not implicate underlying pathology in children.* **(Right)** *Oblique radiograph of the foot in a 13-year-old boy after a basketball injury (L) shows new proximal retraction of the 5th metatarsal base apophysis as compared to a normal appearance 5 months prior (R). Point tenderness at this level confirmed an acute avulsion fracture.*

Incomplete Fractures

KEY FACTS

TERMINOLOGY

- Incomplete fracture: Macroscopic fracture line does not traverse entire bony diameter
- Buckle fracture: Fracture on compression side
- Greenstick fracture: Fracture on tension side
- Plastic deformity: Smooth abnormal bending of diaphysis without visible fracture line

IMAGING

- 2 tangential views: At least 1 cortex disrupted & 1 intact
  - Exception: Smooth bowing of plastic deformity
- Contralateral comparison views may be helpful
  - Especially in plastic deformity
- Most commonly occurs in radial & ulnar diaphyses & metaphyses
  - Look for subtle fracture line extending distally to physis as Salter-Harris type II (SH II) fracture has different follow-up requirements

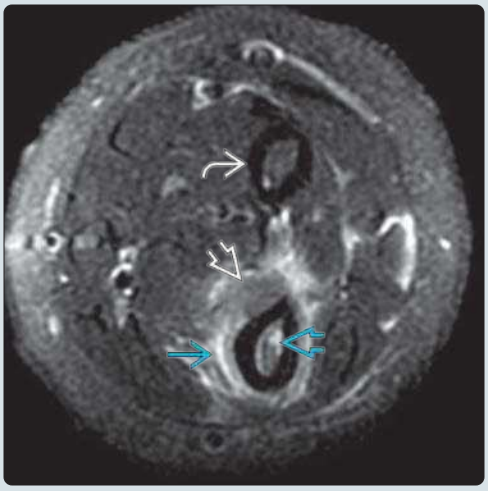
TOP DIFFERENTIAL DIAGNOSES

- Bowing due to underlying skeletal disease
- Normal developmental variants
- SH II fracture

PATHOLOGY

- Immature bone is more pliable with greater bending before breaking
- Fall on outstretched hand is most common mechanism

CLINICAL ISSUES



- Most common < 10 years of age
- Greenstick fracture is unstable: Refracture in 7-20%
- Reduction if needed + splint or cast immobilization
  - Acceptable displacement varies by age, location, type
- Greater remodeling potential in younger children
  - Will not correct rotational deformity
  - Limited remodeling potential in plastic deformity even when young

(Left) *PA & lateral wrist radiographs in an 11-year-old after a fall shows a buckle fracture of the distal radial diaphysis ➡ with minimal angulation. A focal contour protuberance of a nondisplaced ulnar buckle fracture ➡ is more subtle, best seen on the lateral view.* **(Right)** *AP & lateral radiographs of the forearm in a 5-year-old after a fall show incomplete fractures of the distal radial & ulnar diaphyses. Note the intact "bent but not broken" posterior cortex of each bone ⇨, typical of greenstick fractures.*

(Left) *AP radiograph of the forearm in a 5-year-old after a fall shows a plastic (bowing) deformity of the ulnar diaphysis ⇨. The radial curvature is within normal limits. Note that the ulnar deformity is not readily visible on the lateral view.* **(Right)** *Axial T2 FS MR in the same patient 4 days later (performed for specific elbow complaints) shows marrow ⇨, periosteal ⇨, & soft tissue edema in/about the ulnar diaphysis with no cortical break. Subperiosteal hemorrhage ➡ is noted. The radius ➡ is normal.*

TERMINOLOGY

Definitions

- Incomplete fracture: Macroscopic fracture line does not traverse entire bony diameter
- Buckle fracture: Fracture on compression side
- Greenstick fracture: Fracture on tension side
- Plastic deformity: Smooth, abnormal bending of diaphysis without visible fracture line

IMAGING

General Features

- Best diagnostic clue
  - Cortical bump, break, or angulation at site of pain + overlying soft tissue swelling
- Most common locations
  - Buckle fracture: Distal radial & ulnar diaphysis or metadiaphysis, tibia, proximal 1st metatarsal
  - Greenstick fracture: Radial & ulnar diaphysis
  - Plastic deformity: Radial, ulnar, & fibular diaphysis

Radiographic Findings

- Obtain at least 2 tangential views
  - At least 1 cortex is intact
- Buckle fracture
  - Focal protuberance of cortex on compression side
  - May be very subtle; suspect with any disruption of smooth cortical contour
- Greenstick fracture
  - Cortical disruption on tension side
  - Usually angulated with fracture on convex margin
- Plastic deformity
  - ↑ curvature of long bone diaphysis without cortical disruption
  - Adjacent bone of forearm or lower leg is often fractured
    - May be different type or dislocation
    - Monteggia equivalent fracture: Plastic deformation of ulna with anterior dislocation of radial head

Ultrasonographic Findings

- Focal interruption/bulging of echogenic cortex ± subperiosteal hemorrhage, soft tissue edema

DIFFERENTIAL DIAGNOSIS

Bowing Due to Underlying Skeletal Disease

- Systemic or localized bony dysplasias
- Metabolic bone diseases

Normal Developmental Variants

- Few sites of normal cortical angulation/protuberance
- Comparison views of contralateral side may be helpful

Salter-Harris Type II (SHII) Fracture

- Fracture line extends to physis

PATHOLOGY

General Features

- Immature bone is softer, more pliable → greater bowing or bending before breaking
  - Thicker periosteum, ↑ porosity, ↓ mineralization
- Forearm is most common site
  - Fall on outstretched hand is most common mechanism
  - Rotational component is common with greenstick fracture & plastic deformity

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, swelling, tenderness, disuse of limb, limp, or deformity

Demographics

- Most common < 10 years of age

Natural History & Prognosis

- Buckle fracture: Stable, typically heals without deformity
- Greenstick fracture: Unstable, at risk for refracture (7-20%)
- Plastic deformation: Limited remodeling potential, even in younger children

Treatment

- Nonsurgical reduction if needed + splint or cast immobilization
  - Fractured bones have greater remodeling potential in younger children (especially < 6 years)
    - Rotational deformity is not corrected with growth remodeling
  - Acceptable displacement, angulation, & malrotation varies by age, location, fracture type
- Buckle fracture
  - 3-week immobilization with splint
  - May not require follow-up imaging
- Greenstick fracture
  - May require closed reduction & casting
  - Some advocate completing fracture for improved alignment
  - Prolonged immobilization may reduce refractures
- Plastic deformation
  - May require closed reduction
    - Requires significant force over several minutes, adequate sedation

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Look carefully for metaphyseal fracture line extending to physis (implying SH II fracture)
  - Complications & follow-up are different from buckle

Child Abuse, Metaphyseal Fracture

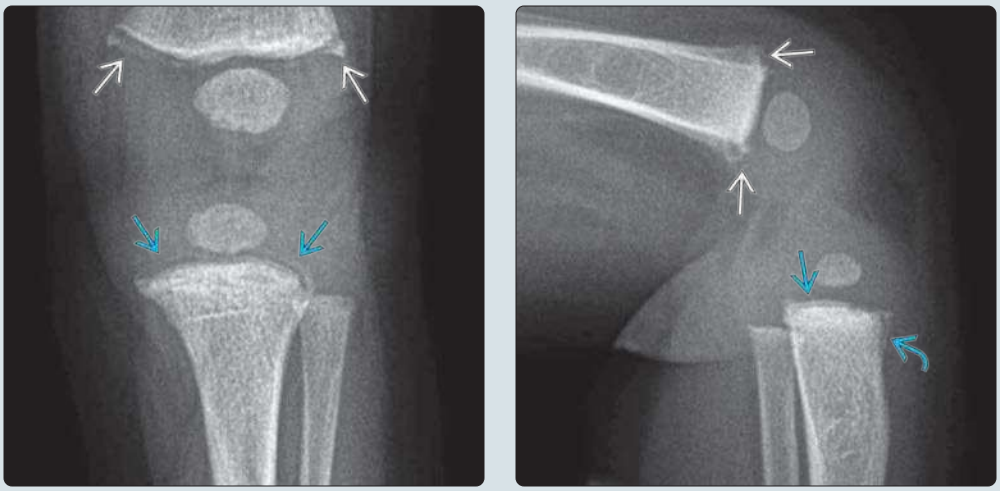
KEY FACTS

TERMINOLOGY

- Classic metaphyseal lesion (CML) or metaphyseal corner fracture: Transverse fracture of subphyseal metaphysis that undercuts subperiosteal bone collar (SPBC) peripherally
  - Fracture of infants with high specificity for child abuse

IMAGING

- Most common at distal femur, proximal & distal tibia
- Radiographic appearance
  - Triangular fragment at metaphyseal corner when x-ray beam is perpendicular to bone long axis
  - Bucket-handle fragment adjacent to metaphysis when x-ray beam is angled caudal or cranial relative to physis
  - Healing fractures are more conspicuous
    - Extension of physeal lucency into metaphysis
    - May see sclerosis along fracture margin
    - Subperiosteal new bone formation & callus
- Tc-99m MDP bone scan & F-18 NaF PET are complementary to initial skeletal survey
  - Sensitivity is greater for most fractures except CML, skull, scapula, & remote



PATHOLOGY

- Planar fracture through junction of primary & secondary spongiosa at trabecular transition zone; fracture undercuts SPBC peripherally
- Due to tensile & torsional forces from twisting or pulling extremity or from acceleration/deceleration of shaking
- No established evidence that rickets or metabolic bone disease can cause CML

CLINICAL ISSUES

- Initial skeletal survey is obtained if
  - < 2 years old with suspicion of NAT
  - < 5 years old with suspicious fracture
  - Concern for NAT in any child unable to communicate
- Obtain follow-up skeletal survey in 2 weeks as healing ↑ fracture conspicuity
- 95% of cases with CML have ≥ 1 additional injury

(Left) *AP radiograph of the left knee of a 9-month-old with lower extremity bruising shows the typical appearance of bucket-handle metaphyseal fractures [classic metaphyseal lesions (CMLs)] at the distal femur ➡ & proximal tibia ⇨.* **(Right)** *Lateral radiograph of a 5-month-old's knee demonstrates CMLs of the distal femur ➡ & proximal tibia ⇨. The tibial fracture extends anteriorly along the course of the unossified tibial tubercle ⇨.*

(Left) *AP radiograph of a 5-month-old with unexplained fractures at presentation (left) demonstrates a subtle metaphyseal fracture of the distal tibia ➡. A follow-up radiograph 3 weeks later (right) shows further healing changes with persistent subphyseal lucency ⇨.* **(Right)** *AP radiographs in the same patient (at presentation) show bilateral metaphyseal corner fractures of the distal radial metaphyses ⇨.*

TERMINOLOGY

Synonyms

- Nonaccidental trauma (NAT), battered child syndrome
- Metaphyseal corner fracture, classic metaphyseal lesion (CML), bucket-handle fracture

Definitions

- Fracture of infants that extends though subphyseal metaphysis & undercuts subperiosteal bone collar (SPBC) peripherally

IMAGING

General Features

- Best diagnostic clue
  - Triangular bone fragments at corners of metaphysis or bucket-handle, rim-like fragment of subphyseal metaphysis
- Location
  - Metaphyses of long bones, most commonly distal femur, proximal & distal tibia, proximal humerus

Radiographic Findings

- Acute fractures can be subtle & difficult to identify on initial skeletal survey
  - Transverse subphyseal lucency separates thin bone fragment from metaphysis & undercuts SPBC peripherally
    - May fully or partially extend across metaphysis
  - Appearance depends on radiographic projection
    - Triangular fragment lies at metaphyseal corner when x-ray beam is perpendicular to metaphysis long axis
    - Bucket-handle fragment lies along metaphysis when x-ray beam is angled caudal or cranial relative to physis
- Healing fractures are more conspicuous
  - Focal extension of physeal lucency into metaphysis due to persistent unossified cartilage
    - Most common at site of SPBC undercutting
    - May be broad with extensive fracture
  - Callus & subperiosteal new bone formation (SPNBF)
  - May see sclerosis along fracture margin
- Most common at distal femur, proximal & distal tibia
  - More commonly seen medially at these locations
  - Lateral & anterior fractures are always accompanied by medial fractures in series of cases
  - Proximal tibial fracture may extend anteriorly along tibial tubercle region, best seen in healing phase with sclerosis on lateral view
  - Distal tibial fracture vertical component undercutting SPBC is typically longer than in proximal tibia
- General comments on dating fractures
  - SPNBF appears after 7-10 days
  - SPNBF thickness ↑ with time
  - Callus develops by 15 days, not before 9 days
  - Callus thickness ↓ with age
  - Subphyseal lucency is late finding in healing
  - Up to 1/3 of distal tibial CML fails to demonstrate SPNBF
    - Normalization of metaphysis on follow-up does not exclude healed CML

CT Findings

- Not advocated for identification of fractures
- Evaluate proximal humeri & femurs on CT obtained to evaluate intrathoracic or intraabdominal injuries

MR Findings

- Whole-body MR shows very low sensitivity for signal abnormalities at sites of CML seen on skeletal survey: 31%
- May be complementary given ability to detect soft tissue abnormalities

Ultrasonographic Findings

- ↓ sensitivity (63%), ↑ specificity (97%)
  - Positive US may be helpful if radiographs are equivocal
- Metaphyseal collar fracture
- Metaphyseal collar thickening or deformity
- Irregularity of zone of provisional Ca^{2+}
- May see subtle edema in adjacent soft tissues

Nuclear Medicine Findings

- Tc-99m MDP skeletal scintigraphy or F-18 NaF PET is complementary to initial skeletal survey
  - Focal ↑ in radionuclide activity within 24 hours, normalizing within 6 months
  - Overall sensitivity of scintigraphy for detecting fractures > initial skeletal survey; exceptions include CML, skull & scapular fractures, remote injuries
    - ↓ sensitivity for CML due to physiologic uptake at physes
      - Tc-99m MDP bone scan 35%, F-18 NaF PET 67%
  - Scintigraphy specificity is lower than initial skeletal survey

Imaging Recommendations

- Initial skeletal survey
  - Indications
    - < 2 years old with suspicion of NAT
    - < 5 years old with suspicious fracture
    - Concern for NAT in any child unable to communicate
  - Images include: AP & lateral skull, lateral cervical & lumbar spine, AP & lateral & both obliques thorax (ribs), AP pelvis, AP humeri, AP forearms, shallow oblique hands, AP femurs, AP lower legs, AP feet
  - Additional views based on clinical & imaging findings
- Follow-up skeletal survey
  - Typically 2 weeks from initial evaluation
    - Minimum of 10 days
  - Indications
    - Concerning fractures on initial study
    - Normal initial study with persistent suspicion based on clinical or imaging findings
  - Used to confirm suspected fractures & identify additional fractures
  - In one study, clarified questionable fractures or identified new fractures in 48% of cases
    - Of 27 new fractures, 2 were CML
    - Of 29 questionable fractures, 6 were confirmed CML
- Tc-99m MDP skeletal scintigraphy or F-18 NaF PET as complementary or problem-solving tools
- CECT for suspected intrathoracic or intraabdominal injury

DIFFERENTIAL DIAGNOSIS

Osteogenesis Imperfecta

- Multiple fractures ± wormian bones, blue sclera
- ± osteoporosis

Metaphyseal Spur

- Distal extension of SPBC beyond chondroosseous junction, may be seen at lateral distal femur & other sites
- Typically lacks underlying lucency

Rickets

- Metaphyseal fraying, cupping, widening ± fractures
- Demineralization

Birth Trauma

- CML-like injuries are rarely reported with C-section

Leukemia

- Metaphyseal lucent bands ± fractures or more aggressive permeative lesions

Menkes Syndrome

- Osteoporosis, metaphyseal corner spurs, wormian bones, tortuous intracranial arteries, & brittle hair from abnormal copper metabolism

Spondylometaphyseal Dysplasia

- Metaphyseal irregularities resembling corner fractures due to abnormal endochondral ossification
- Scoliosis, platyspondyly, coxa vara, pectus carinatum

Metaphyseal Chondrodysplasia

- Early metaphyseal cupping → severe expansion → fragmentation or cystic changes
- Frontonasal hyperplasia, hypertelorism, proptosis, micrognathia, curved forearms & legs

PATHOLOGY

General Features

- Planar fracture through junction of primary & secondary spongiosa at trabecular transition zone; fracture undercuts SPBC peripherally
- Due to tensile & torsional forces from twisting or pulling extremity or from acceleration/deceleration of shaking
- No established evidence that rickets/metabolic bone disease can cause CML
- No established evidence that rickets/metabolic bone disease can cause fractures of any kind in absence of radiographic findings of underlying metabolic bone disturbance

CLINICAL ISSUES

Presentation

- Wide range of clinical presentations for NAT
  - Injury inconsistent with history or stage of development
  - Multiple injuries in various stages of healing
  - Bruising in nonmobile infant
  - Retinal hemorrhages
- CML
  - One study evaluating bruising as indicator for fracture
    - 25% had bruising at sites other than fracture site
    - Only 13% had bruising at/near fracture site
  - Another study found that 95% of cases with CML had at least 1 additional injury
    - 84% had additional non-CML fractures, most commonly long bone & rib
    - 43% had cutaneous injuries (bruising or burns)
    - 28% had traumatic brain injury

Demographics

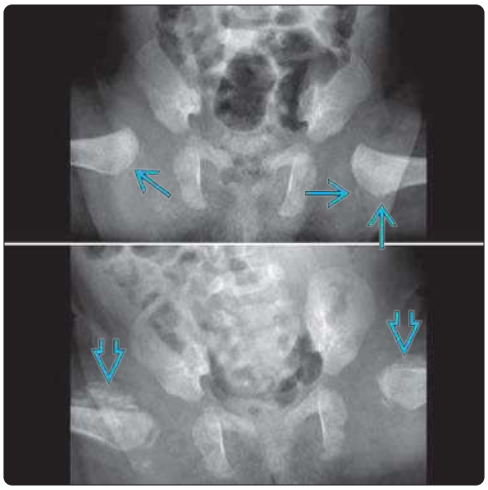
- Epidemiology
  - ~ 702,000 child maltreatment victims in USA in 2014
    - Infants ≤ 1 year old are most at risk, account for 36.7%
    - Physical abuse in 41% of child maltreatment cases
  - CML has high specificity for NAT
    - Most common fracture in fatal NAT cases in one study
    - Present in 50% of infants at high risk for NAT compared to 0% in infants at low risk for NAT

Natural History & Prognosis

- ~ 1,580 fatalities from child maltreatment in USA in 2014
  - Death rate greatest in infants < 1 year old: 17.96/100,000 same-aged children in population
  - 71% of all deaths occurred in children < 3 years old
  - 79% of fatalities involved parent as perpetrator

Treatment

- Multidisciplinary investigation of maltreatment allegation
- Ensure at risk child & siblings are placed in safe environment



DIAGNOSTIC CHECKLIST

Reporting Tips

- Concern for child abuse raised by imaging must be discussed with referring clinician immediately
- Report represents legal document: Review carefully
- Provide clear, detailed description of each fracture, including location, fragments, & estimated age (i.e., acute, healing, healed/remote)

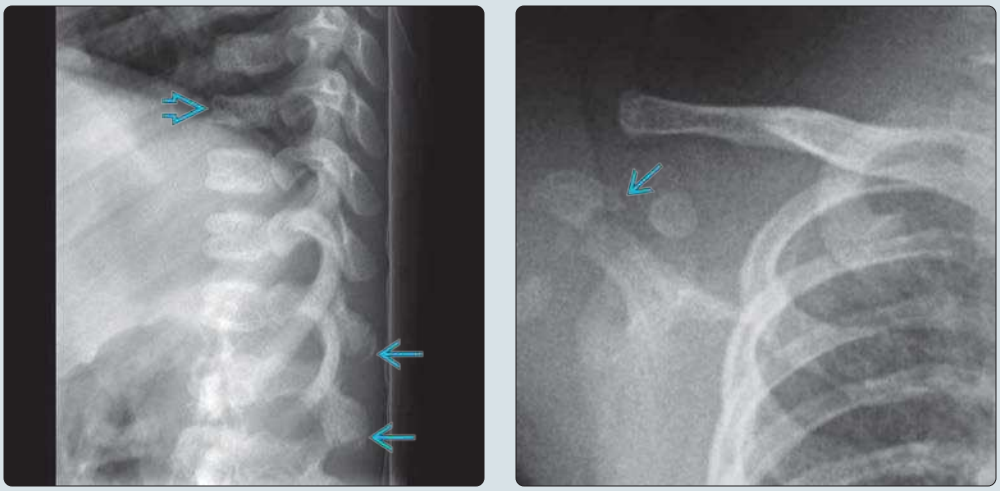
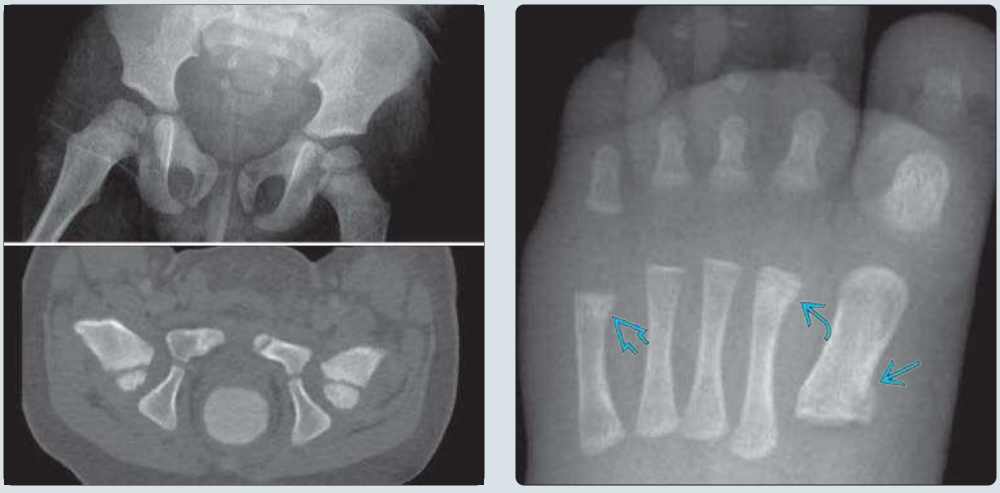
(Left) *Frog leg lateral radiograph in a 2-month-old with bruising (top) shows bilateral metaphyseal corner/bucket-handle fractures of the proximal femurs. MR (not shown) confirmed fractures traversing the primary spongiosa. Follow-up radiograph 2 weeks later (bottom) shows marked periosteal reaction.* **(Right)** *AP radiograph in a 3-month-old infant shows a bucket-handle fracture of the distal tibial metaphysis with overlying soft tissue swelling.*

(Left) *AP radiograph of the right knee in a newborn who suffered birth trauma shows a CML-like fracture at the distal femur. This is similar in appearance to metaphyseal fractures related to nonaccidental trauma (NAT).* **(Right)** *Longitudinal US from the same patient with birth trauma demonstrates the metaphyseal fracture with associated hematoma. There has been ↑ interest in using US to evaluate similar-appearing NAT-related CMLs, particularly when initial radiographs are unclear.*



(Left) *AP radiographs of the right knee in a 3-month-old with a skull fracture (not shown) at presentation (left) & 7 weeks later (right) show evolution of a distal femoral metaphyseal corner fracture with subphyseal lucency on follow-up. A tibial CML is seen on the 2nd study.* **(Right)** *Lateral view of the tibia in a 6-month-old with failure to thrive shows a metaphyseal fracture. The periphery of the fracture undercuts the subperiosteal bone collar, which is thicker than the thin central component.*

KEY FACTS



IMAGING

- High specificity for child abuse
  - Classic metaphyseal lesions, posterior rib fractures
  - Scapular fractures
    - Transverse or oblique fractures of midacromion process are most common
    - Acromion tip fracture mimics ossification center
  - Sternal fractures
    - Linear lucency or buckling of anterior cortex
    - Widened sternal synchondrosis or malalignment of sternal segments
  - Spinous process fractures
    - Cartilage/bone avulsion at interspinous ligamentous attachment due to hyperflexion & shaking
    - Ossific density adjacent to spinous process may represent acute or remote injury
- Moderate specificity for child abuse
  - Vertebral body fractures
    - Compression deformity &/or anterosuperior endplate fracture
  - Vertebral fracture-dislocations
    - Neurocentral synchondrosis fracture extending through endplate apophyses with retropulsion of vertebral centrum
    - Facet dislocation ± fracture
  - Transphyseal fracture/distal humeral epiphyseal separation
    - Capitellar ossification center, radius, & ulna are displaced posteriorly & medially relative to distal humerus
    - Distal humeral cartilage maintains alignment with radius & ulna (not true dislocation)
  - Complex skull fractures, hand & foot fractures, pelvic fractures
- Low specificity for child abuse
  - Clavicle, long bone shaft, & linear skull fractures common but have low specificity for nonaccidental trauma

(Left) *Lateral radiograph of the spine in an 8-month-old with bruising & a subdural hematoma shows irregularity, lucency, & sclerosis of the T12 & L1 spinous processes as well as compression of the T9 vertebral body. Spinous process fractures are highly suggestive of child abuse.* **(Right)** *Frontal radiograph in an abused 6-week-old shows an acromial fracture with irregularity & elevation of the distal fragment. Follow-up images confirmed the presence of healing changes.*

(Left) *AP radiograph (top) & axial CT (bottom) of an abused 2-year-old with numerous other high-specificity fractures (not shown) demonstrate sclerosis at the right superior pubic ramus, compatible with healing fracture. Radiographic cortical irregularity at the left superior pubic ramus shows lucency on CT, also compatible with fracture.* **(Right)** *AP radiograph of the foot in the same patient shows healing fractures of the 1st, 2nd, & 5th metatarsals.*

TERMINOLOGY

Synonyms

- Nonaccidental trauma (NAT), battered child syndrome

IMAGING

General Features

- Best diagnostic clue
  - Classic metaphyseal lesions (CMLs) & posterior rib fractures: High specificity for NAT
    - Other high-specificity injuries include scapular, spinous process, & sternal fractures
  - Multiple fractures, bilateral fractures, & fractures of varying ages: Moderate specificity for NAT
    - Other moderate-specificity injuries include epiphyseal separation, vertebral body, digital, complex skull, & pelvic fractures
  - Injury incompatible with age &/or history suspicious for NAT
- Distribution of fractures due to NAT
  - Skull 27%, ribs 18%, vertebra 2%, pelvis < 1%
  - Humerus 11%, forearm 7%, clavicle 4%, hand < 1%
  - Femur 18%, tibia & fibula & ankle 12%, tarsal & metatarsal < 1%

High-Specificity Fractures

- Scapular fractures
  - Acromion is most commonly involved
    - Transverse or oblique fractures of midprocess
    - Tip fractures are less common
    - Ossification centers can mimic fractures but are anterior/inferior & typically arise in 2nd decade
  - Coracoid & glenoid fractures are rare
  - Best evaluated on humerus & oblique rib views
  - CT or radionuclide exam for challenging cases
- Sternal fractures
  - Rare; result from direct force to sternum
  - Linear lucency or buckling of anterior cortex
  - Widened sternal synchondrosis or malalignment of sternal segments
  - Irregularity & sclerosis of synchondrosis osseous margins with healing
  - May require dedicated views or CT for evaluation
  - Likelihood of accidental cause ↑ > 1 year of age
- Spinous process fractures
  - Avulsion of cartilage &/or bone at interspinous ligamentous attachments due to shaking, hyperflexion
  - ± vertebral body compression deformity

Moderate-Specificity Fractures

- Vertebral body fractures
  - Compression &/or anterosuperior endplate fracture
  - Healing results in
    - Central vertebral body sclerosis
    - Anterosuperior endplate notching/lucency + marginal sclerosis with remote injuries
  - Findings may be subtle, underestimate injuries
    - MR & F-18 NaF PET are more sensitive
- Vertebral fracture-dislocations
  - Neurocentral synchondrosis injury
    - Fracture extends through superior & inferior endplate apophyses & neurocentral synchondrosis posteriorly due to hyperflexion
    - Extrusion of vertebral centrum, typically posteriorly
      - Retropulsion of vertebral body on lateral view
    - Widened interpediculate distance & disc space narrowing on AP view
    - ± vertebral body compression deformity
    - ± mass effect on thecal sac on MR
  - Facet dislocation ± fracture
    - Widened interspinous distance on AP & lateral views
    - Retrolisthesis on lateral view
    - Facet joint disruption/widening
    - ± compression deformity &/or fractures involving facets, posterior elements, endplates
  - Paraspinal Ca^{2+} with healing
- Epiphyseal separations (or transphyseal fractures)
  - Have also been described with birth trauma
  - US or MR can be very helpful for showing
    - Displacement of unossified epiphysis
    - Periosteal elevation along metaphysis acutely
  - Abundant periosteal new bone is typical of healing
  - Distal humeral epiphyseal separation
    - Largely unossified capitellar ossification center is translated posteriorly & (usually) medially relative to distal humerus but maintains alignment with radius
    - In absence of epiphyseal/capitellar ossification, posterior & medial translation of radius & ulna is suggested if
      - Radius aligns with central & medial humeral metaphysis with ulna medial to humerus
      - Dislocation is initially suspected: Rare in infants, & most dislocations occur laterally
    - ± metaphyseal fracture fragment
    - MR, US, or arthrogram is helpful to confirm diagnosis & evaluate degree of displacement
      - Discontinuity of distal humeral epiphyseal cartilage from bony metaphysis
      - Posterior & medial translation of epiphysis, which maintains alignment with radius & ulna
    - Up to 50% are due to NAT but can occur with birth or accidental trauma
  - Proximal humeral epiphyseal separation
    - Rare; classically seen with birth injuries
  - Proximal femoral epiphyseal separation
    - Proximal femoral diaphysis is translated laterally & proximally relative to ossified capital femoral epiphysis (or acetabulum if epiphysis is unossified)
    - If epiphysis is unossified, may simulate dislocation on radiograph
    - May develop coxa vara deformity
  - Distal femoral epiphyseal separation
    - Rare: Requires more force than CML
- Complex skull fractures
  - > 1 fracture line, stellate or branching, comminuted
- Digital fractures of hands & feet
  - Relatively uncommon, present in 4.9% of all positive skeletal surveys obtained for NAT
    - Buckle fractures of metatarsals, usually medial 1st metatarsal

  - Buckle fractures of metacarpals & phalanges
  - Likely result from twisting or bending forces
- Pelvic fractures
  - Subtle, typically involve superior pubic ramus in infants
  - ± association with sexual assault in older children
  - MR & F-18 NaF PET may be helpful

Low-Specificity Fractures

- Clavicle, long bone shaft, & linear skull fractures are common but have low specificity for NAT

Dating Fractures

- Soft tissue swelling only in first 1-2 days, ↓ by 7 days; seen again (less pronounced) from 15-35 days
- Subperiosteal new bone formation after 7-10 days, ↑ thickness until 25 days
- Soft callus usually by 15 days, ↓ by 35 days
- Bridging & remodeling by 14-21 days
- Hard callus by > 35 days

DIFFERENTIAL DIAGNOSIS

Accidental Trauma

- Age & clinical history are consistent with fracture

Osteogenesis Imperfecta

- Multiple fractures, wormian bones, diffuse osteoporosis, ± blue sclera

Birth Trauma

- Correlates with age, birth history, & typical location

Rickets

- Demineralization with metaphyseal fraying, cupping, widening; loss of normal zone of provisional Ca^{2+}

Metabolic Disorder-Related Bone Changes

- Mucopolysaccharidoses: Vertebral body beaking, oar-shaped ribs, short, thick metacarpals with proximal pointing
- Menkes disease: Metaphyseal spurs, brittle hair, tortuous intracranial arteries

Normal Variants Confused With Fractures

- Normal variant vertebral notching typically occurs at 1 level; no disc space narrowing or malalignment
- Minimal anterior sloping of midthoracic vertebrae

PATHOLOGY

General Features

- Hyperextension/hyperflexion with acceleration-deceleration forces from shaking account for many NAT-related fractures, including CMLs, posterior rib fractures, spinal fractures, & avulsion-type injuries of scapula
- Grabbing & twisting/torsional forces: Transphyseal & digital fractures
- Direct impact mechanism: Sternal, skull, & scapular body fractures

CLINICAL ISSUES

Presentation

- Wide range of clinical presentations for NAT
  - Injury inconsistent with history or stage of development
  - Multiple injuries in various stages of healing
  - Bruising in nonmobile infant
  - Burns, retinal hemorrhages
  - Seizures, altered mental status, acute life-threatening event
- Majority of spinal fractures are clinically inapparent
  - Severe & undiagnosed; may result in cord injury
  - Significant association with intracranial injury

Demographics

- Epidemiology
  - 678,000 child maltreatment victims in 2018 in USA
    - Infants ≤ 1 year old most at risk

Natural History & Prognosis

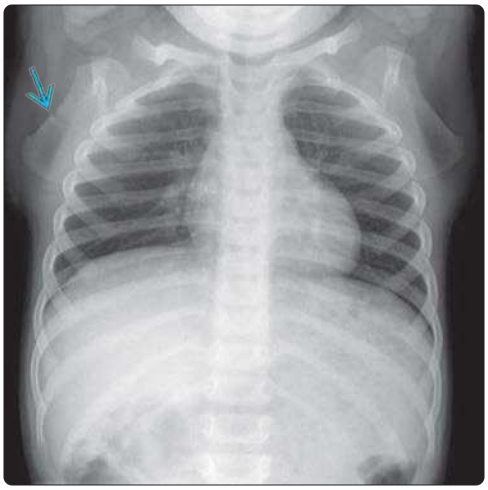
- 1,770 fatalities from child maltreatment in 2018
  - Death rate greatest in infants < 1 year old
  - 79% of fatalities involved parent as perpetrator

Treatment

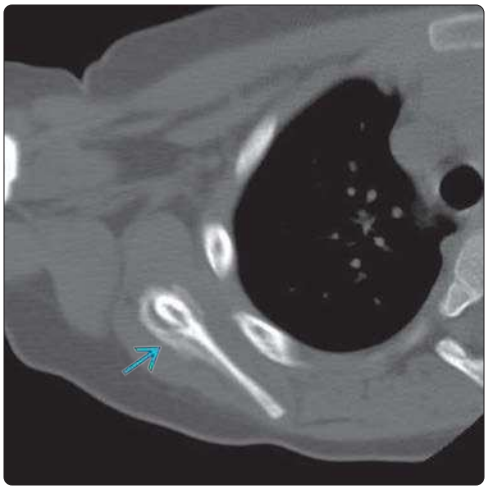
- Multidisciplinary investigation of maltreatment allegations must involve physicians, social worker, Child Protective Services, legal authorities
- Ensure at risk child & siblings are given safe environment
  - May involve removal of child from home, temporary/protective custody

DIAGNOSTIC CHECKLIST

Consider



- Imaging findings & their specificity for NAT must be correlated with clinical history & physical exam findings



Reporting Tips

- Concern for child abuse raised by imaging must be discussed with referring clinician ASAP
- Report represents legal document; review carefully
- Provide clear, detailed description of each fracture, including location, fragments, & approximate age

(Left) *AP chest radiograph in a 2-year-old with bruising shows a fracture of the right scapular body.* **(Right)** *Axial bone CT in the same 2-year-old patient with bruising shows callus formation about the right scapular body fracture. Scapular fractures in young children have a high specificity for child abuse, & those of the scapular body are typically the result of direct impact.*

(Left) *External oblique radiograph in a 1-month-old not using his arm shows medial translation of the capitellar ossification center, radius, & ulna relative to the distal humerus.* **(Right)** *Posterior longitudinal US of the elbow in the same patient shows posterior translation of the hypoechoic trochlear cartilage relative to the humerus. The olecranon still articulates with the trochlea. These findings are consistent with a distal humeral epiphyseal separation fracture rather than an elbow dislocation.*

(Left) *Sagittal T2 FS MR in a 6-month-old after a reported fall shows a fracture through the distal humerus with posterior translation & angulation of the unossified trochlear cartilage & articulating olecranon cartilage. These findings are consistent with a distal humeral epiphyseal separation.* **(Right)** *Axial CECT (in bone windows) in a young child with abdominal pain shows healing fractures of the sternum & a posterior left rib. Both of these fractures are highly suggestive of child abuse.*

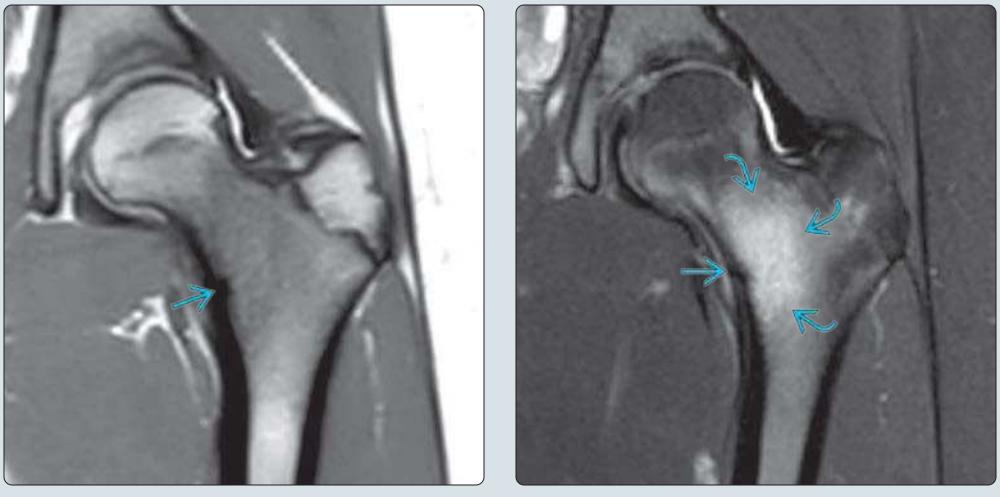
KEY FACTS

TERMINOLOGY

- Fatigue fracture: Fracture due to abnormal stresses applied (over time) to normal bone
- Insufficiency fracture: Fracture due to normal stresses applied to abnormal bone
- Stress response/reaction: Result of stresses upon bone prior to development of macroscopic fracture
- Chronic physeal stress injury: Repetitive stress to growth plate interrupts normal endochondral ossification

IMAGING

- Stress injury of formed bone
  - Periosteal new bone ± transversely oriented lucent cortical fracture or band of sclerosis on radiographs
  - Transverse linear focus of unicortical & medullary ↓ T1 & T2 signal (fracture line) + poorly defined surrounding ↑ T2 signal (edema) on MR = stress fracture
  - Limited marrow, periosteal, & soft tissue abnormalities without discrete fracture line = stress response
- Chronic physeal stress injury
  - Asymmetric lengthening (widening) of lucent growth plate with metaphyseal irregularity on radiographs
  - Broad metaphyseal extension of cartilaginous physeal signal intensity on MR (especially PD/T2 FS or T2* GRE)



CLINICAL ISSUES

- Fatigue fractures occur in
  - Athletes with recent changes in routine
  - Newly ambulating children
  - Children with malalignment or altered weight bearing
  - Preadolescent children without ↑ activity intensity
- Insufficiency fractures occur in children with focal or systemic processes leading to bone weakening
- Treatment includes cessation of stresses with adequate time for bone repair & recovery of normal ossification
  - Rest & immobilization to prevent completion of fracture or permanent growth disturbance from physeal injury

(Left) *Frontal radiograph of the right proximal leg in a 13-year-old girl with leg pain shows periosteal reaction along the proximal fibula. A very subtle linear lucency is also seen, suggesting a stress fracture that is poorly visualized on this study.* **(Right)** *Coronal T1 (left) & STIR (right) MR images of the proximal leg in the same child show a linear low signal intensity fracture line. Adjacent periosteal & soft tissue edema are also seen on the STIR MR.*

(Left) *Coronal PD MR in a 17-year-old female track athlete with left hip pain shows linear low signal intensity at the medial aspect of the left femoral neck.* **(Right)** *Coronal T2 FS MR in the same patient shows the low signal intensity fracture line with surrounding marrow edema. This half-moon configuration of marrow edema in the femoral neck has been described with both osteoid osteoma & stress fractures.*

TERMINOLOGY

Definitions

- Fatigue fracture: Fracture due to abnormal stresses applied (over time) to normal bone
- Insufficiency fracture: Fracture due to normal stresses applied to abnormal bone
  - Demineralized or otherwise weakened bone from focal or systemic process
- Stress response/reaction: Result of stresses upon bone prior to development of macroscopic fracture
- Chronic physeal stress injury: Repetitive stress to metaphyseal vasculature & cartilaginous growth plate interrupts normal endochondral ossification

IMAGING

Radiographic Findings

- Stress fracture
  - Poor cortical definition with varying degrees of cortical thickening/periosteal new bone
  - ± transversely oriented findings, including
    - Hairline fracture lucency extending centrally from involved cortex
    - Sclerotic band of medullary cavity
- Chronic physeal stress injury
  - Broad or focal lengthening (widening) of lucent physis
  - Metaphyseal irregularity with loss of normal thin, radiodense zone of provisional calcification (ZPC)

CT Findings

- Hairline, transversely oriented, unicortical lucency extending centrally with adjacent solid, smooth periosteal reaction

MR Findings

- T1WI
  - Transverse hypointense stress fracture line extending from cortex into medullary cavity
  - Varying degrees of surrounding poorly defined hypointense marrow edema
- T2WI FS
  - Poorly defined hyperintense signal of marrow, periosteum, & soft tissues without discrete fracture line: Stress response
  - Transverse linear hypointense focus of medullary signal: Stress fracture
  - Metaphyseal extension of cartilaginous physeal signal intensity: Chronic physeal stress injury
    - Broad vs. small "tongue" of unossified cartilage
- T2* GRE
  - Cartilage-sensitive sequences nicely demonstrate abnormalities at interface of physis-metaphysis (i.e., chronic physeal stress injuries & rare secondary bony bridges)
- T1WI C+ FS
  - Enhancing marrow, periosteal, & soft tissue edema

Nuclear Medicine Findings

- Bone scan: Intense cortical uptake; sensitivity ~ 100%
- SPECT-CT: ↑ specificity for location & etiology
  - May help separate fracture from osteoid osteoma
  - Excellent for pars interarticularis stress fracture

DIFFERENTIAL DIAGNOSIS

Focal Periosteal Reaction, Marrow Edema

- Osteoid osteoma
- Osteomyelitis
- Bone malignancy
  - Ewing sarcoma, metastatic neuroblastoma, leukemia

Linear Sclerosis Within Bone

- Infarction

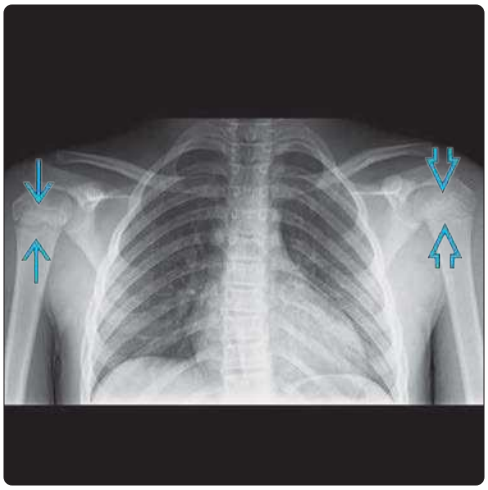
Lucent & Irregular Physes/Metaphyses

- Rickets
- Epiphysiodesis (drill type)
- Leukemia

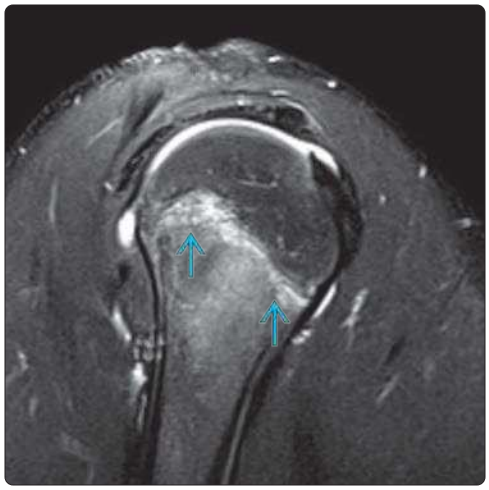
CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Stress fracture: Pain, swelling with appropriate history
  - Chronic physeal stress injury: Pain; rarely asymptomatic
  - Symptoms typically are present for weeks prior to presentation
- Clinical profile
  - Fatigue fractures in
    - Athletes with recent changes in routine
      - Medial tibial stress syndrome: Overuse or repetitive stress injury to shin area; may progress to fracture
    - Newly ambulating children
      - Young child with new refusal to bear weight
    - Children with malalignment or altered weight bearing
    - Preadolescent children with normal play activities & no elevation of activity intensity
  - Insufficiency fractures in
    - Children with focal or systemic processes leading to bone weakening
      - New stress reaction/insufficiency fracture in osteoporotic hindfoot due to ↑ ambulation after weeks of casting for preceding distal tibial fracture



Treatment



- Stress fracture
  - Prevention is paramount: Gradual ↑ in new activity intensity + prompt activity reduction when pain occurs
  - Combination of reduced activity, rest, immobilization, casting, & (rarely) internal fixation
- Chronic physeal stress injury: Rest & immobilization are typically sufficient for endochondral ossification to resume

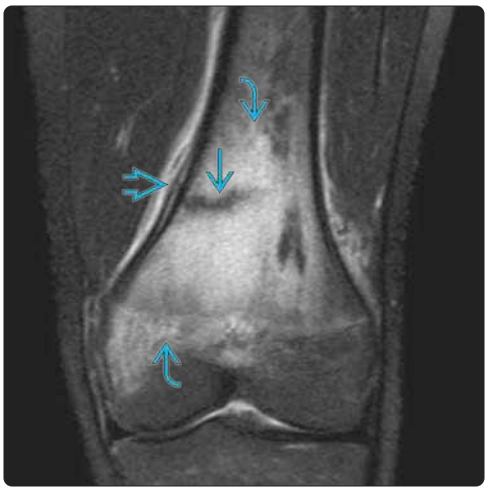
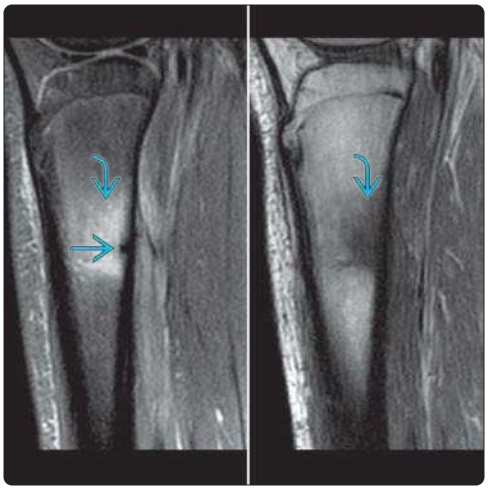
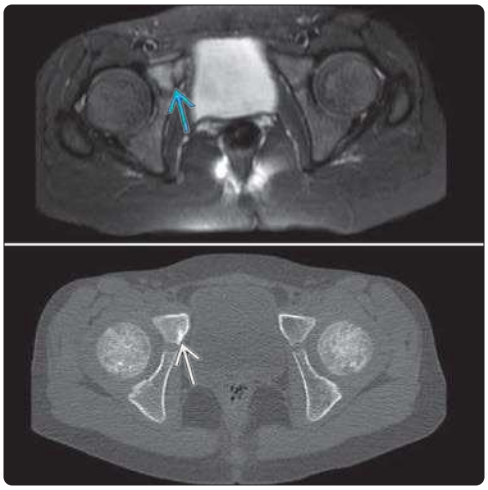
(Left) *AP radiograph of the shoulders in a 14-year-old pitcher with weeks of right shoulder pain shows lengthening of the proximal right humeral physis ⇨ as compared to the normal left side ⇨. Note the pseudofracture appearance of both proximal humeri due to the normal obliquity of the growth plates.* **(Right)** *Sagittal T2 FS MR in the same patient shows an abnormally long, irregular, & hyperintense physis ⇨, typical of a chronic repetitive stress injury of the growth plate in this pitcher (Little Leaguer's shoulder).*

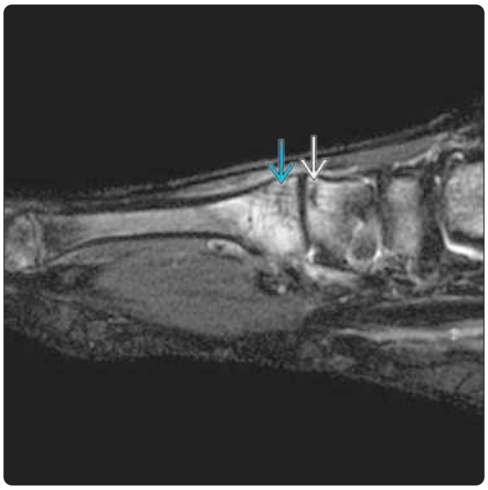


(Left) *PA wrist radiograph in a 13-year-old female gymnast with pain shows abnormal lengthening of the cartilaginous distal radial physis with metaphyseal irregularity ⇨ & loss of the normal thin, dense zone of provisional Ca^{2+}. Note the normal distal ulnar physis ⇨.* **(Right)** *Coronal T2* GRE MR in this patient confirms abnormal lengthening of the radial physis ⇨ due to repetitive microtrauma (gymnast wrist). The ulnar physis is normal ⇨ as it does not endure the same physical stresses as the radius.*



(Left) *Coronal T2 FS MR in a 16-year-old with knee pain shows a transverse band of low signal intensity ⇨ in the distal femoral diaphysis, consistent with an incomplete stress fracture. There is surrounding marrow edema ⇨ & overlying periosteal reaction ⇨.* **(Right)** *Follow-up AP radiograph in the same patient 4 weeks later shows sclerosis of the healing stress fracture ⇨ with focal solid periosteal reaction at this level ⇨.*





(Left) *Lateral radiograph in a 14-year-old with lower leg pain shows subtle solid periosteal reaction focally at the posterior proximal right tibial diaphysis. **(Right)** Sagittal T2 FS (left) & T1 (right) MR images of the same patient show poorly defined marrow edema surrounding a small linear corticomedullary focus of low signal intensity, consistent with a stress fracture.*

(Left) *Axial T2 FS MR (top) of the pelvis in a 6-year-old with pain shows a low signal intensity fracture line of the superior pubic ramus with surrounding marrow edema. Axial bone CT (bottom) shows sclerosis at this same level, consistent with a healing stress fracture. **(Right)** Sagittal STIR MR in a 16-year-old cross country runner with pain shows linear low signal intensity foci in the 2nd metatarsal base & middle cuneiform with surrounding marrow edema, consistent with stress fractures.*

(Left) *PA wrist radiographs taken 6 weeks apart in a 6-year-old after a fall show incomplete fractures of the distal radius & ulna initially (left). The capitate is normal on the initial radiographs. Six weeks later (right), there is disuse osteoporosis distally with horizontal stress reaction of the capitate. **(Right)** Lateral radiograph of the foot in a 3-year-old shows a band of vertically oriented sclerosis in the posterior aspect of the cuboid, a common location for a stress injury.*

Osteochondritis Dissecans

KEY FACTS

TERMINOLOGY

- Osteochondritis dissecans (OCD): Juvenile OCD (JOCD) when physes are open vs. adult OCD when physes are closed
- Focal joint disorder with progressive changes in subchondral bone & overlying articular cartilage that may lead to early joint degeneration

IMAGING

- Findings reported as specific for instability in JOCD
  - Fluid-filled osteochondral defect
  - High T2 signal intensity cartilage fracture line
  - Fluid signal intensity surrounding OCD
  - Multiple breaks in subchondral bone plate on T2 MR
  - Outer rim of T2 low signal intensity
  - Multiple cysts or single cyst > 5 mm
- Findings reported as specific for instability in adult OCD
  - Fluid-filled osteochondral defect
  - High T2 signal intensity rim
  - High T2 signal intensity cartilage fracture line
  - Cysts surrounding OCD

TOP DIFFERENTIAL DIAGNOSES

- Normal irregular distal femoral epiphyseal ossification
- Osteonecrosis
- Osteochondral impaction fracture
- Stress or insufficiency fracture

PATHOLOGY

- Etiology is likely multifactorial (traumatic, ischemic, genetic)
  - Favored mechanism: Repetitive microtrauma
  - JOCD may represent growth disturbance of secondary physis; little necrosis or inflammation on histology

CLINICAL ISSUES

- Most common in adolescent athletes
- Studies show high variability in MR accuracy for predicting instability compared to arthroscopy

(Left) *Coronal oblique graphic shows circumferential fissuring of the articular cartilage of the posterolateral aspect of the medial femoral condyle.* **(Right)** *Coronal T2 FS MR in a 15-year-old girl shows the in situ portion of a complex osteochondral lesion of the medial femoral condyle. Fluid ➡ undercuts the fragment with an overlying T2-hypointense cartilage crack ➡ noted, which are MR findings consistent with an unstable lesion.*

(Left) *Slightly more anterior T2 FS MR slice in the same patient shows fluid filling an osteochondral defect ➡ of the parent femoral condyle.* **(Right)** *Sagittal midline T2* GRE MR in the same patient shows the displaced osteochondral fragment ➡ along the inferior patellar articular surface. The fragment was shown to be loose (rather than synovialized & fixed) by interval changes in position on radiographs (not shown).*

TERMINOLOGY

Abbreviations

- Osteochondritis dissecans (OCD)

Synonyms

- Osteochondral lesion, juvenile OCD (JOCD), adult OCD

Definitions

- Focal joint disorder with progressive changes in subchondral bone & overlying articular cartilage that may lead to early joint degeneration
- JOCD is limited to skeletally immature patients (open physes)

IMAGING

General Features

- Best diagnostic clue
  - Osteochondral lesion at lateral aspect of medial femoral condyle ± loose fragment in young adolescent athlete
- Location
  - Large multicenter study of OCD: Knee is most common location
    - Medial femoral condyle: 77%
    - Lateral femoral condyle: 17%
    - Others at knee: Patella (7%), trochlea (1%), tibial plateau (0.2%)
    - Bilateral: ~ 15-30%
  - Less frequent in elbow, ankle, hip
- Morphology
  - Crescentic/ovoid osteochondral lesion contiguous with parent bone (in situ) vs. detached intraarticular fragment

Radiographic Findings

- Crescentic/ovoid lucent subchondral bone lesion surrounded by sclerotic margin
- ± in situ or displaced intraarticular osseous fragment
- Underestimates size, cannot assess cartilage integrity
- Radiographic findings of healing on follow-up exams
  - ↑ ossification within lesion
  - ↓ sclerotic halo between parent bone & lesion
  - Less defined lucency between parent bone & lesion
  - ↑ convexity of articular surface shape
  - ↓ overall volume of lesion

MR Findings

- T1WI
  - Hypointense fragment
  - ± hypointense subchondral marrow edema
  - ± hyperintense fibrovascular tissue on 3D T1 FS SPGR
- T2WI
  - Variable hyperintense signal in osteochondral fragment & adjacent marrow
  - Overlying fissures/defects in articular cartilage are best appreciated on PD/T2 ± FS
  - PD/T2 FS may demonstrate direct cartilaginous &/or bony extension of fluid
  - ± hyperintense cysts or fibrovascular tissue deep to lesion
  - ± hyperintense synovial thickening or joint fluid
  - Specifically in JOCD
    - Oreo cookie sign: Laminar T2 hyperintensity with deep & superficial margins of hypointensity
    - Disruption of thin, circumferential, hyperintense secondary physis overlying OCD lesion
    - Thickened overlying unossified epiphyseal cartilage
- T2* GRE
  - May help visualize displaced osteochondral fragment
    - Purely chondral fragments may be best seen on FSE FS images
- MR arthrography with gadolinium-based agent
  - Contrast between OCD fragment & parent bone = unstable fragment
- MR features for treatment planning (most studied in knee)
  - Findings reported as specific for instability in JOCD
    - Fluid-filled osteochondral defect
    - High T2 signal intensity cartilage fracture line
    - High T2 signal rim equal to fluid signal intensity surrounding OCD
    - Multiple breaks in subchondral bone plate on T2
    - Outer rim of T2 low signal intensity
    - Multiple cysts or single cyst > 5 mm
  - However, other studies have shown some JOCD with MR findings of instability to heal without surgery
  - Findings reported as specific for instability in adult OCD
    - Fluid-filled osteochondral defect
    - High T2 signal intensity rim
    - High T2 signal intensity cartilage fracture line
    - Cysts surrounding OCD
  - Predictors of stability
    - Fragment continuity with parent bone without linear fluid signal intensity interface, cyst, high T2 signal cartilage fracture line, or breaks in subchondral bone plate
  - MR accuracy for predicting stable vs. unstable OCD lesion as compared to arthroscopy: 30-92%
  - MR findings of healing after therapy
    - Variable osteochondral changes depending on type of intervention
    - In general, healing is indicated by
      - ↓ lesion size, cysts, marrow edema
      - ↑ bone filling OCD lesion bed
      - Improved morphology of articular cartilage surface

Imaging Recommendations

- Best imaging tool
  - MR or MR arthrography
- Protocol advice
  - PD/T2 FS MR sagittal, coronal ± axial sequences (depending on OCD site)
  - 3D GRE FS MR cartilage-sensitive sequence
  - MR arthrography with gadolinium-based contrast agent can aid instability assessment

DIFFERENTIAL DIAGNOSIS

Normal Irregular Distal Femoral Epiphyseal Ossification

- Asymptomatic younger patients
- Most commonly in posterior condyle
- Often has "puzzle piece" fragment-parent bone interface
- Deep rather than flat

- No adjacent bone marrow edema
- Overlying cartilage is intact, including thin, T2-hyperintense secondary physis

Osteonecrosis

- Serpentine sclerotic foci with characteristic double-line appearance on T2 MR
  - May lead to subchondral collapse
- History of steroid therapy, lupus, sickle cell disease, or other predisposing condition

Osteochondral Impaction Fracture

- Single traumatic event
- Different location than typical OCD lesion

Stress or Insufficiency Fracture

- Sclerotic band, often horizontal to bone long axis
- Not usually subchondral

PATHOLOGY

General Features

- Etiology
  - Favored mechanism: Repetitive microtrauma
    - Acute trauma, ischemia, &/or genetic predisposition may be contributory
  - JOCD may represent symptomatic growth disturbance of epiphyseal secondary physis
  - Adult OCD may be incompletely healed JOCD lesion

Staging, Grading, & Classification

- Arthroscopic grading: Multiple systems
  - Research in Osteochondritis of the Knee (ROCK)
    - Immobile lesions
      - Cue ball: No arthroscopic abnormality
      - Shadow: Cartilage intact but subtly demarcated
      - Wrinkle: Cartilage fissure, buckle &/or wrinkle
    - Mobile lesions
      - Locked door: Cartilage fissure, cannot hinge open
      - Trap door: Cartilage fissure, can hinge open
      - Crater: Exposed subchondral bone defect

Microscopic Features

- No substantial necrosis or inflammation in JOCD lesions
- Abundant fibrovascular tissue at osteochondral interface & in subchondral bone

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain aggravated by activity
  - Mechanical symptoms (clicking, catching, grinding, locking) raise concern for unstable OCD
- Other signs/symptoms
  - Can be asymptomatic

Demographics

- Age
  - Most present at 13-21 years of age
  - Mean age of JOCD is 11.3 years by one study
  - Symptoms often last > 1 year prior to diagnosis
- Sex
  - M:F = 2-4:1 (but ↑ in females with ↑ sports participation)
- Epidemiology
  - Incidence of JOCD = 2.3/100,000 to 31.6/100,000
  - Often seen in athletes

Natural History & Prognosis

- ↑ rate of spontaneous healing in JOCD vs. adult OCD
  - 50-67% of JOCD lesions heal in 6-18 months with conservative therapy only
    - Spontaneous healing: Stable > > unstable
- American Academy of Orthopaedic Surgeons (AAOS) practice guidelines state, "natural history of OCD of the knee remains unclear"

Treatment

- AAOS 2010 review of OCD evidence was largely inconclusive regarding diagnosis + treatment recommendations
- Stable lesions are generally treated with rest, casting, NSAIDs over 3-12 months
  - Failure to heal on conservative therapy → surgery
    - Drilling (transarticular or retroarticular) to create vascular channels
- Stable but symptomatic OCDs that fail nonoperative management may be treated with arthroscopic drilling
- Unstable lesions → surgery
  - Salvageable: Internal fixation of fragment
    - Metal screws; bioabsorbable pins, screws, or nails
    - ± bone autograft or allograft
  - Unsalvageable: Cartilage repair/restoration
    - Chondroplasty
    - Microfracture
    - Osteochondral autograft/allograft transfer system
    - Autologous chondrocyte implantation

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Careful evaluation for signs of instability ± loose body

(Left) *Sagittal T2 FS MR in a 15-year-old with an unstable JOCD lesion shows a large, fluid-filled gap in the medial femoral condyle with multiple subjacent cysts in the parent bone. A large, displaced osteochondral fragment is noted.* **(Right)** *Sagittal T2 FS MR in the same patient status post autologous bone graft to the donor site shows interval healing with early incorporation of the bone graft. The overlying articular cartilage is smooth & continuous with the adjacent native articular cartilage.*

(Left) *AP ankle radiograph in a 16-year-old boy shows a crescentic lucent lesion in the medial talar dome with a bony fragment protruding into the joint space.* **(Right)** *Coronal T2 FS MR in the same patient confirms the OCD lesion of the medial talar dome with adjacent cartilage fissuring. Cystic change & surrounding edema are noted in the parent bone. While no fluid is seen undercutting the fragment, the constellation of radiographic & MR findings remains suspicious for an unstable lesion.*

(Left) *AP elbow radiograph in a 13-year-old boy with pain & locking shows an irregular lucent defect with sclerotic margin in the humeral capitellum, typical of OCD. An ossific body projects over the olecranon fossa.* **(Right)** *Sagittal T2 FS MR in the same patient confirms an intraarticular osteochondral body in the olecranon fossa with high signal within the body. An associated elbow joint effusion & synovitis are also present.*

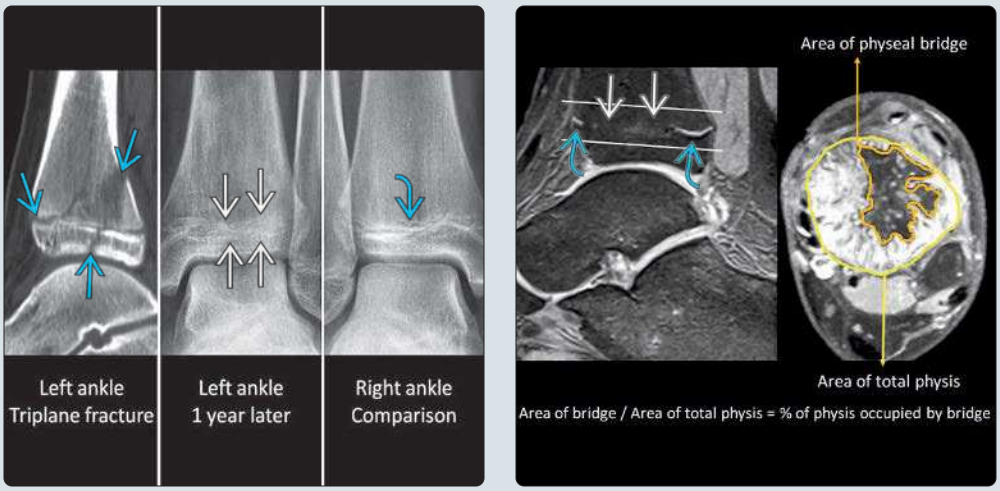
KEY FACTS

TERMINOLOGY

- Nonunion: Lack of progression to union > 6 months after injury with corresponding clinical signs & symptoms
- Malunion: Nonanatomic alignment of fracture fragments
- Premature physeal closure: Osseous physeal bridge (bar) formation across cartilaginous physis

IMAGING

- Nonunion: Sclerosis at fragment margins, absence of bridging trabecula, persistence of fracture line
- Premature physeal closure
  - Progressive focal narrowing or interruption of lucent physis ± discrete bone bridge/bar
  - Abnormal (obliquely oriented or asymmetric) growth arrest/growth recovery lines
    - Angulated toward & tethered by bridge
  - Peripheral bridge → angular deformity
  - Central bridge → longitudinal growth restriction
  - 3D SPGR or T2* GRE FS MR can generate physeal map
    - Assess percent of physis occupied by bridge
- Posttraumatic lipid inclusion cyst
  - Radiographs: Round or ovoid, lucent, eccentric, subperiosteal lesion, typically in distal radius or tibia
  - CT/MR: Fat characteristics
- Osteonecrosis: T1 C+ FS MR can help determine viability of proximal fragment in scaphoid nonunions



CLINICAL ISSUES

- Malunion is common in pediatric fractures (but there is high corrective potential due to remodeling in growing skeleton)
- Physeal bridges begin 1-2 months following injury but may not manifest until years later during adolescent growth

DIAGNOSTIC CHECKLIST

- Imaging findings of nonunion & malunion must be clinically correlated
  - From medicolegal standpoint, it may be best to be descriptive & discuss with orthopedist rather than use these terms in report

(Left) *Sagittal bone CT in a 13-year-old boy shows a triplane fracture. Follow-up frontal radiographs show poor definition of the central physis due to a physeal bridge of the distal left tibia. Note the normal open distal right tibial physis.* **(Right)** *Sagittal 3D SPGR FS MR (left) in the same patient shows a dark osseous bridge interrupting the bright cartilaginous physis. The axial MIP of the physis (right) allows calculation of the areas of the osseous bridge (outlined in orange) & total physis (outlined in yellow).*

(Left) *AP radiograph in an 11-year-old girl with a deformity of the elbow (following a previously treated distal humeral supracondylar fracture) shows malunion with varus configuration to the distal humerus (cubitus varus).* **(Right)** *Coronal T1 FS C+ MR in a 14-year-old girl with a scaphoid fracture shows a diffuse lack of enhancement within the proximal pole of the scaphoid, which suggests nonviability.*

TERMINOLOGY

Complications Encountered

- Nonunion: Lack of bony union > 6 months after injury with corresponding clinical signs/symptoms
- Delayed union: Lack of union by 6 months but with imaging &/or clinical signs of healing; eventually heals
- Malunion: Healing with nonanatomic alignment of fracture fragments
- Premature physeal closure/growth arrest: Osseous physeal bridge (bar) forms across otherwise unfused cartilaginous physis
- Osteonecrosis: Disruption of blood supply to fracture fragment with resulting infarction
- Chondrolysis: Progressive destruction of articular cartilage; may lead to premature degenerative arthritis
- Posttraumatic lipid inclusion cyst: Subperiosteal focus of marrow fat entrapped in remodeled cortex (due to transposition of fatty marrow during prior fracture)
- Others: Infection, degenerative changes, refracture

IMAGING

General Features

- Nonunion
  - Radiographic findings
    - Absence of bridging trabecula with persistence of fracture lucency
    - Sclerosis of fragment margins along fracture
    - Lack of healing/callus progression on serial radiographs
      - Callus may not be seen normally with rigid fixation
  - Scaphoid nonunion
    - Humpback deformity
      - ↑ angulation between proximal & distal poles with settling/impaction of fragments & eventual dorsal bone formation
    - Carpal instability
    - Late complications
      - Scaphoid nonunion advanced collapse: Late development of arthritis
- Premature physeal closure
  - Peripheral bridge → angular deformity
    - Medial proximal femur → coxa vara
    - Anterior proximal tibia → genu recurvatum
    - Medial distal tibia → ankle varus
  - Central bridge → longitudinal growth restriction
    - Leg length discrepancy
    - Distal radial bridge → ulnar positive variance → ulnar abutment/impaction
  - Radiographs
    - May show bone bridge across physis; contralateral radiographs are helpful for comparison
      - Focal poor definition/frank interruption of lucent physis
    - Angled growth arrest/growth recovery line
      - Obliquely oriented or tethered growth recovery line extends to bony bridge at physis instead of paralleling physis
      - Asymmetry of transverse growth recovery line indicates focally diminished growth
    - Altered relative length of bone (as compared to adjacent long bone)
    - ↑ angulation of epiphysis
  - CT: Can depict bony physeal bridges but MR is preferred due to ability to evaluate residual cartilaginous physis
  - MR
    - Spin-echo T1 & PD/T2 FS sequences can demonstrate larger physeal bridges
    - 3D GRE FS sequences (with multiplanar reformatted images) detect even small bridges & can generate axial MIP physeal map
      - Cartilaginous physis is bright; bone bridge is dark
      - Area of bridge/area of total physis = % of physis occupied by bridge (used to determine therapy)
- Posttraumatic lipid inclusion cyst
  - Radiographs: Small, eccentric, round or ovoid lucent subperiosteal lesion, typically in distal radius or tibia
  - CT/MR: Fat characteristics
- Osteonecrosis
  - Scaphoid
    - Osteonecrosis in ~ 30% of midbody fractures & up to 100% of proximal pole fractures
    - Relative sclerosis of proximal pole on radiographs
    - STIR/T2 FS MR is not helpful in determining viability (i.e., lack of necrosis) of proximal pole
    - T1 MR may be of value with regard to assessing viability; literature is conflicting
    - T1 C+ FS MR is useful to assess viability of proximal fragment
      - Most studies report lack of contrast enhancement in proximal pole as being specific for osteonecrosis
      - However, enhancement of proximal pole can be seen in cases of osteonecrosis
    - T1 C+ FS MR is also helpful in guiding treatment & predicting surgical outcome
      - Higher rates of union when vascularized (vs. nonvascular) bone grafts are used when there is ↓ T1 signal or lack of enhancement on pretreatment MR
    - Dual-energy CECT: Early study shows promise for evaluating viability of proximal pole
  - Distal humerus: Fishtail deformity
    - Osteonecrosis of distal humerus predominantly involving radial aspect of trochlea
    - Reported after fractures of various types (e.g., supracondylar, lateral condylar)

CLINICAL ISSUES

Nonunion

- Rare complication in pediatrics
- Risk factors: Open fractures, infection, severe soft tissue loss, & insufficient fixation
- Types of nonunion
  - Reactive/hypertrophic: Callus formation without bridging
  - Nonreactive/atrophic: No callus at nonunion site
  - Infected: Due to acute or chronic osteomyelitis
- Most common in children: Diaphyseal long bone fractures & elbow (especially displaced lateral condyle) fractures
- Scaphoid nonunions are rare in children

- Nonunion typically results from delayed or missed diagnosis
- Treatment options: Debridement of nonunion site, bone grafting, electrical stimulation, & rigid internal fixation

Malunion

- Common in children but with high corrective potential due to ↑ chance for remodeling in growing skeleton
- Recommendations regarding maximum acceptable displacement at fracture sites in children are controversial & depend on age, location, & type of displacement
- Subsequent functional limitation & cosmetic deformity depend on site of fracture
  - Forearm shaft & distal radial fractures have great capacity for remodeling
  - Supracondylar fractures have less potential for remodeling
- Common sites of malunion
  - Supracondylar fracture
    - Cubitus varus deformity with medial angulation of distal fragment, not growth disturbance
    - Baumann (humerocapitellar) angle is used to predict final carrying angle following reduction of supracondylar fractures to attempt to avoid cubitus varus deformities
      - Angle formed by line along long axis of humeral shaft & line along physis of capitellum
      - Normal range: 64-81° (comparison to contralateral side is helpful)
  - Forearm fractures
    - May cause limited pronation/supination, refracture, cosmetic deformity, or distal radioulnar joint pain
    - Acceptable angulation is controversial
      - Some authors: > 10° in children > 8 years old = malunion
      - Other definitions: > 20° in children > 9 years old = malunion
  - Distal radius fracture
    - Usually remodels satisfactorily if < 11-12 years old
    - Malunion may result in functional limitation, pain, or cosmetic deformity
    - Features appear similar to adults prior to remodeling
      - ↓ radial inclination; abnormal dorsal tilt, radial shortening, articular incongruity
    - Adolescents & young adults can still develop significant distal radius malunion
      - One source suggests malunion if dorsal tilt ≥ 5°, radial inclination ≤ 10°, loss of radial height ≥ 5 mm
      - Normal values: Volar tilt (11°, range: 2-20°), radial inclination (21-25°), radial length (10-13 mm)
  - Femur fracture (definitions vary)
    - Some contend > 10° in coronal plane & > 15° in sagittal plane; others suggest > 5° & 10°, respectively
- Treatment may consist of osteotomy & epiphysiodesis

Premature Physeal Closure

- Secondary to fracture involving cartilaginous growth plate
- 15-30% of injuries to long bones in children involve physis
  - ~ 10% of physeal injuries are associated with significant growth disturbance
- Bridges start to form 1-2 months following injury but may not manifest until years later
  - Clinical follow-up to skeletal maturity is recommended in high-risk fractures due to possibility of delayed presentation during adolescent growth spurt
  - If caught early, only resection of bar may be necessary vs. correction of angular deformity
- Treatment
  - Indicated when deformity is present/developing & patient has 2 years or ≥ 2 cm of growth remaining
  - Bridge resection is considered if bridge occupies < 50% of physis
    - If resected, various interposition materials are placed to ↓ recurrence
  - Other treatments may include: Corrective osteotomy, completion epiphysiodesis, contralateral epiphysiodesis, bone lengthening

Posttraumatic Lipid Inclusion Cysts

- Seen at sites of prior fracture; thought to be due to extension of intramedullary fat through disrupted cortex with intact periosteum
- May mimic more aggressive process
- Distal radius is most common, followed by distal tibia

Degenerative Change

- Intraarticular fractures are at risk for posttraumatic arthrosis
- Fixation is typically necessary to reestablish articular congruence with articular surface disruption > 2 mm

Osteonecrosis

- Proximal pole of scaphoid: Sclerosis & humpback deformity
- Distal humerus: Fishtail deformity

DIAGNOSTIC CHECKLIST

Reporting Tips

- Describe residual deformity; however, radiographic appearance may not correlate with clinical outcome
  - Malunion may not be clinically relevant (e.g., patient with worrisome radiograph may have no functional limitation &/or may completely remodel over time)
- Lack of fracture healing may be suggestive of nonunion union if > 6 months but must be correlated with clinical findings
  - From medicolegal standpoint, best to describe & discuss with orthopedist, avoiding term "nonunion" in report
- Note changes in growth plate in setting of prior physeal fracture
  - Indicators of bridge: Focal poor definition of physis, new angulation, or tethered growth recovery line

(Left) *Lateral wrist radiograph (obtained after cast removal) in a 6-year-old girl recently diagnosed with a Salter-Harris fracture shows an aggressive lytic process at the distal radius with cortical bone destruction & periosteal reaction. These findings should raise concern for infection.* **(Right)** *Sagittal T1 C+ FS MR in the same patient shows a peripherally enhancing subperiosteal fluid collection. Pus was found at surgery, & the patient was diagnosed with Staphylococcus aureus osteomyelitis.*

(Left) *Frontal radiograph of the distal forearm in a 4-year-old boy at presentation (left) shows a comminuted distal ulnar fracture & a distal radial metadiaphyseal fracture. A 6-year follow-up radiograph (right) shows marked negative ulnar variance & suggestion of a distal ulnar physeal bridge.* **(Right)** *Coronal 3D GRE MR in the same child shows osseous bridging across the lateral aspect of the distal ulnar physis. The distal radial & medial distal ulnar physes remain open.*

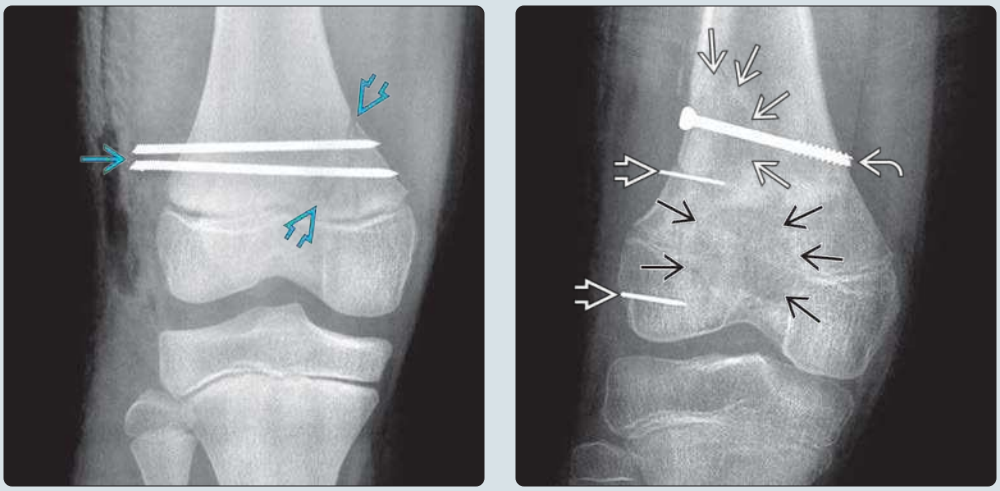
(Left) *Oblique radiograph of the distal forearm in a girl with a distal radial fracture 2 years prior shows a small, ovoid lucent lesion. This is consistent with a lipid inclusion cyst.* **(Right)** *Axial T1 MR in the same patient shows an eccentrically located ovoid lesion in the volar distal radial cortex with ↑ T1 signal intensity. This lesion followed the signal of fat on all sequences, compatible with a small lipid inclusion "cyst" related to the prior fracture.*

KEY FACTS

TERMINOLOGY

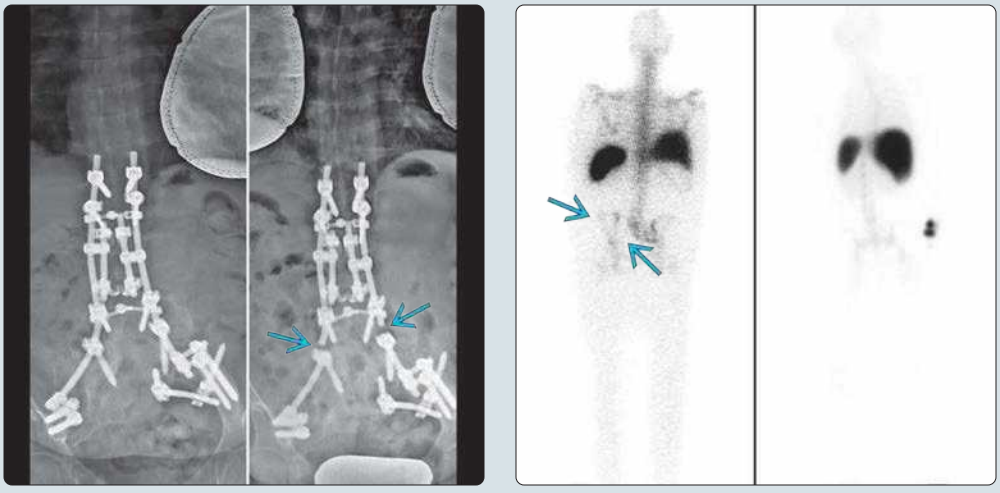
- Orthopedic hardware: Any of innumerable devices used for fracture fixation, realignment, ligament repair/reconstruction, arthroplasty, & other procedures

IMAGING



- External vs. internal fixation
- Goal of rigid fixation: Reduce motion
  - Look for endosteal rather than periosteal callus to indicate appropriate healing
    - Periosteal callus indicates motion at fracture site
- Radiographs remain primary evaluation of hardware
  - Malpositioning/migration or fracture of hardware
  - Fracture of bone at/adjacent to fixation site
  - Loosening or infection of hardware
  - Malunion, delayed union, or nonunion of fracture
- CT is more sensitive; used in select cases of clinical/imaging concern
- Comparing nuclear In-111 leukocyte & Tc-99m sulfur colloid exams is most specific evaluation of infected hardware
- MR for evaluation of ligament repair/reconstruction, soft tissue abscesses, & adverse local tissue reaction

CLINICAL ISSUES



- Goal of fracture treatment is to improve alignment & stabilize fracture to aid in healing & return function
- Numerous indications for orthopedic devices in children other than fracture fixation
  - Scoliosis, congenital deformity, growth disturbance, sports-related injuries

DIAGNOSTIC CHECKLIST

- Understanding purpose/function of orthopedic devices aids in evaluation of
  - Appropriate positioning of hardware
  - Hardware complications
  - Expected healing

(Left) *AP radiograph of a 12-year-old boy shows 2 fully threaded Steinmann pins transfixing a Salter-Harris II fracture.* **(Right)** *AP radiograph shows the same patient ~ 8 months later following a physeal bar resection. The bone block from the distal femoral window osteotomy is fixed with a single partially threaded cannulated screw. Steinman pins were placed to evaluate for subsequent growth. Cranioplasty material was placed across the physis to prevent new bar formation.*

(Left) *Initial (L) & follow-up (R) frontal radiographs in a boy with neurofibromatosis type 1 & posterior spinal fusion for kyphoscoliosis show interval fractures of the hardware. The patient had a fever at this time.* **(Right)** *Posterior images from In-111 leukocyte (L) & Tc-99m sulfur colloid (R) scans were obtained in the same patient. There is ↑ uptake in the left sacrum & iliac bones on the leukocyte scan with no corresponding ↑ uptake on the sulfur colloid scan. This discordance is consistent with infection.*

IMAGING

Radiographic Findings

- Radiographs: Primary modality for hardware assessment
- Evaluate for
  - Malpositioning/migration of hardware
  - Fracture of hardware components
  - Fracture of bone at or adjacent to fixation site
  - Loosening: Progressive lucency around hardware
  - Infection: Perihardware lucency, extensive periosteal reaction, erosions, subcutaneous emphysema, or ↑ edema
  - Malunion, delayed union, or nonunion of fracture
  - Osteonecrosis: Interruption of periosteal blood supply
  - Heterotopic bone formation

Fluoroscopic Findings

- Intraoperatively guides/confirms hardware placement

CT Findings

- More sensitive evaluation for hardware complications
- Modification of CT protocols to minimize artifacts
  - ↓ pitch setting, ↑ mAs, ↑ kVp (↑ radiation dose)
  - Dual-energy CT (no additional radiation)
  - Soft-tissue image reconstruction filters
- Must adjust window width/level for metal evaluation, not just bone

MR Findings

- MR is useful in certain postoperative situations
  - Ligament repair/reconstruction
  - Assessment of soft tissue abscesses
  - Adverse local tissue reaction (ALTR)
    - Various reactions to arthroplasty-related products (e.g., hypersensitivity reaction, metallosis)
    - Can lead to: Osteolysis, synovitis, soft tissue pseudotumors, soft tissue destruction
    - Most commonly described after hip arthroplasty
    - Recent studies have described metallosis with growing spinal rods in children
- Limited by metallic artifact; techniques to ↓ artifacts include

Ultrasonographic Findings

- Can be used to evaluate for fluid collections/abscesses
- May be helpful in evaluating nonmetallic hardware

Nuclear Medicine Findings

- Bone scan
  - Normal bone scan can exclude hardware infection
  - ↑ radiotracer activity may be due to infection or loosening
- Labeled leukocyte scintigraphy
  - ↑ radiotracer activity on leukocyte exam
    - Osteomyelitis
    - Marrow adjacent to fracture or hardware
  - Compare leukocyte & Tc-99m sulfur colloid exams
    - ↑ activity on labeled leukocyte exam but normal sulfur colloid exam = infection
    - Any other pattern is negative for infection

PATHOLOGY

General Features

- Fractures heal by primary or secondary mechanisms
  - Primary (direct) healing
    - Direct bone healing without callus formation
    - Occurs with rigid fracture fixation
  - Secondary (indirect) healing
    - Healing via callus formation
    - Occurs with flexible fracture fixation

CLINICAL ISSUES

Treatment

- Conservative treatment
  - Closed reduction with goal of restoring bone alignment
  - Stabilization via traction or external splinting
- Fracture fixation
  - External or internal fixation
  - Flexible vs. rigid fixation
    - Flexible: Allows interfragmentary movement under functional load
    - Rigid: Utilizes compression → ↑ stability; ↓ motion → primary healing without callus
      - Important at intraarticular sites where incongruity → osteoarthritis
- External or internal fixation is also used for nontraumatic purposes (i.e., leg lengthening, corrective osteotomy, etc.)
- External fixation advantages
  - Surgeon can control flexibility of fixation
  - ↓ injury to soft tissues, vasculature, & periosteum
- External fixation indications
  - Avoidance of physes in skeletally immature patients
  - Osteomyelitis (internal hardware must be avoided)
  - Substantial soft tissue injury requiring vascular procedures
  - Limb lengthening & other corrective osteotomies
- External fixation complications
  - Pin tract infection, breakage, or loosening
  - Delayed union, nonunion, malunion
- Internal fixation advantages
  - Potential for rapid return of function & rehabilitation
- Internal fixation indications & complications (categorized by different types of hardware)
  - Pin (K-wires & Steinman pins) indications
    - Temporary fixation of fragments during reduction
    - Attachment of skeletal traction devices
    - Guide accurate placement of larger cannulated screws
    - Occasionally used for definitive fracture treatment
    - Also used in setting of external fixation
  - Pin complications
    - Migration when used for definitive fracture treatment
  - Wire indications
    - Reattach osteotomized bone fragments
    - Tension banding (in combination with pins or screws, e.g., patella, olecranon fractures)
      - Converts tensile forces from adjacent tendon insertions into compressive forces across fracture
      - Aids with stability & fracture healing
    - Suture bone & soft tissue

- Cerclage wires (used with intramedullary fixation to stabilize long bone fragments)
- Wire complications
  - Breakage (insignificant if fragments maintain position)
  - Interruption of periosteal blood supply with subsequent osteonecrosis or fracture nonunion
- Screws: Types & indications
  - 2 basic types: Cortical & cancellous
    - Distance between threads = pitch
    - Screw diameter with threads = thread diameter
    - Core = diameter of screw without threads
  - Cortical screws
    - Designed for use in diaphysis
    - Typically fully threaded (threads along entire length) with smaller thread diameter & pitch
  - Cancellous screws
    - Can cross long segments of cancellous bone
    - Typically has deeper threads, larger thread diameter, greater pitch, partially threaded
  - Interfragmentary screw
    - Screw that crosses fracture line
    - Purpose: Act as lag screw providing compression of fragments → ↑ stability & healing
  - Cannulated screw
    - Possesses hollow shank, so can be placed over guide pin for ↑ accuracy
    - May be inserted percutaneously under fluoroscopy
  - Suture anchor
    - Anchor can be fixed into bone by screwing or lodging (e.g., press fit)
    - Used for capsular, ligamentous, or tendinous repair
  - Washer
    - Prevents screw head from sinking into bone
    - Enhances compressive area of screw in regions of thin cortex
    - Prevent fractures under screw
- Screw complications
  - Breakage, loosening, change in position
- Plates
  - Techniques for plating
    - Compression plating: Eccentric screw placement within sloped holes drives fragments into compression
    - Neutralization plating: Holds fracture fragments in place without compression; useful for severely comminuted fractures (bridging plate) & fractures with bone loss
    - Tension band plating: Placed along tension side of fracture; with loading, converts tensile to compressive force
    - Buttress plating: Often used in association with metaphyseal/epiphyseal shear or split fractures; prevents shear forces across fracture from displacing fragments
  - Dynamic compression plate: Can be used in compression, neutralization, tension band, or buttress
  - Additional plates
    - Tubular plate, reconstruction plate (malleable, used for pelvic fractures), less invasive stabilization system (LISS) plate, T-plate, blade plate, other special anatomically shaped plates
  - Locking plates may contain locking screws that contain threads at screw heads, allowing construct to better act as unit
- Plate complications
  - Plates have large contact area, may disrupt periosteal capillaries → compromise cortical perfusion
    - Low contact plates are available, reduce area of contact between plate & bone
  - Underlying bone resorption & old screw holes after plate removal may lead to fracture
  - Malposition, i.e., plate or screws violating articular surface or impinging upon joint motion
- Intramedullary nails or rods
  - Standard treatment for diaphyseal fractures of femur & tibia; may also be used in humerus
  - Rods are locked "statically" (proximal & distal interlocking screws) or "dynamically" (fixed at 1 end)
    - Dynamic locking ↑ compression across fracture site
    - Interlocking screws ↑ fixation stability & prevent rotation
  - Skeletally immature patients receive flexible intramedullary nails inserted through metaphysis
    - Typically 2 rods are placed through multiple insertion sites diverging at metaphyseal ends
    - Require additional external stabilization with cast
- Intramedullary nail or rod complications
  - Hardware fracture, loosening, or infection
  - Violation of joint by rods or screws
  - Intramedullary reaming is associated with ↑ infection rates (due to damage to internal cortical vasculature) & pulmonary fat embolism

- Antibiotic beads
  - Used for infected fractures
- Autogenous bone graft, allograft, or bone graft substitute
  - Treatment of bone defects

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- On initial preoperative studies: Carefully evaluate fractured bone for any sign of underlying aggressive lesion
  - Placement of hardware may spread tumor cells
- On fluoroscopic intraoperative images: Carefully assess for hardware malposition or iatrogenic fracture
- On follow-up postoperative studies: Carefully evaluate full complement of hardware (& adjacent bone) for interval change compared with prior studies

A fractured portion of the screw has migrated into the posterior aspect of the joint ⇨.*

Soft Tissue Foreign Bodies, Acute and Chronic

KEY FACTS

TERMINOLOGY

- Penetrating injury → soft tissue foreign body (FB)
- Chronic FB → granulomatous reaction → soft tissue mass

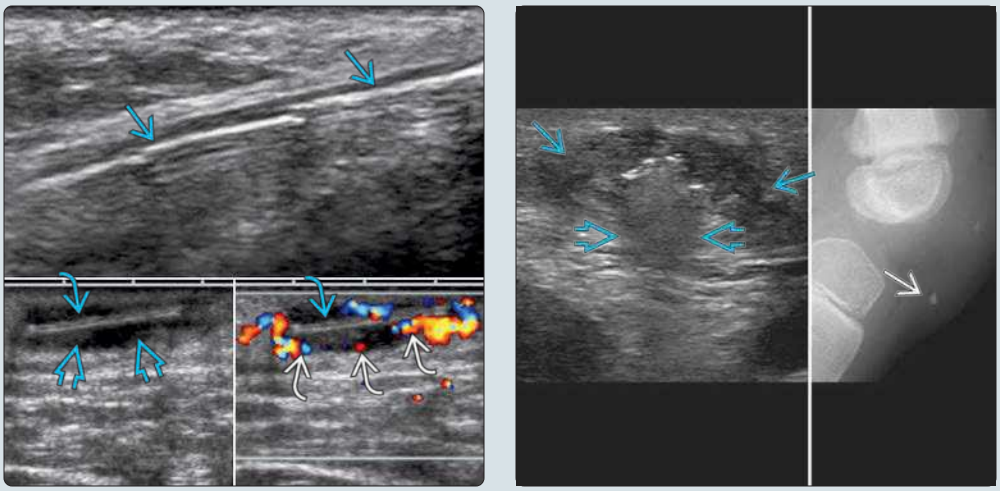
IMAGING

- Most FBs are not radiopaque (e.g., wood splinters)
- Some FBs are radiopaque (e.g., metal, glass, bone)
- Radiographs assess radiopaque FBs & osseous changes
- US: Excellent detection of superficial FBs
  - Typically echogenic
  - ± posterior shadowing, depending on composition
  - Hypoechoic rim of edema/granulomatous reaction
- MR: FB is typically of low signal on all sequences
  - Nonanatomic, geographic shape (e.g., linear, triangular)
  - FB may be small or very subtle
  - GRE may show blooming if FB is metallic or Ca^{2+}
  - Adjacent edema or granulomatous reaction
  - Detects associated cellulitis, abscess, osteomyelitis

TOP DIFFERENTIAL DIAGNOSES

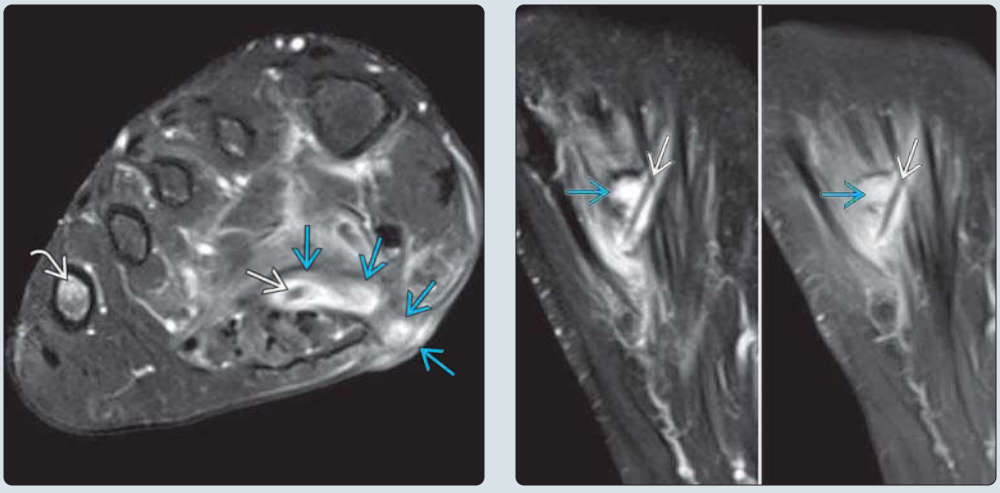
- Posttraumatic fat necrosis
- Soft tissue sarcoma
- Benign soft tissue tumors
- Venous malformation

PATHOLOGY



- Chronic FB → granulomatous reaction

CLINICAL ISSUES



- Acute: Sensation of FB under skin after injury
- Chronic: Firm, painless soft tissue mass
  - May occur long after injury that introduced FB
  - Often no specific trauma is recalled
- Treatment
  - Surgical or US-guided removal

DIAGNOSTIC CHECKLIST

- If radiolucent superficial FB is suspected → US

(Left) *US (top) of the left buttock in a 5-year-old who fell on a plastic toy shows a linear subcutaneous echogenic foreign body (FB). Removal was performed without imaging guidance. Repeat US 6 weeks later (bottom) shows a retained portion of the FB with adjacent hypoechoic but hypervascular granulation tissue.* **(Right)** *US in a 5-year-old patient with an anterior knee lump shows a heterogeneous mass with posterior shadowing. Lateral radiograph confirms a glass FB at this site from a remote injury.*

(Left) *Axial T2 FS MR in a 9-year-old girl who removed a toothpick from her foot 5 months prior shows a linear tract of ↑ signal extending from the plantar surface to a central focus of low signal, concerning for a retained FB. There is adjacent soft tissue edema & distant marrow edema in the 5th metatarsal from infection vs. stress changes.* **(Right)** *Coronal T2 FS (left) & T1 C+ FS (right) MR images in the same patient show the linear low-signal retained toothpick surrounded by high-signal granulation tissue.*

TERMINOLOGY

Abbreviations

- Foreign body (FB)

Synonyms

- Chronic FB: FB granuloma, giant cell granulomatous reaction, fibrohistiocytic reaction

Definitions

- Penetrating injury → soft tissue FB deposition
  - Injury & retention of FB may not be recognized/recalled
- Chronic FB may lead to mass of granulomatous reaction

IMAGING

General Features

- Best diagnostic clue
  - Radiopaque FB identified on radiographs
  - Radiolucent FB may be identified on US, MR, or CT
- Location
  - Often confined to subcutaneous fat
  - Typically in areas prone to injury
    - Walking barefoot: Plantar aspect of feet
    - Areas commonly injured from fall: Anterior knee/shin, hands, elbows, buttocks

Radiographic Findings

- Radiodensity depends upon FB composition
- Conspicuity depends on size & degree of difference in radiodensity from surrounding soft tissues
- Most FBs are not radiopaque (e.g., wood splinters, thorns, plastic)
  - May only show nonspecific soft tissue fullness
- Some FBs are radiopaque (e.g., metal, glass, bone)
- ± findings of osteomyelitis in subacute/chronic setting

MR Findings

- FB: Typically low signal intensity on all sequences
  - Nonanatomic, geographic shape (e.g., linear or square)
  - Low signal intensity may be small or very subtle
  - GRE sequence can be helpful depending on composition
    - Blooming artifact if metal or bone
- Acute FB: Poorly defined edema in adjacent soft tissues
  - Reticular ↑ signal on T2 FS/STIR, ↓ signal on T1
  - Reticular enhancement on T1 C+ FS
- Chronic FB: May lead to granulomatous reaction
  - Mass-like ↑ signal on T2 FS/STIR, ↓ signal on T1
  - Diffuse enhancement on T1 C+ FS
- Associated findings
  - Linear tract of fluid signal extending from skin
  - Soft tissue abscess: Localized fluid collection with peripheral enhancement (vs. diffuse enhancement of FB granuloma)
  - Marrow edema/hyperenhancement of adjacent bone may be seen with osteomyelitis or stress changes (due to altered weight bearing in setting of pain)

Ultrasonographic Findings

- Excellent for identifying superficial acute & chronic FBs
- FBs are typically echogenic; often punctate or linear
- Variable posterior shadowing depending on composition
- Peripheral ↓ echogenicity from edema (acute) or granulomatous reaction (chronic)
- Exam may be confusing if US is only performed after attempted FB removal

Imaging Recommendations

- Best imaging tool
  - Radiography for radiopaque FBs (e.g., glass, metal, bone)
    - Also shows bone involvement by penetrating trauma
  - US for suspected superficial radiolucent FB

DIFFERENTIAL DIAGNOSIS

Posttraumatic Fat Necrosis

- Injury of subcutaneous fat with associated hematoma
- No central FB is seen at imaging

Soft Tissue Sarcomas

- More common in areas not prone to FBs (i.e., proximal to midextremities)
- No central FB is seen at imaging
- Typically well circumscribed without surrounding edema

Benign Soft Tissue Tumors

- Variety of nonmalignant soft tissue tumors occur in children
  - e.g., fibrous lesions (fibromatosis, nodular fasciitis), subcutaneous granuloma annulare
- No central FB is seen at imaging
- Can be well circumscribed or poorly defined & infiltrative

Venous Malformations

- Compressible serpentine tangle or mass of abnormal veins
- ↑ signal on T2 FS + gradual contrast enhancement
- ± phleboliths, fluid-fluid levels

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute: Sensation of FB under skin after injury
  - Chronic: Firm, painless soft tissue mass
    - May come to attention long after injury
    - Often no specific trauma is recalled
- Other signs/symptoms
  - Erythema, swelling, &/or induration of overlying skin
  - Sinus tract to skin surface may develop

Treatment

- Surgical removal: US or fluoroscopy can localize FB
- Alternatively, US-guided removal with needle or forceps
  - Hydrodissection technique may assist procedure

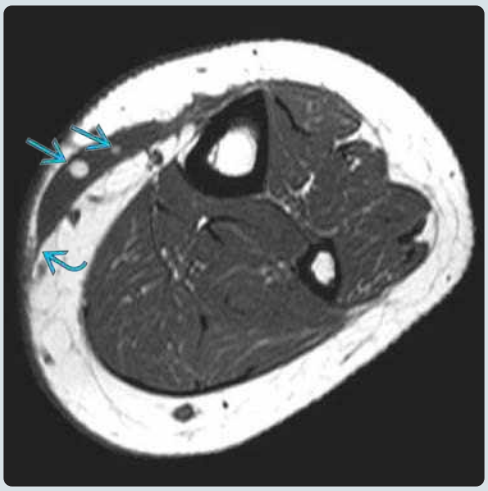
Morel-Lavallée Lesion

KEY FACTS

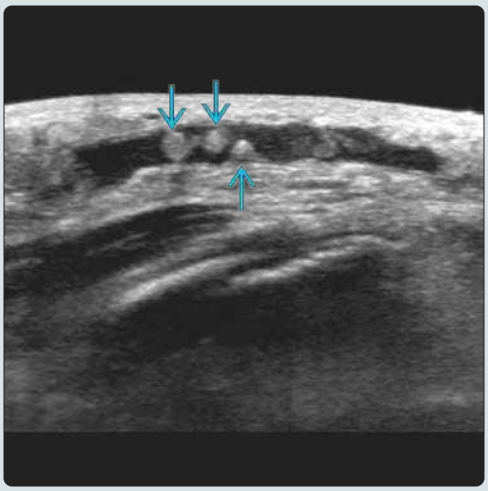
TERMINOLOGY

- Closed degloving injury of subcutaneous fat at interface with fascia, often overlying bony protuberance
- Results in chronic fluid collection (blood, lymph, fat)

IMAGING

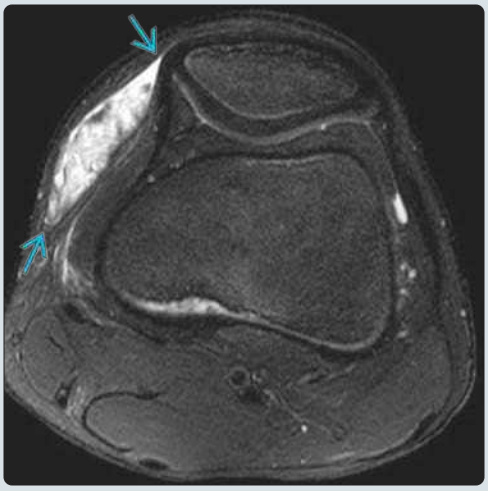


- Classic Morel-Lavallée lesion occurs at hip/proximal thigh overlying greater trochanter
  - Other sites: Abdominal wall, lumbar spine, buttock, sacrum, thigh, knee, lower leg, scapula, scalp
- Mean size: 8 cm; range: 3-17 cm
- Appearance depends on timing of imaging & complications
  - Acute/subacute: Elongated with irregular margins & internal heterogeneity
  - Chronic: Elongated & smooth; ↓ heterogeneity
  - Angular margins of shear plane are suggestive
- MR: Collection ultimately follows fluid signal intensity internally except for fat nodules, blood products
  - Fibrous pseudocapsule is hypointense on all sequences
  - Nodular enhancement, typically peripheral, may be seen with granulation tissue, inflammation, or infection
- Ultrasound: Ultimately hypoechoic to anechoic internally (due to ↓ complexity over time)
  - Echogenic fat nodules are characteristic

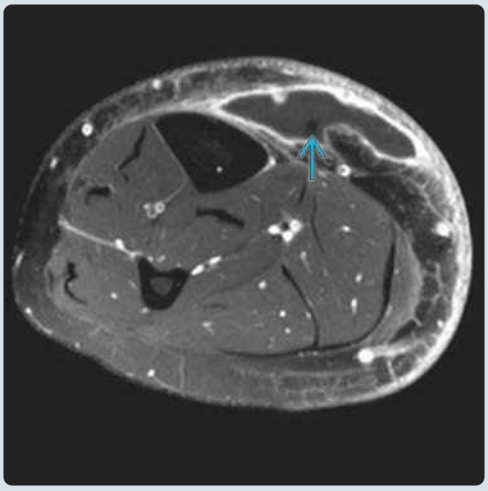


PATHOLOGY

- Blunt trauma with compressive & shear forces creates potential space with disruption of vessels & nerves



CLINICAL ISSUES



- Fluctuant mass, bruising, ↑ skin mobility, ↓ skin sensation
  - Delayed presentation after injury in 1/3 of patients
- Variable course: Resolution, persistence, enlargement
  - Risk for infection: Up to 50%
- Treatment
  - Conservative: Compression wraps, rest, physical therapy
  - Intervention: Percutaneous drainage ± steroid injection or sclerodesis; surgical debridement or excision

(Left) *Axial T1 MR of the lower leg in a 16-year-old soccer player shows an elongated collection containing nodules that followed fat signal on all sequences. A Morel-Lavallée-type injury was diagnosed. Note the acute angle at the margin of the shear plane.* **(Right)** *Transverse ultrasound over the right iliac crest in a 15-year-old patient with a recent fall from a bicycle shows an elongated, hypoechoic subcutaneous collection containing echogenic fat nodules, typical of a Morel-Lavallée lesion.*

(Left) *Axial T2 FS MR in a 12-year-old patient after an American football injury shows an elongated collection in the medial soft tissues with internal heterogeneity. The collection lies in a single plane of shear injury in the subcutaneous fat & shows margins with acute angles, typical of a Morel-Lavallée lesion.* **(Right)** *Axial T1 C+ FS MR in a 17-year-old with a history of leg hematoma 4 months prior & now presenting with new swelling & fever shows a superinfected Morel-Lavallée lesion containing a fat nodule.*

KEY FACTS

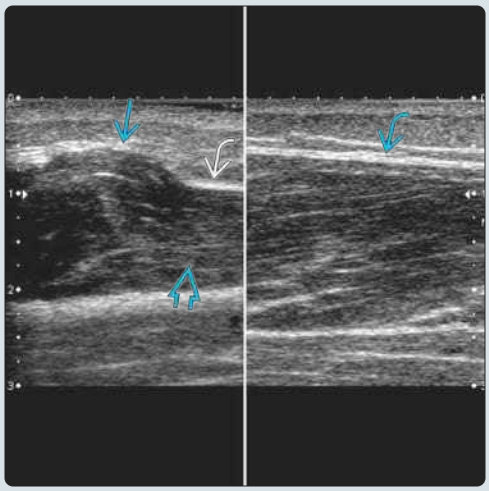
TERMINOLOGY

- Defect in fascia directly overlying muscle → focal muscle protrusion

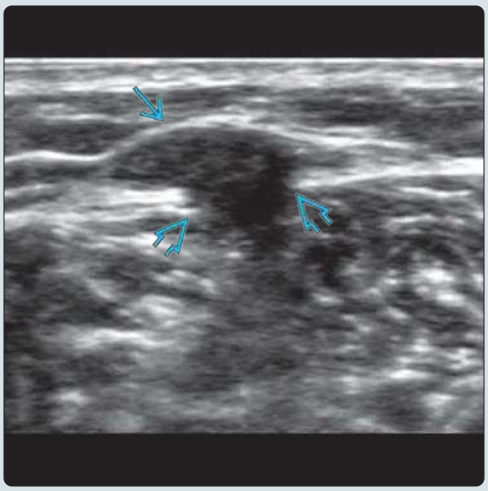
IMAGING

- Lower > upper extremity
  - Most commonly affected muscle: Anterior tibialis
- MR: Bulging nodule should be isointense with muscle
  - Subtle defect of hypointense fascia may be only finding if hernia is reduced at time of static exam
- Ultrasound: Focal interruption of thin, linear hyperechoic fascia overlying hypoechoic, striated muscle
  - Focal bulge of hypoechoic muscle through fascial defect; may create mushroom cap appearance
    - Superficial broadening of herniated muscle directly overlying fascia with narrow waist of muscle in defect
  - Hernia accentuated by contraction or vigorous activity, reduced with relaxation or ↑ transducer pressure
    - Ankle dorsiflexion ↑ anterior tibialis muscle herniation
- Protocol advice (to optimize hernia visualization)
  - Use variety of provocative maneuvers
  - Reduce pressure applied by ultrasound transducer or MR skin marker (capsule) over site of clinical concern
  - Compare with contralateral extremity

TOP DIFFERENTIAL DIAGNOSES

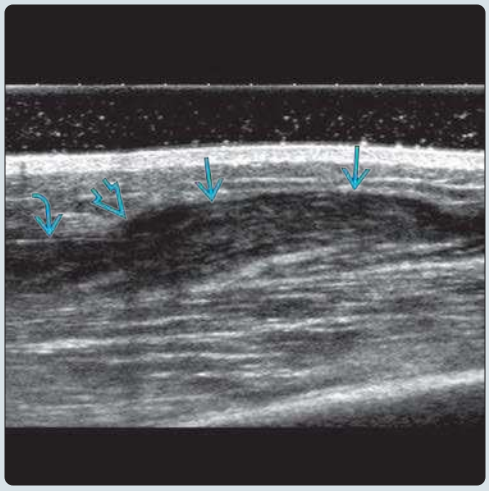


- Vascular malformation
- Soft tissue malignancy
- Lipoma

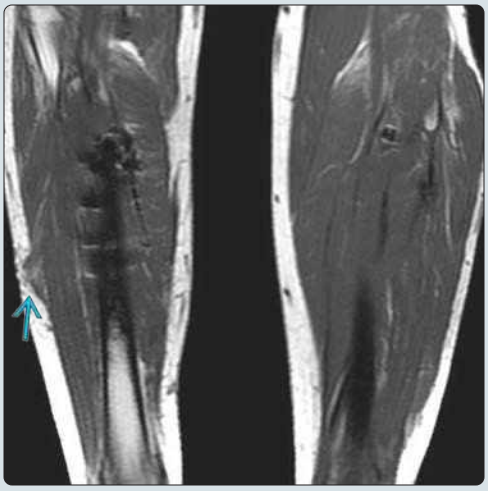


PATHOLOGY

- Congenital or constitutional fascial hernia
- Acquired or traumatic fascial tear/rupture



CLINICAL ISSUES



- Asymptomatic vs. intermittent painless bulge/nodule vs. painful nodule appearing after vigorous exertion
- Surgery (fasciotomy favored over repair) for symptomatic cases not responding to conservative measures

(Left) *Longitudinal ultrasound of the right lower leg in an 11-year-old girl with a palpable lump shows herniation of the anterior tibialis muscle through a fascial defect. Note the thin, linear, echogenic appearance of intact fascia distally on the right & in the contralateral left leg.* **(Right)** *Transverse ultrasound through the right lower leg in a 17-year-old girl shows herniation of muscle through a fascial defect, creating a mushroom cap appearance. The hernia intermittently reduced with relaxation.*

(Left) *Longitudinal ultrasound through the lower leg in a 16-year-old girl shows a focal muscle herniation through the overlying fascia. The convex superficial margin & overhanging edge of the herniated muscle are typical.* **(Right)** *Coronal T1 MR in an 18-year-old woman with a history of surgery for a right tibial osteosarcoma shows a focal herniation of peroneal muscle through a fascial defect.*

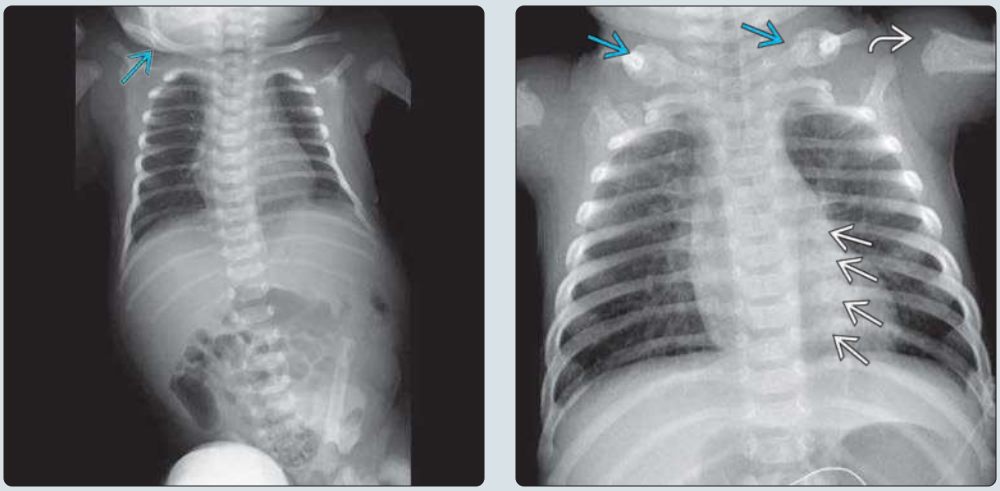
Clavicle Injuries

KEY FACTS

TERMINOLOGY

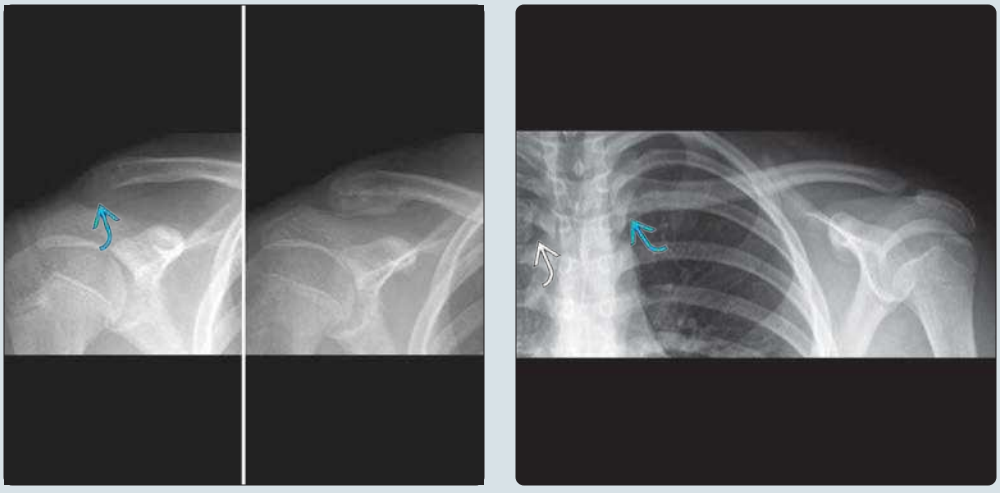
- Can be midshaft or medial or lateral ends
- Epiphyses are present at medial & lateral ends of clavicle
  - 2° ossification centers do not appear until teenage years
    - Fuse in late 2nd-3rd decades of life
  - Displaced fractures through unossified cartilage mimic acromioclavicular (AC) & sternoclavicular (SC) joint dislocations

IMAGING



- Lateral/medial fractures: Apparent AC or SC joint widening
- Apparent AC & SC dislocation on radiographs are typically Salter-Harris (SH)-type fractures in skeletally immature
  - Unossified epiphyses at ends of clavicle (not visible on radiographs) are areas of relative weakness
- CT in acute setting for suspected fracture/displacement of medial clavicle; compare alignment of bilateral medial clavicles on radiographs
  - CECT for posterior displacement → vascular injury

TOP DIFFERENTIAL DIAGNOSES



- Child abuse
  - Correlation with history is essential to distinguish accidental injury from abuse
  - Clavicle fractures have low specificity for abuse
- Congenital pseudoarthrosis
  - 2 separate portions of clavicle show smooth, intact cortices without callus
- AC & SC joint dislocations
  - Apparent AC or SC widening on radiographs is typically SH fracture in skeletally immature
- Normal unossified cartilage
  - Comparison contralateral view is helpful

DIAGNOSTIC CHECKLIST

- Infant fracture: Correlate age, radiographic findings, & clinical history to distinguish birth injury from abuse
- In skeletally immature, lateral & medial SH fractures can mimic AC & SC joint dislocations

(Left) *Frontal radiograph of the chest & abdomen in a newborn taken while still in the hospital shows a right clavicle fracture secondary to birth injury. This was not apparent on clinical exam.* **(Right)** *AP chest radiograph in a 2-month-old boy with apnea shows healing bilateral clavicle fractures. There are also multiple healing posterior left rib fractures & a healing left humeral metaphyseal corner fracture. Subdural hematomas were found on a head CT, & abuse was clinically confirmed.*

(Left) *Frontal radiographs at initial presentation (L) & 1 month (R) in a 13-year-old boy with an injury show a subtle fracture fragment aligned with the acromion with elevation of the more proximal clavicle. Callus at 1 month confirms that this was a healing fracture, not acromioclavicular joint dislocation.* **(Right)** *Frontal radiograph of the left clavicle in a 14-year-old boy with an acute injury shows elevation of medial left clavicle compared to right. CT confirmed a Salter-Harris fracture of medial left clavicle.*

TERMINOLOGY

Definitions

- Occur at midshaft or at medial or lateral ends
- Growth plates & epiphyses are present at medial & lateral ends of clavicle
  - 2° ossification centers do not appear until 2nd decade of life & often do not fuse until 3rd decade
  - Displaced fractures through unossified cartilage mimic acromioclavicular (AC) & sternoclavicular (SC) joint dislocations

IMAGING

General Features

- Best diagnostic clue
  - Lateral/medial fractures: Apparent AC or SC widening
  - Midshaft fracture: Abnormal angulation
- Location
  - Fractures of clavicle are typically classified by location
    - Mid 1/3: 80-85% (most common)
    - Lateral 1/3: 15-20%
    - Medial 1/3: < 5%

Radiographic Findings

- Midclavicle fracture
  - Evolution of subperiosteal new bone & callus formation in birth trauma
    - No subperiosteal new bone < 7 days
    - Subperiosteal new bone is typically present by 10 days
    - Callus formation is typically not seen < 9 days but is often present by 15 days
- Apparent AC or SC dislocation on radiographs is typically Salter-Harris (SH)-type fracture in skeletally immature
  - Unossified epiphyses at ends of clavicle, not visible on radiographs, are areas of relative weakness
  - Distal clavicle SH fracture + periosteal avulsion
    - Periosteal sleeve avulsion allows superior displacement of clavicle relative to AC joint
    - Follow-up radiographs show callus formation
  - Medial clavicle fracture may be SH I or II
    - Clavicle may displace anterior, posterior, or superior
    - Can be very subtle on radiographs; compare to contralateral side

CT Findings

- CT in acute setting for suspected fracture/displacement of medial clavicle; CECT if concern for vascular injury
  - Posterior displacement may cause neurovascular, lung, tracheal, &/or esophageal injuries

MR Findings

- Allows visualization of cartilaginous epiphyses
- Allows delineation of associated soft tissue injuries in setting of distal clavicular fractures
- Can help differentiate posterior SC joint dislocation & medial clavicular physeal fracture

Imaging Recommendations

- Protocol advice
  - CT if concern for medial clavicle fracture or dislocation
    - CECT if concern for vascular injury

DIFFERENTIAL DIAGNOSIS

Child Abuse

- Correlation of radiographic findings & history is essential
- Clavicle fractures have low specificity for abuse
- Look closely for other fractures

Congenital Pseudoarthrosis

- Can be confused with fracture from birth trauma or abuse
- 2 separate portions of clavicle have smooth, intact cortices without callus

Acromioclavicular & Sternoclavicular Dislocations

- Apparent AC & SC widening on radiographs are typically SH fractures in skeletally immature children

Normal Unossified Cartilage

- AC joint often appears wide (by adult standards) prior to skeletal maturity
- Comparison view of contralateral side is helpful

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Birth-related clavicle fractures
    - Not moving extremity, tenderness, deformity
    - May go undetected if nondisplaced
  - Other presentations: Fall on outstretched arm, direct blow, child abuse
    - Tenderness, swelling, palpable deformity (if displaced)

Treatment

- Midclavicle fractures
  - Acute non-/minimally displaced fractures: Nonoperative management, immobilization
  - Open fractures & significant skin tenting/compromise: Open reduction internal fixation
- Medial & lateral clavicle fractures
  - Immobilization ± closed reduction
  - If fails → open reduction + various types of fixation

DIAGNOSTIC CHECKLIST

Consider

- Compare left & right medial clavicle positions for subtle malalignment of medial fracture/displacement
- CT in questionable cases (+ contrast if concern for posterior displacement & vascular injury)

Image Interpretation Pearls

- Infant clavicle fracture: Correlate age, radiographic findings, & clinical history to distinguish birth injury from abuse
- In skeletally immature, lateral & medial SH fractures can mimic AC & SC joint dislocations

Supracondylar Fracture

KEY FACTS

IMAGING

- AP radiograph
  - Transverse fracture of distal humeral metadiaphyseal junction at level of coronoid & olecranon fossae
  - ± medial or lateral cortical buckling or angulation
- Lateral radiograph
  - Visible posterior fat pad due to joint effusion
    - May be only finding of nondisplaced fracture
  - Anterior humeral line fails to bisect capitellum due to apex volar angulation ± dorsal translation of distal fracture fragment
- Radiocapitellar alignment is generally maintained on all views (in contradistinction to true dislocation)

TOP DIFFERENTIAL DIAGNOSES

- Lateral condylar fracture
- Posterior dislocation
- Distal humeral epiphyseal separation/transphyseal fracture

PATHOLOGY

- Extension/FOOSH (fall on outstretched hand) mechanism (98%) vs. flexion injury with direct trauma (2%)
- Modified Gartland classification (I-IV) to direct treatment
  - Classified by degree of displacement, rotation, instability
  - Treatment ranges from casting to closed reduction with percutaneous fixation to open reduction internal fixation
- Neurovascular injury is much higher with completely displaced fractures (types III & IV)
  - Vascular injury requires urgent reduction + pinning at minimum; may need ORIF

CLINICAL ISSUES

- 60% of pediatric elbow fractures; peak age: 5-7 years

DIAGNOSTIC CHECKLIST

- Consider follow-up radiographs in 10-14 days to identify healing occult fracture if joint effusion is only finding initially (in setting of trauma)

(Left) *AP radiograph in a 5-year-old after a fall shows a complete, transversely oriented distal humeral fracture through the olecranon & coronoid fossae with > 50% medial translation of the metaphysis* ⇨. **(Right)** *Lateral radiograph in the same patient shows no cortical contact of the posteriorly translated distal fragment* ⇨ *with the proximal fragment (a Gartland III or IV supracondylar fracture). The elbow articulations remain intact on both views.*

(Left) *Lateral radiograph after a fall shows anterior cortical disruption* ➡ *in the typical location of a supracondylar fracture. There is mild apex volar angulation (with hinged but intact posterior cortex), such that an anterior humeral line no longer bisects the capitellum (Gartland IIA). There is a large elbow joint effusion with elevation of the anterior* ➡ *& posterior* ➡ *fat pads.* **(Right)** *AP radiograph in the same child shows subtle medial cortical buckling* ➡ *of the supracondylar humerus.*

TERMINOLOGY

Synonyms

- Gartland fracture

Definitions

- Supracondylar fracture: Transverse fracture of distal humeral metadiaphyseal junction with varying degrees of displacement & comminution
- FOOSH injury: **F**all **o**n **o**ut**s**tretched **h**and
- Anterior humeral line: Vertical line drawn along anterior cortex of humeral diaphysis; normally bisects capitellum
  - Often courses through anterior 1/3 of capitellum in very young children
- Radiocapitellar (RC) line: Line drawn through long axis of radius; normally bisects capitellum on any view
  - Due to eccentric ossification of capitellum, RC line often does not bisect ossified capitellum < 10 years of age

IMAGING

General Features

- Best diagnostic clue
  - Lateral radiograph
    - Dorsal translation of distal humeral metaphysis/epiphysis with failure of anterior humeral line to bisect capitellum
      - Volar angulation of fracture apex
    - Displacement of anterior & posterior fat pads by joint effusion → may be only finding of nondisplaced fracture
  - AP radiograph
    - Transverse metadiaphyseal junction fracture lucency
- Location
  - Fracture occurs at thin distal humerus between olecranon (posterior) & coronoid (anterior) fossae
- Morphology
  - Various configurations depending on degree of angulation, translation, rotation, & comminution

Radiographic Findings

- Radiography
  - AP view
    - Transversely oriented linear lucency of distal humeral metadiaphyseal junction
    - Varying degrees of angulation, translation, & rotation of distal fragment
    - Fracture line may not be visible in up to 25%
    - Subtle buckling or angulation of medial or lateral cortex may be only finding on this view
  - Lateral view
    - Displacement of fat pads due to joint effusion
      - Posterior fat pad is not normally visible
    - Apex volar angulation ± dorsal translation of distal humeral fracture fragment
      - Anterior humeral line no longer bisects capitellum in majority
  - RC line is typically maintained
    - Disruption would indicate radial head subluxation/dislocation (or possibly patient < 10 years old if mild), which does not typically occur in this setting
  - Follow-up imaging
    - Baumann angle (shaft-capitellum angle) on AP view: Superolateral angle between humeral diaphyseal long axis & physis deep to capitellar ossification center
      - Normally 64-81° → mild valgus carrying angle
      - ↑ Baumann angle (> 5° vs. contralateral side): Cubitus varus (5-10%)
    - Fishtail deformity of central humeral epiphysis due to lateral trochlear avascular necrosis
      - Uncommon complication of distal humeral fractures (most frequently supracondylar)
      - May lead to proximal migration of ulna + radial head subluxation/dislocation

DIFFERENTIAL DIAGNOSIS

Lateral Condylar Fracture

- Fracture extends obliquely through lateral humeral metaphysis to central physis

Posterior Dislocation

- Ulna & radius are displaced posteriorly, laterally, & proximally
  - RC line no longer intersects capitellum
- No supracondylar metadiaphyseal fracture

Medial Epicondyle Avulsion

- Avulsion ± intraarticular entrapment of medial epicondyle
- Elbow dislocation in 50%

Distal Humeral Epiphyseal Separation (Transphyseal Fracture)

- Uncommon fracture of young children (< 2 years of age) through distal humeral physis
- May be difficult to recognize due to lack of radiographically visible ossification centers
- Capitellum, radius, & ulna translate medially
  - RC line is maintained (if capitellum visible)
- 25-50% are associated with child abuse

T-Condylar Fracture

- Generally considered variant of supracondylar fracture (with additional intraarticular extension) in skeletally immature patients

PATHOLOGY

General Features

- Etiology
  - Supracondylar humerus is susceptible to fracture due to thin bone between medial & lateral pillars at coronoid fossa anteriorly & olecranon fossa posteriorly
  - Mechanism: Hyperextension form (98%) in FOOSH injury vs. flexion type (2%) from fall onto posterior elbow with direct trauma to olecranon
- Associated abnormalities
  - Concomitant elbow & forearm fractures (11%)
    - Olecranon, medial epicondyle, distal radius
    - Floating elbow: Forearm fractures become unstable in setting of supracondylar fracture (5%)
      - ↑ risk of neurovascular injury & compartment syndrome
  - Nerve injuries (10-20%)

- Anterior interosseous/median, ulnar, &/or radial nerves
  - Ulnar nerve injury is more likely with flexion mechanism
  - Transection is uncommon, usually radial nerve
- Vascular injuries (3-14%)
  - Spasm, laceration, thrombus, rupture

Staging, Grading, & Classification

- Modified Gartland classification
  - Type I
    - Nondisplaced or minimally displaced (< 2 mm)
    - Intact anterior humeral line
    - Posterior fat pad sign may be only finding
  - Type IIA
    - Mildly displaced (> 2 mm) anterior cortex
    - Posterior cortex is intact but hinged
    - Anterior humeral line touches anterior capitellum but does not extend through middle 1/3
    - No rotational deformity on AP view
  - Type IIB
    - Mildly displaced + malrotation or lateral displacement with maintenance of cortical contact
  - Type III
    - Displaced fracture with no cortical contact
    - Periosteum is torn
    - Often with soft tissue & neurovascular injuries
  - Type IV
    - Multidirectional instability (determined intraoperatively)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, loss of function, swelling, discoloration
  - Varying degrees of deformity depending on displacement
- Other signs/symptoms
  - ↓ distal radial pulse, cool extremity
  - Open fracture in 3%

Demographics

- Age
  - Most common in children 5-7 years old
  - Suggestive of abuse in nonambulatory infants
- Epidemiology
  - 60% of pediatric elbow fractures
  - 3-16% of all pediatric fractures
  - Rare in adults (< 3%)
  - Common in nondominant side (1.5:1)

Natural History & Prognosis

- Return of function in > 90% regardless of Gartland type
- Return of range of motion may take 1 year
- In patients with cool, pulseless extremity, radial pulse often returns quickly (> 50%) after closed reduction
- Nerve dysfunction is typically transient; may require months

Treatment

- Conservative
  - Type I: Above elbow cast in 90° flexion for 3-4 weeks
- Surgical
  - Type II: Treatment controversial
    - Closed reduction & casting vs. pin fixation
  - Type III/IV: Percutaneous lateral pin fixation vs. open reduction internal fixation (ORIF)
  - Prompt reduction & pinning for vascular compromise or floating elbow
    - Delayed treatment of 8-24 hours is otherwise increasingly accepted
  - ORIF may be needed in up to 20%
    - Open fractures
    - Entrapped soft tissues preventing closed reduction
    - Worsening neurovascular compromise after closed treatment
- Complications
  - Neurovascular injury, compartment syndrome, infection, loss of reduction (even with pinning), malunion, restricted motion, hyperextension, cubitus varus or cubitus valgus, fishtail deformity

DIAGNOSTIC CHECKLIST

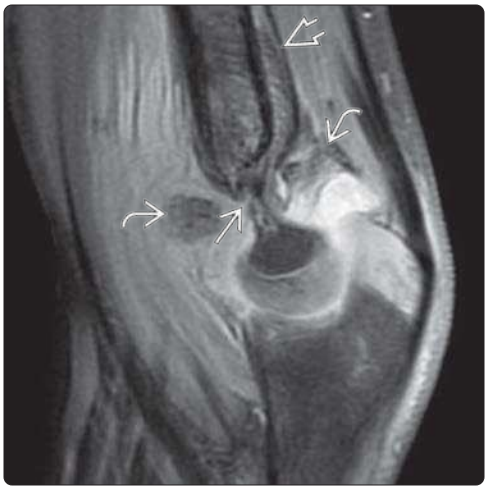

Image Interpretation Pearls

- Be sure to look for other elbow & forearm fractures
- Consider follow-up radiographs in 10-14 days to identify healing occult fracture if joint effusion is only finding initially (in setting of trauma)

(Left) *Lateral radiograph shows that the anterior humeral line fails to intersect the capitellar ossification center. This finding is consistent with a supracondylar fracture. Note the elevation of both the anterior & posterior fat pads, indicating an elbow joint effusion.* **(Right)** *Sagittal PD FS MR in a 9-year-old with a healing supracondylar fracture shows anterior cortical disruption with displacement of the humeral fat pads by a joint effusion. Note the posterior humeral periosteal reaction.*

(Left) *Lateral radiograph in a patient after a fall shows a horizontally oriented fracture lucency through the supracondylar humerus with minimal apex volar angulation.* **(Right)** *Lateral radiograph in an 8-year-old girl after a fall shows an uncommon pattern of displacement for a supracondylar fracture with anterior translation & apex dorsal angulation. This pattern is associated with the less common (2%) mechanism of injury in supracondylar fractures (flexion injury with direct olecranon impact).*

(Left) *AP radiograph in a 23-month-old patient shows slight cortical irregularity of the supracondylar humerus with overlying soft tissue swelling.* **(Right)** *Lateral radiograph in the same patient shows displacement of the posterior fat pad overlying a mildly angulated posterior humeral cortex. The anterior humeral line fails to bisect the capitellum.*

Lateral Condylar Fracture

KEY FACTS

TERMINOLOGY

- Posterior oblique fracture through lateral condyle of humeral metaphysis with distal extension through unossified epiphyseal cartilage (Salter-Harris IV)
  - Fracture line may dissipate within epiphyseal cartilage before reaching articular surface, leaving cartilaginous hinge/bridge

IMAGING

- AP view: Ranges from sliver of nondisplaced metaphyseal fracture fragment to marked translation & rotation of larger triangular metaphyseal fragment + capitellum
- Lateral view: Posterior oblique metaphyseal fracture plane; displacement of lucent anterior & posterior fat pads by joint effusion
- Internal oblique radiographs: More accurate for detecting fracture & determining displacement
- Distal cartilaginous extension is not radiographically visible but is implied by degree of bone fragment displacement
  - Lack of bone fragment displacement does not ensure cartilage integrity/fracture stability
  - Arthrography, MR, or US characterizes extent of cartilaginous articular surface injury

PATHOLOGY

- Jakob classification is used to determine therapy
  - Type I (≤ 2-mm displacement): Typically casted
  - Type II (> 2-mm displacement without rotation): Closed reduction with percutaneous pinning
  - Type III (> 2-mm displacement with rotation): Open reduction & fixation

CLINICAL ISSUES

- 10-20% of pediatric elbow fractures (2nd most common)
- Typically 5-10 years old; peak age: 6 years
- Complications include stiffness, late displacement, nonunion, delayed union, malunion, prominence or spurring of lateral condyle, capitellar osteonecrosis, tardy ulnar nerve palsy

(Left) *AP radiograph in an 18-month-old after falling out of bed shows a subtle Jakob type I (≤ 2 mm of displacement) lateral condylar fracture ➡ of the distal humerus. Note the marked lateral soft tissue swelling.* **(Right)** *AP radiograph in the same child 1 week later shows ↑ displacement of the fracture ➡ despite immobilization. Delayed displacement is a known risk of nonoperative management in Jakob type I fractures.*

(Left) *Lateral radiograph in the same child shows an elbow joint effusion with elevation of the posterior ➡ fat pad. The fracture line ➡ has an oblique course posteriorly ⇨, typical of lateral condylar fractures.* **(Right)** *AP radiograph in the same patient 8 months later shows a healed fracture with an enlarged lateral condyle & mild cubitus varus, both of which are recognized complications of lateral condylar fractures. This patient's fracture had been previously transfixed by 3 percutaneous K-wires.*

TERMINOLOGY

Definitions

- Posterior oblique fracture through lateral condyle of humeral metaphysis with distal extension through unossified epiphyseal cartilage
  - Fracture line may dissipate within epiphyseal cartilage before reaching articular surface

IMAGING

General Features

- Morphology
  - Metaphyseal fracture line parallels physis (or slightly steeper) on AP view
  - Salter-Harris IV fracture: Distal extension through unossified epiphyseal cartilage is not radiographically visible

Radiographic Findings

- AP view: Ranges from sliver of nondisplaced metaphyseal fracture fragment to marked translation & rotation of larger triangular metaphyseal fragment + capitellum
  - Nondisplaced fracture may be occult or easily missed
  - If missed &/or not treated appropriately, may lead to nonunion & joint incongruence
- Lateral view: Posterior oblique metaphyseal fracture plane; displacement of lucent anterior & posterior fat pads by joint effusion
- Internal oblique radiographs: More accurate for detecting fracture & determining displacement
  - May still underestimate true displacement
- External oblique views are rarely helpful
- Arthrography characterizes extent of cartilage/articular surface injury

CT Findings

- CT with reformation: Best assessment of displacement; also helpful for understanding complex fracture components to determine classification & treatment

MR Findings

- Horizontal to oblique linear high or low T1/T2 signal intensity fracture component in lateral metaphyseal humerus, ± surrounding marrow edema
- Vertical/oblique linear focus of fluid signal intensity through unossified distal humeral epiphyseal cartilage
- MR is also useful for follow-up of complications

Ultrasonographic Findings

- May be used to assess cartilage

Imaging Recommendations

- Protocol advice
  - Radiographs: AP & lateral views initially
    - Internal oblique view: Most sensitive for occult lateral condylar fractures & determining displacement
  - MR
    - Coronal & sagittal PD & T2 FS
    - Useful in assessing cartilage integrity/disruption
    - More expensive & often requires sedation in young child

DIFFERENTIAL DIAGNOSIS

Supracondylar Fracture

- Most common pediatric elbow fracture
- Transversely oriented fracture of distal humerus extending through level of olecranon fossa & coronoid fossa
  - Variable degrees of displacement
  - Disruption of anterior humeral line (normally bisects middle 1/3 of capitellum) on lateral view
  - May be occult, showing only elbow joint effusion

Olecranon Fracture

- Association with lateral condylar & other elbow fractures
- Must not confuse normal ossification center for fracture

Medial Epicondyle Avulsion

- ~ 10% of elbow fractures in pediatrics, usually in older children
- Distraction of medial epicondyle (ME) ossification center
  - Can become entrapped in elbow joint, simulating trochlear ossification center
- Unreliable fat pad displacement: ME tends to be extracapsular > 2 years old
- 50% are associated with elbow dislocations

Radial Neck Fracture

- 5% of elbow fractures in children
- Salter-Harris II fracture: 90%

Transphyseal Fracture

- Distal humeral epiphyseal separation, usually < 2 years old
- Displacement of largely unossified epiphyseal cartilage medially, resulting in malalignment between humeral metaphysis & radius (thereby suggesting elbow joint dislocation)
  - May be difficult to distinguish from dislocation when capitellum is not ossified
    - In true dislocation, radiocapitellar alignment is disrupted with radius displaced laterally & posteriorly
    - In transphyseal fracture, capitellum still aligns with radial head & radius/capitellum are usually shifted medially
- > 50% are associated with nonaccidental trauma

PATHOLOGY

General Features

- Etiology
  - Push-off: Fall on outstretched hand causing impaction of lateral condyle into radial head
  - Pull-off: Avulsion by lateral collateral ligamentous complex & common extensor tendons
  - Combination of push-off & pull-off

Staging, Grading, & Classification

- Distal extension of fracture through epiphysis (Salter-Harris IV) is much more common than extension through medial physis (Salter-Harris II)
- Jakob classification: Most common system used by surgeons; based on fragment displacement on internal oblique radiograph
  - Type I
    - Nondisplaced or ≤ 2 mm of displacement

- Fracture line is presumed not to extend to articular surface
- Type II
  - > 2 mm of displacement (typically < 4 mm)
  - Partial disruption of articular surface with intact hinge/bridge of cartilage
    - No rotation of lateral condylar fragment
- Type III
  - > 2 mm of displacement
  - Complete disruption of articular surface
    - Metaphyseal fragment & capitellum are rotated
    - Loss of radiocapitellar alignment → elbow instability

- Milch classification: Less commonly used due to high radiographic-surgical discordance
  - Type I
    - Fracture extends through capitellar ossification center lateral to trochlear groove
  - Type II
    - Fracture extends into trochlea rather than through capitellar ossification center

CLINICAL ISSUES

Presentation

- Lateral elbow swelling
- Lateral supracondylar ridge tenderness
- Absent pain over medial supracondylar ridge
- Ecchymosis

Demographics

- 10-20% of pediatric elbow fractures
  - 2nd in frequency after supracondylar fracture
  - Most common intraarticular pediatric elbow fracture
- Age: Typically 5-10 years old; peak: 6 years

Natural History & Prognosis

- Complications
  - Stiffness is most common
  - ↓ range of motion
  - Late fracture displacement 3 days to 3 weeks after nonoperative cast placement in ~ 11%
  - Nonunion
    - ↑ in intraarticular fractures
      - Bathed by synovial fluid, leading to ↓ healing
      - Pull of extensor muscles
      - Poor circulation to distal fracture fragment
    - ↑ in inadequately treated or displaced fractures
    - ↑ in missed or unrecognized fractures
  - Delayed union
    - > 6-8 weeks
  - Malunion
    - Fishtail deformity
      - Concavity with deepening of trochlear groove due to osteonecrosis
      - Rare; more common in supracondylar fractures
      - Usually minimal symptoms early; may have limited flexion & extension long term
    - Cubitus varus
      - More common than cubitus valgus
      - Most common with nondisplaced or minimally displaced fractures
    - Cubitus valgus
      - Fragment migration vs. lateral growth arrest
      - May lead to tardy ulnar nerve palsy
  - Tardy ulnar nerve palsy
    - Slow progressive paralysis of ulnar nerve
      - Atrophy of intrinsic hand muscles, sensory loss
      - Latency period of several months to many years
    - Treated by anterior transposition of ulnar nerve
  - Enlarged &/or spurred lateral condyle (nearly 50%)
    - Usually cosmetic without affecting function
  - Osteonecrosis of capitellum
    - Rare complication of extensive surgical dissection
  - Degenerative arthritis

Treatment

- Type I (≤ 2 mm of displacement)
  - Controversial: Some advocate surgical treatment
    - Occult extension to joint may occur without initial fracture displacement (thereby predisposing to late displacement if only casted initially)
  - Most commonly treated with long arm cast
    - Frequent follow-up radiographs every 7-10 days
      - Due to risk of late displacement
- Type II (> 2 mm of displacement without rotation)
  - Closed reduction with percutaneous pinning
    - Consider compression screws
  - Intraoperative arthrography is helpful in determining articular surface congruity
- Type III (> 2 mm of displacement with rotation)
  - Open reduction & fixation
    - K-wires &/or compression screws
- Cast is maintained for 4-6 weeks with operative or nonoperative treatment
- Removal of hardware after healing
- Physical therapy for stiffness

(Left) *Internal oblique radiograph in an 8-year-old after a fall shows a ≤ 2-mm displaced Jakob type I lateral condylar fracture with marked overlying soft tissue swelling.* **(Right)** *Oblique radiograph at 1 week of follow-up in a 5-year-old shows 4 mm of displacement to the lateral condylar fracture fragment. On the initial images (not shown), the fracture was displaced ≤ 2 mm. There is also an olecranon process fracture. Internal oblique radiographs are more accurate for fracture detection & displacement.*

(Left) *AP radiograph in a 4-year-old who injured her elbow after falling off of a scooter shows a displaced & rotated Jakob type III lateral condylar fracture.* **(Right)** *Coronal reformatted bone CT in a 15-year-old who sustained a lateral condylar fracture while playing football 3 years ago shows nonunion of a displaced fragment. This complication is seen more often in children with inadequately treated or displaced fractures.*

(Left) *Coronal T1 MR in a 5-year-old who sustained an elbow injury shows a hypointense oblique fracture line extending across the lateral condyle. No intraarticular extension of the fracture was identified.* **(Right)** *Coronal T2 FS MR in a patient after a fall shows an oblique hyperintense fracture line in the trochlear cartilage extending from the disrupted lateral condylar metaphysis to the articular surface.*

Medial Epicondyle Avulsion

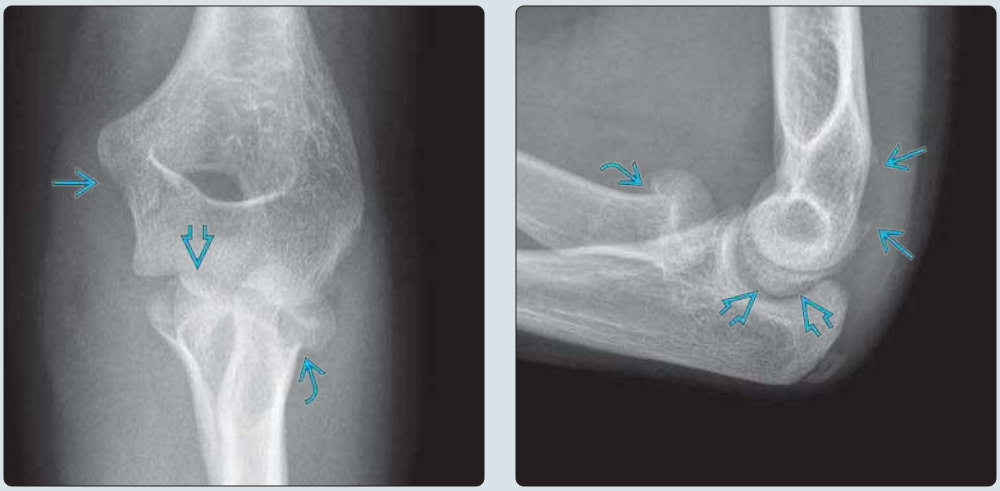
KEY FACTS

TERMINOLOGY

- Acute injury: Avulsion fracture of medial epicondyle (ME) ossification center
- Chronic stress injury: Traction apophysitis, medial epicondylitis, Little Leaguer's elbow

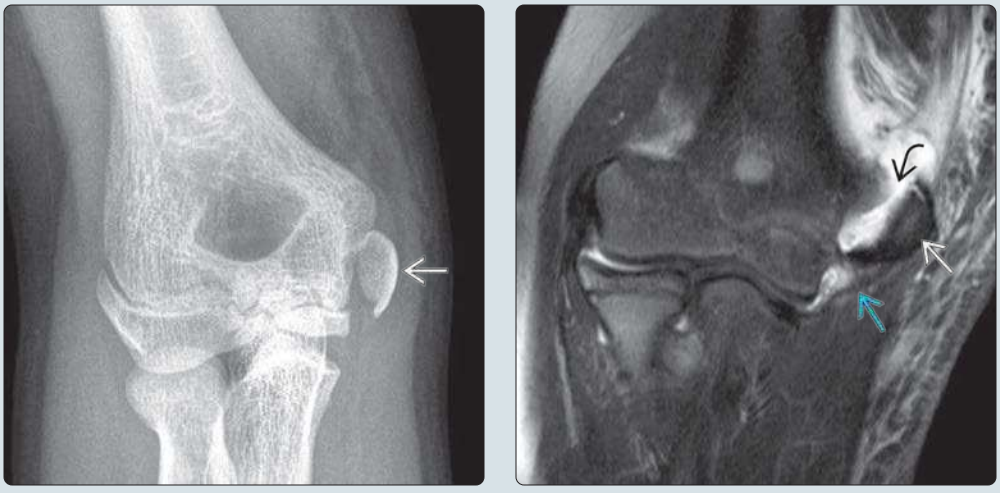
IMAGING

- Acute injury: Distal & anterior translation of ME ossification center with moderate soft tissue swelling
  - May occur in setting of elbow dislocation
  - Remember CRITOE pattern of ossification at elbow
    - Should normally see ME in expected location on AP radiograph if trochlea is present
      - Avulsed, incarcerated ME can simulate trochlear ossification center
  - Unreliable fat pad sign: Joint effusion may be absent
- Chronic injury: Widening & irregularity of cartilaginous physis deep to ME
  - Less pronounced ME separation & soft tissue swelling
  - ± fragmentation & edema of ME on MR



PATHOLOGY

- Weakest link of immature musculoskeletal system: Osteocartilaginous interface
  - Acute tensile force → osteocartilaginous avulsion
    - Skeletally mature patients are more likely to injure ligaments, tendons, muscles
  - Chronic submaximal valgus forces (repetitive microtrauma) exceed healing capacity of system → irritation & disturbance of normal ossification



CLINICAL ISSUES

- Typical age for acute & chronic ME injuries: 8-14 years
- Acute avulsion fracture: Elbow dislocation in 50%, entrapped ME in 15-20%
- Chronic stress injury: Same valgus forces predispose to capitellar osteochondritis dissecans (OCD) & olecranon stress injuries
  - Typically overhead-throwing athletes (e.g., pitchers)

(Left) *AP radiograph in a 13-year-old girl after a fall shows an irregular defect at the expected site of the medial epicondyle (ME), which is entrapped in (& widening) the ulnohumeral articulation. Also note the impacted radial neck fracture.* **(Right)** *Lateral radiograph in the same patient shows the donor site for the avulsed, incarcerated ME along the posterior aspect of the distal humerus. The impacted radial neck fracture is again noted.*

(Left) *AP radiograph shows an acute avulsion of the ME ossification center with mild rotation & distal translation of the fragment.* **(Right)** *Coronal T2 FS MR in a 13-year-old pitcher with an acute injury shows a displaced ME ossification center. Hyperintense fluid is interposed between the fragment & the medial humeral metaphysis, & there is moderate adjacent soft tissue edema. There is a low-grade tear of the ulnar collateral ligament.*

TERMINOLOGY

Synonyms

- Acute medial epicondyle (ME) injury: Avulsion fracture
- Chronic injury: Stress injury, medial epicondylitis, traction apophysitis, Little Leaguer's elbow

Definitions

- Acute injury: Avulsion of ME ossification center
- Chronic stress injury: Repetitive traction microtrauma exceeds healing capacity, causes inflammation, growth disturbance, degeneration
  - Skeletally immature: Apophysitis of ME
  - Skeletally mature: Partial tearing/degeneration of common flexor tendon, medial/ulnar collateral ligament

IMAGING

General Features

- Best diagnostic clue
  - Acute: Radiographic displacement of ME ossification center + overlying soft tissue swelling after injury
  - Chronic: MR fluid-sensitive sequence showing marrow & soft tissue edema at ME + widening, irregularity of physis
- Morphology
  - Should normally see ME in expected location on AP radiograph if trochlea is identified → excludes avulsed & entrapped ME, which can simulate trochlear ossification

Radiographic Findings

- Acute injury: Displacement of ME ossification center distally & anteriorly
  - Or laterally into joint (especially with lateral/posterior elbow dislocation) between olecranon & trochlea
  - ± joint effusion (therefore fat pad sign is unreliable)
- Chronic injury: Enlargement, sclerosis, fragmentation of ME with subjacent physeal widening & irregularity ± thickening of medial humeral cortex

MR Findings

- Acute: Separation of osteocartilaginous ME ossification center from humerus with interposed fluid signal
  - Moderate adjacent soft tissue edema ± marrow edema
- Chronic: Widening & irregularity of cartilaginous physis mimicking mild ME separation from humerus
  - Mild marrow & soft tissue edema, ± fragmentation of ME

DIFFERENTIAL DIAGNOSIS

Ulnar/Medial Collateral Ligament Injury

- More common with skeletal maturity
- Complete tear: Disruption of taut, linear/fan-shaped hypointense band
- Sprain: Thickened ligament with intermediate/high signal

Medial Condyle Avulsion

- Rare Salter-Harris type IV fracture with displaced sliver of bone along medial distal humeral metaphysis
  - Includes displacement of trochlea, which may be partially/completely unossified

Olecranon Stress Injury

- Olecranon fragmentation, edema, &/or physeal widening with appropriate history

Capitellar Osteochondritis Dissecans

- Repetitive impaction of radial head on capitellum with valgus stresses
- Lucent defect with flattening of anterior/midcapitellum
- Lateral pain & locking with loose intraarticular body

PATHOLOGY

General Features

- Etiology
  - ME serves as attachment for medial/ulnar collateral ligament & flexor-pronator muscle group of forearm
  - Osteocartilaginous interface is most likely site to fail under acute tensile stress in skeletally immature patients
    - Musculotendinous junction or ligament in adults
- Associated abnormalities
  - Elbow dislocation in 50% of acute avulsions
    - Ulnar nerve injury: 10-50%
    - ME trapped in elbow joint: 15-20%

CLINICAL ISSUES

Demographics

- Age: Similar ranges for acute ME avulsion fractures & chronic apophysitis: 8-14 years of age; peaks at 11-12 years of age
- Sex: M > F (4:1)
- Epidemiology: Acute avulsion is traditionally considered 3rd most common pediatric elbow fracture (10-20%)

Treatment

- Acute avulsion fracture treatment is controversial
  - Operative management
    - Absolute indications: Open fracture, incarcerated ME, entrapped ulnar nerve
    - Relative indications: Elbow instability, ME displacement, high-level athletes
      - Degree of displacement necessitating fixation is unclear: 2 vs. 5 vs. 10 mm
  - Nonoperative management
    - Good functional outcomes despite high nonunion rate
- Treatment of chronic stress injuries is largely conservative

Forearm Fractures

KEY FACTS

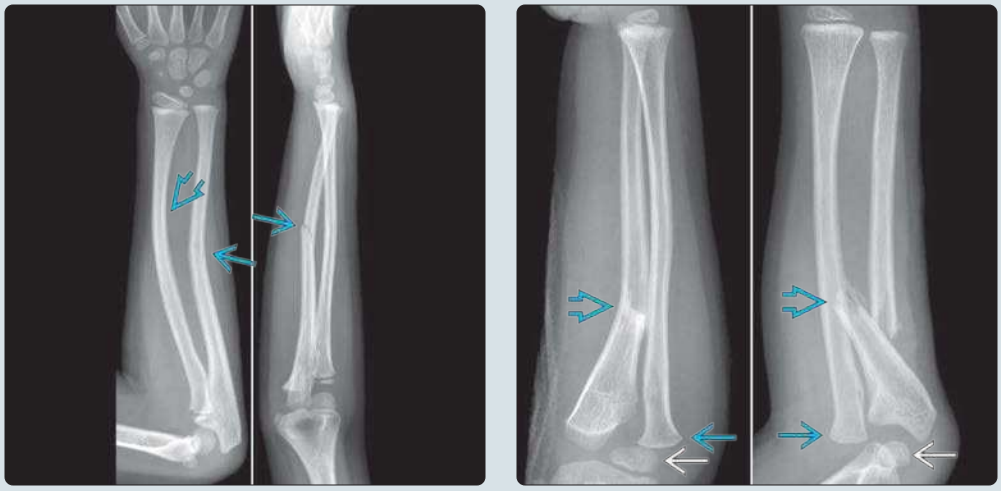
TERMINOLOGY

- Complete fracture: Macroscopic fracture line traverses entire bony diameter
  - Physeal (Salter-Harris): Fracture through cartilaginous growth plate, typically with adjacent bony involvement
- Incomplete fracture: Macroscopic fracture line does not traverse entire bony diameter
  - Buckle fracture, greenstick fracture, plastic deformity

IMAGING

- Focal abrupt cortical angulation, protuberance, &/or discrete fracture line with overlying soft tissue swelling
  - ± physeal extension with displacement of metaphyseal fragment & epiphysis
- Radius & ulna are often fractured together unless dislocated
  - Fractures may be of different types
- Distal radius: Buckle, complete transverse, or physeal
  - Up to 85% of pediatric forearm fractures
  - Distal ulnar injury is usually present: Styloid or incomplete metadiaphyseal fracture
- Radial & ulnar diaphyses: Complete, greenstick, or plastic deformity
- Proximal radius & ulna fractures are usually considered with elbow

PATHOLOGY



- Fall on outstretched hand > > direct blow
- Immature bone is more pliable → incomplete fractures (particularly < 10 years of age)

CLINICAL ISSUES

- Greater remodeling potential in younger children with remaining growth
- Usually managed with closed reduction as needed + cast/splint immobilization
- Risk of growth arrest with Salter-Harris fracture

(Left) *PA & lateral radiographs of the wrist in a 5-year-old after a fall show a mildly angulated complete fracture of the distal radial metadiaphyseal junction. A buckle fracture of the distal ulna is also noted. Ulnar fractures usually accompany distal radial fractures but may be subtle.* **(Right)** *PA & lateral views of the wrist in a 12-year-old show a comminuted Salter-Harris II (SHII) fracture of the distal radius with dorsal translation of the distal fracture fragment. An ulnar styloid fracture is present.*

(Left) *AP & lateral forearm radiographs show 2 types of incomplete fractures with a greenstick fracture of the ulnar diaphysis (with cortical disruption on the tension or convex side) & a plastic deformity of the radial diaphysis.* **(Right)** *AP & lateral forearm radiographs in a 4-year-old show a complete fracture of the proximal ulnar diaphysis & dislocation of the proximal radius relative to the capitellum (the Monteggia fracture-dislocation complex). The radial head has not yet ossified.*

TERMINOLOGY

Definitions

- Complete fracture: Macroscopic fracture line traverses entire bony diameter
  - Physeal (Salter-Harris): Fracture through cartilaginous growth plate, typically with adjacent bony involvement
  - Monteggia: Radial head dislocation + proximal ulnar shaft fracture
  - Galeazzi: Distal radial fracture + distal ulnar dislocation
- Incomplete fracture: Macroscopic fracture line does not traverse entire bony diameter
  - Buckle: Focal cortical deformity on compression side
    - Component of buckling often accompanies physeal fracture → look for subtle extension of lucency to growth plate
  - Greenstick: Cortical disruption on tension side
  - Plastic deformity: Smooth abnormal curvature of diaphysis without cortical interruption

IMAGING

General Features

- Best diagnostic clue
  - Abrupt angular deformity or frank interruption of normally smooth cortical contour
  - Radius & ulna are often both fractured ("both bone forearm fractures") unless dislocated
- Location
  - Distal radius: Buckle, complete transverse, or physeal
    - 25-43% of all pediatric fractures
    - 15% involve physis; almost all are Salter-Harris II (SHII)
    - Accompanying ulnar injury: Styloid or incomplete metadiaphyseal fracture is most common
      - Less commonly: Physeal injury or dislocation
  - Radial & ulnar diaphyses: Complete, greenstick, or plastic deformity
    - 10-30% of all pediatric fractures
  - Proximal radius & ulna fractures are typically considered as elbow fracture
    - Radial neck SHII & ulnar olecranon are most common

Radiographic Findings

- Focal abrupt cortical angulation, protuberance, &/or discrete fracture line with overlying soft tissue swelling
- ± physeal extension with displacement of metaphyseal & epiphyseal fragments
- May see displacement of pronator quadratus fat pad at volar radius

Ultrasonographic Findings

- Focal interruption/bulging of echogenic cortex ± subperiosteal hemorrhage, soft tissue edema

Imaging Recommendations

- Vast majority are diagnosed & managed by radiographs
- Obtain 2 tangential views as fracture may be subtle

DIFFERENTIAL DIAGNOSIS

Normal Developmental Variants

- Few sites of normally occurring mild cortical angulation/protuberance or bowing
- Contralateral comparison radiographs are helpful

Metabolic Bone Diseases

- Pathologically weakened bones ± multiple fractures, may show chronic bowing

Skeletal Dysplasias

- Bones of abnormal shapes & sizes, typically bilateral
- ± abnormal mineralization

PATHOLOGY

General Features

- Fall on outstretched hand > > direct blow
- Immature bone is softer, more pliable → greater bowing or bending before breaking → incomplete fractures
  - Particularly children < 10 years of age

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, swelling, tenderness, ↓ use, deformity

Natural History & Prognosis

- Acceptable degree of displacement, angulation, & malrotation varies by fracture type, location, patient age
  - Greater remodeling potential in children (especially < 6-10 years of age)
    - Tolerate ↑ degrees of residual displacement of nonarticular fractures after closed reduction
  - 21-39% of reduced distal radial fractures will redisplace
    - Risk factors: Initial displacement ≥ 1 shaft width, "both bone" fractures, nonanatomic reduction
- Buckle fractures
  - 3-week immobilization with splint
  - Follow-up imaging is often not necessary
- Complete or incomplete diaphyseal fractures
  - > 90% are managed with closed reduction & casting
- Physeal injuries
  - < 5% develop subsequent symptomatic growth arrest at distal radius vs. ~ 50% growth arrest rate at distal ulna
- Ulnar styloid injuries
  - Vast majority are not treated; nonunion is common
  - Few patients will have long-term symptoms
- Forearm fracture patterns more likely to be managed operatively: Proximal 1/3, comminuted, Monteggia, older children/adolescents, & severe soft tissue injuries precluding cast placement

ACL Injuries

KEY FACTS

TERMINOLOGY

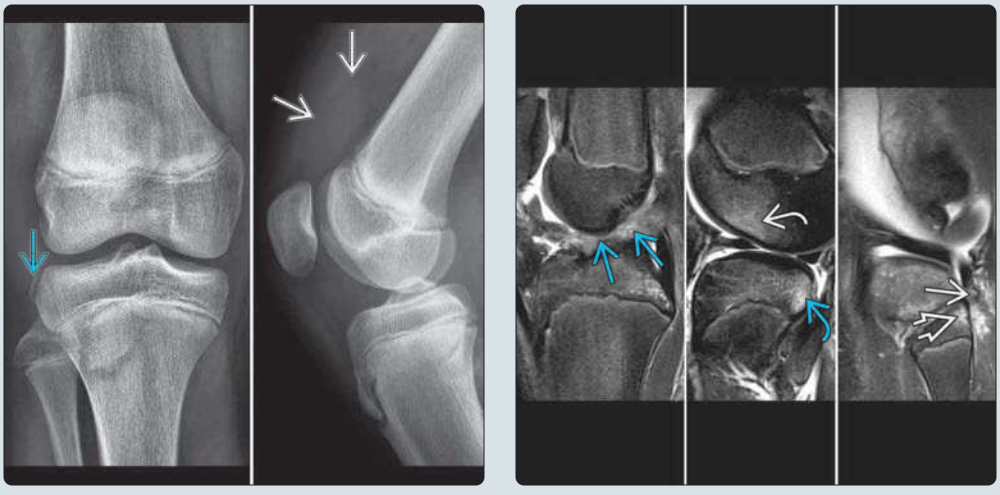
- Intrasubstance anterior cruciate ligament (ACL) tears may be complete or partial; differentiation can be difficult
- Avulsion fractures of tibial eminence at distal ACL attachment are more frequent in skeletally immature patients
- Femoral avulsion fractures of ACL are rare

IMAGING

- Radiographs: Joint effusion is common but nonspecific
  - Less common but more specific secondary findings: Deep lateral condylar notch sign & Segond fracture
- MR: ↑ intrasubstance signal of ACL with disrupted fibers
  - Empty lateral intercondylar wall on coronal PD/T2 FS
  - "Kissing" contusions: Edema in lateral femoral & posterolateral tibial condyles
  - ACL tibial eminence avulsion
    - Meniscus or transverse ligament may be entrapped under avulsed tibial eminence fracture fragment

CLINICAL ISSUES

- Mid or proximal substance ACL tears are typical of athletic patients at or approaching skeletal maturity (F > M)
- Tibial eminence avulsion fractures are most common at 8-14 years of age (M > F); ACL is intact or partially torn



DIAGNOSTIC CHECKLIST

- Evaluate integrity of ACL in 3 standard planes
  - Oblique planes along course of ACL may improve detection of partial tears
- Important associated MR findings in setting of ACL tear
  - Meniscal tears
    - Posterior horn medial meniscus-capsular separation: "Ramp lesion"
      - May result in graft failure & joint degeneration
    - Posterior horn lateral meniscal tears are often missed
      - Closely inspect lateral meniscal-meniscofemoral ligament attachment
  - Posterolateral corner/medial collateral ligament injuries

(Left) *Lateral radiograph in a 17-year-old girl with a right knee injury during a soccer game shows a joint effusion & a deep lateral condylar notch that measures > 3 mm.* **(Right)** *Sagittal PD (left) & T2 FS (right) MR images (same patient) show a corresponding subchondral fracture of the lateral femoral condyle with underlying edema + complex tear of the lateral meniscus posterior horn. The more central PD image shows a complete midsubstance anterior cruciate ligament (ACL) tear.*

(Left) *Frontal (left) & lateral (right) radiographs in a boy with a right knee injury show a joint effusion & a Segond fracture. Segond fractures are nearly always associated with ACL tears.* **(Right)** *Sagittal T2 FS MR images from central (left) to lateral (right) in the same boy show a complete intrasubstance ACL tear, "kissing" contusions in the lateral femoral & posterolateral tibial condyles, & partial tearing of the popliteofibular ligament with edema in the fibular head.*

TERMINOLOGY

Abbreviations

- Anterior cruciate ligament (ACL)

Definitions

- ACL has anteromedial & posterolateral bundles
- ACL tears can be complete or partial

IMAGING

General Features

- Best diagnostic clue
  - Radiographs: Large joint effusion
    - Less common: Deep lateral condylar notch, Segond fracture
  - MR: ↑ intrasubstance T2 signal & disrupted fibers
    - Empty lateral intercondylar wall on coronal PD/T2 FS
    - "Kissing" contusions (lateral femoral & posterolateral tibial condyles)
- Location
  - Intrasubstance: Typically midsubstance or proximal
  - Tibial eminence avulsion fractures of ACL in younger (skeletally immature) children
  - Femoral avulsion fractures of ACL are rare but do occur

Radiographic Findings

- Intrasubstance ACL tears
  - Large joint effusion
    - Absence of joint effusion following acute injury virtually excludes ACL tear
  - Segond fracture: Vertically oriented avulsion from lateral proximal tibia
    - Associated ACL tear: 75-100%
    - Associated meniscal tear: 66-75%
  - Deep lateral femoral notch sign
    - Suggests ACL tear if > 1.5-2 mm
  - Fibular head avulsion fracture (arcuate sign)
    - Indicates injury to arcuate ligament complex
    - Associated with cruciate ligament [posterior cruciate ligament (PCL) > ACL] tears
- Tibial eminence fractures
  - Meyers & McKeever classification (modified)
    - Type I: Minimal displacement
    - Type II: "Trapdoor" configuration (elevation of anterior portion of fragment)
    - Type III: Completely displaced fragment
    - Type IV: Comminution of fragment
- Femoral avulsion fracture
  - Avulsion fracture at posteromedial aspect of lateral femoral condyle
  - May be radiographically occult if nondisplaced or predominantly cartilaginous

MR Findings

- T2 FS useful for marrow & soft tissue edema, ligamentous injuries
- PD useful to evaluate associated meniscal injuries
- Primary signs
  - ↑ intrasubstance signal, diffuse thickening, & clearly disrupted fibers
    - May be partial or complete: Can be difficult to distinguish, even at 3T
  - Empty lateral intercondylar wall on coronal images
    - Fluid signal at femoral attachment of ACL
  - Abnormal horizontal or bowed orientation of ligament relative to roof of intercondylar notch
- Secondary & associated signs
  - "Kissing" contusions: Edema in lateral femoral & posterolateral tibial condyles
  - Anterior tibial translation
  - Uncovered lateral meniscus sign
  - Laxity of PCL; posterolateral corner (PLC) injury
  - Medial collateral ligament (MCL) injury
  - Meniscal tears, including medial meniscus posterior horn meniscocapsular separation ("ramp lesion")
    - Posterior horn lateral meniscus tear: Most commonly missed tear associated with ACL injury
      - Often confused with "pseudotear" at lateral meniscal-meniscofemoral ligament attachment
      - Apparent ↑ lateral extension of this attachment site should raise suspicion for tear [≥ 4 images (on 3-mm slices) lateral to PCL = tear]
    - Lateral meniscus root tears with meniscal extrusion also associated with ACL tears
- Chronic ACL tears
  - Complete: Fatty signal in notch without ACL fibers
  - Chronic partial tears: Attenuated ACL
- Tibial eminence fracture
  - MR performed to assess for associated injuries
    - Partial intrasubstance ACL tears
    - Interposition of menisci or transverse ligament under avulsed fracture fragment
      - Up to 33% of type II & 65% of type III fractures
      - Can prevent reduction & healing
- Femoral avulsion fracture
  - MR may show radiographically occult femoral avulsion fracture & associated injuries
  - Avulsion fracture at posteromedial aspect of lateral femoral condyle at ACL femoral attachment

Imaging Recommendations

- Best imaging tool
  - Radiographs in acute setting
    - Evaluate for joint effusion, deep lateral condylar notch, Segond fracture, or tibial eminence avulsion
  - MR confirms ACL tear & evaluates associated injuries
    - Meniscal, MCL, PLC, & cartilaginous injuries
- Protocol advice
  - Evaluate ACL on all 3 standard planes (not just sagittal)

DIFFERENTIAL DIAGNOSIS

Congenital Absence of Anterior Cruciate Ligament

- Hypoplasia to complete absence of ACL
  - Could mimic chronic partial or complete ACL tears
- Small/absent intercondylar notch & dysplasia of tibial eminence

Anterior Cruciate Ligament Ganglion

- Lobular, septated fluid signal mass along or within ACL

Synovial Cleft of Anterior Cruciate Ligament

- Variant herniation of fluid-containing synovium into ACL

PATHOLOGY

Gross Pathologic & Surgical Features

- ACL is intraarticular but extrasynovial (i.e., encased by synovial lining such that joint fluid does not directly contact ACL)
- Tibial intercondylar eminence is divided into 4 regions
  - Medial & lateral intercondylar tubercles or spines
  - Anterior & posterior intercondylar area
- ACL footprint lies at anterior intercondylar area, between anterior attachments of medial & lateral menisci
- Due to this proximity, menisci &/or transverse ligament can become trapped under avulsed tibial eminence fragment → prevents fracture reduction & healing
- Strong association between ACL tears & meniscal tears

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Complete ACL tear
    - Acute swelling & pain with knee "giving out"
    - Sensation of &/or audible "pop" at time of injury
- Clinical profile
  - Complete ACL tears
    - Pivot shift injury
      - Noncontact injury seen commonly in American football players & skiers
      - Valgus stress is applied to flexed knee & external rotation of tibia or internal rotation of femur loads ACL → tear
      - ACL rupture → unrestrained anterior translation of tibia relative to femur → impaction of central lateral femoral & posterolateral tibial condyles
      - Various degrees of flexion may alter location of bone bruise in femoral condyle (i.e., ↑ flexion → more posterior, ↓ flexion → more anterior)
      - Can get contrecoup injury with bone contusion to posteromedial tibial condyle
  - Tibial eminence fractures
    - Typically hyperextension force ± valgus or rotational component
    - May occur from direct blow to femur with knee flexed
- Clinical examination
  - ACL injury
    - Lachman test: Anterior translation force applied to proximal tibia with knee mildly flexed
      - Lack of solid/firm endpoint = (+) test
    - Anterior drawer test: Anterior translational force applied to proximal tibia with knee flexed at ~ 80-90°
      - ↑ translation (vs. contralateral side) = (+) test

Demographics

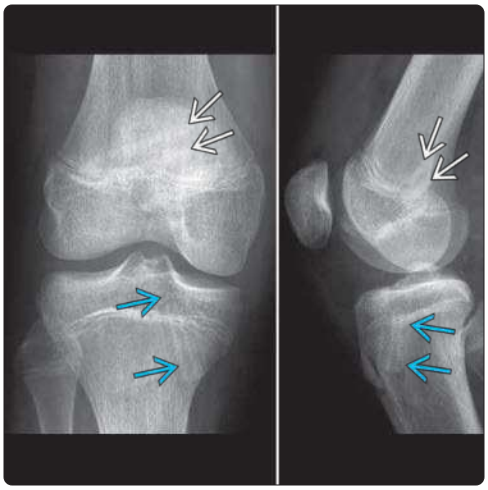
- Epidemiology
  - ↑ frequency related to ↑ childhood athletic activities
  - Tibial eminence avulsion fractures are most common at 8-14 years of age (M > F)
  - Frequency of ACL tears in skeletally mature adolescents approaches that in adults (F > M)

Natural History & Prognosis

- Conservatively managed complete ACL tears in skeletally immature patients often have poor outcomes
  - Instability → degenerative change, meniscal tears, & chondral injury
  - Few patients return to preinjury sports level
- Partial ACL tears can progress to complete tears & symptomatic laxity within 1 year
- Tibial eminence fractures: May be associated with partial tear of ACL; contributes to residual sagittal laxity even following "anatomic" reduction & healing

Treatment

- Complete ACL tears need ligamentous reconstruction
  - May be complicated by presence of open growth plates
    - Various physeal-sparing approaches for children with substantial growth remaining
      - Intra- & extraarticular iliotibial band autograft
      - All epiphyseal approach: Uses epiphyseal tunnels & fixation
    - Transphyseal approach with metaphyseal fixation for children past peak growth
  - Adult reconstruction techniques in patients with closed or closing growth plates
- Tibial eminence fractures
  - Type I: Immobilization in long leg cast or fracture brace with knee flexed at ~ 10-20°
  - Type II: Optimal treatment is controversial
    - Closed reduction & casting
    - Surgical (typically arthroscopic) reduction & fixation
  - Type III-IV
    - Surgical (open or arthroscopic) reduction & fixation



DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Important associated MR findings in setting of ACL tear
  - Posterior horn lateral meniscal tears are often missed
    - Closely inspect lateral meniscal-meniscofemoral ligament attachment
    - Apparent extension of attachment ≥ 4 images (with 3-mm slices) lateral to PCL indicates tear
  - Medial meniscus posterior horn ramp lesions
  - PLC & MCL injuries
  - Meniscus or transverse ligament trapped under avulsed tibial eminence fracture fragment

(Left) *Frontal (left) & lateral (right) radiographs after an ACL repair show that this boy was close enough to skeletal maturity to perform a transphyseal reconstruction. Note how the tibial tunnel & interference screw cross his tibial physis. Two bioabsorbable pins fix the graft to the femur.* **(Right)** *Frontal (left) & lateral (right) radiographs in a 12-year-old with a physeal-sparing ACL reconstruction show that the femoral tunnel interference screw & the tibial tunnel are completely epiphyseal & do not cross the physes.*

(Left) *Frontal (left) & lateral (right) radiographs in a 7-year-old boy with a left knee injury show an elevated tibial eminence avulsion fracture with a joint effusion.* **(Right)** *Sagittal PD MR in the same boy shows that the intact ACL is attached to the avulsed tibial eminence fragment, the anterior portion of which is elevated (consistent with a type II tibial eminence fracture). In this case, there is no meniscal tissue or transverse ligament trapped deep to the avulsed fragment.*

(Left) *AP radiograph in a 14-year-old boy with a left knee injury during a soccer game shows an avulsion fracture along the central aspect of the lateral femoral condyle at the femoral attachment of the ACL.* **(Right)** *Coronal T1 MR in the same patient shows the avulsion fracture at the ACL femoral attachment site on the posteromedial aspect of the lateral femoral condyle. A lateral condyle bone contusion is also noted. Avulsion fractures at the ACL femoral attachment are rare & mostly occur in the skeletally immature.*

Patellar Dislocation

KEY FACTS

TERMINOLOGY

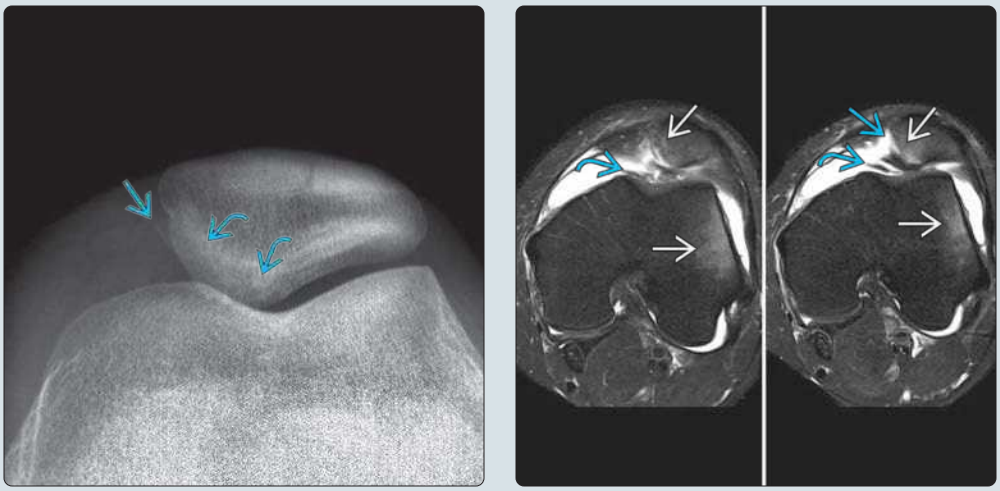
- Transient patellar dislocation (TPD): Lateral dislocation & relocation of patella from direct/indirect injury
  - Shearing, tensile, compressive forces → medial patella, lateral femur, & soft tissue injuries

IMAGING

- Radiographs
  - Large joint effusion after acute TPD
  - Osseous fragments (of patella & lateral femoral condyle)
- MR
  - Medial patella & lateral femoral condyle contusions
  - Chondral & osteochondral injuries
  - Medial patellofemoral ligament (MPFL) tears

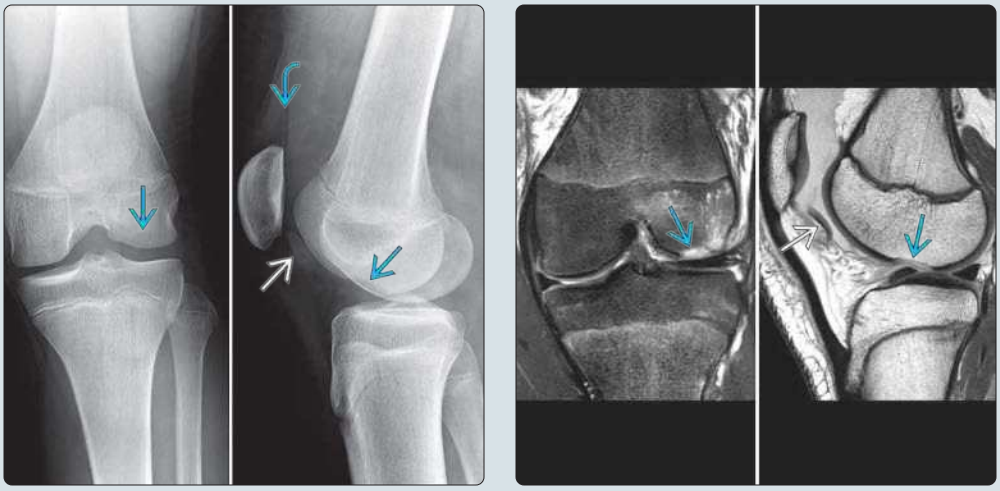
PATHOLOGY

- MPFL = condensation of medial retinaculum
  - Extends from superomedial patella to medial femur (between adductor tubercle & medial epicondyle)
  - Strongest passive medial stabilizer of patella



CLINICAL ISSUES

- Predisposing factors may be congenital or acquired
  - Patella: Alta, lateral subluxation/tilt, dysplasia
  - Trochlear dysplasia
  - Lateralization of tibial tubercle
  - Deficient/absent soft tissue medial stabilizers
  - Generalized ligamentous laxity (e.g., Ehlers-Danlos or Marfan syndrome)



DIAGNOSTIC CHECKLIST

- Radiographic axial patellar view: Evaluate for small fragments & patellar articular surface integrity
- MR: Diagnosis (if unsuspected) + characterization of injuries
  - Patellar & lateral femoral condylar articular cartilage injuries ± osteochondral/chondral intraarticular bodies
  - MPFL tears (must evaluate entirety of MPFL)

(Left) *Axial radiograph of the patella in a 16-year-old boy with a recent transient patellar dislocation (TPD) shows an osseous fragment ⇨ adjacent to the medial patella with irregularity ⇨ of the entire medial facet.* **(Right)** *Axial T2 FS MR (superior on the left, inferior on the right) in the same patient shows bone contusions ➡ of the lateral femoral condyle & medial patella. There is also full-thickness articular cartilage loss of the medial patellar facet ⇨ with an associated intraarticular osteochondral body ⇨.*

(Left) *Frontal & lateral radiographs in a 14-year-old boy with a recent TPD show a large osseous fragment in the anterior knee joint ➡ with an associated lucency in the lateral femoral condyle ⇨. A lipohemarthrosis is also present ⇨.* **(Right)** *Coronal T2 FS (left) & sagittal PD (right) MR images in the same boy confirm a displaced, rotated osteochondral fracture fragment ➡ in the anterior aspect of the joint with a donor site ⇨ at the lateral femoral condyle.*

TERMINOLOGY

Abbreviations

- Transient patellar dislocation (TPD)

Definitions

- Lateral dislocation of patella from direct/indirect injury
- Dislocation/relocation → shearing, tensile, & compressive forces → injuries of medial patella, lateral femur, & soft tissues

IMAGING

General Features

- Best diagnostic clue
  - Radiographs
    - Large hemarthrosis
    - Patellar or femoral osseous/osteochondral fragments
  - MR
    - Medial patella & lateral femoral condyle contusions
    - Patellar & femoral osteochondral injuries
    - Medial patellofemoral ligament (MPFL) tear
- Morphology
  - Predisposing anatomic abnormalities of knee
    - Trochlear dysplasia, lateral patellar subluxation/tilt, patella alta, & tibial tubercle lateralization
  - MPFL is normally dark, linear, oblique band extending from medial distal femur to superior 2/3 of patella

Radiographic Findings

- Large joint effusion after acute TPD
- Osseous fragments
  - Medial patellar osseous avulsion (at MPFL attachment)
  - Patellar & femoral osteochondral fracture fragments from dislocation/relocation
- Importance of axial view of patella (e.g., Merchant, sunrise)
  - Avulsion & osteochondral fragments at medial patella
  - Patellar articular surface irregularities
  - Medial soft tissue swelling
- Patella typically relocates prior to radiographs

MR Findings

- T1WI
  - Bone contusions: Poorly defined ↓ marrow signal in medial patella & lateral femoral condyle
- T2WI FS
  - Bone contusions: Poorly defined ↑ marrow signal in medial patella & lateral femoral condyle
  - MPFL injury can occur at femoral or patellar attachments, midsubstance, or multiple sites
    - Grade 1/sprain: ↑ signal about ligament
    - Grade 2/partial tear: Intrasubstance ↑ signal, partial fiber discontinuity
    - Grade 3/complete tear: Complete fiber discontinuity
    - Chronic tears
      - Focal or diffuse attenuation of MPFL
  - Vastus medialis obliquus (VMO) muscle tears
  - Chondral abnormalities
    - Cartilage injury: Range from softening (↑ signal but normal morphology) to partial- or full-thickness defects
    - Osteochondral fractures
    - Displaced chondral & osteochondral fragments → intraarticular bodies
      - Often laminar in appearance from layered structure of cartilage & subchondral bone
  - Joint effusion
    - Hemarthrosis may be evident with hematocrit layer
    - Lipohemarthrosis is seen with osteochondral fractures
- Patella alta
  - Traditionally defined on radiographs
    - Insall-Salvati index = patellar tendon length (TL)/patella length (PL) → > 1.2 considered patella alta
  - Proposed MR criteria
    - Measured on single midsagittal image
    - Length of inner patellar tendon (TL)/anteroinferior to posterosuperior edge of patella (PL)
    - Ratios change during range of skeletal maturity
      - Values not definitively established in children
      - Some authors propose MR ratio > 1.3 in children
- Trochlear dysplasia
  - Lateral trochlear inclination (of femur)
    - Shallow lateral inclination predisposes to TPD
    - Angle between lines along subchondral bone of lateral trochlea & posterior aspect of femoral condyles on axial image
    - Inclination angle < 11° = trochlear dysplasia
  - Trochlear facet asymmetry (of femur)
    - On axial image 3 cm above tibiofemoral joint, ratio of length of medial facet:lateral facet x 100%
    - Facet ratio < 40% = trochlear dysplasia
  - Trochlear depth (of femur)
    - Measured on axial image 3 cm above knee joint
    - Reference line drawn along posterior femoral condyles
    - AP measurements are made perpendicular to posterior condylar line for largest AP dimensions of medial (A) & lateral (B) trochlear facets & deepest trochlear sulcus (C)
    - Trochlear depth = [(A+B)/2] - C
    - Trochlear depth ≤ 3 mm = trochlear dysplasia
- Tibial tubercle to trochlear groove (TT-TG) distance
  - Transverse distance from anterior-most osseous tibial tubercle to trochlear groove (deepest osseous portion)
    - Measurement of lateral offset of extensor mechanism
  - Mark anterior-most tibial tubercle on inferior image
  - Scroll to superior slice with deepest trochlea & mark position of tibial tubercle on this image
    - Posterior condylar line is drawn on this axial slice
  - Line perpendicular to posterior condylar line is drawn between marks for
    - Deepest portion of osseous trochlea
    - Position of tibial tubercle
  - Distance between these lines = TT-TG distance
  - TT-TG distance varies with age; general guideline
    - Normal < 15 mm, borderline 15-20 mm, abnormal > 20 mm
- Patellar tendon to trochlear groove (PT-TG) distance
  - Measurement of lateral offset of extensor mechanism developed specifically on MR, where soft tissue & cartilage landmarks can be seen
  - Similar but not equivalent to TT-TG distance

- Center of patellar tendon (PT) (on superior-most axial slice of tibial attachment) is used as distal landmark rather than tibial tubercle
- Deepest portion of cartilaginous (vs. osseous) trochlea is used as proximal landmark for TG location
- PT-TG vs. TT-TG distances may differ ≥ 4 mm in same individual
- PT-TG distance has better inter- & intraobserver reliability

- Postoperative: MPFL reconstructions
  - Normal graft: Low signal intensity with intact fibers
    - Continuous, taut, & oriented as native MPFL
  - Graft tear: Intrasubstance ↑ signal on T2 FS MR + partial or complete disruption of fibers

DIFFERENTIAL DIAGNOSIS

Dorsal Patellar Defect

- Well-defined lucent lesion in superolateral aspect of patella
- Location & appearance distinguish from fracture

Bipartite/Multipartite Patella

- Typical fragmentation at superolateral aspect of patella
- Location & appearance distinguish from fracture

PATHOLOGY

Gross Pathologic & Surgical Features

- Condensations of medial patellar retinaculum form complex of medial patellar retinacular ligaments
  - MPFL is most important
    - Strongest passive medial stabilizer of patella
      - Considerable variation in size & thickness of MPFL in normal individuals
    - Contributes up to 60% of medial restraining force on patella
    - Broader patellar attachment: Superomedial patella deep to fibers of VMO, creating bilaminar appearance on axial MR images
    - Narrower femoral attachment: Most often described between adductor tubercle & medial epicondyle on anatomic studies
  - Other condensations of medial patellar retinaculum include: Medial patellotibial ligament & medial patellomeniscal ligament
    - Growing realization of importance of medial patellotibial ligament for patellar tracking

CLINICAL ISSUES

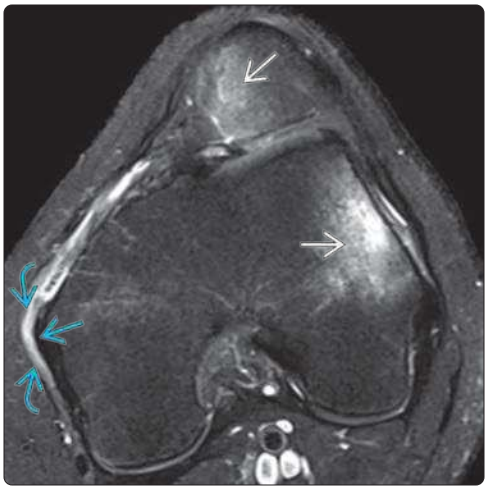
Presentation

- Most common signs/symptoms
  - Knee giving way, swelling, tenderness along medial retinaculum, sensation of impending dislocation with manual pressure upon patella
  - Patellar dislocation is clinically occult in 45-73% of cases
    - Due to transient nature of process, patients are frequently unaware that patella has dislocated
- Clinical profile
  - May occur from direct or indirect injuries
  - Persons who dislocate with less forceful injuries typically have more predisposing factors
  - Predisposing factors may be congenital or acquired
    - Osseous factors
      - Patella: Alta, lateral subluxation/tilt, dysplasia
      - Trochlear dysplasia: ↓ depth, ↓ lateral inclination
      - Lateralization of tibial tubercle
    - Soft tissue factors
      - Deficiency/absence of medial retinacular complex
      - Hypoplasia of vastus medialis muscle
      - Tight lateral retinaculum
      - Generalized ligamentous laxity (e.g., Ehlers-Danlos or Marfan syndrome)
  - True congenital dislocation is rare & frequently associated with syndromes

Demographics

- Epidemiology
  - Overall incidence of 1st-time TPD = 5.8/100,000
  - In 10- to 17-year-olds, incidence ↑ to 29/100,000

Natural History & Prognosis



- After single episode of TPD
  - 50% of patients have persistent anterior knee pain
  - 15-40% have recurrent TPD (after conservative management of initial episode)
- After 2nd TPD, chance of recurrence ↑ to 50%
- Recurrent dislocations ↑ risk for persistent symptoms & degenerative changes

Treatment

- Treatment of acute TPD is controversial
- Conservative management is considered if
  - No osteochondral injury
  - Patella is stable on clinical exam
  - No more than partial injury to medial patellar stabilizers
- Conservative management
  - Patellar-stabilizing orthotic & early mobilization
  - Physical therapy to strengthen medial patellar stabilizers
- Surgical management is indicated for
  - 1st-time TPD with intraarticular bodies or major tear of medial stabilizers
  - Recurrent TPD
- Surgical procedures (performed alone or in combination)
  - Lateral retinacular release
  - MPFL repair or reconstruction
    - Reconstruction: Single or double graft fixed to medial distal femur & medial patella
  - Growing interest in medial patellotibial ligament reconstruction (with MPFL reconstruction)
  - Distal realignment procedure
    - Tibial tubercle repositioning medial &/or distal

(Left) *Axial T2 FS MR in a 17-year-old boy with a recent TPD shows medial patella & lateral femoral condyle bone contusions. There is ↑ signal at the MPFL femoral attachment with complete disruption of the fibers. Note the normal MCL attachment deep to the torn MPFL.* **(Right)** *Tunnel radiograph in a 12-year-old girl who was splinted immediately after a knee injury shows lateral dislocation of the patella. Typically, the patella reduces spontaneously with knee extension prior to radiographic evaluation.*

(Left) *Axial T2 FS MR (inferior on the left, superior on the right) in the same girl shows bone contusions in the lateral femoral condyle & medial patella with tearing of the MPFL throughout its course.* **(Right)** *AP & lateral radiographs in a 15-year-old girl with prior patellar dislocations show findings of MPFL reconstruction & tibial tubercle repositioning. The MPFL graft loops through a patellar tunnel & is fixed to the medial femur with an interference screw. Two screws fix the medially repositioned tibial tubercle.*

(Left) *Axial radiograph in the same girl shows the patellar tunnel through which the MPFL graft is looped. The femoral interference screw & tibial tubercle screws are also seen.* **(Right)** *Axial PD MR (clockwise superior to inferior from the upper left) in the same patient shows the MPFL graft within the patellar tunnel extending posteriorly in an oblique course (similar to the native MPFL). The graft has normal low signal intensity & is fixed in a femoral tunnel with an interference screw.*

Patellar Sleeve Avulsion

KEY FACTS

TERMINOLOGY

- Avulsion injury of patellar pole in skeletally immature
- Small bone fragment & larger sleeve of unossified "epiphyseal" cartilage are avulsed from patella at
  - Inferior pole by patellar tendon (more common)
  - Superior pole by quadriceps tendon (less common)
- **Not** periosteal sleeve avulsion (as patella has no periosteum)

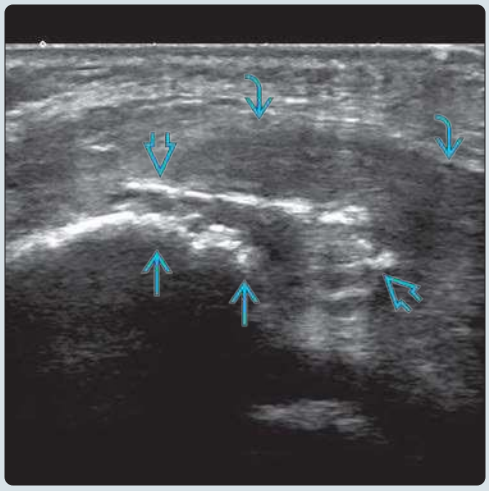
IMAGING

- Radiographs
  - Inferior pole: Small, ossific fragment is displaced distally from irregular inferior pole, ± patella alta
  - Superior pole: Small, ossific fragment is retracted proximally from irregular superior pole, ± patella baja
  - Either site: Lax quadriceps &/or patellar tendons, soft tissue swelling, ± joint effusion
  - Extent of patellar injury & degree of fragment displacement are underestimated by radiographs alone
- Ultrasound & MR reveal larger sleeve of unossified cartilage surrounding displaced bony fragment
  - With minimal displacement, fluid signal intensity in fracture cleft stands out against darker unossified "epiphyseal" cartilage on fluid-sensitive MR sequences

TOP DIFFERENTIAL DIAGNOSES

- Normal variant ossification
- Sinding-Larsen-Johansson syndrome
- Tibial tubercle avulsion
- Isolated tendon rupture

CLINICAL ISSUES



- Peak incidence: 12-13 years; range: 8-16 years
- Sudden pain with "explosive force" (such as jumping) or fall
- Clinical findings: Swelling, extensor lag, palpable defect
- Treatment: Restore extensor mechanism function
  - Immobilization if minimally displaced (< 2-3 mm)
  - Open reduction, internal fixation is otherwise required

(Left) *Lateral radiograph in a 10-year-old girl after a fall shows ossific irregularity at the inferior pole of the high-riding patella (alta). The avulsed irregular ossific fragments remain attached to the proximal patellar tendon.* **(Right)** *Sagittal T2 FS MR in the same patient shows interruption of the low signal intensity unossified "epiphyseal" cartilage at the inferior pole of the superiorly retracted patella. An avulsed osteochondral sleeve remains attached to the patellar tendon.*

(Left) *Lateral radiograph of the right knee in a 10-year-old boy after a fall shows elevation of the patellar ossification center with irregularity of the inferior pole. Several small, ossific fragments are retracted distally by the patellar tendon.* **(Right)** *Longitudinal ultrasound in the same patient confirms retraction of the osteocartilaginous fragments from the irregular inferior patellar pole by the patellar tendon, consistent with a patellar sleeve avulsion fracture.*

KEY FACTS

IMAGING

- Fragment of largely ossified but unfused anterior tibial tubercle is retracted proximally &/or rotated superiorly
- Many variables, including fragment size & shape, degree of comminution & displacement, pattern of extension
- Adjacent soft tissues may become entrapped

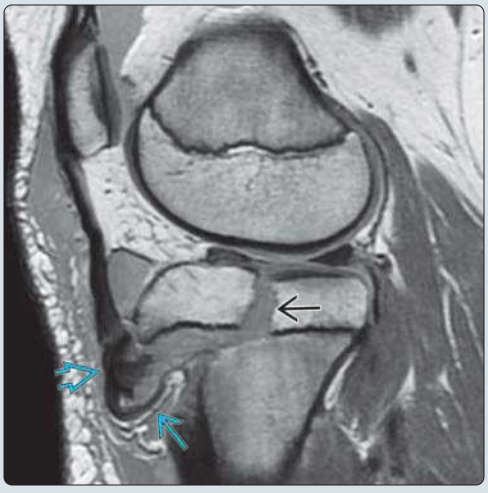
TOP DIFFERENTIAL DIAGNOSES

- Normal ossification variant
- Osgood-Schlatter disease
- Patellar sleeve avulsion fracture
- Patellar tendon rupture

PATHOLOGY

- Predisposing anatomy
  - Portion of physis deep to tibial tubercle ossification center is uniquely composed of strong fibrocartilage
  - As patient nears physeal closure, this growth plate converts to weaker hyaline cartilage
  - Timing coincides with ↑ muscle strength & athletic activity
- Prior Osgood-Schlatter disease in 25-31%
- Mechanisms include forceful quadriceps contraction with extension (i.e., jumping), passive knee flexion during quadriceps contraction (i.e., landing), or direct blow
- Associated injuries: Tears of patellar tendon, ACL, menisci
  - Anterior compartment syndrome in 2-20%

CLINICAL ISSUES



- Vast majority: Boys 11-17 years old
- Presentations include swelling, tenderness, knee held in flexion with inability to fully extend actively
- Nonoperative management for minimally displaced fractures limited to distal tibial tubercle
- Open reduction, internal fixation is otherwise required to
  - Restore extensor mechanism alignment
  - Establish congruence of articular surface of tibia

(Left) *Lateral radiograph in a 14-year-old boy after a jumping injury shows marked retraction & rotation of the avulsed tibial tubercle. There is intraarticular extension of the fracture plane with a moderate joint effusion. The findings are typical of an Ogden type III fracture.* **(Right)** *Sagittal bone CT in the same patient with a tibial tubercle avulsion better demonstrates the degree of articular surface distraction than radiographs.*

(Left) *Lateral knee radiograph in a 15-year-old boy after a fall shows mild widening & irregularity of the growth plate deep to the tibial tubercle with posterior extension to the proximal tibial physis & metaphysis as a Salter-Harris II fracture (modified Ogden type IV).* **(Right)** *Sagittal PD MR in a 15-year-old boy after a fall shows avulsion of a tibial tubercle fragment. The fracture extends proximally with a Salter-Harris III configuration. Stripped distal periosteum is entrapped in the fracture.*

Trampoline Fracture

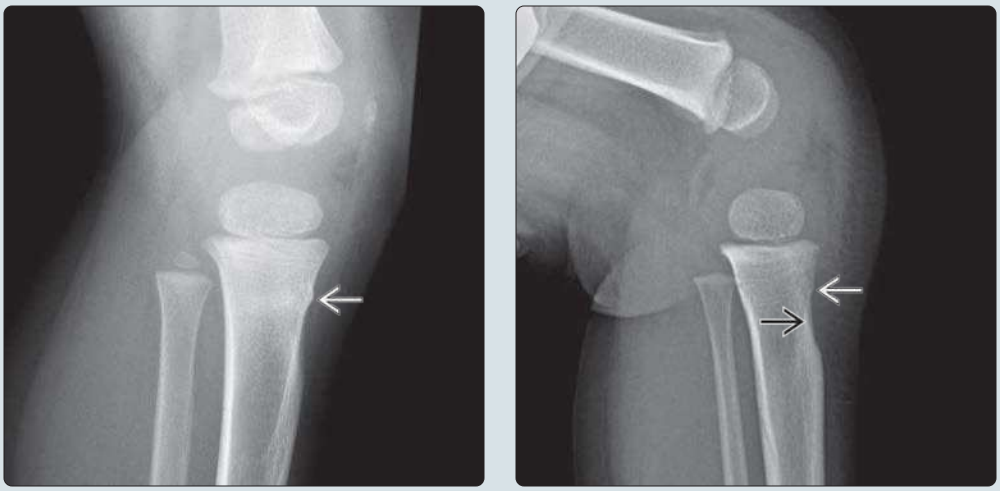
KEY FACTS

TERMINOLOGY

- Proximal tibial impaction fracture seen in young children (2-5 years of age), incurred on bouncing surface

IMAGING

- Focal cortical buckling/convexity/disruption
  - More likely in younger child: Focal convexity is superimposed on normally smooth, concave proximal tibial metadiaphysis at site of unossified tibial tuberosity on lateral view
  - Exaggerates anterior tibial "scoop" (may be very subtle)
- Transverse/oblique fracture lucency may extend to physis
  - Salter-Harris II fracture in ~ 11%
  - More likely in older child
- Anterior tilt of proximal tibial physis
- May be initially occult → healing on follow-up in 7-10 days



PATHOLOGY

- Hyperextension injury & axial loading on bouncing surface
  - Often occurs when bouncing with larger individual
    - Recoil of mat as larger individual goes up, impacts foot of child coming down
  - ↑ risk with multiple bouncers
  - Surface: Trampoline >> inflatable bouncer > bed

CLINICAL ISSUES

- Beware of misleading history: Direct impact or fall is often reported, but fall typically occurs after fracture
- ↑ incidence in recent decades due to home trampolines & indoor trampoline parks
- Generally good outcomes with immobilization for 4-6 weeks
- Risk of late valgus deformity with proximal tibial fractures (Cozen phenomenon)
  - Valgus overgrowth over course of up to 18-24 months
  - Usually spontaneously resolves
  - Recent evidence suggests relatively low-impact, nondisplaced trampoline fracture may not be at risk

(Left) *Lateral radiograph of the knee in a 3-year-old with pain after jumping on a trampoline shows buckling of the anterior proximal tibia, consistent with a nondisplaced trampoline fracture. The anterior proximal tibia normally has a smooth, concave contour at this age.* **(Right)** *Lateral knee radiograph in a 2-year-old after a trampoline injury demonstrates cortical buckling in the anterior proximal tibia, exaggerating the normal anterior tibial "scoop". There is also adjacent soft tissue swelling.*

(Left) *AP & lateral radiographs of the knee in a 4-year-old with leg pain after jumping on a trampoline with their father show irregular contour of the anterior proximal tibia. A subtle oblique fracture lucency is also seen with extension toward the physis.* **(Right)** *Follow-up radiographs in the same patient 4 weeks after the injury demonstrate healing with sclerosis along the fracture plane. Extension to the physis is evident.*

KEY FACTS

TERMINOLOGY

- Toddler's fracture: Nondisplaced spiral fracture of tibial diaphysis in newly ambulatory child
- Synonym: Childhood accidental spiral tibial (CAST) fracture
- "Toddler's fracture" is sometimes applied to other low-energy lower extremity fractures in young child (such as cuboid)

IMAGING

- Spiral or oblique fracture of mid/distal tibial diaphysis ± metaphysis
  - Fibula is intact
- Nondisplaced or minimally displaced
- May be best seen on oblique view
- Radiographically occult in up to 39%
  - Follow-up radiographs show healing change
- Ultrasound: Cortical disruption, hypoechoic subperiosteal hematoma

PATHOLOGY

- Axial loading &/or torsional forces
- Typically from low-energy injury, often goes unrecognized
  - Fall or twisting while walking
  - Also described with foot caught on slide, especially when riding on adult's lap

CLINICAL ISSUES

- Ambulatory child 9 months to 4 years of age
- Presentation: Refusal to bear weight, limp
- Isolated toddler's fracture in ambulatory child should not raise concern for child abuse
  - Lack of known injury is common
- Treatment: Immobilization with cast (short vs. long leg), walking boot, or long leg splint
  - Symptomatic follow-up without radiographs may be sufficient
  - Presumptive treatment is employed for high clinical suspicion despite negative radiographs

(Left) *AP & lateral radiographs of the tibia & fibula in a 20-month-old with pain after a fall while walking show a thin lucency ➡ in the distal tibial diaphysis, consistent with a nondisplaced spiral fracture. Mild overlying soft tissue swelling is seen in this child but is not reliably present.* **(Right)** *AP & lateral radiographs in a 2-year-old with pain after a twisting injury on a playground slide show a nondisplaced spiral fracture of the mid & distal tibial diaphysis ➡.*

(Left) *Frontal radiograph in a 16-month-old after a fall does not demonstrate a visible fracture line. Normal structures that may mimic a fracture line include superimposed intermuscular fat planes ⇨ & nutrient canals.* **(Right)** *Follow-up radiographs in the same patient 14 days later show healing with periosteal reaction ➡ & sclerosis ⇨. Oblique views may be used to improve sensitivity if initial radiographs are negative in the setting of high clinical suspicion.*

Triplane Fracture

KEY FACTS

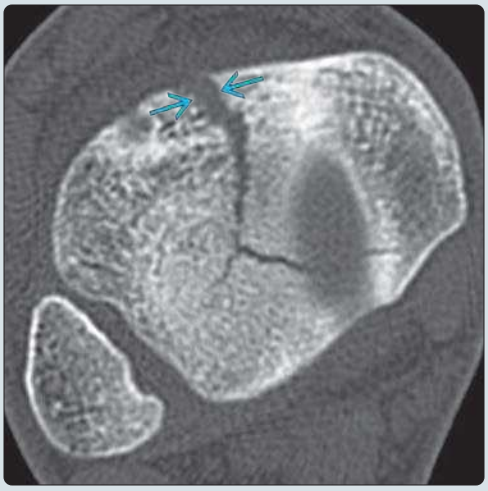
IMAGING

- Distal tibial fracture in 3 planes; may be true Salter-Harris IV (SH IV) or combinations of SH II & III
- Classic triplane fracture pattern
  - Oblique coronal fracture plane through posterior distal tibial metaphysis & diaphysis
  - Transverse fracture plane through physis (growth plate)
  - Sagittal fracture plane through epiphysis
    - Extension to tibial plafond (intraarticular) vs. medial malleolus (intra- or extraarticular)
- Oblique coronal plane of metaphysis/diaphysis may be hidden on lateral radiograph if nondisplaced & overlapping tibial-fibular interface
- CT is more accurate for determining course & comminution of fracture, amount of displacement, articular surface involvement, & presence of free intraarticular fragments

PATHOLOGY

- Triplane fracture occurs around time of earliest physeal closure, which has unique pattern in distal tibia
  - Earliest fusion at anteromedial tibial physis (Kump bump)
  - Affects planes of fracture extension
- Rapariz triplane fracture classification: Variations of 2-, 3-, or 4-part fractures for 6 possible subtypes

CLINICAL ISSUES



- 5-10% of pediatric intraarticular ankle fractures
- Typically affects adolescents within 18 months of tibial growth plate closure (12-15 years old)
- Nonoperative treatment
  - ≤ 2 mm of displacement
  - Extraarticular fractures
- Operative treatment
  - > 2 mm of articular step-off or distraction
- Complications: Growth arrest, pain, degenerative joint changes

(Left) *AP radiograph shows a triplane fracture ➡ with extension through the tibial epiphysis into the joint space & along the lateral physis. A tiny posterior metaphyseal fragment was also present (not shown).* **(Right)** *Sagittal bone CT in a 2-part triplane fracture shows a widened oblique coronal fracture plane along the posterior tibial metaphysis with extension across the anterior physis, creating a single posterolateral fragment ➡.*

(Left) *Axial bone CT in a 15-year-old shows the predominantly sagittal fracture plane through the distal tibial epiphysis. In many cases, this plane allows the most accurate assessment of the articular surface distraction ➡, which is a key determinant for treating with a closed vs. open reduction.* **(Right)** *Coronal bone CT in a 13-year-old who sustained an ankle injury after falling from a scooter shows an extraarticular intramalleolar triplane fracture variant ➡.*

TERMINOLOGY

Synonyms

- Adolescent triplane fracture, transitional injury

IMAGING

General Features

- Best diagnostic clue
  - Complex fracture of adolescent distal tibia involving metaphysis, physis, & epiphysis
    - Fracture components in transverse, sagittal, & coronal planes
- Location
  - Classic triplane fracture pattern
    - Coronal fracture plane through posterior distal tibial metaphysis & diaphysis
    - Transverse fracture plane through physis (growth plate)
    - Sagittal fracture plane through epiphysis
      - Extension to tibial plafond (intraarticular) vs. medial malleolus (intra- or extraarticular)
- Morphology
  - Distal tibial growth plate closes in predictable unique pattern: Begins in anteromedial tibial physis at Kump bump
    - Injury at time of early closure affects planes of fracture extension

Radiographic Findings

- Distal tibial fracture in 3 planes; may be true Salter-Harris IV (SH IV) or combinations of SH II & III
  - Oblique coronal plane of metaphysis/diaphysis may be hidden on lateral view if it is nondisplaced & overlaps tibial-fibular interface
- Fibular fracture in 50%
- Soft tissue swelling & joint effusion

CT Findings

- Bone CT
  - Axial with sagittal & coronal reformations, ± 3D
  - More accurate than radiographs for determining course & comminution of fracture, amount of displacement, articular surface involvement, & presence of free intraarticular fragments
  - Axial fracture line may be helpful in determining optimal screw orientation for reduction

PATHOLOGY

General Features

- Mechanism: External rotation

Staging, Grading, & Classification

- Rapariz triplane fracture classification: Variations of 2-, 3-, or 4-part fractures for 6 possible subtypes
  - 2-part fracture: Most common
    - True SH IV fracture
    - Either medial or lateral
  - 3-part fracture: Combination of fractures: SH II (AP view) & SH III (lateral view)
    - ± separation at Kump bump
  - 4-part fracture: Combinations of above
- 2- or 3-part intramalleolar variant
  - Depending on fracture line extension, fracture may be intra- or extraarticular
    - Type I: Intraarticular at junction of medial malleolus & tibial plafond
    - Type II: Intraarticular outside weight-bearing zone of plafond
    - Type III: Extraarticular

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain
  - Swelling
  - Inability to bear weight
- Other signs/symptoms
  - Bruising
  - Associated fibular fracture in ~ 50% of patients

Demographics

- Age
  - Adolescent within 18 months of tibial growth plate closure
    - 12-15 years old
      - Males: 15-16 years old
      - Females: 13-14 years old
  - 2-part triplane fractures occur in younger children than 3-part triplane fractures
- Sex
  - M > F
- Epidemiology
  - 5-10% of pediatric intraarticular ankle fractures

Treatment

- Nonoperative treatment
  - ≤ 2 mm of displacement or extraarticular
  - Most 2-part fractures
  - Closed reduction with internal rotation of foot
    - Immobilization & long leg cast
- Operative treatment
  - > 2 mm of articular surface distraction or step-off
  - Most 3-part fractures
  - Internal fixation with screws, percutaneous K-wires

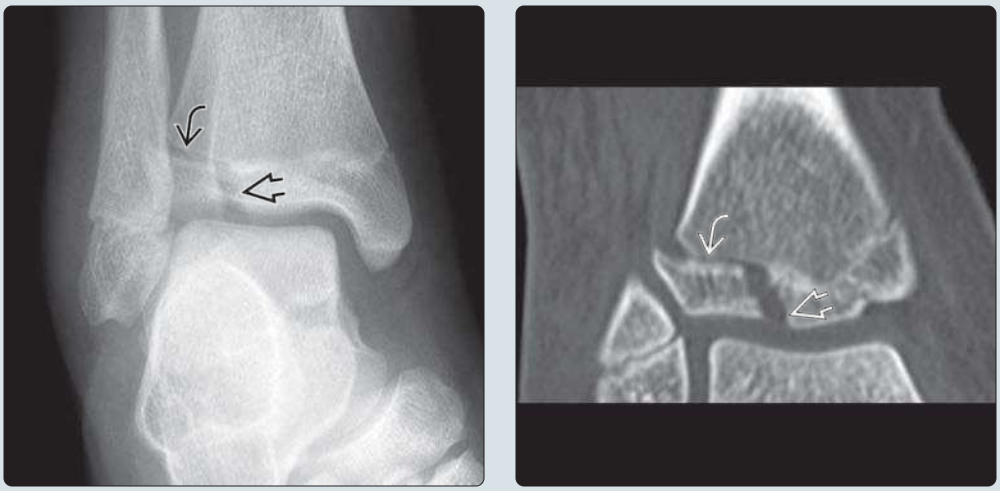
Juvenile Tillaux Fracture

KEY FACTS

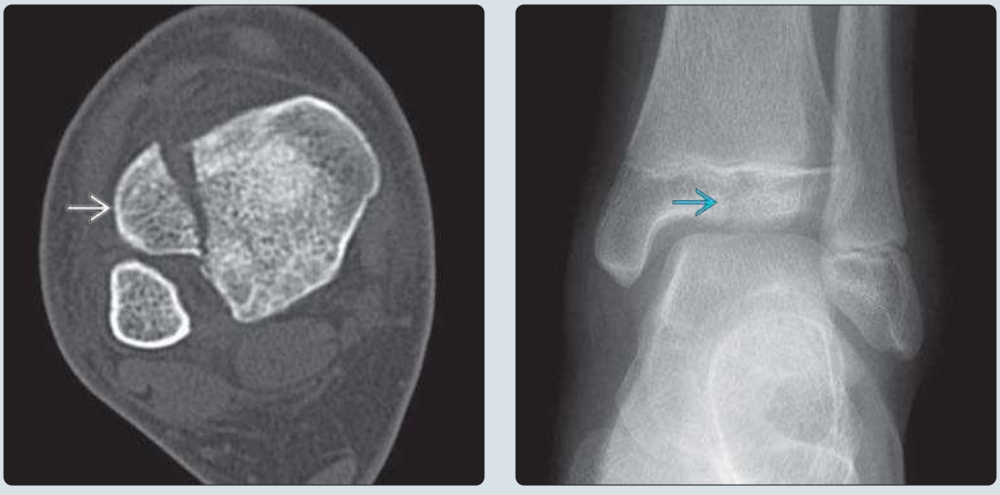
IMAGING

- Salter-Harris III fracture of anterolateral distal tibial physis & epiphysis
  - Sagittal fracture component extending through epiphysis to tibiotalar joint
  - Widening of physis anterolaterally
- Occurs after fusion of central & medial physis but before anterolateral physis closes
  - Avulsion of anterolateral tibial epiphyseal fragment by anterior inferior tibiofibular ligament
  - Ligament usually remains intact
- Radiographs are typically diagnostic
  - Often best seen on mortise view
- CT is obtained to assess articular surface distraction (> 2 mm necessitates operative fixation)
  - Reformatted images in 3 planes are essential to fully characterize fracture



CLINICAL ISSUES

- 3-5% of pediatric ankle fractures
- Affects adolescents < 18 months from complete distal tibial growth plate closure
  - Age range: 12-15 years old
  - Median age: 12 years in females, 14 years in males
- Nonoperative treatment with fracture displacement < 2 mm
- Internal fixation with screws & K-wires for articular surface fracture displacement > 2 mm
  - Anatomic reduction at articular surface is required to restore joint function, prevent premature degeneration
- Subsequent growth disturbance is rare as majority of physis has already closed



DIAGNOSTIC CHECKLIST

- Differentiate from triplane fracture
  - Salter-Harris IV fracture with coronal metadiaphyseal fracture plane

(Left) *AP radiograph of the right ankle in a 13-year-old patient after a trampoline injury shows a Salter-Harris III fracture of the distal tibia. The fracture extends horizontally through the lateral physis & vertically through the epiphysis to the articular surface, typical of a juvenile Tillaux fracture.* **(Right)** *Coronal bone CT in the same patient demonstrates the physeal & epiphyseal fracture planes. The tibial articular surface gap is > 2 mm, requiring surgical fixation.*

(Left) *Axial bone CT in the same patient shows distraction & rotation of the anterolateral epiphyseal fracture fragment. This displacement is due to traction from the anterior inferior tibiofibular ligament.* **(Right)** *AP radiograph of the ankle in a 12-year-old girl after a fall shows the sagittal epiphyseal component of this juvenile Tillaux fracture. With only 1 mm of displacement at the articular surface, this fracture was successfully managed with closed reduction & casting.*

TERMINOLOGY

Synonyms

- Tillaux fracture

IMAGING

General Features

- Best diagnostic clue
  - Sagittal fracture plane through distal tibial epiphysis with widening of lateral physis ± displacement of anterolateral epiphyseal fragment
- Location
  - Anterolateral aspect of distal tibial physis & epiphysis

Radiographic Findings

- Salter-Harris III fracture of anterolateral distal tibial epiphysis
- ± lateral displacement of epiphyseal fracture fragment
- Soft tissue swelling ± joint effusion
- Often best seen on mortise view, may be obscured by distal fibula on AP view

CT Findings

- Obtained to assess articular surface distraction
  - > 2 mm necessitates operative fixation
- Reformatted images in 3 planes are essential to fully characterize fracture
  - Width & location of greatest distraction
  - Degree of vertical step-off
  - Presence of loose intraarticular fragments
  - May reveal radiographically obscured metaphyseal fracture in coronal plane → triplane fracture

Imaging Recommendations

- Best imaging tool
  - AP, lateral, & mortise/oblique radiographic views
  - Bone CT to determine articular surface distraction

PATHOLOGY

General Features

- Salter-Harris III fracture of distal tibia extending through open lateral aspect of partially closed physis
  - Distal tibial physeal closure: Central → medial → lateral
  - Transitional fractures = fractures that occur in partially closed physis
    - Juvenile Tillaux & triplane fractures
- Avulsion of anterolateral tibial epiphyseal fragment by anterior inferior tibiofibular ligament
  - Ligament usually remains intact
- Mechanisms of injury
  - External rotation & supination of foot
  - Medial rotation of leg on fixed foot

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Anterior &/or lateral ankle pain, tenderness
  - Lateral swelling, bruising
  - Inability to bear weight
- Other signs/symptoms
  - Limp, external rotation of foot

Demographics

- Age
  - Adolescents < 18 months prior to complete distal tibial growth plate closure
    - Most common 12-15 years
    - Median age: 12 years in females, 14 years in males
    - After closure of central & medial physis, but before lateral physis
- Sex
  - More common in girls (F:M = 4:1)
- Epidemiology
  - 3-5% of pediatric ankle fractures

Natural History & Prognosis

- Risk for premature degeneration with residual articular surface irregularity
- Subsequent growth disturbance is rare as majority of physis has already closed

Treatment

- Displacement < 2 mm at articular surface: Closed reduction + immobilization
- Displacement > 2 mm: Operative management
  - Internal fixation with screws & K-wires
    - Anatomic reduction at articular surface is required to restore joint function, prevent premature degeneration
  - Alternatively, percutaneous pinning ± arthroscopic assistance may be considered

DIAGNOSTIC CHECKLIST

Consider

- Differentiate from triplane fracture
  - Salter-Harris IV fracture with coronal metadiaphyseal fracture plane

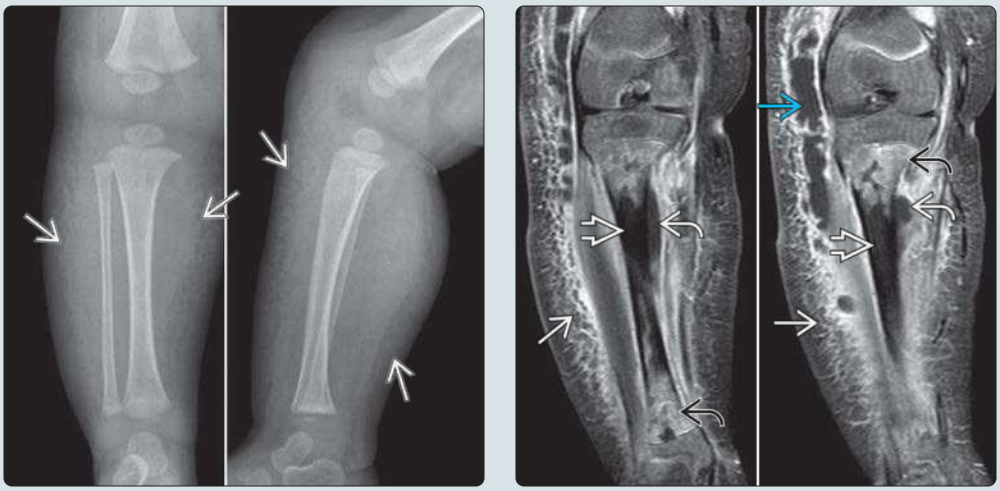
Osteomyelitis

KEY FACTS

IMAGING

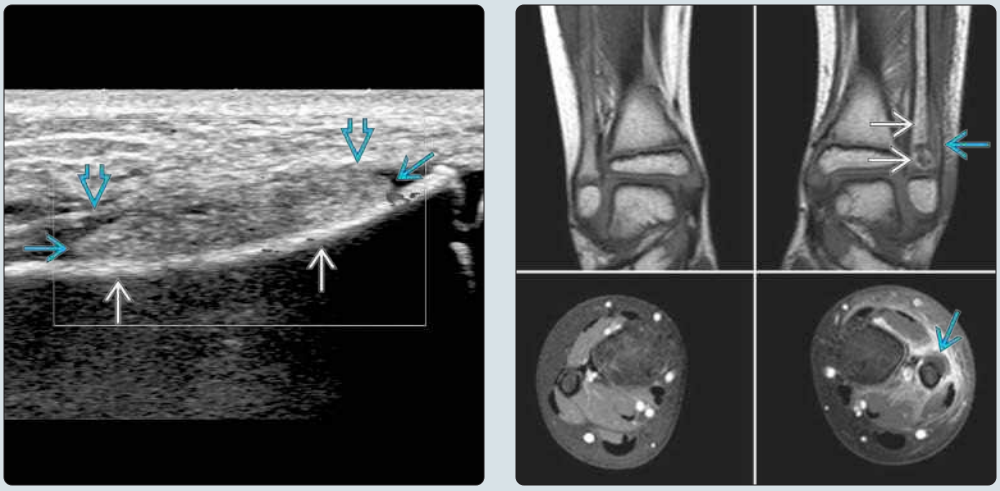
- Long bone metaphyses 70% (femur > tibia > humerus), short bones 6%, pelvis 5%, spine 2%
  - Metaphysis or equivalent > epiphysis, diaphysis
  - Multifocal in 10% overall but 22-55% in neonates
- Absence of radiographic bone findings does not exclude early osteomyelitis
  - Earliest finding: Soft tissue swelling next to bone
  - Bone destruction, periosteal reaction by 7-14 days
- MR: Best advanced imaging choice if diagnosis is unclear with localized symptoms or concern for complications
  - T1: Poorly defined metaphyseal marrow abnormality
  - T2 FS/STIR: Bright marrow, periosteal, & soft tissue edema; ± adjacent joint effusion
  - T1 C+ FS: Rim-enhancing abscesses (soft tissue, subperiosteal, intraosseous); ↓ enhancement of otherwise occult, unossified epiphyseal cartilage lesions in infants

TOP DIFFERENTIAL DIAGNOSES



- Ewing sarcoma
- Neuroblastoma metastases
- Langerhans cell histiocytosis
- Septic arthritis
- Bone infarct
- Leukemia
- Chronic recurrent multifocal osteomyelitis

PATHOLOGY



- Hematogenous source is most common
- *Staphylococcus aureus* > 80-90% of cases
  - Identification of infectious agent often fails despite blood cultures & site sampling

CLINICAL ISSUES

- Fever, pain, limp, tenderness, swelling
- Presentation is often nonspecific, may delay diagnosis
- Treat with IV then PO antibiotics + abscess drainage

(Left) *AP (left) & lateral (right) radiographs in a 9-month-old infant show extensive, subcutaneous edema of the lower leg with blurring of soft tissue planes ➡ but no discrete bony abnormality.* **(Right)** *Coronal T1 C+ FS MR images in the same patient show foci of marrow necrosis ➡ with adjacent ↑ enhancement ⇨ from infected or reactive viable marrow. Subperiosteal ➡ & soft tissue ⇨ fluid collections & overlying fat edema ➡ are noted in this patient with MRSA osteomyelitis.*

(Left) *Longitudinal color Doppler ultrasound in a 6-year-old with fever & lower extremity swelling shows an echogenic, avascular collection ⇨ that is lifting the periosteum ⇨ off of the cortex ➡.* **(Right)** *Coronal T1 (top) & axial T1 C+ FS (bottom) MR images in the same patient show heterogeneous marrow of the distal left fibula ➡ with a rim-enhancing subperiosteal abscess ⇨. Surrounding soft tissue edema is also noted in this patient with MSSA osteomyelitis.*

TERMINOLOGY

Definitions

- Osteomyelitis: Bone infection, most commonly bacterial
- Osteoarticular infection: Osteomyelitis &/or septic arthritis

IMAGING

General Features

- Best diagnostic clue
  - Radiographs: Nonspecific soft tissue edema in setting of limp, pain, swelling, &/or fever (< 7-10 days)
  - MR: Heterogeneous, poorly defined metaphyseal or metadiaphyseal marrow signal abnormalities + subperiosteal fluid & soft tissue edema
- Location
  - Long bone metaphyses 70% (femur > tibia > humerus), short bones 6%, pelvis 5%, spine 2%
    - Metaphysis or equivalent > epiphysis, diaphysis
      - Bone adjacent to growth cartilage (e.g., synchondrosis or apophysis) is considered metaphyseal equivalent
  - Multifocal in 10% overall but 22-55% in neonates

Radiographic Findings

- Absence of findings does not exclude early osteomyelitis
- Earliest finding: Soft tissue swelling next to bone
  - Displacement or obliteration of fat planes
  - Reticulation of subcutaneous fat
- Lytic bone lesion in 7-14 days (or longer) after onset
  - Vague lucency → permeation → destruction
- Periosteal reaction is seen by 7-14 days
- Epiphyseal displacement/separation may occur in infants
- Healing changes on follow-up may look bizarre due to extensive bone involvement &/or superimposed pathologic fracture (due to ↑ activity on weak bone)
- Subacute: Lucent lesion + sclerotic rim (Brodie abscess)
- Chronic: Sclerosis or mixed sclerotic/lucent foci
  - ± cloaca (lucent drainage tract through cortex)
  - ± sequestrum (radiodense necrotic bone)
  - Garré sclerosing osteomyelitis (thick cortex)

Ultrasonographic Findings

- Sensitive for drainable fluid collections
  - Joint effusions; soft tissue &/or subperiosteal fluid
- Cortical bone changes are rarely seen

MR Findings

- T1WI
  - Poorly defined, heterogeneous dark marrow (due to loss of normal fatty marrow signal)
  - Subperiosteal foci of bright fat (from cortical disruption & marrow lipocyte necrosis)
  - Penumbra sign (in subacute Brodie abscess): ↑ T1 signal rim of granulation tissue
- T2WI FS/STIR
  - Bright marrow + soft tissue edema
    - Soft tissue changes are usually moderate to marked
  - Discrete soft tissue & subperiosteal fluid collections
    - Elevated thin, dark periosteum
    - Disrupted dark cortex
  - ± adjacent joint effusion
    - Concomitant septic arthritis in up to 55%
      - Spread of infection to joint ↓ > 1-2 years of age
  - Chronic: Dark signal sclerotic sequestrum & involucrum
- T1WI C+ FS
  - ↑ marrow enhancement: Hyperemia/edema
  - ↓ marrow enhancement: Pressure necrosis, vessel thrombosis, pus
  - Rim-enhancing soft tissue & subperiosteal abscesses
  - Brodie abscess: Central nonenhancement (pus), inner rim of ↑ enhancement (granulation tissue), outer low signal rim (sclerosis)

Nuclear Medicine Findings

- Bone scan: ↑ uptake in angiographic, blood pool, & delayed phases: 80-94% sensitive
  - Positive in 24-72 hours; can demonstrate multiple sites
  - Central photopenia with bone infarct or abscess

Imaging Recommendations

- Best imaging tool
  - MR is most sensitive & specific modality for early infection with localized symptoms
    - Confirms diagnosis or delineates alternative processes
    - Shows drainable abscesses & intraspinal extension
  - Bone scintigraphy can be helpful if site & diagnosis are unclear (as less likely to require sedation than MR)
  - Whole-body MR is helpful for localizing multifocal, drainable collections in ill patient
- Protocol advice
  - T2 FS or STIR MR is crucial for edema/fluid detection
  - T1 C+ FS MR delineates drainable fluid & otherwise occult foci of epiphyseal cartilage involvement in infancy
    - Contrast is of questionable utility with otherwise normal study beyond 18 months of age

DIFFERENTIAL DIAGNOSIS

Ewing Sarcoma

- Aggressive lytic diaphyseal/metadiaphyseal lesion, most common in patients > 5 years old
- Sharply marginated interface of intramedullary tumor with normal fatty marrow on T1 MR; large, heterogeneously enhancing soft tissue mass with contrast

Neuroblastoma Metastases

- Aggressive but frequently subtle lytic lesions, most common in patients < 5 years old
- Calcified primary suprarenal/paraspinal tumor

Langerhans Cell Histiocytosis

- Punched-out, well-defined lytic lesions + enhancing mass
- Flat bones & spine are frequently involved

Septic Arthritis

- Effusion + enhancing, mildly thickened synovium
- Adjacent marrow & soft tissue edema favor infected joint

Bone Infarct

- Acute: Focal, poorly defined marrow edema with nonenhancement & mild, adjacent soft tissue changes
- Chronic: Serpentine medullary sclerosis on radiographs; MR shows characteristic double line sign (low/high T2 signal)

Leukemia

- Metaphyseal lucent bands &/or permeative lytic lesions in patients < 10 years old
- Diffuse marrow replacement on T1 MR is classic

Chronic Recurrent Multifocal Osteomyelitis

- Noninfectious, episodic bone inflammation
- Mixed bubbly, lucent, & sclerotic periphyseal lesions of femur, tibia; spine, pelvis, clavicle, & mandible also typical
- Multifocal, often symmetric sites of MR marrow edema on either side of physis, ± physeal widening

PATHOLOGY

General Features

- Pathophysiology
  - Hematogenous seeding >> penetrating injury or contiguous spread
    - After infancy, transphyseal vessels resolve
      - Avascular physis maintains relative barrier between epiphysis & metaphysis, making continuous epiphyseal & intraarticular spread less likely
      - Barrier is nonexistent in infants or after skeletal maturity → ↑ rates of septic arthritis
    - Slow flow through looping metaphyseal venules
      - Primary sites for bacterial lodging
    - Intramedullary infection → edema, vascular congestion → ↑ pressure → transcortical spread
    - Periosteal attachment is tight at physis, loose at metaphysis/diaphysis in children
      - Marked elevation by pus or tumor is possible
- Organisms
  - Identified in only 35-66% of needle aspirates, 36-55% of blood cultures
  - *Staphylococcus aureus* > 80-90% of cases (> 55% due to methicillin-resistant strains)
    - Panton-Valentine leukocidin: Necrotizing toxin secreted by some strains of MRSA or MSSA → more invasive infections
      - Persistent bacteremia despite IV antibiotics
      - ↑ rates of shock, septic emboli, deep venous thrombosis, & fluid collections requiring drainage
  - Streptococcus in ~ 10%: Group A β hemolytic, *S. pyogenes*, *S. pneumoniae*
  - Children 6 months to 4 years of age: *Kingella kingae*
    - Relatively ↓ bone & soft tissue reaction & ↑ epiphyseal cartilage lesions vs. other organisms
    - PCR is much more sensitive than culture
  - Neonates: MSSA (premature infants with multifocal infection), group B *Streptococcus* (term infants with single-site disease)
  - Sickle cell disease: *Salmonella* in children; *S. aureus* also reported in adults
  - Immunocompromised: *Streptococcus pneumoniae*, tuberculosis
  - Penetrating foot trauma: *Pseudomonas aeruginosa*
  - Purpuric rash, shock: Meningococcemia (severe infarctions → amputation; less severe → growth arrest)
  - Kitten exposure (cat-scratch disease): *Bartonella henselae*

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, ↓ range of motion, ↓ weight bearing, tenderness, swelling, fever
  - Minor trauma history in 1/3 of patients
- Labs: ↑ ESR, CRP > ↑ WBC
  - Higher inflammatory markers are more likely with disseminated than localized infection

Demographics

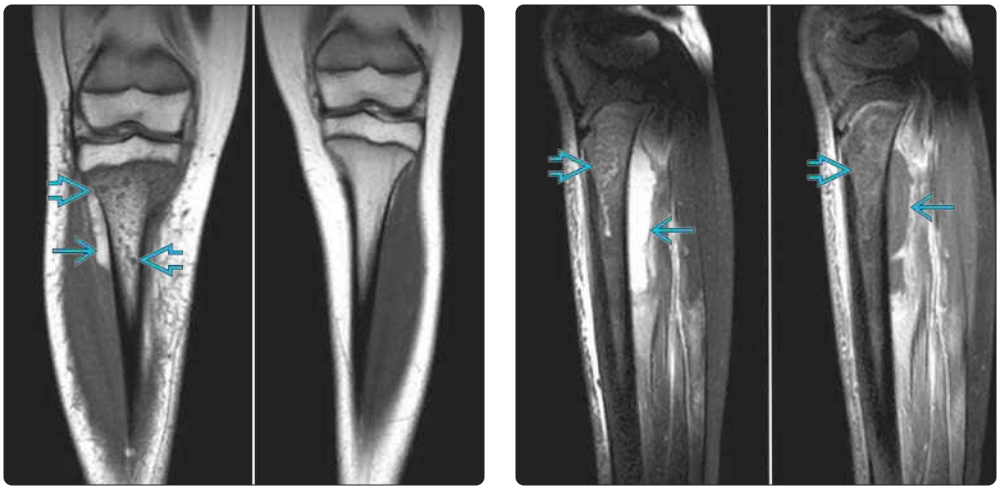
- Age
  - Primarily disease of infants & young children
    - 1/2 of cases occur before 5 years of age
- Epidemiology
  - Incidence has nearly tripled in USA in last several decades

Natural History & Prognosis

- Complications include septic arthritis, deep venous thrombosis, fracture, septic emboli, multisystem failure, growth disturbance
  - More likely with treatment delay of > 4 days

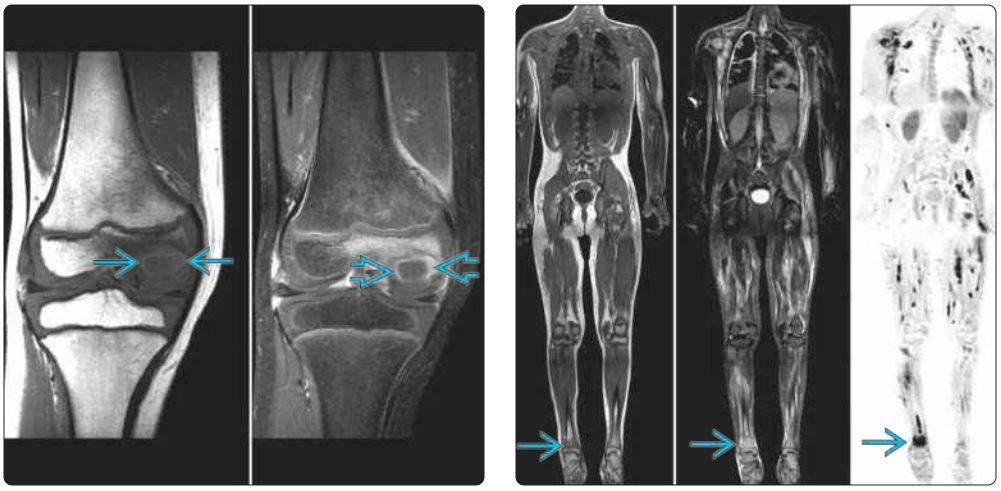
Treatment

- Identify infectious agent: Image-guided needle aspiration or open surgical biopsy + blood culture
- Antibiotics (IV followed by PO), pain management
  - Longer antibiotic therapy is required for multifocality
- Surgery/intervention: Abscess (intraosseous, subperiosteal, soft tissue) drainage, sequestrectomy, management of sinus tracts & pathologic fractures



DIAGNOSTIC CHECKLIST

Consider



- Immediate preoperative MR will require concurrent interpretation to facilitate single sedation (for imaging & surgery) in young children
- Imaging after treatment: Uncomplicated osteomyelitis may require 6 months for MR normalization
  - Nonspecific for ongoing bone infection vs. resolving inflammation/healing
  - Drainable collections can be sampled to guide therapy

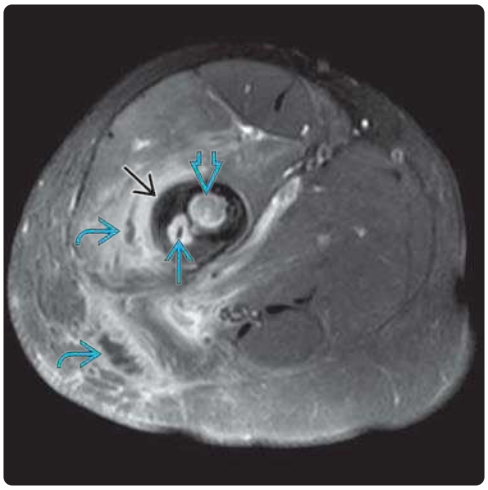
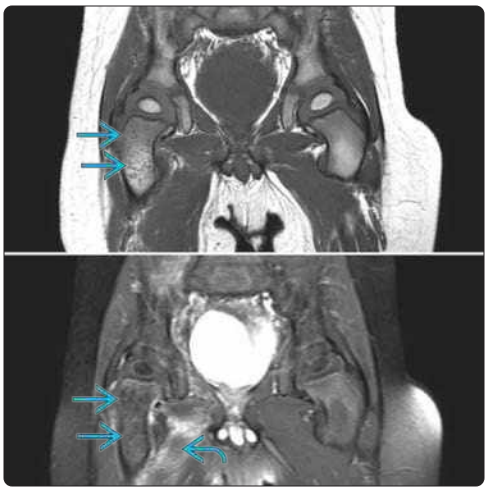
(Left) *Coronal T1 MR in an 11-year-old with 5 days of fever & leg swelling shows heterogeneous, "speckled" signal abnormalities in the proximal right tibia. Fat within an overlying subperiosteal collection is due to marrow lipocyte necrosis by PVL, an enzyme often associated with aggressive MRSA infections.* **(Right)** *Sagittal T2 FS (L) & T1 C+ FS (R) MR images in the same patient show the heterogeneous proximal tibial marrow & large subperiosteal abscess. MRSA was cultured at surgery.*

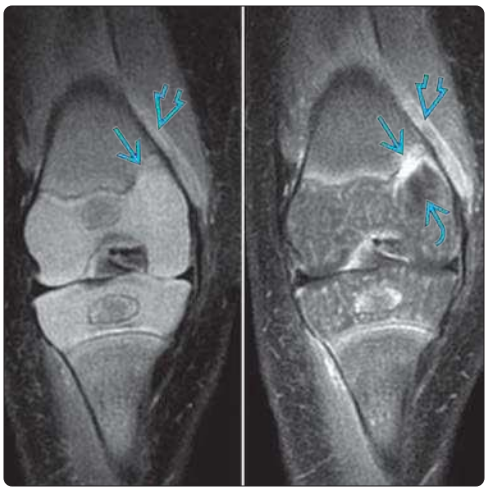
(Left) *Coronal T1 (L) & T1 C+ FS (R) MR images in a 5-year-old with 3 weeks of pain after an injury show a Brodie abscess of the medial femoral condyle with high T1 signal of granulation tissue along the abscess rim (the penumbra sign) that enhances after contrast.* **(Right)** *Coronal T1 (L), STIR (middle), & DWIBS (R) MR images in a 9-year-old with MRSA bacteremia & septic emboli show right distal tibial osteomyelitis, pulmonary nodules, & numerous foci of myositis & fasciitis with muscular abscesses.*

(Left) *Axial T1 C+ FS MR in a 7-year-old with septic emboli shows osteomyelitis of the left femoral neck & thrombus of the left common femoral vein. MSSA was grown from blood cultures in this patient.* **(Right)** *Sagittal STIR (L) & T1 C+ FS (R) MR images in a 19-day-old with MRSA septic emboli & known pelvic abscesses show diminished enhancement of the unossified proximal tibial epiphyseal cartilage due to infection. Note the lack of signal abnormality at this level on the STIR image.*



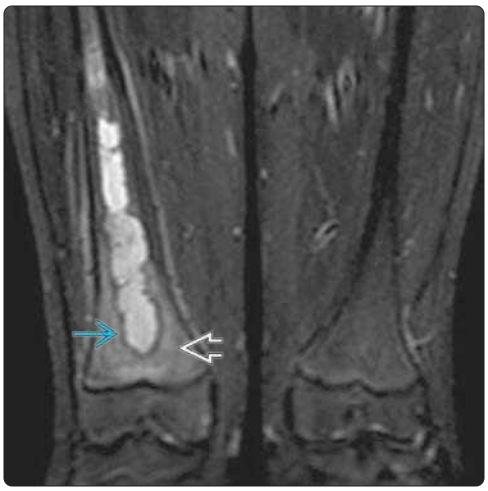
(Left) *Coronal ultrasound of the proximal right humerus in a 5-month-old boy shows a subperiosteal fluid collection with disruption of the metaphyseal cortex & disturbed underlying medullary echotexture. Compare the normal left humeral sonographic architecture.* **(Right)** *Coronal STIR MR of the same patient with osteomyelitis shows abnormal fluid signal throughout the right humerus + a nondisplaced, pathologic metaphyseal fracture. A subperiosteal fluid collection is noted.*





(Left) *Lateral radiograph in an 11-year-old with 3 weeks of thigh pain & swelling shows eccentric intramedullary lucencies with overlying cortical thickening & subtle aggressive periosteal reaction.* **(Right)** *Axial T1 C+ FS MR in the same patient shows a sequestrum with surrounding involucrum & marrow signal abnormalities. A cloaca was visible superior to this level (not shown). Note the overlying soft tissue abscesses. MSSA grew from cultures in this case of chronic osteomyelitis.*

(Left) *Coronal T1 (top) & T1 C+ FS (bottom) MR images in a 1-year-old with fever & a limp show abnormal, poorly defined marrow heterogeneity of the proximal right femur with surrounding soft tissue edema, typical of osteomyelitis.* **(Right)** *Coronal PD FS (L) & T1 C+ FS (R) MR images in a neonate with femoral osteomyelitis show focal loss of normal low-signal zone of provisional calcification (ZPC) with poor enhancement of unossified epiphyseal cartilage & overlying soft tissue edema.*



(Left) *Lateral radiograph (L) & sagittal STIR MR (R) images in an infant with ulnar osteomyelitis show soft tissue edema, a large subperiosteal abscess, & marrow heterogeneity. A small, subperiosteal globule followed fat signal on all sequences, consistent with marrow lipocyte necrosis.* **(Right)** *Lateral radiographs 1 (L) & 3 (R) weeks after a nailbed injury in an 11-year-old show a subtle Salter-Harris 2 fracture with subsequent metaphyseal bone loss & periosteal reaction due to osteomyelitis.*

(Left) *AP (L) & lateral (R) radiographs of the distal femur in a teenager with months of pain show central, elongated lucent lesions, some of which have narrow zones of transition. There is mild expansile remodeling with foci of endosteal scalloping intermixed with cortical thickening.* **(Right)** *Coronal T1 MR in the same patient shows a high-signal rim to the central medullary lesion, the typical penumbra sign of granulation tissue in a subacute to chronic Brodie abscess.*

(Left) *Coronal STIR MR in the same patient shows that the high signal intensity intramedullary collection is surrounded by a hypointense outer rim of fibrosis &/or sclerosis, a feature not seen with acute infections. There is surrounding poorly defined marrow edema.* **(Right)** *Coronal T1 C+ FS MR in the same patient shows intense rim enhancement of the medullary abscess. The periosteal & soft tissue edema in this case of subacute to chronic osteomyelitis is less pronounced than is typically seen with acute infection.*

Syphilis

KEY FACTS

TERMINOLOGY

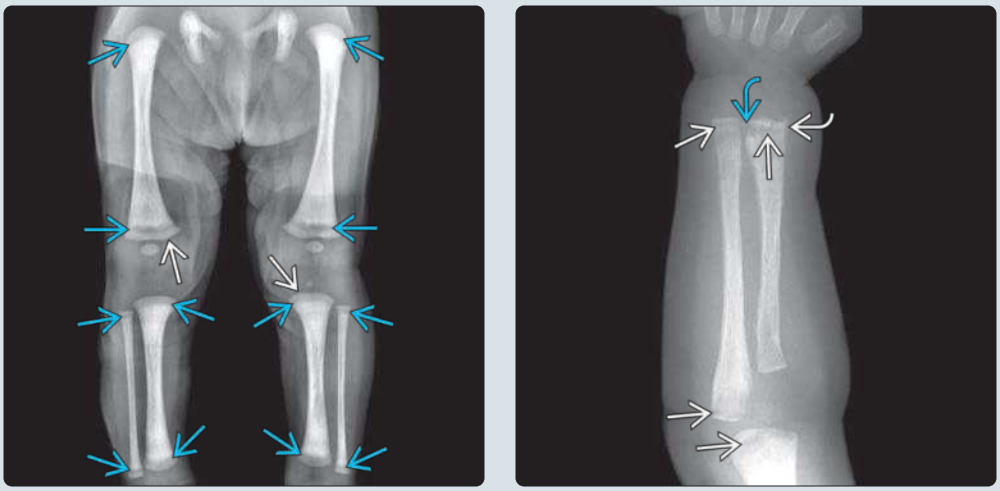
- Congenital syphilis (CS): Transmission of *Treponema pallidum* to fetus from infected mother
  - Early-onset CS: Clinically manifests < 2 years of age
  - Late-onset CS: Clinically manifests > 2 years of age

IMAGING

- Usually widespread, symmetric
  - Can be asymmetric or solitary
- Periosteal reaction is most common finding
- Metaphyseal lesions
  - Nonspecific lucent bands with intact zone of provisional calcification (ZPC) are typical
    - Can have serrated/sawtooth metaphyses
  - Wimberger corner sign: Destruction of proximal medial tibias with sparing of 1st few mm of new bone
- Saber shins: Anterior tibial cortical thickening & bowing (in older children)
- Pathologic fractures, usually metaphyseal

TOP DIFFERENTIAL DIAGNOSES

- Bacterial osteomyelitis
- Neuroblastoma or leukemia
- Physiologic periosteal reaction
- Infantile myofibromatosis
- Child abuse



CLINICAL ISSUES

- Fetal/perinatal demise in 40% of infants with CS
- 2/3 of infants with CS are asymptomatic at birth
  - Prenatal screening is important for early treatment
- Symptoms: Hepatosplenomegaly, rhinitis ("snuffles"), rash
  - Parrot pseudoparalysis: Not moving painful extremity
- Prevention of CS: Treatment of seropositive mothers
- Treatment of CS: IV penicillin for infants

DIAGNOSTIC CHECKLIST

- Consider CS in infant with widespread polyostotic findings
- Infant with CS & multiple fractures may mimic abuse

(Left) *Frontal radiograph of the lower extremities in a 3-week-old girl with acute congenital syphilis (CS) shows metaphyseal lucent bands in all of the long bones, though the ZPCs are intact. This finding is nonspecific as systemic stress, neuroblastoma, & leukemia can cause a similar appearance.* **(Right)** *AP radiograph shows metaphyseal lucent bands in the radius, ulna, & humerus. Periosteal reaction & a destructive metaphyseal lesion are also seen in the distal radius.*

(Left) *AP radiographs in a 2-month-old girl with known CS show destructive lytic lesions in the bilateral medial tibial metaphyses with sparing of the proximal few mm of bone. This is the Wimberger corner sign, which is highly suggestive of (but not specific for) CS.* **(Right)** *Newborn ankle radiograph of CS shows a fracture through a lucent band in the distal fibula. Periostitis & permeation are seen in the distal tibia. Fractures in CS can be confused with abuse.*

TERMINOLOGY

Definitions

- Congenital syphilis (CS): Transmission of *Treponema pallidum* to fetus from infected mother
  - Early-onset CS: Clinically manifests < 2 years of age
  - Late-onset CS: Clinically manifests > 2 years of age
- "Great imitator" (coined by Sir William Osler)

IMAGING

General Features

- Best diagnostic clue
  - Infant with widespread metaphyseal findings
  - Wimberger corner sign: Bilateral destruction of proximal medial tibias
    - Spares 1st few mm of newly formed bone
    - Highly suggestive but not specific for CS
- Location
  - Often widespread but can involve single bone

Radiographic Findings

- Periosteal reaction is most common finding
  - Typically symmetric
- Long bones
  - Metaphyses: Typically 1st area of involvement
    - Nonspecific horizontal lucent bands, classically sparing thin radiodense periphyseal zone of provisional calcification (ZPC)
      - Can see metaphyseal irregularity (serrated, sawtooth)
    - Destructive lucent lesion
      - Tibia > femur > humerus
      - Wimberger corner sign: Upper medial tibias
  - Diaphyses
    - Cortical thickening ± destructive lesions
      - Saber shin: Anterior tibial cortical thickening/bowing (late childhood)
- Pathologic fractures, frequently multiple
  - Most common at metaphysis
  - May mimic nonaccidental trauma
- Skull: Multiple lytic calvarial lesions
- Chest: Diffuse pulmonary opacities

DIFFERENTIAL DIAGNOSIS

Bacterial Osteomyelitis

- Usually monostotic with edema ± fluid collections

Leukemia

- Symmetric, metaphyseal lucent bands

Neuroblastoma

- Diffuse bone metastases (asymmetric)

Systemic Stress

- May cause metaphyseal lucent bands with intact ZPC
- Common in 1st month of life

Rickets

- Metaphyseal cupping, fraying, & splaying
- Loss of ZPC

Physiologic Periosteal Reaction

- Symmetric & smooth along entire diaphysis
- Most commonly of humeri, femurs, & tibias
- Appears > 1 month, peaks ~ 6 months

Infantile Myofibromatosis

- Relatively symmetric, bubbly, metadiaphyseal lucent lesions of infant, often with ≥ 1 soft tissue myofibroma

Child Abuse

- Healing classic metaphyseal lesion can mimic CS

PATHOLOGY

General Features

- Typically due to transplacental transmission

Microscopic Features

- Focal erosions are due to syphilitic granulation tissue
- Metaphyseal lucent bands may be secondary to
  - Stress response from systemic disease
  - Syphilitic granulation tissue

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Hepatosplenomegaly, rhinitis ("snuffles"), rash
  - 2/3 of infants with CS are asymptomatic at birth
    - Prenatal screening is important for early treatment
    - Adequately treated maternal syphilis 30 days before delivery prevents up to 98% of CS
    - Untreated CS typically shows symptoms by 5 weeks
- Other signs/symptoms
  - Early-onset (0-2 years) CS
    - Parrot pseudoparalysis: Immobile limb due to pain
      - Radiograph of limb shows destructive lesion
  - Late-onset (2 to ~ 30 years) CS
    - Bone changes: Frontal bossing, saddle nose, maxillary hypoplasia, saber tibia, gummatous periostitis

Natural History & Prognosis

- Fetal/perinatal demise in 40% of infants with CS
- Early CS bone lesions usually resolve with treatment

Treatment

- Prevention of CS: Treatment of seropositive mothers
- IV penicillin for infected infants

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Consider CS in infant with widespread polyostotic findings
- Infant with CS & multiple fractures may mimic abuse

Septic Arthritis

KEY FACTS

TERMINOLOGY

- Septic arthritis: Microbial (typically bacterial) invasion of joint leading to inflammation & purulence

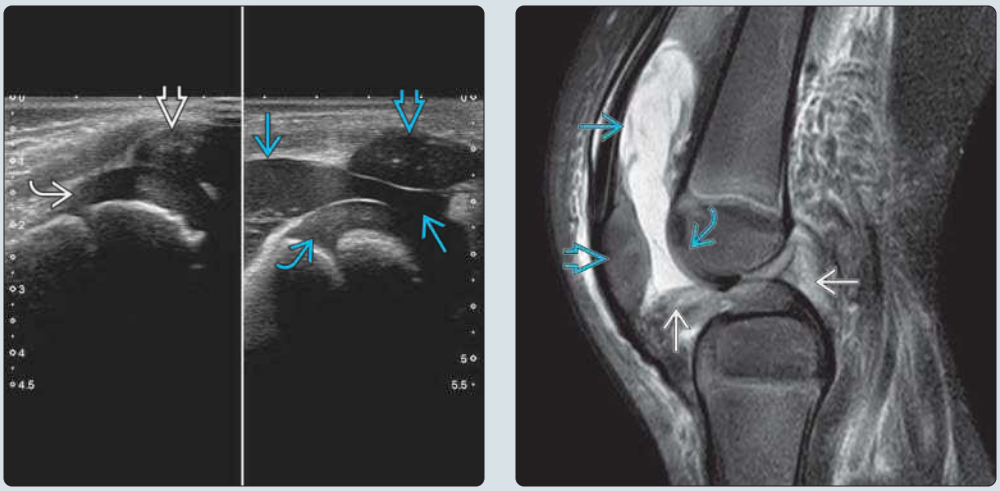
IMAGING

- Best clue: Joint effusion in non-weight-bearing child with fever > 38.5°C + ↑ serum inflammatory markers
- Radiographs: Displacement of fat pads ± widened joint
- US: Highly sensitive for fluid distending joint capsule
  - Complexity & volume do not predict/exclude infection
- MR: Nonspecific joint fluid with synovial thickening & enhancement
  - Findings favoring septic arthritis over transient synovitis
    - Presence of marrow &/or soft tissue edema
    - ↓ early enhancement/perfusion of articular epiphysis

TOP DIFFERENTIAL DIAGNOSES

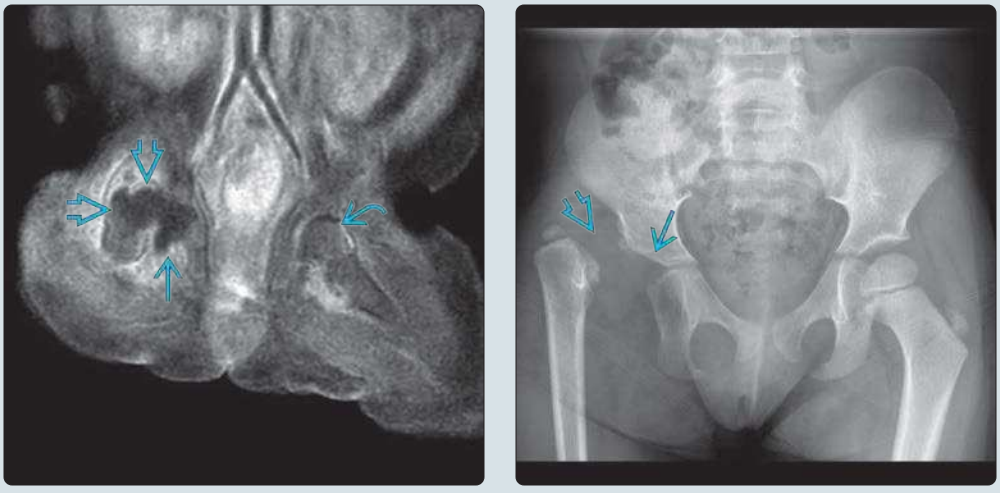
- Transient synovitis
- Juvenile idiopathic arthritis
- Trauma
- Reactive effusion due to adjacent bone pathology

PATHOLOGY



- Mechanism: Hematogenous spread vs. direct spread from adjacent osteomyelitis or puncture wound
- Most common organisms overall: *Staphylococcus aureus* > streptococcal species
  - Neonates: Group B streptococci, gram-negative rods, *Neisseria gonorrhoeae*
  - < 4 years of age: *Kingella kingae* most common

CLINICAL ISSUES



- Treatment: Emergent arthroscopy/arthrotomy with joint irrigation + IV antibiotics to prevent long-term sequelae

DIAGNOSTIC CHECKLIST

- Synovitis has many etiologies; always consider infection
  - Imaging alone cannot exclude infection of joint fluid
  - Joint aspiration required for 100% confidence

(Left) *Sagittal US in a 2-year-old with Staphylococcus aureus septic arthritis shows a large joint effusion of the left knee displacing the unossified patellar cartilage from the femoral condylar cartilage. There is no fluid separating the right knee patellar & femoral cartilages.* **(Right)** *Sagittal T2 FS MR in the same child shows the large effusion separating the patellar & femoral cartilages. The inflamed synovium is of intermediate signal intensity. Note the surrounding soft tissue edema.*

(Left) *Coronal T1 C+ FS MR in a 1-month-old with S. aureus bacteremia shows nonenhancing fluid of the right hip joint displacing & eroding a necrotic right femoral head. Note the surrounding inflammation. The left femoral head is normal without joint effusion.* **(Right)** *AP radiograph in the same patient 4 years later shows no discernible right femoral head or neck with displacement of the femur from an abnormal acetabulum. Hip destruction is a feared complication of septic arthritis.*

TERMINOLOGY

Definitions

- Septic arthritis: Microbial (typically bacterial) invasion of joint leading to inflammation & purulence

IMAGING

General Features

- Location
  - Affects lower extremity joints in ≥ 75% of cases
  - Multiple joints in ~ 10-15%

Radiographic Findings

- Displacement of fat pads ± widening of joint space, soft tissue edema with blurred fat-muscle interfaces
- Sensitivity for fluid distending joint capsule varies on location: Knee, ankle, elbow > > hip, shoulder
  - Only 20-73% sensitive at hip

Ultrasonographic Findings

- Anechoic to complex fluid distending joint capsule; complexity & volume do not predict sterile vs. infected fluid
  - Septic joint is unlikely if fluid is absent (but must know where to look)
- Synovial thickening, ± hyperemia

MR Findings

- Nonspecific synovitis (as with many etiologies)
  - Bright T2/STIR fluid in joint
    - ± debris, fluid-fluid level
  - Synovial thickening & enhancement
- Findings favoring septic arthritis over transient synovitis
  - Presence of marrow &/or soft tissue edema
  - ↓ early enhancement/perfusion of articular epiphysis, especially in tight joint (e.g., femoral head at hip)
- Findings favoring septic arthritis over reactive fluid secondary to adjacent metaphyseal osteomyelitis
  - Epiphyseal marrow edema, surrounding soft tissue edema, epiphyseal nonenhancement

Imaging Recommendations

- Best imaging tool
  - US: Highly sensitive for joint fluid; ~ 5% false-negative rate in first 24 hours
  - MR ± contrast
    - Best tool for detecting adjacent bone & soft tissue infections/collections
    - Can detect other diagnoses

DIFFERENTIAL DIAGNOSIS

Transient Synovitis

- Typically occurs at hip, leading to limp
- Usually without fever or ↑ serum inflammatory markers
- Nonspecific MR appearance of synovitis
  - Joint fluid + mild synovial thickening & enhancement
  - Lacks surrounding marrow or soft tissue edema

Juvenile Idiopathic Arthritis

- ± rice bodies: Numerous, tiny low T2 signal intensity bodies of uniform size throughout joint fluid

Trauma

- ± marrow & soft tissue edema, ligament & cartilage injuries

Reactive Effusion Due to Adjacent Bone Pathology

- Osteomyelitis, bone tumor, Legg-Calvé-Perthes

PATHOLOGY

General Features

- Mechanisms of joint seeding
  - Hematogenous spread: Vascularized synovium lacking basement membrane allows bacterial entry
  - Direct spread: Adjacent osteomyelitis, puncture wound
    - Epiphyseal osteomyelitis leading to septic arthritis is common in neonates
- Causative organisms
  - *Staphylococcus aureus* > streptococcal species overall
  - Neonates: Group B streptococci, gram-negative rods, *Neisseria gonorrhoeae*, *S. aureus*
  - 3 months to 4 years of age: Gram-negative bacteria, streptococcal species, *Kingella kingae*
    - *K. kingae* often lacks systemic markers of inflammation
- Osteocartilaginous destruction caused by
  - Neutrophil & bacterial proteolytic enzymes → articular & unossified epiphyseal cartilage damage
  - ↑ joint pressure by pus → ↓ perfusion of articular epiphysis → ischemic injury

CLINICAL ISSUES

Presentation

- Fever, pain, swelling, ↓ motion, non-weight-bearing
- Kocher criteria: ↑ likelihood for hip septic arthritis over transient synovitis with ↑ number of predictors
  - Fever > 38.5°C (101.3°F) , non-weight-bearing, WBC > 12,000 cells/mm³, ESR ≥ 40 mm/hour; later addition to original criteria: CRP > 20 mg/L
    - If all are present, specificity is ~ 60-99%

Demographics

- Peak age: ~ 2-3 years
- Coexistent osteomyelitis in 15-68%

Natural History & Prognosis

- Long-term sequelae in 10-50%
  - Limited motion, dislocation, degeneration, ankylosis, limb length discrepancy, avascular necrosis

Treatment

- Emergent arthroscopy or arthrotomy + joint irrigation
  - Serial joint aspiration + lavage may be acceptable in certain scenarios
- IV antibiotics for 2-4 days followed by oral antibiotics for 10 days; longer course for concomitant osteomyelitis

Transient Synovitis

KEY FACTS

TERMINOLOGY

- Idiopathic, self-limited inflammation of pediatric hip
- Synonyms: Toxic synovitis

IMAGING

- Radiographs: Low sensitivity for hip joint effusion; look for convex gluteal fat pad & medial joint space widening
- US: Highly sensitive for joint fluid
  - Distention of joint capsule by anechoic or hypoechoic fluid
  - ± synovial thickening, hyperemia
- MR: Nonspecific fluid + synovial enhancement
  - Findings favoring transient synovitis over septic arthritis
    - Absence of adjacent marrow or soft tissue edema
    - Normal enhancement/perfusion of femoral head

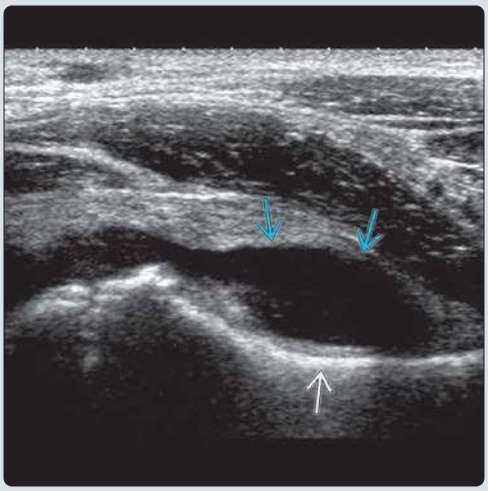
TOP DIFFERENTIAL DIAGNOSES

- Septic arthritis
- Lyme arthritis
- Juvenile idiopathic arthritis
- Trauma
- Reactive effusion due to adjacent bone pathology

PATHOLOGY

- Viral etiology is considered most likely

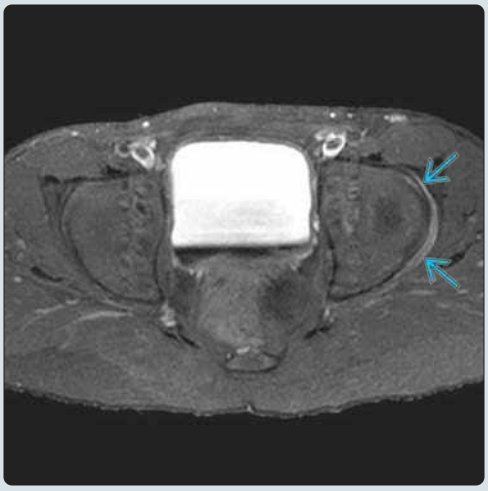
CLINICAL ISSUES



- 3-8 years of age; mean: 4.7-5.5 years
- Limping ± pain; fever is typically absent or low
- Kocher criteria: ↑ likelihood for septic arthritis over transient synovitis with ↑ number of positive parameters
  - Fever > 38.5°C (101.3°F), non-weight-bearing, ↑ WBC, ↑ ESR; ↑ CRP is also predictive
- Transient synovitis is self-limited, lasting 7-10 days
- Conservative management with bed rest + NSAIDs
  - Hip aspiration expedites clinical improvement

DIAGNOSTIC CHECKLIST

- Imaging alone cannot exclude infection of fluid



(Left) *AP radiograph of the pelvis in an afebrile 5-year-old with the new onset of a limp & left hip pain shows bowing of the left gluteal fat pad ⇨ as compared to the normal right side ⇨, suggesting a left hip joint effusion.* **(Right)** *Sagittal US of the left hip in the same patient shows convex bowing of the joint capsule ⇨ by hypoechoic fluid that distends the joint at the femoral neck ➡. The patient had normal laboratory markers & was successfully treated conservatively for transient synovitis.*

(Left) *Coronal T2 FS MR in a 4-year-old with several days of left thigh pain & limping shows a small left hip joint effusion ⇨ with no adjacent marrow or soft tissue edema.* **(Right)** *Axial T1 C+ FS MR in the same patient shows mildly ↑ synovial enhancement of the left hip joint ⇨ as compared to the right. The patient was successfully treated conservatively for transient synovitis given the combination of clinical & imaging features.*

TERMINOLOGY

Synonyms

- Toxic synovitis

Definitions

- Idiopathic, self-limited inflammation of pediatric hip

IMAGING

General Features

- Best diagnostic clue
  - Hip effusion & limp in child with absent to mild systemic findings of inflammation (i.e., fever & elevated serum markers)
- Location
  - Bilateral in ~ 5%

Radiographic Findings

- Low sensitivity for hip joint effusion
- ± convex gluteal fat pad & medial joint space widening

Ultrasonographic Findings

- Distention of joint capsule by fluid
  - Anterior joint capsule demonstrates convex bulge (rather than normal concavity) over femoral neck
- ± synovial thickening, hyperemia

MR Findings

- Features of nonspecific synovitis (with many etiologies)
  - Homogeneously bright T2/STIR fluid in hip joint
  - Mild synovial thickening & enhancement
- Findings favoring transient synovitis over septic arthritis
  - Absence of adjacent marrow or soft tissue edema
  - Normal enhancement/perfusion of femoral head

Imaging Recommendations

- Best imaging tool
  - US: Highly sensitive for hip joint fluid
    - Not specific for sterile vs. infected fluid (regardless of size or complexity)
- Protocol advice
  - US: Patient lies supine with hip in neutral position
    - Anterior oblique approach with transducer oriented along femoral neck long axis
    - Obtain comparison images of contralateral hip
  - MR: Coronal plane is key to compare femoral heads
    - T1, T2 FS/STIR, T1 C+ FS

DIFFERENTIAL DIAGNOSIS

Septic Arthritis

- Favored over transient synovitis with
  - High number of clinical/laboratory Kocher criteria
  - MR showing adjacent marrow & soft tissue edema &/or ↓ enhancement/perfusion of femoral head

Juvenile Idiopathic Arthritis

- ± rice bodies: Numerous, tiny low T2 signal intensity bodies of uniform size throughout joint fluid

Lyme Arthritis

- Presentation tends to be less acute
- Traditionally limited to certain geographic regions

Trauma

- ± marrow & soft tissue edema, ligament & cartilage injuries

Reactive Effusion Due to Adjacent Bone Pathology

- Osteomyelitis, bone tumor, Legg-Calvé-Perthes

PATHOLOGY

General Features

- Viral etiology is more likely than trauma or allergy

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute pain + limping; afebrile (> 90%)
    - Pain at groin, thigh, or medial knee
- Clinical profile
  - Kocher criteria must be considered to differentiate from septic arthritis: Fever > 38.5°C (101.3°F), non-weight-bearing, WBC > 12,000 cells/mm³, ESR ≥ 40 mm/hour
    - ↑ likelihood for septic arthritis with ↑ number of positive parameters
      - CRP > 20 mg/L also suggests septic joint

Demographics

- Typically 3-8 years of age; mean: 4.7-5.5 years
- M:F = 2-3:1

Natural History & Prognosis

- Self-limited; lasts 7-10 days

Treatment

- Conservative management with bed rest + NSAIDs
- Hip aspiration expedites clinical improvement
  - Also allows confident exclusion of septic joint

DIAGNOSTIC CHECKLIST

Consider

- Primary concern: Missing septic joint that needs emergent drainage & IV antibiotics to prevent long-term damage
- Imaging alone cannot exclude infection of fluid
  - Combination of certain clinical & imaging parameters can raise or lower likelihood
  - Joint aspiration is required for 100% confidence

Image Interpretation Pearls

- Synovitis has many etiologies; always consider infection

Soft Tissue Abscess

KEY FACTS

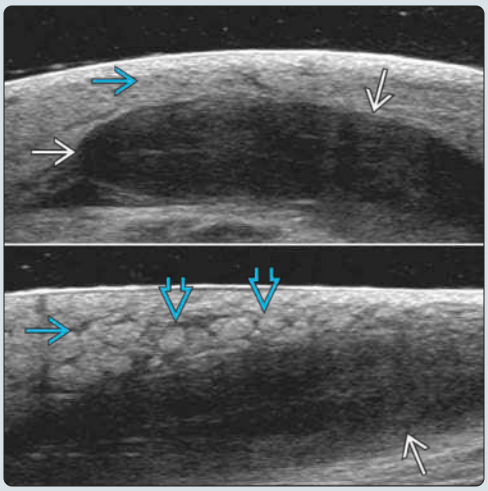
TERMINOLOGY

- Abscess: Walled-off, liquefied collection of necrotic tissue, inflammatory cells, & bacteria

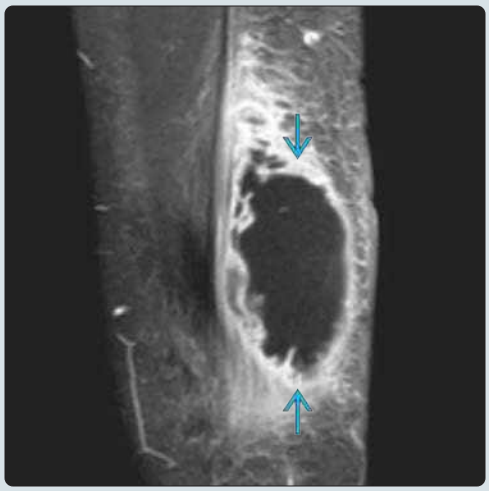
IMAGING

- Most commonly affects single site: Expected lymph node location vs. other subcutaneous or intramuscular focus
  - Septic emboli can cause multifocal collections
- US: Excellent for detecting superficial collections & defining drainability
  - Thick-walled, centrally avascular collection with surrounding edema ± hyperemia
  - Swirling internal debris upon compression
- MR: Clearly defines deep extent, evaluates adjacent bone/joint, & helps exclude other diagnoses
  - Centrally nonenhancing fluid collection with thick, enhancing wall & peripheral, poorly defined edema
  - Restricted diffusion centrally

TOP DIFFERENTIAL DIAGNOSES

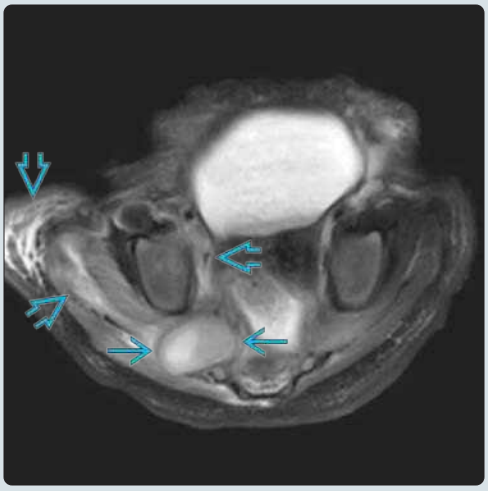


- Soft tissue sarcoma
- Lymphatic malformation
- Hematoma
- Myositis ossificans
- Morel-Lavalleé lesion

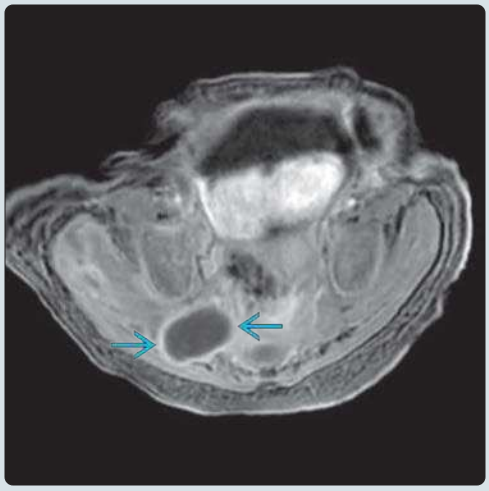


PATHOLOGY

- *Staphylococcus aureus* > > streptococcal species
- *Bartonella henselae*: Regional lymphadenitis ± suppuration in cat-scratch disease



CLINICAL ISSUES



- Presentation: Swelling, erythema, tenderness, limited motion, fever; ± fluctuance, sepsis
- Treatment: Drainage procedure + IV antibiotics
  - Whole-body MR may be useful to screen large territories for drainable collections in setting of systemic infection

(Left) *Longitudinal US images in an 11-year-old with thigh swelling & tenderness show thickening & reticular edema of the subcutaneous fat overlying a heterogeneously hypoechoic, ovoid collection. The more inferior image demonstrates the typical cobblestone appearance of the fat that can imply purulence.* **(Right)** *Sagittal T1 C+ FS MR in the same patient shows thick, irregular rim enhancement of the fluid collection, typical of an abscess. Pus was encountered upon surgical drainage.*

(Left) *Axial T2 FS MR in a 20-day-old with Staphylococcus aureus bacteremia shows a well-defined collection traversing the right greater sciatic notch with a low-signal rim & high-signal center. Note the adjacent soft tissue edema.* **(Right)** *Axial T1 C+ FS MR in the same patient shows only rim enhancement of the collection, typical of an abscess. This collection was percutaneously drained.*

TERMINOLOGY

Definitions

- Suppurative or purulent: Pus forming/pus containing
- Abscess: Walled-off, liquefied collection of necrotic tissue, inflammatory cells, & bacteria
- Phlegmon: Poorly defined focus of necrotic & inflammatory tissue ± components of liquefaction
- Cellulitis: Poorly defined changes of superficial (i.e., skin & subcutaneous fat) soft tissue infections
- Fasciitis: Inflammation in & along superficial & deep fascial planes investing muscles
- Pyomyositis: Deep muscle infection
- Skin & soft tissue infections (SSTI): Any of above

IMAGING

General Features

- Best diagnostic clue
  - US: Focal, thick-walled, avascular collection with swirling internal echoes (upon compressions) & overlying edema
  - MR: Centrally nonenhancing fluid collection with thick, enhancing wall & peripheral, poorly defined edema

Radiographic Findings

- Edema: Subcutaneous reticulation with blurring of normally sharp fat-muscle interfaces
- ± focal bulge at site of collection
- ± retained foreign body, gas

Ultrasonographic Findings

- Grayscale ultrasound
  - Well-defined collection with thick, irregular wall
  - Contents range from anechoic to isoechoic
    - Internal debris swirls with dynamic compression
  - Branching interstitial fluid throughout edematous & lobulated subcutaneous fat ("cobblestoning")
    - May also be purulent; overlaps with classic description of nonpurulent cellulitis
  - May detect retained foreign body
- Color Doppler
  - No internal vascularity; ± ↑ peripheral vascularity

MR Findings

- T2 FS/STIR
  - Collection of hyperintense fluid centrally
  - Wall may show hypointense inner rim (minerals, hemorrhage, fibrous tissue) & hyperintense outer rim (granulation tissue)
  - Surrounding edema
- T1 C+ FS: Mildly thickened, irregular, enhancing rim after contrast without substantial nodularity
- DWI: Restricted diffusion centrally

Imaging Recommendations

- Best imaging tool
  - US is excellent for detecting superficial collections & defining drainability
  - MR more clearly defines collection deep extent & relationships to vital structures, evaluates adjacent bone & cartilage, & helps exclude other diagnoses

DIFFERENTIAL DIAGNOSIS

Soft Tissue Sarcoma

- Typically solid, well-circumscribed mass with little (if any) surrounding edema

Lymphatic Malformation

- Multicystic mass crossing soft tissue compartments
- Fluid-fluid levels due to internal hemorrhage

Myositis Ossificans

- Heterogeneous, intramuscular mass with marked surrounding edema
- Peripheral Ca^{2+} within weeks is diagnostic

Morel-Lavalleé Lesion

- Closed degloving injury of subcutaneous fat, usually over bony protuberance
- Typically elongated with angular margins
- Often contains foci of fat in collection

PATHOLOGY

General Features

- Most common organisms
  - *Staphylococcus aureus* > > streptococcal species
    - ↑ incidence of methicillin-resistant *S. aureus* (MRSA) → ↑ number of SSTIs in last 20 years
  - *Bartonella henselae*: Regional lymphadenitis ± suppuration in cat-scratch disease
    - Axillary, epitrochlear > head/neck or inguinal nodes

CLINICAL ISSUES

Presentation

- Swelling, erythema, tenderness, limited motion, fever; ± fluctuance, septic shock

Treatment

- Drainage procedure + IV antibiotics
  - Drainage may not be necessary if collection is < 2 cm in noncritical location

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- US cine clips with dynamic compression can help confirm drainable fluid within collection
- Make sure US visualizes entirety of soft tissues down to bone → prevents missing deep collection
  - Cortical irregularity & subperiosteal collections can provide clue about site of origin (i.e., osteomyelitis)

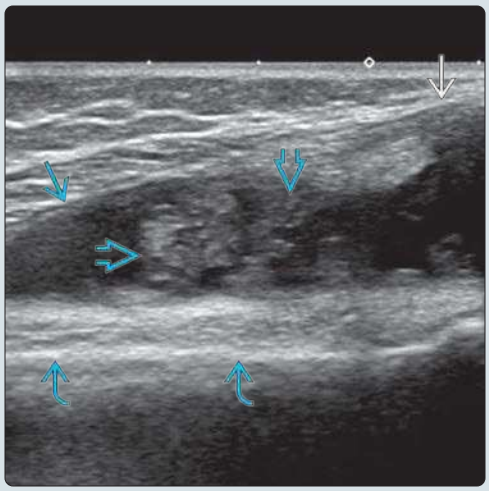
Juvenile Idiopathic Arthritis

KEY FACTS

TERMINOLOGY

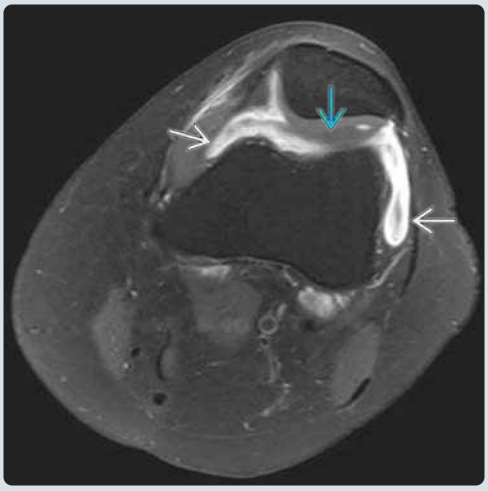
- Synovial inflammation of unknown cause
- Diagnostic criteria
  - Arthritis begins < 16 years of age
  - ≥ 6 weeks of symptoms
  - Other conditions have been excluded
- International League of Associations for Rheumatology (ILAR) classification of juvenile idiopathic arthritis (JIA)
  - Systemic arthritis: Arthritis of ≥ 1 joint + daily spiking fever for ≥ 3 consecutive days
    - Accompanied by ≥ 1 of following: Evanescent rash, hepatomegaly &/or splenomegaly, serositis
  - Oligoarticular arthritis: Arthritis of < 5 joints in first 6 months of disease
  - Polyarticular arthritis: Arthritis of ≥ 5 joints in first 6 months of disease; RF positive or negative
  - Psoriatic arthritis
  - Enthesitis-related arthritis
  - Undifferentiated or unclassified arthritis

IMAGING



- Radiographs: Classic findings are seen late in disease
  - Early to intermediate: Osteoporosis, periarticular soft tissue swelling, joint capsule distention (by effusion &/or thickened synovium/pannus), marginal erosions
  - Late: Joint space loss with gradual ankylosis, growth disturbances (e.g., hypoplasia vs. overgrowth)
- MR: Joint effusion with synovial thickening & enhancement, bone marrow edema, cartilage loss ± bone erosions
  - Hypointense rice bodies in joint fluid
- US: Compressible hypoechoic joint fluid vs. noncompressible synovial pannus
  - Color/power Doppler for active vs. inactive synovitis

CLINICAL ISSUES



- Presents with joint swelling/effusion, stiffness, pain & tenderness, ↑ warmth
- 1-3 years of age (largest peak); 8-10 years (smaller peak)

(Left) *Lateral radiograph in a 5-year-old with weeks of knee pain & swelling shows a moderate joint effusion distending the suprapatellar pouch* ⇨. **(Right)** *Longitudinal US of the knee in the same patient shows hypoechoic fluid distending the suprapatellar pouch* ⇨. *There is moderate internal debris with regions of synovial thickening* ⇨ *due to juvenile idiopathic arthritis (JIA). The patella* ➡ *& femur* ⇨ *are noted for reference.*

(Left) *Axial T1 C+ FS MR in an 18-year-old with a history of JIA shows moderate diffuse synovial thickening & enhancement (synovitis)* ➡ *of the knee. Only a small joint effusion* ⇨ *is present.* **(Right)** *Coronal T2 FS MR in a toddler with JIA shows a large knee joint effusion containing numerous small (& uniform in size) hypointense rice bodies* ➡.

TERMINOLOGY

Synonyms

- Juvenile rheumatoid arthritis (JRA), juvenile chronic arthritis

Definitions

- Juvenile idiopathic arthritis (JIA): Synovial inflammation of unknown cause
- Diagnostic criteria: Arthritis begins < 16 years of age, ≥ 6 weeks of symptoms, & other conditions excluded (diagnosis of exclusion)
- Most widely used classification developed by International League of Associations for Rheumatology (ILAR)
  - Systemic arthritis (sJIA), previously known as Still disease: 10-20%
    - Arthritis of ≥ 1 joint + fever of ≥ 2-weeks duration with daily (quotidian) fever for at least 3 consecutive days
    - Accompanied by ≥ 1 of following: Evanescent rash, hepatomegaly &/or splenomegaly, serositis (pericarditis, pleuritis, peritonitis), generalized lymphadenopathy
    - Can be associated with interstitial lung disease, macrophage activation syndrome, amyloidosis
  - Oligoarticular arthritis: Most common form of JIA (50%)
    - Arthritis of < 5 joints in first 6 months of disease
      - Persistent: < 5 joints affected during entire disease
      - Extended: ≥ 5 joints affected after first 6 months
    - Young girls
    - Large joints: Knee, ankle, elbow
    - Iridocyclitis in up to 30%
  - Polyarticular rheumatoid factor (RF)-positive arthritis
    - Arthritis of ≥ 5 joints in first 6 months of disease
    - ≥ 2 positive tests for RF at least 3 months apart within first 6 months of disease
    - More commonly adolescent girls
    - Typical: Symmetric, small joints of hands
  - Polyarticular RF-negative arthritis
    - Arthritis of ≥ 5 joints in first 6 months of disease
    - No characteristic pattern
    - Any age throughout childhood
  - Psoriatic arthritis (< 15%)
    - Arthritis & psoriasis or arthritis & ≥ 2 of following: Dactylitis ("sausage digit"), nail pitting or onycholysis, psoriasis in 1st-degree relative
  - Enthesitis-related arthritis (< 7%)
    - Arthritis & enthesitis, or
    - Arthritis or enthesitis with ≥ 2 of following
      - Sacroiliac joint tenderness &/or inflammatory lumbosacral pain
      - Positive HLA-B27 antigen test
      - Onset of arthritis in male ≥ 6 years old
      - Symptomatic anterior uveitis
      - Presence of 1st-degree relative with ankylosing spondylitis, enthesitis-related arthritis, inflammatory bowel disease with sacroiliitis, Reiter syndrome, or acute anterior uveitis
    - Enthesitis is most commonly at Achilles, plantar fascia
  - Undifferentiated arthritis
    - Does not fulfill criteria for any category or fulfills criteria for multiple categories

IMAGING

General Features

- Best diagnostic clue
  - Joint effusion with synovial thickening & enhancement in patient with symptoms suggestive of JIA
- Location
  - Any joint; large joints are most common
    - Polyarticular also involves small joints (hands & feet)
    - Cervical spine apophyseal joints are rare at presentation but > 50% eventually develop involvement

Radiographic Findings

- Classic findings are seen late in disease
- General
  - Early to intermediate: Osteoporosis, periarticular soft tissue swelling, joint capsule distention (by effusion &/or pannus/thickened synovium), marginal erosions
  - Late: Joint space loss with gradual ankylosis, subluxation, adjacent periosteal reaction, growth disturbances (including shortening/hypoplasia due to premature growth plate closure, enlarged overgrown epiphyses, limb length discrepancy)
- Mandible
  - Micrognathia or unilateral hypoplasia
  - Antegonial notching of mandible (concave undersurface)
- Wrist
  - Squared or angular carpal bones
  - Carpal erosions (which overlap normal indentations)
  - Accelerated maturation
- Hip
  - Coxa valga, coxa magna, protrusio acetabuli
  - Overgrowth of femoral capital epiphysis
  - Abnormal growth of femoral neck
- Knee
  - Squared inferior margin of patella
  - Widened intercondylar notch
- Cervical spine
  - Atlantoaxial subluxation
  - ↓ disc space with narrowed vertebral body height, ankylosis

MR Findings

- Only modality for marrow edema (preerosive finding)
- Most sensitive technique for detecting active inflammation (synovitis & marrow edema)
- T2 FS/STIR
  - Intermediate to hyperintense pannus & hyperintense joint effusion
    - Small, hypointense rice bodies (generally of uniform size): Detached fragments of necrotic synovium
  - Patchy, hyperintense marrow edema
  - Cartilage loss ± bone erosions
  - Hyperintense tenosynovitis: Most common at extensor tendons of hand & feet, peroneal & posterior tibialis tendons of ankle
  - Hypoplastic menisci & cruciate ligaments
  - Regional lymphadenopathy
- T1 C+ FS

- Early scanning after contrast administration (< 5 minutes) is most sensitive & specific for abnormal synovium
  - Contrast gradually leaks into joint fluid
- Actively inflamed enhancing synovium largely outlines (except where synovium is routinely lacking) nonenhancing joint effusion &/or fibrotic/necrotic pannus
  - Early dynamic synovial enhancement correlates with active disease & better reflects treatment response than synovial volumes
- T2* GRE
  - Marginal erosions
- Advanced techniques
  - T2 mapping, DTI, perfusion,T1 rho, dGEMRIC: May reveal microstructural cartilage changes prior to conventional sequences

Ultrasonographic Findings

- More sensitive for synovitis than clinical exam
- Distinguishes articular vs. tenosynovial disease
- Compressible hypoechoic joint fluid vs. noncompressible, synovial pannus
- Color/power Doppler is helpful for active vs. inactive synovitis
  - Developing role for CEUS
- Can visualize some erosions, evaluate cartilage thickness
- Guides injections & biopsies

DIFFERENTIAL DIAGNOSIS

Septic Arthritis

- Majority are monoarticular, often from adjacent osteomyelitis
  - *Staphylococcus aureus* is most common
- Rapid presentation with adjacent marrow & soft tissue edema favor infection
  - Synovial thickening is typically less severe in acute pyogenic infections as compared to JIA
- Kocher criteria: If specific thresholds are met for fever, non-weight-bearing, leukocytosis, ESR, & CRP → strongly favor infected joint
  - Urgent washout is required to prevent long-term damage

Transient Synovitis

- Self-limited, typically at hip of children 3-6 years of age
- Diagnosis of exclusion: Absence of Kocher criteria

Recent Trauma

- Nonspecific effusion ± synovitis with trauma history

Leukemia

- Can present with arthritis symptoms
- ± lucent metaphyseal bands, permeative lesions, osteoporosis

Synovial Venous Malformation

- Septated, fluid-filled channels/cysts infiltrating synovium → hemarthrosis → eventual joint degeneration
- ± phleboliths, fluid-fluid levels, delayed patchy enhancement

Lyme Disease

- Characteristic rash + history of tick bite

Hemophilic Arthropathy

- Relevant clinical history is usually apparent
- Repetitive hemorrhage into joints with hemosiderin deposition & eventual joint degeneration

Pigmented Villonodular Synovitis

- Monoarticular with hemosiderin deposition

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Arthritis (≥ 1 joints): Swelling/effusion, stiffness, pain & tenderness, ↑ warmth
- Other signs/symptoms
  - Fatigue, fevers, weight loss, rash, growth failure
  - TMJs are often involved but often asymptomatic

Demographics

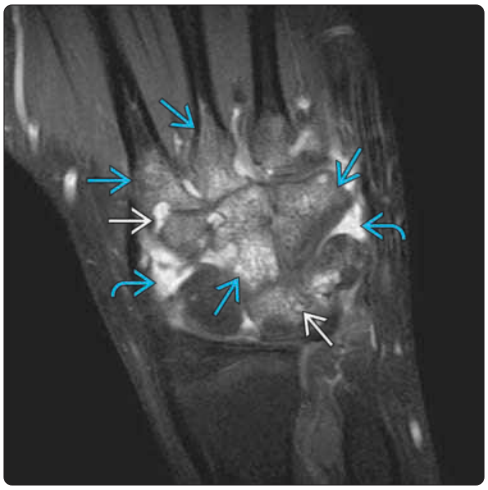
- Age
  - 1-3 years (largest peak); 8-10 years (smaller peak)
- Sex
  - M < F overall; systemic form: M = F

Treatment

- NSAIDs, systemic/local corticosteroids, disease-modifying agents (e.g., methotrexate), biologic agents (monoclonal antibodies or soluble receptors), anti-TNF
- Interleukin-1 & interleukin-6 inhibitors
- Stem cell transplant in very rare cases

DIAGNOSTIC CHECKLIST

Consider



- Whole-body MR may have prognostic & therapeutic implications, as active synovitis may be detected in clinically asymptomatic joints

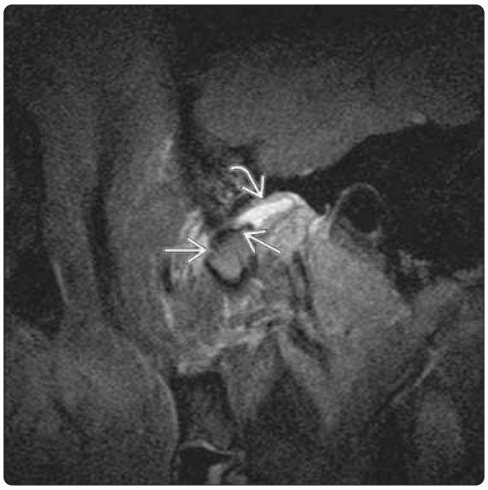


Image Interpretation Pearls

- Synovitis has many causes; use clinical & imaging clues to narrow differential diagnosis
  - Do not overlook septic arthritis
- Difficult to distinguish ongoing active inflammation vs. reactive & degenerative changes in longstanding JIA

(Left) *Coronal T1 C+ FS MR in a teenager shows multiple wrist erosions & moderate synovial enhancement (or synovitis). The marrow edema is much more extensive than seen on the precontrast T1 sequence (not shown).* **(Right)** *Open-mouth sagittal T1 C+ FS MR of the TMJ shows erosions & flattening of the mandibular condyle with synovial thickening & enhancement. The normally visible articular disc is unrecognizable, & is likely degenerated & torn.*

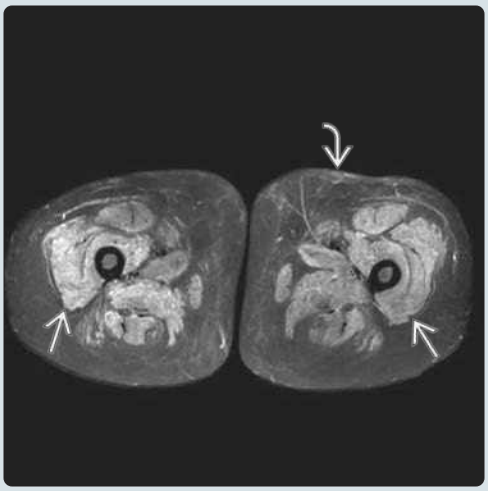
(Left) *Axial T1 C+ FS MR of the ankle shows marked synovial enhancement (or tenosynovitis) surrounding the posterior tibial, flexor digitorum longus, flexor hallucis longus, & peroneal tendons. Diffuse ankle joint synovitis was also present.* **(Right)** *Sagittal T2 FS MR in a 17-year-old with a history of JIA shows plantar fascial enthesitis with edema of the calcaneal bone marrow & adjacent soft tissues at & surrounding the attachment of the plantar fascia.*

(Left) *Coronal STIR MR MIP in a 15-month-old girl with refusal to bear weight for days shows synovial proliferation at multiple joints but is most pronounced at the knees. The patient had ↑ inflammatory markers & was ultimately diagnosed with polyarticular JIA.* **(Right)** *Sagittal T1 C+ FS MR of the right knee in the same patient shows moderate synovial thickening with a moderate joint effusion. The degree of synovial thickening is > typically seen with septic arthritis.*

Dermatomyositis

KEY FACTS

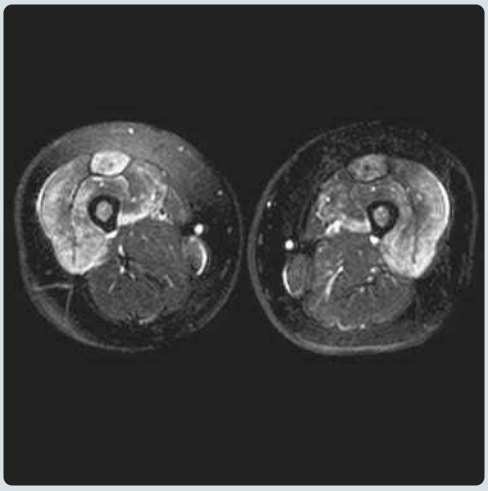
TERMINOLOGY



- Juvenile dermatomyositis (JDM): Diffuse, nonsuppurative inflammation of striated muscle, subcutaneous fat, & skin
- Most common (85%) of juvenile idiopathic inflammatory myopathies

IMAGING

- Patchy to diffusely infiltrative ↑ fluid signal intensity of muscles on STIR or T2 FS MR
  - Symmetric involvement of proximal musculature
    - Thighs > pelvis > shoulders
      - Vastus lateralis & intermedius are most common
  - ± fatty muscle infiltration & atrophy chronically; not prominent feature early
- Subcutaneous fat involvement: High specificity (but low sensitivity) for predicting progression to chronic forms
- Soft tissue Ca^{2+} (30-70%)
  - Develops months to years after disease onset; usually periarticular



CLINICAL ISSUES

- Median age of onset of JDM: 7-11 years
- Most common symptoms
  - Proximal muscle weakness ± tenderness, easily fatigued
  - Rash (heliotrope eyelid rash & Gottron papules)
- Other manifestations: Arthritis, pericarditis, pulmonary fibrosis, gastrointestinal symptoms, including dysphagia & ulceration, fever, weight loss
- JDM diagnosis is classically made by characteristic skin rash + 3 of following
  - Symmetric proximal muscle weakness
  - ↑ muscle enzymes in serum
  - Characteristic electromyography
  - Characteristic changes on muscle biopsy
- Diagnosis confirmation now more commonly employs characteristic MR findings & autoantibody profiles
- Variable disease course: Up to 73% with active disease > 10 years after diagnosis; 3% mortality

(Left) *Axial STIR MR in a 12-year-old patient with proximal muscle weakness, myalgias, & a malar heliotrope rash shows diffuse symmetric muscle abnormalities of the bilateral thighs, including ↓ muscle bulk & muscle edema. Hyperintense signal within the subcutaneous fat has a significant association with a more aggressive course of juvenile dermatomyositis (JDM).* **(Right)** *Lateral elbow radiograph shows diffuse, periarticular Ca^{2+} in this young patient several years after the initial presentation of JDM.*

(Left) *Axial T2 FS MR in an 8-year-old girl with suspected JDM shows abnormal hyperintense signal of muscles within the anterior compartments of both thighs. The study was performed to help localize a biopsy target.* **(Right)** *Coronal STIR MR in a patient with JDM shows diffusely infiltrating, hyperintense signal abnormalities in all visible pelvic & thigh musculature. Extensive reticular signal abnormalities of the subcutaneous fat are also noted.*

TERMINOLOGY

Definitions

- Juvenile dermatomyositis (JDM): Diffuse, nonsuppurative inflammation of striated muscle, subcutaneous fat, & skin
- Most common (85%) of juvenile idiopathic inflammatory myopathies

IMAGING

General Features

- Best diagnostic clue
  - Patchy to diffusely infiltrative ↑ fluid signal intensity of muscles on MR, symmetric in anterior thighs & pelvis
- Location
  - Proximal musculature: Thighs > pelvis > shoulders
    - Most common: Vastus lateralis & vastus intermedius
  - ± pharyngeal striated muscles → dysphagia

Radiographic Findings

- Soft tissue Ca^{2+} (30-70% of JDM patients)
  - Develops from months to years after disease onset
  - Amorphous, globular, or sheet-like; usually periarticular

CT Findings

- High-resolution NECT of lung
  - Interstitial lung disease, chest wall Ca^{2+}, airway disease
  - ≥ 50% of JDM patients have abnormal pulmonary function tests

MR Findings

- Streaky or infiltrative ↑ fluid signal intensity (edema) of affected muscles, most conspicuous on T2 FS or STIR
- ± elongated, crescentic, & reticular foci of fluid signal intensity along fascial planes & in subcutaneous fat
  - Subcutaneous fat involvement: High specificity (but low sensitivity) for predicting progression to chronic forms
    - May lead to calcinosis or lipodystrophy (focal or generalized subcutaneous fat loss)
- ± chronic fatty muscle atrophy (not predominant feature)
- Whole-body STIR MR: Potential screening for disease extent &/or therapy-induced osteonecrosis (ON)

PATHOLOGY

General Features

- Etiology
  - Common reports of preceding illness or ultraviolet exposure
  - Multiple autoantibodies have been identified
    - Profiles/panels are helpful in distinguishing subtypes of myopathy & myositis overlap syndromes

Staging, Grading, & Classification

- Classifications of JDM disease patterns include
  - Limited, chronic nonulcerative, chronic ulcerative (involves skin & gastrointestinal tract)
  - Monocyclic, polycyclic, chronic continuous

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Symmetric proximal muscle weakness ± tenderness; easily fatigued
- Other signs/symptoms
  - Heliotrope rash & Gottron papules are classic; may occur prior to, during, or after muscle weakness symptoms
    - Heliotrope rash: Purplish or violet rash of upper > lower eyelids
    - Gottron papules: Elevated violaceous papules on extensor surfaces of metacarpophalangeal, proximal interphalangeal, or distal interphalangeal joints of hands; elbows & knees are also affected
  - Other cutaneous manifestations
    - Periungual telangiectasis, scaly alopecia, ulcers
    - Photosensitive rash
    - Shawl sign: Poikilodermatous rash on upper chest or V-shaped rash on upper back
  - Subcutaneous & periorbital edema
  - Other manifestations: Arthritis, pericarditis, pulmonary fibrosis, gastrointestinal symptoms, including dysphagia & ulceration, fever, weight loss
- JDM diagnosis is classically made by characteristic skin rash + 3 of following
  - Symmetric proximal muscle weakness
  - ↑ muscle enzymes in serum
    - Creatine kinase (CK), aldolase, aspartate aminotransferase (AST), lactate dehydrogenase (LDH)
  - Characteristic electromyography
  - Characteristic changes on muscle biopsy
- Diagnosis confirmation now more commonly employs combination of characteristic MR findings & autoantibody profiles in correct clinical setting

Demographics

- Age
  - Median age of onset of JDM: 7-11 years
  - Bimodal distribution of dermatomyositis overall
    - 5-14 years is less common than 40s-50s
- Epidemiology
  - 3-5/1,000,000

Natural History & Prognosis

- Variable course of disease
  - Up to 73% with active disease > 10 years after diagnosis
- Complications: Calcinosis, contractures, ON (steroids)
- Mortality up to 3%

Chronic Recurrent Multifocal Osteomyelitis

KEY FACTS

TERMINOLOGY

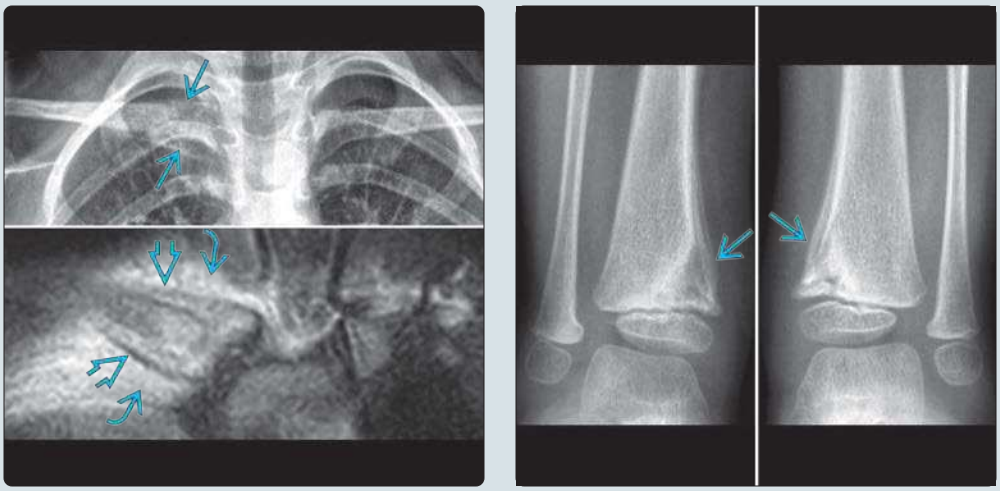
- Idiopathic disorder with nonpyogenic inflammatory bone lesions, typically multifocal with relapsing/remitting course
- Associated with other inflammatory conditions (e.g., psoriasis, inflammatory bowel disease)

IMAGING

- Multiple sites involved over course of disease: > 80%
  - Can be bilateral with relatively symmetric distribution
- Most commonly at periphyseal long bone metaphyses or metaphyseal-equivalent regions
- Most common sites: Tibia, femur, clavicle, spine, pelvis
  - Most common disease to involve medial clavicle
- Radiographs: Features may be mixed at presentation
  - Acute: Lytic lesion (usually in metaphysis near physis)
  - Late: Progressive adjacent sclerosis
  - Recurrence: New lytic areas or periosteal reaction
- MR with contrast
  - Edema & enhancement of lesion & surrounding marrow
  - ± soft tissue & periosteal inflammation but no abscess
  - ± mild reactive adjacent joint effusion/synovitis

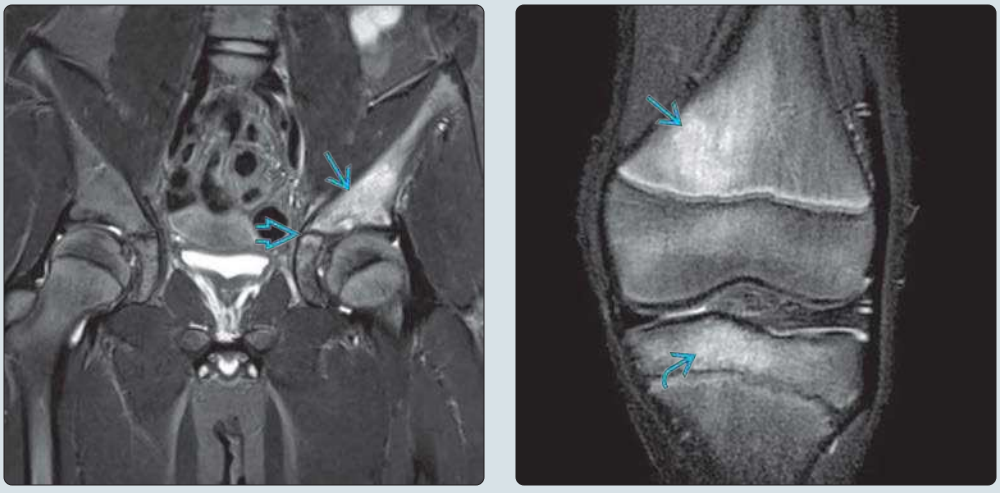
TOP DIFFERENTIAL DIAGNOSES

- Bacterial osteomyelitis
- Ewing sarcoma
- Langerhans cell histiocytosis
- Leukemia
- Scurvy



CLINICAL ISSUES

- Most common age: 9-14 years
- Typically presents with symptoms at 1 site
  - Most (not all) develop other symptomatic sites



DIAGNOSTIC CHECKLIST

- Whole-body MR or bone scan to screen asymptomatic sites
- Report physeal involvement (due to risk of premature physeal closure)

(Left) *AP radiograph (top) in a 4-year-old girl with right clavicle & bilateral ankle pain shows expansion & permeation of the right medial clavicle. On the coronal STIR MR (bottom), there is ↑ signal within & periosteal reaction along the right clavicle with adjacent soft tissue inflammation.* **(Right)** *Frontal ankle radiographs in the same child with chronic recurrent multifocal osteomyelitis (CRMO) show lucent lesions in the distal tibial metaphyses with cortical thinning & layered periosteal reaction.*

(Left) *Coronal T2 FS MR of the pelvis in a 12-year-old boy with left hip & knee pain shows poorly defined, hyperintense signal within the left iliac bone. This region of the iliac bone is considered a metaphyseal equivalent due to its proximity to the triradiate growth cartilage.* **(Right)** *Coronal T2 FS MR of the left knee in the same patient shows poorly defined signal abnormalities within the distal femoral metaphysis & proximal tibial epiphysis. The patient was ultimately diagnosed with CRMO.*

TERMINOLOGY

Abbreviations

- Chronic recurrent multifocal osteomyelitis (CRMO)

Synonyms

- Chronic nonbacterial osteomyelitis (CNO)
  - Newer term proposed as process may be unifocal

Definitions

- Idiopathic disorder with multifocal, nonpyogenic inflammatory bone lesions & relapsing/remitting course

Associated Syndromes

- May be in spectrum of diseases with SAPHO (**s**ynovitis, **a**cne, **p**ustulosis, **h**yperostosis, **o**steitis)
- Associated with other inflammatory conditions [e.g., psoriasis, inflammatory bowel disease (IBD)]

IMAGING

General Features

- Best diagnostic clue
  - Multifocal lytic & sclerotic lesions of periphyseal metaphyses/metaphyseal equivalents or medial clavicle
- Location
  - Multiple sites over course of disease: > 80%
    - Can be bilateral with relatively symmetric distribution
  - Most common location: Long bone metaphyses (periphyseal)
    - Lower extremity > upper extremity (3:1)
  - Most commonly involved bones
    - Tibia, femur, clavicle (especially medial), spine, pelvis
  - Additional locations
    - Metaphyseal equivalent bones (next to growth cartilage)
    - Fibula, ribs, mandible, sternum, scapula, hands, & feet

Radiographic Findings

- Early: Lytic lesion (usually metaphyseal)
- Late: Progressive adjacent sclerosis
  - Chronic lesions may be mixed lytic/sclerotic or purely sclerotic
  - Hyperostosis with cortical thickening
- Recurrence
  - New lytic area &/or periosteal reaction

MR Findings

- T1WI
  - ↓ signal within metaphysis adjacent to growth plate
- T2WI FS/STIR
  - Focal, well-circumscribed, periphyseal metaphyseal lesion of ↑ signal
    - ± breach of physis (which can lead to subsequent growth arrest)
  - Less pronounced, poorly defined ↑ signal of bone marrow in adjacent metadiaphysis & epiphysis
    - Epiphyseal signal may be out of proportion to physeal involvement
  - ± periosteal/soft tissue edema/inflammation
  - ± small reactive adjacent joint effusion
- T1WI C+ FS
  - Diffuse enhancement of bone & soft tissue abnormalities
    - No drainable soft tissue or subperiosteal collection
  - ± small foci of peripheral enhancement in bone (due to sterile intraosseous abscess or necrosis)
  - ± mild synovial thickening & enhancement in adjacent joints
- Whole-body MR
  - Techniques differ but typically include coronal STIR ± T1, DWI; ± sagittal STIR for vertebral involvement
  - Detects clinically asymptomatic lesions
  - At long-term follow-up (≥ 10 years), clinically asymptomatic patients may still have lesions

Nuclear Medicine Findings

- Bone scan
  - Tc-99m whole-body bone scan can also evaluate for asymptomatic lesions: ↑ radiotracer uptake

Imaging Recommendations

- Best imaging tool
  - Imaging work-up should begin with radiographs
  - Targeted MR helps confirm diagnosis & define extent of symptomatic disease
  - Whole-body imaging (MR or bone scan) to evaluate for additional asymptomatic sites
    - May play role in long-term follow-up

DIFFERENTIAL DIAGNOSIS

Osteomyelitis

- Single site is most common; medial clavicle is rare
- Typically presents before lytic lesions occur
- Soft tissue &/or subperiosteal abscesses are common

Ewing Sarcoma

- Permeative bone tumor with aggressive periosteal reaction
- Sharp interface between tumor & normal marrow on T1 MR
- Relatively large soft tissue mass is common

Langerhans Cell Histiocytosis

- Punched-out lytic lesion is classic
- Homogeneously enhancing soft tissue mass fills defect & emanates from bone
- Marked surrounding marrow edema with less pronounced soft tissue findings
- Peak age: 5-10 years

Leukemia

- Osteoporosis, lucent metaphyseal bands ± subtle permeative lytic lesions & aggressive periosteal reaction
- Diffuse replacement of fatty marrow on T1 MR
- Peak age: 2-10 years

Scurvy

- Rare, but seen in patients with restrictive diets (e.g., autism)
- Lucent metaphyseal bands
- Multifocal metaphyseal ↑ T2 signal
  - ± periosteal edema/hyperenhancement
  - May develop subperiosteal hemorrhages

PATHOLOGY

General Features

- Etiology
  - Unknown; genetic & autoinflammatory causes have been suggested
  - Diagnosis of exclusion
- Genetics
  - Susceptibility locus identified at 18q21.3-22
- Associated abnormalities
  - Dermatologic disorders
    - Palmoplantar pustulosis
    - Psoriasis
  - Autoinflammatory disorders
    - Takayasu arteritis
    - Wegener granulomatosis
  - Gastrointestinal disorders
    - IBD: Crohn disease & ulcerative colitis
  - Genetic disorders
    - Majeed syndrome
  - Others
    - Enthesis-related arthritis
    - SAPHO syndrome
      - Thought to be adult equivalent of CRMO but with some distinct differences
      - Etiology unknown (genetic, immunologic, & bacterial mechanisms are proposed)
      - Mean age: 28 years
      - Chest wall & pelvic disease predominates (especially at sternoclavicular & 1st sternocostal joints)
      - Arthritis of peripheral joints
      - Associated dermatologic disorders are more common

Gross Pathologic & Surgical Features

- Microscopic features
  - Nonspecific inflammatory changes with granulocytic infiltration
  - Acute: Polymorphonuclear leukocytes, osteoclastic bone resorption, ± multinucleated giant cells
  - Chronic: Lymphocytes, plasma cells, histiocytes with occasional granulomas, ↑ osteoblastic activity
  - Acute to chronic findings may be found in single lesion
  - Appearance of biopsy specimen may not correlate with clinical time course of disease
- Cultures are negative for organisms

Laboratory Tests

- Nonspecific laboratory markers
  - Mildly elevated C-reactive protein (CRP) & erythrocyte sedimentation rate
  - Normal WBC count

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Typically starts with 1 symptomatic site: Pain, tenderness, swelling, limited range of motion
    - Most (not all) develop other symptomatic sites
  - May be symptomatic days to years prior to presentation
    - Often insidious with vague, nonspecific symptoms
- Other signs/symptoms
  - Systemic signs may be present but are uncommon
    - Fever, weight loss, lethargy
  - Associated with dermatologic disorders & IBD

Demographics

- Age: Most commonly 9-14 years old
  - Reported as young as 6 months & as old as 55 years
- Sex: Female predominance
  - M:F = 1:2.1

Natural History & Prognosis

- Most patients undergo spontaneous resolution over months to years
  - Symptoms up to 25 years following initial diagnosis

Treatment

- 1st-line treatment: NSAIDs
- 2nd-line treatment: Methotrexate, TNF inhibitors, bisphosphonates

DIAGNOSTIC CHECKLIST

Consider

- Lack of improvement on antibiotics & presence of associated inflammatory disorder lend support to imaging findings suggestive of CRMO
- Whole-body MR or bone scan to evaluate multifocality
- Medial clavicular involvement strongly suggests CRMO

Image Interpretation Pearls

- Carefully inspect metaphyses on radiographs in patients with extremity pain
- ± soft tissue inflammation & joint effusion/synovitis
- ± small, intraosseous fluid collections or necrotic bone
  - Soft tissue abscess, sequestra, or presence of fistula suggests bacterial osteomyelitis

Reporting Tips

- Suggest diagnosis along with appropriate differential considerations if imaging appearance is characteristic
- Include presence/absence of transphyseal involvement
  - ↑ risk of growth disturbance

(Left) *Frontal (left) & lateral (right) ankle radiographs in a 12-year-old girl with left ankle & knee pain show a lytic lesion in the distal tibial metaphysis with mild adjacent sclerosis.* **(Right)** *Sagittal T2 FS (left) & T1 C+ FS (right) MR images in the same girl show a focal metaphyseal lesion with ↑ T2 signal & enhancement. There is physeal extension with adjacent metaphyseal, epiphyseal, & periosteal edema.*

(Left) *AP knee radiograph in the same girl at presentation (left) shows a focal lytic lesion in the proximal left tibial metaphysis. Biopsy with culture grew no organisms. After treatment with a TNF-a antagonist, her symptoms & tibial lesion resolved (right), typical of CRMO.* **(Right)** *Long-axis T2 FS MR images of the feet in a 13-year-old girl with bilateral foot & ankle pain show edema of several metatarsals. Note the transphyseal extension in both 2nd metatarsals. Biopsy & culture revealed no organism, typical of CRMO.*

(Left) *Sagittal T2 MR in a patient with Crohn disease & rashes shows ↑ signal within the T1, T6, & T7 vertebral bodies with height loss at T6 & T7. The patient was ultimately diagnosed with CRMO.* **(Right)** *Coronal T2 FS MR in a 13-year-old patient with CRMO shows relatively symmetric foci of ↑ signal in the pelvis & proximal femurs adjacent to growth cartilages. There is also left sacroiliitis.*

Infantile Hemangioma

KEY FACTS

TERMINOLOGY

- Widespread misuse of term "hemangioma" in literature
  - True hemangioma: Benign vascular neoplasm
- Infantile hemangioma (IH)
  - Most common soft tissue tumor of childhood
  - Predictable life cycle: Usually absent at birth, rapid growth over 1st few weeks/months of life (proliferating phase), spontaneous regression over subsequent months to years (involuting phase)

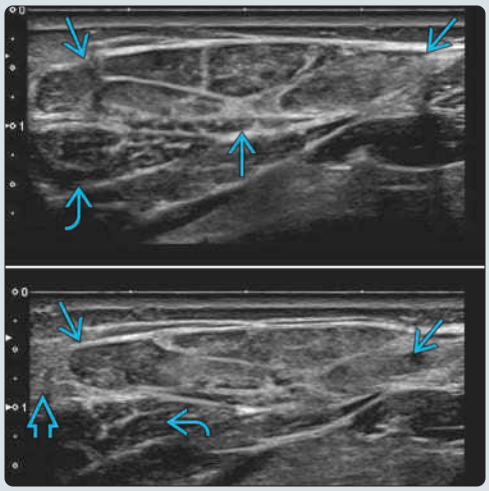
IMAGING

- Soft/"squishy," elongated, lobulated, well-defined, highly vascular, solitary or multifocal superficial soft tissue mass
- Grayscale US shows moderately compressible subcutaneous mass with variable internal echogenicity & few discrete vessels
- Doppler US should clearly document characteristic internal vascularity (i.e., high vessel density with many low-resistance arterial waveforms) throughout proliferating IH
- MR shows diffusely high T2 signal with scattered flow voids, relatively high ADC values, & diffuse enhancement
- Imaging features change with involution

TOP DIFFERENTIAL DIAGNOSES

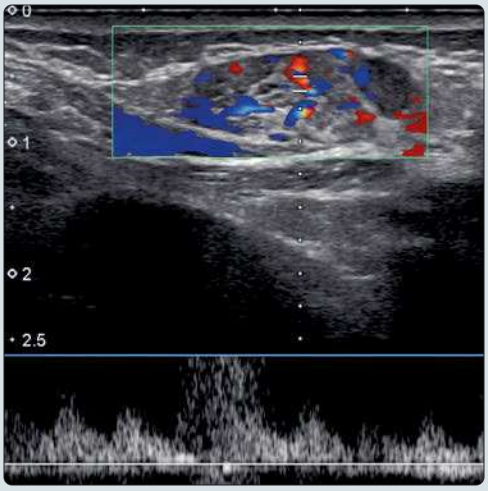
- Other vascular neoplasms: Congenital hemangioma, kaposiform hemangioendothelioma
- Vascular malformations: Venous, lymphatic, arteriovenous
- Soft tissue sarcomas

CLINICAL ISSUES

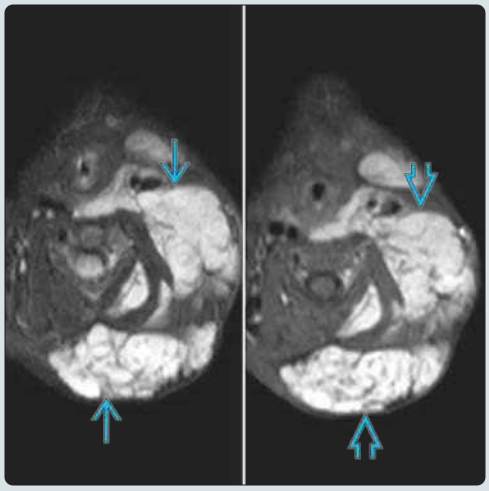


- Most follow benign course without requiring therapy
- Complications &/or associated anomalies are more likely if IH is large, segmental, facial, or multifocal
  - 1st-line therapy: Propranolol (β-blocker)

DIAGNOSTIC CHECKLIST



- If imaging appearance, timeline, or physical exam findings are atypical for IH, exclude other lesions by biopsy



(Left) *Photograph of a 4-month-old patient shows a well-defined, raised strawberry lesion on the neck that appeared after birth, typical of a proliferating infantile hemangioma (IH).* **(Right)** *Longitudinal US images in a 3-month-old with a soft, growing palpable mass of the back show a well-circumscribed elongated mass that lies within the subcutaneous fat & does not extend deeper into muscle. The mass is somewhat lobulated & mildly heterogeneous in echogenicity.*

(Left) *Transverse Doppler US of the same mass shows a high vessel density with many low-resistance arterial waveforms. The overall findings are very typical of an IH.* **(Right)** *Axial STIR (left) & T1 C+ FS (right) MR images in an infant with facial IHs & aortic coarctation show numerous lobulated lesions of the superficial & deep neck with bright (nearly fluid) signal & diffuse enhancement. The findings are consistent with IHs, though deeper extension is typically seen only with an associated syndrome (such as PHACE in this patient).*

TERMINOLOGY

Synonyms

- Capillary hemangioma, strawberry hemangioma
- Not cavernous hemangioma (actually venous malformation)
- Not synovial hemangioma (actually venous malformation)
- Not hemangioendothelioma (actually intermediate-grade vascular tumor)

Definitions

- 2018 revised classification by International Society for Study of Vascular Anomalies (ISSVA) retains 2 main categories
  - Vascular tumors (true neoplasms with cellular proliferation that generally grow out of proportion to patient)
  - Vascular malformations (congenital errors of vessel development that generally grow commensurate with patient)
- Hemangioma: Benign vascular neoplasm with predictable life cycle
  - Infantile hemangioma (IH)
    - Most common soft tissue tumor of childhood
    - Usually absent at birth with rapid growth over 1st few weeks/months of life (proliferating phase) followed by spontaneous regression over subsequent months to years (involuting phase)
  - Congenital hemangioma (CH)
    - Fully developed at birth
    - Rapidly involuting (RICH) vs. noninvoluting (NICH) vs. partially involuting (PICH)
      - RICH is mostly involuted by 14 months

IMAGING

General Features

- Best diagnostic clue
  - Lobular, well-defined, highly vascular solitary or multifocal superficial soft tissue masses appearing in 1st few weeks of life
    - Common cutaneous lesions are not usually imaged due to typical appearance & timeline
    - Deeper subcutaneous lesions without typical skin findings are likely to be imaged, as diagnosis is less clear to clinician
- Location
  - Head & neck (60%), trunk (25%), extremities (15%)
  - Typically confined to cutaneous or subcutaneous tissues
    - Deeper lesions are typically only seen in syndromic cases or with multifocal cutaneous lesions
- Morphology
  - Frequently ovoid or elongated rather than round
- Other imaging characteristics
  - Depends on timing of imaging
    - Proliferating phase: Homogeneous & diffuse enhancement; high-flow vessels in/adjacent to mass
    - Involuting phase: Heterogeneous with varying fatty infiltration; ↓ flow/enhancement of mass

Radiographic Findings

- Soft tissue mass without Ca^{2+}
  - Phleboliths are found in venous malformations, not IH

Ultrasonographic Findings

- Grayscale ultrasound
  - Lobular mass with variable echogenicity & few macroscopic vessels
    - Relative to subcutaneous fat: ~ 30% hypoechoic, 30% hyperechoic, 40% mixed echogenicity
  - Soft "squishy" mass: Moderately compressible with relatively high elasticity/strain
- Color Doppler
  - "Lights up" during proliferating phase
    - High vessel density on color Doppler (> 5 vessels/cm^2)
    - High systolic Doppler shift (> 2 kHz): Many arterial tracings with low resistive index but no arterialized veins to suggest shunting
  - With involution/treatment: ↓ vessel density & size, ↓ flow velocity, ↑ resistive index

MR Findings

- Proliferating phase
  - Largely homogeneous except for occasional flow voids & intervening thin septa
  - T1: Intermediate signal intensity
  - T2 FS/STIR: High signal intensity
    - May not be as bright as fluid
    - Many internal low signal flow voids are often present
  - T1 C+ FS: Diffuse early homogeneous enhancement
  - DWI: ADC values are higher in IHs vs. pediatric soft tissue malignancies
    - IHs: ~ 1.3-1.6 x 10^{-3} mm^2/s
    - Sarcomas: ~ 0.6-1.1 x 10^{-3} mm^2/s
- Involuting phase
  - Varying degrees of fatty infiltration with ↓ flow/enhancement

Imaging Recommendations

- Best imaging tool
  - Cutaneous IH (majority) can be diagnosed by physical appearance & temporal growth history without imaging
  - For deeper lesions, US with Doppler can be highly suggestive of IH in right age range
  - Imaging may also be employed when location/number of cutaneous lesions implicate associated anomalies &/or complications
    - IH over lower midline back: Spine anomalies
    - Perineal IH: PELVIS/LUMBAR syndrome
    - Segmental or bearded facial IH: PHACE(S), airway involvement
    - Periocular IH: ± intraorbital components, various ophthalmologic complications
    - ≥ 5 cutaneous IHs: ↑ likelihood of visceral involvement, especially liver
      - Numerous liver lesions can lead to hepatic & heart failure, abdominal compartment syndrome, &/or hypothyroidism

DIFFERENTIAL DIAGNOSIS

Venous Malformation

- Multiple serpentine channels &/or lobular soft tissue mass(es) infiltrating various compartments
- Fluid signal intensity mass ± fluid-fluid levels

- Delayed/gradual patchy enhancement (except for thrombi)
- Phleboliths are virtually diagnostic in children

Lymphatic Malformation

- Multicystic mass crossing soft tissue planes
- May contain fluid-fluid levels, debris
- Rim/septal enhancement
  - Microcystic components may appear more solid

Arteriovenous Malformation

- Tangle of high-flow vessels with shunting
- ± other soft tissue components

Congenital Hemangioma

- Solid, heterogeneous, less well-defined mass ± Ca^{2+}, hemorrhage, necrosis, & larger vessels
- Fully developed at birth; different cutaneous features vs. IH

Kaposiform Hemangioendothelioma

- Usually poorly defined, infiltrating, solid enhancing mass presenting in infant with Kasabach-Merritt phenomenon
- ± marked surrounding edema: Difficult to discern from lesion margins

Soft Tissue Sarcomas

- Usually firm, solid, round mass with heterogeneous enhancement & intermediate to low vascularity
- Relatively uncommon in 1st few months of life
- Restricted diffusion (with lower ADC values)

PATHOLOGY

Microscopic Features

- Proliferating phase: Masses of plump endothelial cells forming small vascular channels
- Involuting phase: Flat endothelial cells + fibrofatty replacement

Immunohistochemical Features

- GLUT1(+) during all phases
  - CH: GLUT1(-)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually presents during infancy as asymptomatic soft mass
    - With cutaneous involvement (most common): Lobular bright red or pink lesion
      - Localized: Nodule, papule
      - Segmental: Plaque-like over region
    - With deeper subcutaneous lesions: Bluish hue to skin
- Other signs/symptoms
  - During proliferation, high flow may cause bruit, warmth
  - May present with complication
    - Compression of vital structures, liver failure, etc.

Demographics

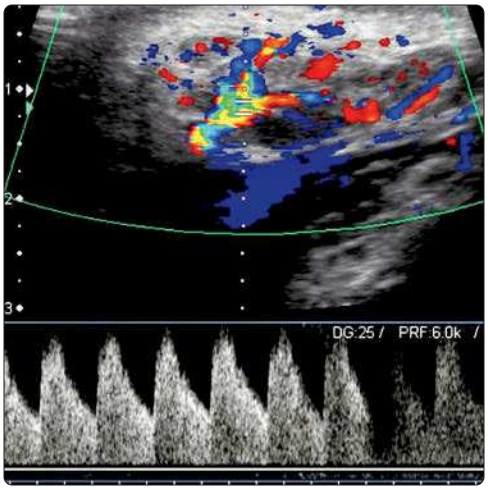
- Age
  - At birth: Typically absent
    - 30% have precursor lesion (pallor, ecchymosis, telangiectasia)
  - 0-2 months: Almost all double in size
  - 3-5 months: 80% of maximum size
  - 9-12 months: Peak size reached in almost all lesions
  - 12-48 months: Most rapid phase of involution
  - By 84-108 months: Involution usually complete
    - 20-50% with cutaneous residua
- Sex
  - Female predominance (F:M = 1.5-4.0:1.0)
- Ethnicity
  - White > > Black, Hispanic, Asian patients
- Epidemiology
  - Multiple lesions in 15-30% of patients
  - Up to 10% of premature infants affected vs. 5% overall

Natural History & Prognosis

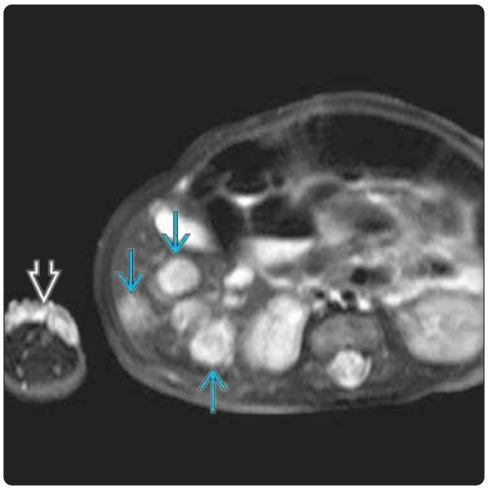
- Most follow benign course
- Complications are more likely if IH is large, segmental, multifocal, or on face
  - Ulceration (most likely with intertriginous & perioral lesions), bleeding
  - Compression of vital structures (airway, orbit)
  - Heart failure, liver failure, hypothyroidism, &/or compartment syndrome with high liver lesion burden
  - Psychologic issues (especially with facial lesions)
  - Coagulopathy is not associated with IH

Treatment

- Most IHs require no imaging or therapy
- Therapy is reserved for large or complicated lesions or for significant residua (such as fibrofatty tissue or cutaneous telangiectasias) following involution
- 1st-line treatment is medical
  - Propranolol (β-blocker) has replaced oral steroids as primary therapy due to low side effect profile
- Other therapies: Intralesional steroids, embolization, surgical removal, pulsed-dye laser



DIAGNOSTIC CHECKLIST



Consider

- If imaging appearance, timeline, or physical exam findings are atypical for IH, exclude other lesions by biopsy
- IH patients with cutaneous segmental lesions, certain facial lesions, or ≥ 5 lesions otherwise require further directed imaging due to associated anomalies/complications

(Left) *Transverse color Doppler US in a 2-month-old at the level of a growing soft tissue mass of the back (which was not present at birth) shows a heterogeneously echogenic mass of the subcutaneous fat. There is a high vessel density with low-resistance arterial waveforms, typical of IH.* **(Right)** *Axial T2 FS MR in a 3-month-old with a known forearm IH shows multiple round, hyperintense hepatic lesions. Having ≥ 5 skin IHs ↑ the risk of visceral lesions with the liver being the most frequently affected organ.*

(Left) *Axial abdominal CECT in a 12-month-old girl with a known superficial IH shows an elongated, well-defined, lobular mass with peripheral enhancement & central fatty infiltration. Note the prominent vessels along the lesion margins. These findings are typical of an IH during early involution.* **(Right)** *Axial CECT in the same patient 7 years later shows minimal residual prominence of fat at the site of the previously visualized lesion, consistent with an involuted IH.*

(Left) *Coronal STIR (left) & axial T1 C+ FS (right) MR images in a 9-month-old show a large, lobulated hyperintense & diffusely enhancing subcutaneous mass with internal flow voids. Numerous large feeding & draining vessels are seen deep to the lesion in the gluteal musculature. Biopsy confirmed an IH.* **(Right)** *Coronal STIR (left) & axial T1 C+ FS (right) MR images in the same patient 10 years later show involution of the IH with minimal residual lesion & substantial ↓ in the subjacent gluteal vessels.*

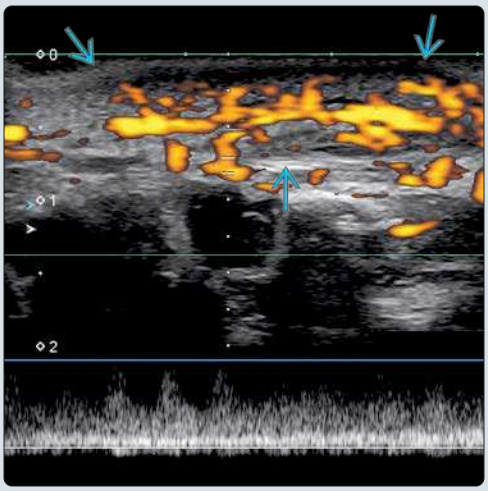
Kaposiform Hemangioendothelioma

KEY FACTS

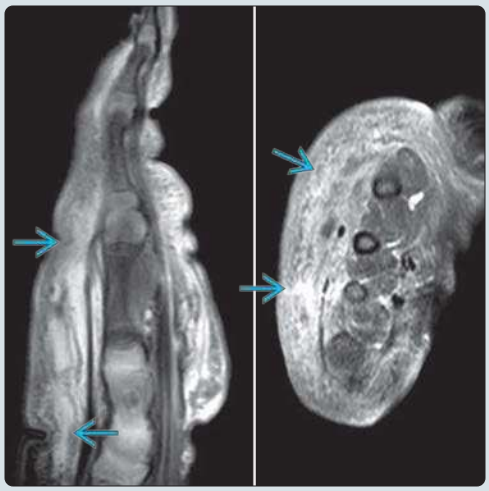
TERMINOLOGY

- KHE: Aggressive, locally invasive vascular neoplasm of spindled endothelial cells & abnormal lymphatics

IMAGING

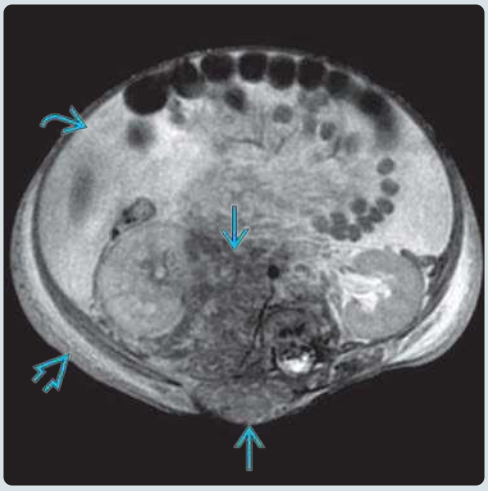


- Best clue: Poorly defined, diffusely enhancing soft tissue mass infiltrating multiple tissue planes/compartments in infant with coagulopathy
  - ~ 80-90% have continuous cutaneous lesions & deep components
- Most common locations: Extremity > trunk > head & neck; regional lymph node involvement is common



CLINICAL ISSUES

- Characteristic cutaneous vascular lesion ~ 90%: Indurated, ill-defined, red-purple mass or plaque
- Profound, sustained consumptive coagulopathy: Kasabach-Merritt phenomenon (KMP) in 33-70%
  - ↓ platelets, fibrinogen, hematocrit; ↑ D-dimer
  - KHE lesions at risk for KMP include those with
    - Deeper > superficial components (78% vs. 36%)
    - Retroperitoneal & thoracic involvement
    - Cutaneous lesion > 8 cm
- > 90% present in infancy; median age: 2-5 months
- Mortality ranges from 12-30%
- Treated lesions do not fully regress & may recur
- Treatment in setting of KMP includes steroids + sirolimus &/or vincristine
  - Limited role for platelet transfusions
  - Complete surgical excision curative but rarely option due to infiltrative nature of KHE with extension into vital regions



DIAGNOSTIC CHECKLIST

- Enhancing poorly defined soft tissue mass in infant with thrombocytopenia should raise concern for KHE
- In conjunction with characteristic cutaneous lesion, these features may obviate biopsy

(Left) *Sagittal power Doppler ultrasound shows an infiltrative, poorly defined, hypervascular mass expanding the right hand dorsal soft tissues of a 3 week old with redness & swelling since birth.* **(Right)** *Sagittal T2 FS (L) & axial T1 C+ FS (R) MR in the same infant 1 week later show heterogeneous enhancement of the infiltrating lesion. The margins are inseparable from surrounding edema. A typical coagulopathy of Kasabach-Merritt phenomenon confirmed kaposiform hemangioendothelioma (KHE).*

(Left) *Axial FS T2 MR in a 3-week-old with consumptive coagulopathy & abdominal distention shows a large, poorly defined intermediate T2 signal intensity mass extending from the skin into the retroperitoneum. There is diffuse body wall edema & a large volume of ascites.* **(Right)** *Coronal T1 C+ FS MR in the same patient shows early, diffuse enhancement of the infiltrative mass, confirmed to be a KHE.*

TERMINOLOGY

Definitions

- Kaposiform hemangioendothelioma (KHE): Aggressive, locally invasive vascular neoplasm of spindled endothelial cells & abnormal lymphatics
  - **Not** equivalent to hemangioma

IMAGING

General Features

- Best diagnostic clue
  - Poorly defined soft tissue mass infiltrating across tissue planes in infant with coagulopathy
- Location
  - Extremity > trunk > head & neck
    - ~ 26% have continuous extension into > 1 region
  - Most have superficial & deep involvement, extending from skin through subcutaneous fat into muscle
  - Regional lymph node involvement is common
  - Visceral & bony involvement are uncommon
  - Very rare reports of multifocality vs. distant metastases
    - May actually represent distinct entity: Kaposiform lymphangiomatosis
- CT/MR/US
  - Classic appearance: Infiltrating, poorly defined mass
    - Thickening/expansion of involved soft tissues
    - Variable degree of reticular foci or stranding extending from mass into surrounding tissues
      - Difficult to distinguish surrounding edema from true tumor margins
  - Less common: Well-defined lesion
  - Often heterogeneous internally: May have foci of hemorrhage & fibrosis
    - Intermediate to dark T2 components amidst otherwise T2 bright lesion on MR
    - Variable enhancement; can be strikingly vigorous & diffuse (particularly on CECT)
  - Moderately ↑ vascularity
    - ± prominent feeding/draining vessels
    - No large tangles of vessels or significant shunting

DIFFERENTIAL DIAGNOSIS

Soft Tissue Infection (Cellulitis/Fasciitis/Myositis)

- Redness, swelling, pain, ↑ inflammatory markers
- Indurated soft tissues with serpiginous hypoechoic fluid

Microcystic Lymphatic Malformation

- Longstanding tissue thickening ± cutaneous blebs

Hemangioma, Infantile vs. Congenital

- Typically well-defined, high-flow cutaneous/subcutaneous mass of infancy without muscular involvement

Infantile Myofibroma

- Solid soft tissue mass of infants with variable heterogeneity, Ca^{2+}, tissue infiltration, bone involvement

Rhabdomyosarcoma

- Well-defined, solid soft tissue mass of children (usually not neonates) with variable vascularity

PATHOLOGY

General Features

- Histologic & clinical overlap with more limited superficial lesion of tufted angioma (TA)

Microscopic Features

- Coalescing nodules of spindled endothelial cells surrounded by abnormal lymphatic channels
  - Intermixed platelet microthrombi, extravasated RBCs, hemosiderin

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Characteristic cutaneous vascular lesion ~ 90%
    - Indurated, ill-defined, red-purple mass or plaque
  - Profound, sustained consumptive coagulopathy with microangiopathic hemolytic anemia: Kasabach-Merritt phenomenon (KMP) in 33-70%
    - ↓ platelets, ↓ fibrinogen, ↓ hematocrit, ↑ D-dimer
    - KHE lesions at risk for KMP include those with
      - Deeper > superficial components (78% vs. 36%)
      - Retroperitoneal & thoracic involvement
      - Cutaneous lesion > 8 cm
- Other signs/symptoms
  - Musculoskeletal symptoms: Pain, ↓ range of motion
  - Clinically inert soft tissue mass

Demographics

- > 90% present in infancy; median age: 2-5 months
  - Patients with KMP present earlier than those without

Natural History & Prognosis

- Mortality ranges from 12-30%
- Treated lesions do not fully regress & may recur

Treatment

- KHE with KMP
  - Steroids, sirolimus (m-TOR inhibitor), &/or vincristine
  - Limited role for platelet transfusions (only prior to surgery or for active bleeding)
  - Complete surgical excision is curative but rarely option due to infiltration & extension into vital regions
  - Embolization can be temporizing
- KHE without KMP
  - Oral steroids alone may be used for growing lesions

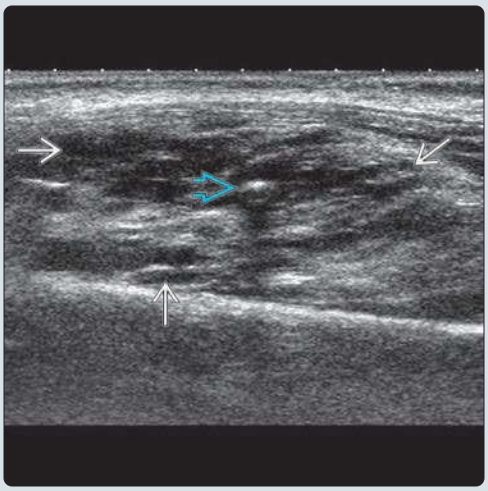
Venous Malformation

KEY FACTS

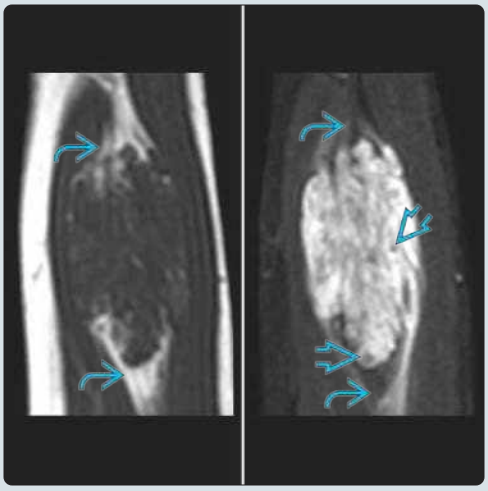
TERMINOLOGY



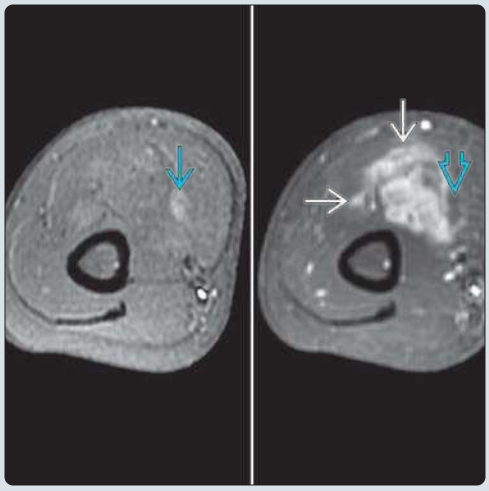
- Subtype of congenital slow- or low-flow vascular malformation due to error in vein formation; not neoplastic
  - **Not** hemangioma (benign vascular neoplasm of capillaries) or arteriovenous malformation (high flow)

IMAGING

- Locations
  - Most commonly subcutaneous &/or intramuscular but may involve bone, synovium, viscera
  - Focal, multifocal, or diffuse throughout region
- Morphology
  - Well-circumscribed, lobulated mass vs. extensive confluent, infiltrative lesion
  - ± discrete serpentine venous channels of abnormal number, size, shape, & location
- Radiography: Phleboliths in mass are essentially diagnostic
- MR: High fluid signal intensity ± layering fluid-fluid levels
  - Phleboliths are typically small, round, & dark
  - Diffuse or patchy delayed enhancement of mass; discrete venous channels will diffusely enhance
- US: Mass of heterogeneous echotexture
  - Hypoechoic/anechoic tubular channels in clusters
    - Compressible; will slowly refill
  - Phleboliths: Round echogenic foci with posterior acoustic shadowing & twinkling artifact
  - Detectable venous waveforms are often sparse



CLINICAL ISSUES



- Soft, compressible mass without thrill
  - Enlarges with Valsalva/crying/dependent positioning
  - Bluish skin discoloration with superficial lesions
  - Episodic pain &/or swelling
- Grow proportional to child but may enlarge suddenly due to hemorrhage, thrombosis, or hormonal changes
- Treatments include conservative therapy (compression garments, antiinflammatory medications), percutaneous procedures (sclerotherapy, laser), surgical resection

(Left) *Longitudinal US of the upper arm in a 9-year-old girl with new pain & swelling shows a multilobulated collection of hypoechoic channels within the biceps muscle. There is an echogenic focus in the mass with posterior acoustic shadowing.* **(Right)** *AP radiograph of the humerus in the same patient confirms numerous round, intralesional Ca^{2+} with lucent centers, typical of phleboliths in a venous malformation (VM).*

(Left) *Coronal T1 (left) & STIR (right) MR images of the same VM show the lobulated soft tissue mass following fluid signal intensity except for the thin septations & phleboliths. Note the associated fat along the margins & septations.* **(Right)** *Axial T1 FS pre- (left) & postcontrast (right) MR images through the same mass show that the lesion is largely isointense to muscle before contrast with subsequent heterogeneous enhancement. A focal thrombus shows T1 shortening before contrast but no enhancement.*

TERMINOLOGY

Synonyms

- Venous anomaly, common venous malformation (VM)
- **Not** hemangioma (benign vascular neoplasm of capillaries) or arteriovenous malformation (high-flow lesion)

Definitions

- Subtype of congenital slow- or low-flow vascular malformation due to error in vein formation; not neoplastic

IMAGING

General Features

- Location
  - Head/neck (40%), extremities (40%), trunk (20%)
  - Focal, multifocal, or diffuse throughout region
  - Most commonly subcutaneous &/or intramuscular but may involve bone, synovium, &/or viscera
    - Often cross soft tissue planes/compartments
- Morphology
  - Well-circumscribed, lobulated (spongiform) mass vs. extensive confluent, infiltrative lesion
  - ± discrete serpentine venous channels of abnormal number, size, shape, & location (phlebectasia)

Radiographic Findings

- Lobulated soft tissue mass ± calcified phleboliths (30%)

MR Findings

- T1WI
  - Largely isointense to muscle
    - Layering stagnant blood &/or thrombi may have ↑ signal intensity
    - Bright fat may be interspersed within & around lesion, particularly intramuscular components
- T2WI FS
  - Serpentine venous channels of high (fluid) signal intensity
    - Tightly clustered masses of abnormal channels show thin, dark, intervening septations
    - Large varicosities may show low signal internally due to disturbed flow; can mimic clot
  - Layering fluid-fluid levels are often present due to settling of blood products
    - Dependent sediment is of intermediate signal intensity vs. bright plasma
  - Absence of flow voids
  - Phleboliths are typically small, round, & dark
- T2* GRE
  - Useful to show chronic joint complications of hemarthroses from synovial VM
    - Blooming (exaggerated signal loss) of synovium from hemosiderin deposits; focal or diffuse cartilage loss
- T1WI C+ FS
  - Discrete ectatic venous channels diffusely enhance
  - Diffuse or patchy enhancement in lobulated mass-like components; thrombi & intermixed lymphatic components will not enhance
    - Dynamic imaging shows gradual contrast filling + absence of large arteries or arteriovenous shunting
- MRV
  - Useful to exclude intralesional high-flow vessels & confirm patency of deep venous system & varicosities
    - Slow-flow or in-plane flow can lose signal & mimic clot

Ultrasonographic Findings

- Grayscale ultrasound
  - Mass of heterogeneous echotexture
    - Hypoechoic/anechoic tubular channels in clusters with ↑ through transmission
      - Often compressible; will slowly refill
    - Intermixed & peripheral patchy foci of ↑ echogenicity due to fat, particularly in atrophied muscle
    - Phleboliths: Round echogenic foci with posterior acoustic shadowing & twinkle artifact
  - ± discrete venous channels of abnormal number, size, shape, & location in surrounding tissues
- Pulsed Doppler
  - Lack of arterial waveforms or arterialized draining veins
    - However, 1-2 normal arteries can be encased by VM
  - Detectable venous waveforms are often sparse
- Color Doppler
  - Majority show little internal vascular flow due to slow flow through dysplastic venous channels
    - Valsalva or compression/release will ↑ flow

Imaging Recommendations

- Best imaging tool
  - US (& potentially radiographs) can be diagnostic of VM
  - MR will show confirmatory features & clarify extent
- Protocol advice
  - US: Assess lesion response to compression
  - MR: Rapid T1 C+ FS 3D GRE sequence (FSPGR or Dixon) can confirm deep venous system or varicosity patency (as noncontrast MRV may be confounded by slow flow)

DIFFERENTIAL DIAGNOSIS

Infantile Hemangioma

- Characteristic life cycle: Small or absent at birth, rapid growth during early infancy, gradual involution over years
- Solid ovoid vs. lobular, elongated soft tissue mass, typically in cutaneous &/or subcutaneous tissues
- Variable sonographic echogenicity due to mix of proliferating & involuting components; no phleboliths
  - Soft & mildly compressible; not firm
- Highly vascular by Doppler US with many low-resistance arterial waveforms
- Bright (but not fluid) T2 signal intensity with diffuse early enhancement on MR

Arteriovenous Malformation

- Tangle of enlarged tortuous arteries & veins with variable soft tissue components
- High flow with shunting by US, MRA/MRV

Lymphatic Malformation

- Another common slow-flow lesion
- Compressible, fluid-filled macrocystic soft tissue mass
  - Thin, enhancing internal septations, internal debris/fluid-fluid levels, no internal vascularity
- Microcystic lesion is more solid-appearing, infiltrative

Soft Tissue Sarcoma

- Typically firm, well-defined, round or ovoid hypovascular solid soft tissue mass with variable enhancement
- ± cystic foci, but solid components are typically visible

Plexiform Neurofibroma

- Elongated lobular masses along courses of nerves
  - In multiple adjacent nerves: Bag of worms appearance
- Cross section of lesion shows target sign on MR
  - Bright peripherally, dark centrally on T2/STIR
  - Dark peripherally, bright centrally on T1 C+ FS

Fibroadipose Vascular Anomaly

- Uncommon solid lesion of extremity musculature
- Contains abnormal veins + dense fibrous & fatty tissue
- Constant pain + contracture

PATHOLOGY

General Features

- Genetics
  - Mutations in *TEK* (*TIE2*) or *PIK3CA*
- Associated abnormalities
  - Klippel-Trenaunay syndrome
    - Capillary-lymphatic-venous malformation of extremity (usually lower) + lipomatous & osseous overgrowth
    - Port-wine capillary stain on lateral extremity with lymphatic vesicles
    - Varicosities of superficial veins
      - Marginal primitive venous system may dominate over diminutive or absent deep venous system
  - Maffucci syndrome
    - Vascular soft tissue masses + enchondromatosis
      - Soft tissue masses likely represent spindle cell hemangiomas rather than true VM

Staging, Grading, & Classification

- 2018 revised classification of VMs by International Society for Study of Vascular Anomalies
  - Common VM (94%)
  - Familial VM cutaneomucosal
    - Multifocal lesions of lips, tongue
    - Dilated neck, upper extremity veins
  - Blue rubber bleb nevus syndrome
    - Multifocal cutaneous, muscular, gastrointestinal VMs
      - Intestinal VMs lead to chronic bleeding, anemia
  - Glomuvenous malformation
    - Presence of glomus cells in VM
    - Darker, less compressible superficial lesions
  - Cerebral cavernous malformation
  - Familial intraosseous vascular malformation
  - Verrucous VM
- Morphologic/drainage classification based on direct injection (Dubois & Puig)
  - Type I: Well circumscribed, isolated without venous drainage
  - Type II: Drainage into normal veins
  - Type III: Drainage into dysplastic ectatic veins
  - Type IV: Composed of ectatic veins

Microscopic Features

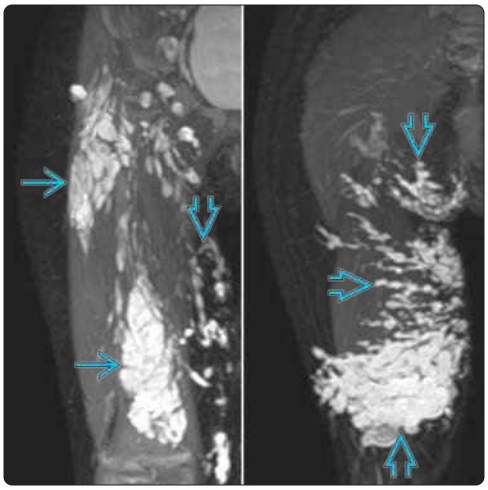
- Irregular, variably sized channels of flattened endothelium with variable smooth muscle & no internal elastic lamina
- Intraluminal thrombi are common
- May contain intermixed lymphatic components

CLINICAL ISSUES

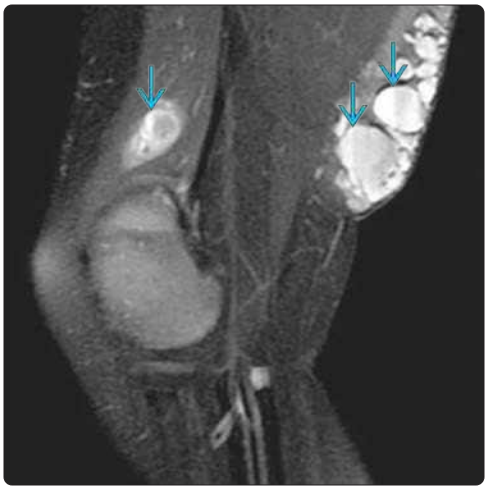
Presentation

- Most common signs/symptoms
  - Soft, compressible mass without thrill
    - ± small internal firm thrombi/hard phleboliths
    - Enlarges with Valsalva/crying/dependent positioning
  - Bluish skin discoloration with superficial lesions
  - Episodic pain &/or swelling, which may be due to
    - Engorgement from stasis
    - Intralesional thrombosis
    - Hemorrhage into adjacent tissues, joints
    - Local compression of adjacent tissues
    - Local muscular dysfunction
- Other signs/symptoms
  - Grow proportional to child but may enlarge suddenly due to hemorrhage, thrombosis, or hormonal changes
  - Large varicosities can lead to thromboembolism

Natural History & Prognosis



- Prognosis depends on lesion size, extent, & location
- Larger, more extensive lesions may cause lifelong morbidity



Treatment

- Conservative therapy
  - Compression garments; antiinflammatory medication
  - Low molecular weight heparin if thrombosis risk is ↑
- Percutaneous procedures
  - Direct injection with sclerosing agent under fluoroscopic/US guidance
    - Multiple procedures may be required
  - Laser ablation (Nd:YAG laser) of superficial VM
  - Endovenous ablation of varicosities
    - Radiofrequency vs. laser
- Surgical resection of focal lesions
  - ± percutaneous sclerosis for more extensive VM

(Left) *Coronal STIR MR MIP images in a 2-year-old show mass-like clusters of malformed intramuscular veins ⇨ as well variably sized abnormal subcutaneous veins ⇨. (Right) Sagittal T2 FS MR in the same patient using a dedicated knee coil shows higher detail of the malformed veins with fluid-fluid levels seen in multiple channels ⇨ (due to layering stagnant blood products). Note that the darker sediment lies dependently vs. the higher signal intensity plasma.*

(Left) *Frontal fluoroscopic image during a presclerotherapy diagnostic injection of the same right thigh VM shows continuity of the mass-like clusters of abnormal veins by elongated, smaller caliber abnormal venous channels.* **(Right)** *Frontal radiograph in the same patient 5 years later shows multiple small phleboliths ⇨ amidst residual lobulated soft tissue masses ⇨, an essentially pathognomonic x-ray appearance of VMs.*

(Left) *Sagittal PD MR in a 9-year-old with an extensive lower extremity VM shows the masses infiltrating all visible muscles ⇨ & extending into the knee joint ⇨. There is marked cartilage loss with a large distal femoral erosion ➡. (Right) Sagittal T2* GRE MR in the same patient shows blooming of hemosiderin within the joint ⇨ due to recurrent hemarthrosis from the synovial VM. Severe cartilage loss & a large femoral erosion ➡ are again noted.*

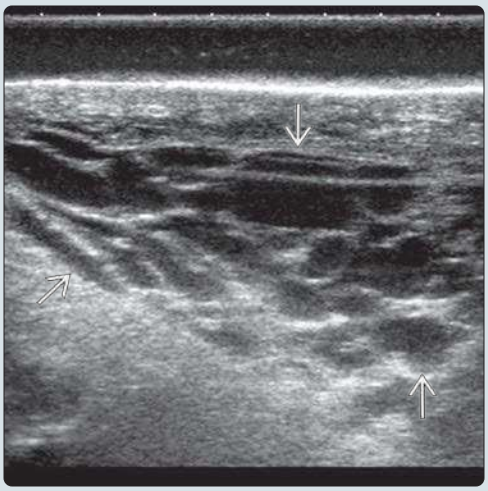
Lymphatic Malformation

KEY FACTS

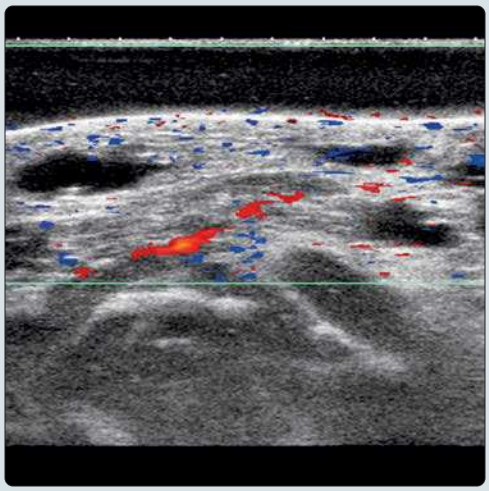
TERMINOLOGY

- Subtype of congenital slow-/low-flow vascular malformation due to error in lymphatic vessel formation
- Results in well-defined, cyst-like (macrocystic) &/or infiltrative, solid-appearing (microcystic) mass of abnormal lymphatic channels
  - Individual cyst size: Macrocyst > 1 cm, microcyst < 1 cm

IMAGING

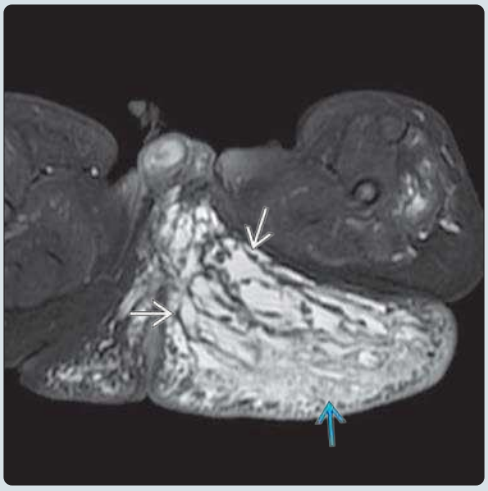


- Macrocystic lymphatic malformation (LM): Lobulated, well-defined cystic lesion with numerous thin internal septations
  - ± multiple fluid-fluid levels, typically due to hemorrhage
  - Soft & compressible by US with internal swirling debris
  - Protein, blood products, chyle/fat may cause bright T1 signal intensity on MR
  - Enhancement is limited to rim, septations
- Microcystic LM: More poorly defined & solid-appearing
  - ± diffuse enhancement
- Locations: Face, neck, chest, axilla > > abdomen, pelvis, extremities
  - Frequently extend across tissue planes/compartments



TOP DIFFERENTIAL DIAGNOSES

- Venous malformation
- Soft tissue sarcoma
- Soft tissue infection



CLINICAL ISSUES

- Soft & pliable mass, often apparent at birth
  - Can compress airway or other vital structures
  - May present later with pain & rapid enlargement due to hemorrhage, inflammation, or hormonal stimulation
- Primary treatment: Surgical resection &/or percutaneous sclerotherapy
  - Reports of successful medical therapy with sirolimus

(Left) *Transverse ultrasound of the left buttock in a 2-day-old with a clinically apparent capillary lymphaticovenous malformation shows a predominantly anechoic mass with thin septations in the subcutaneous soft tissues, typical of a macrocystic lymphatic malformation.* **(Right)** *Longitudinal color Doppler ultrasound in the same patient shows no significant internal vascular flow within the cysts.*

(Left) *Axial T2 FS MR in the same patient shows contiguous cystic foci with internal septations, typical of macrocystic components. The lesion is poorly defined & infiltrative superficially with slightly lower signal intensity, typical of microcystic components. The mildly thickened septations were likely due to interval infection.* **(Right)** *Axial T1 C+ FS MR in the same patient shows mild septal enhancement of the macrocystic components with more confluent enhancement of the microcystic components.*

TERMINOLOGY

Abbreviations

- Lymphatic malformation (LM)

Synonyms

- Common (cystic) LM, lymphatic anomaly
- Avoid incorrect & confusing terminology
  - Cystic hygroma is reserved for abnormal midline posterior nuchal translucency on early fetal US
    - Different than anterolateral neck LM, which does not necessarily implicate chromosomal anomalies
  - Lymphangioma implies neoplasm
    - LM is not neoplastic

Definitions

- Subtype of congenital slow-/low-flow vascular malformation due to error in lymphatic vessel formation
  - Results in well-defined, cyst-like (macrocystic) &/or infiltrative, solid-appearing (microcystic) mass of abnormal lymphatic channels
    - Individual cyst size: Macrocyst > 1 cm, microcyst < 1 cm
  - Mass lacks communication with normal lymphatics

IMAGING

General Features

- Location
  - Face, neck, chest, axilla > > abdomen, pelvis, extremities
  - Focal > > multifocal
  - Soft tissue > > bone
  - Frequently extend across tissue planes/compartments
- Size
  - Highly variable
  - May enlarge rapidly with hemorrhage, infection, or hormonal stimulation (puberty, pregnancy)
- Morphology
  - Macrocystic: Lobulated, well-defined cystic lesion with numerous thin internal septations
  - Microcystic: More poorly defined, infiltrative, & solid-appearing
  - Components of both may be present

Ultrasonographic Findings

- Grayscale ultrasound
  - Macrocystic LM: Anechoic cystic mass, usually with thin internal septations
    - ± ↑ echogenicity related to hemorrhage or proteinaceous fluid
    - Soft, compressible with swirling debris internally
  - Microcystic LM: Poorly defined region of subcutaneous soft tissue thickening
    - Mildly hypo- or hyperechoic
- Color Doppler
  - No vascular flow identified in cysts
  - Flow may be identified in septations, typically from encased normal vessels

MR Findings

- **T2 FS/STIR**: Largely fluid signal intensity mass
  - Intervening hypointense septa
  - Fluid-fluid levels due to hemorrhage within some cysts
    - Less frequently seen on other sequences
- **T1**: Hemorrhage, protein, fat/chyle within cysts may cause bright signal intensity; otherwise follows fluid signal
  - Patchy multifocal ↑ fat deposition may be seen in vertebrae in systemic lymphatic disorders
- **T1 C+ FS**
  - Macrocystic LM: Thin rim/septal enhancement of cysts
    - Septations may be thicker from recent inflammation or hemorrhage
  - Microcystic LM: ± confluent enhancement of infiltrating tissue
- **DWI/ADC**: Internal blood products may restrict diffusion, but mean ADC values are typically > 1.9 x 10^{-3} mm^2/s
- **MRA/MRV**: No high-flow vessels intrinsic to lesion
  - Nearby normal vessels may be encased by infiltrating LM
- **MR lymphangiogram**: Injection of contrast into lymph nodes with passage followed on dynamic 3D T1 FS sequences
  - More commonly used in setting of lymphedema or chylous ascites/effusions

Imaging Recommendations

- Best imaging tool
  - US is often diagnostic for macrocystic LM, though deep extent & relationship to vital structures may be unclear
  - MR will typically confirm diagnosis & extent of disease
- Protocol advice
  - US: For any soft tissue mass include
    - Compression cine to evaluate internal contents
    - Doppler assessment for presence & types of vascularity
  - MR: For any soft tissue mass include
    - Subtracted (pre- from post-) contrast-enhanced FS T1
      - Particularly relevant in LM as intrinsic T1 shortening from hemorrhage/protein may confound postcontrast images

DIFFERENTIAL DIAGNOSIS

Venous Malformation

- Focal mass vs. conglomeration of abnormal tubular slow-flow channels
- Phleboliths in soft tissue mass are essentially pathognomonic
- Bright (fluid) T2 signal intensity ± fluid-fluid levels on MR
- May have fat along margins or septa
- Gradual patchy enhancement after contrast

Soft Tissue Sarcoma

- Typically firm, well-defined round or ovoid hypovascular solid soft tissue mass with variable enhancement
- May have cystic components, but solid components with internal vascularity are usually visible
- Mean MR ADC values are typically < 1.1 x 10^{-3} mm^2/s

Soft Tissue Infection

- Cellulitis: Poorly defined soft tissue thickening with irregular serpentine pockets of fluid
- Abscess: Well-defined hypoechoic collection with mobile debris, thick & irregular walls

PATHOLOGY

General Features

- Associated abnormalities
  - Klippel-Trenaunay syndrome
    - Capillary lymphaticovenous malformation malformation of extremity (usually lower) + lipomatous & osseous overgrowth
    - Port-wine capillary stain on lateral extremity with lymphatic vesicles
    - Varicosities of superficial veins
      - Marginal venous system may dominate over diminutive or absent deep venous system
  - Congenital lipomatous overgrowth with vascular malformations, epidermal nevi, & skeletal anomalies (CLOVES)
    - Truncal lipomatous masses ± LM
    - Other vascular malformations are often present
  - LM may be associated with trisomies 13, 18, 21, or Turner syndrome

Staging, Grading, & Classification

- 2014 revised classification by International Society for Study of Vascular Anomalies (updated 2018)
  - Common (cystic) LM: Macrocystic, microcystic, mixed
  - Generalized lymphatic anomaly (GLA)
    - Multifocal cystic lesions commonly involving pleura, spleen, bones (axial & appendicular skeleton)
      - Progressive cortical destruction is not seen in GLA
    - Macrocystic LM is often present
  - Kaposiform lymphangiomatosis (KLA)
    - May be subtype of GLA
    - Extensive lymphangiectasia of lungs & mediastinum + coagulopathy
  - Gorham-Stout disease (GSD) ("vanishing bone disease")
    - Overlap with GLA but with less extensive disease
    - Favors axial skeleton
    - Progressive regional osteolysis (hallmark of disease) due to focal microcystic LM
      - Multiple adjacent bones are typically involved
  - Channel-type (or "central conducting-type") LM
    - May see dilated central lymphatics &/or secondary manifestations
      - Intestinal lymphangiectasia with bowel wall thickening & abnormal mesentery causing protein-losing enteropathy
      - Chylous pleural effusions & ascites
      - Extremity edema
  - Primary lymphedema

Immunohistochemical Features

- Endothelium stains positive for lymphatic markers
  - PROX1 & VEGFR-3 most sensitive, specific
  - D2-40 & LYVE-1 less sensitive in large channel LM

CLINICAL ISSUES

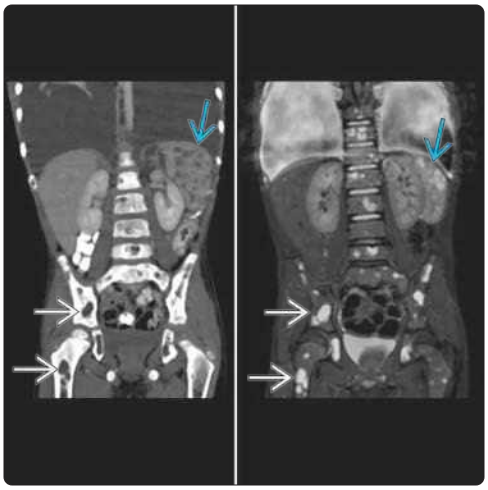
Presentation

- Most common signs/symptoms
  - Soft & pliable mass without pain
- Other signs/symptoms
  - Pain &/or rapid enlargement due to hemorrhage, inflammation, or hormonal stimulation
  - Cutaneous vesicles suggest LM, though overlying skin is often normal
  - Compression of airway or other vital structures
  - Diffuse limb enlargement

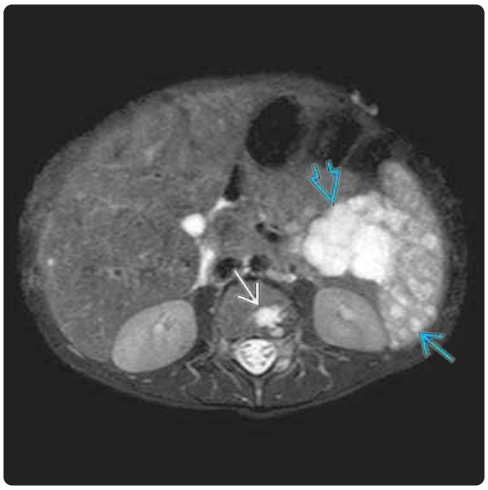
Demographics

- Age
  - Identified at birth or prenatally in majority of cases

Natural History & Prognosis



- LMs generally grow commensurate with patient
  - May enlarge rapidly due to hemorrhage, inflammation, or hormonal stimulation
- Prognosis is better for small focal lesions
  - Difficult to treat entirety of large, infiltrating lesion with surgery or sclerotherapy, leading to recurrence



Treatment

- Compression garments
- Surgical resection &/or percutaneous sclerotherapy
  - Combination is often required for larger infiltrating lesions
  - Sclerotherapy for macrocystic > microcystic disease
    - Direct injection of sclerosing agent into LM under sonographic/fluoroscopic guidance
      - Doxycycline, bleomycin, OK-432, ethanol
      - Utility of bleomycin is also reported in microcystic LM
    - Major complications (skin necrosis, nerve damage, extremity swelling, muscle atrophy, disseminated intravascular coagulation) are uncommon
    - Full results of sclerosis can take months to manifest
      - May take multiple staged procedures to treat lesion
- Medical therapy with sirolimus (mTOR inhibitor) is gaining favor

(Left) *Coronal CECT (left) & STIR MR (right) images of the abdomen in a 5-year-old patient with shortness of breath show large, bilateral pleural effusions, numerous well-defined lucent (CT) & fluid signal intensity (MR) bone lesions without cortical destruction, + multiple splenic lesions.* **(Right)** *Axial T2 FS MR in the same patient shows the bone & splenic lesions as well as a lobulated macrocystic mass in the splenic hilum. The constellation of findings in this case is typical of generalized lymphatic anomaly.*

(Left) *PA radiograph in a 14-year-old patient with years of pain shows severe osteolysis of the wrist & hand, typical of Gorham-Stout disease. The bone resorption had progressed severely over 3 years compared to a prior radiograph (not shown).* **(Right)** *Ultrasound of the axillary soft tissues in a 2-year-old patient with a soft, pliable mass shows a well-defined, lobulated, multicystic lesion with thin internal septations, typical of a macrocystic lymphatic malformation. Note the intact underlying rib.*

(Left) *Axial T2 FS MR shows an elongated, septated fluid signal intensity mass of the subcutaneous left flank, typical of a lymphatic malformation.* **(Right)** *Axial T2 FS MR obtained 1 month later in the same patient shows marked interval enlargement of the mass. Numerous fluid-fluid levels are now seen in the mass, typical of layering blood products due to interval hemorrhage.*

Arteriovenous Malformation (Musculoskeletal)

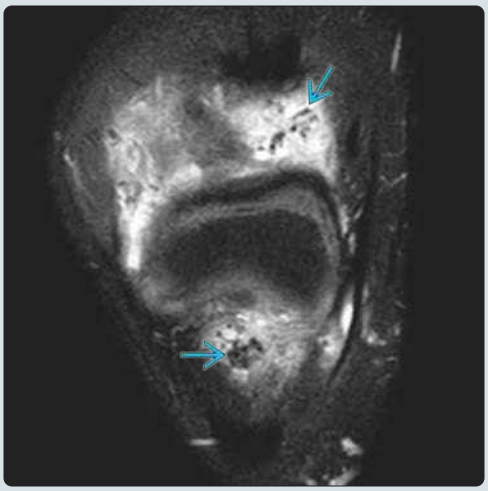
KEY FACTS

TERMINOLOGY

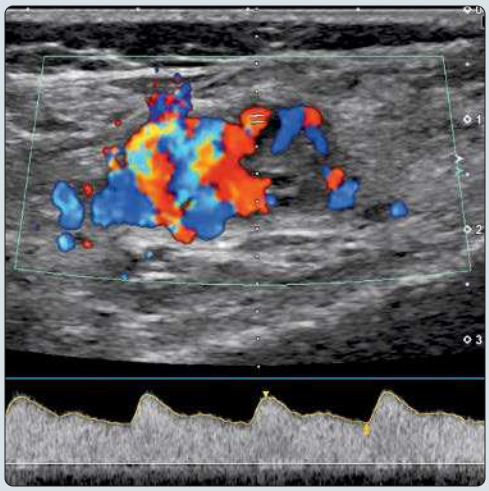
- Congenital high-flow vascular lesion with abnormal direct connections between arteries & veins (with no intervening capillary bed)

IMAGING

- Tangle of abnormal high-flow vessels with variable (often minimal) soft tissue mass
- Draining veins are enlarged > tortuous feeding arteries
- Grayscale US: Clustered, anechoic tubular channels
- Color Doppler US: Channels all fill with color; artifactual flow in surrounding soft tissues due to vibration
- Pulsed Doppler US: Numerous low-resistance (high diastolic flow) arterial waveforms & arterialized venous waveforms; spectral broadening
- MR spin-echo: Tangle of flow voids in lesion (before & after contrast); phase-encoding pulsation artifact at nidus; ± surrounding edema or soft tissue components
- CTA/MRA: Rapid contrast enhancement of nidus; early enhancement of draining veins due to shunting

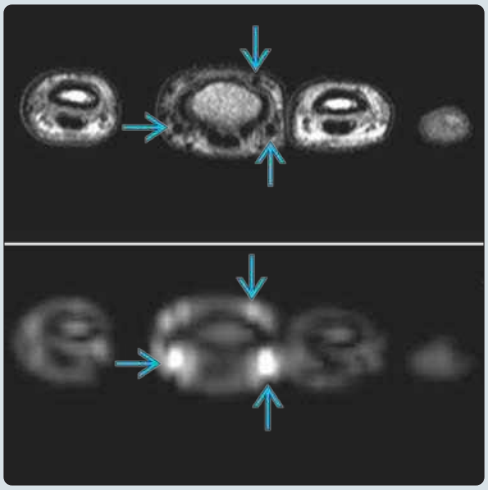


TOP DIFFERENTIAL DIAGNOSES



- Infantile hemangioma
- Venous malformation
- Arteriovenous fistula
- Soft tissue sarcoma
- *PTEN* hamartoma

CLINICAL ISSUES



- Presentation: Warm, pulsatile mass with thrill/bruit, pain, congestive heart failure (< 2%), steal phenomenon, skin discoloration, ulceration, prolonged bleeding
- Treatment generally consists of transarterial embolization without, or in conjunction with, surgical resection
- ~ 80% of superficial AVMs present in childhood
  - Hormonal stimulation of puberty or pregnancy → ↑ AVM size & symptoms in 2nd/3rd decades of life

(Left) *Coronal T2 FS MR in a 5-year-old with a longstanding mass & worsening knee pain shows clusters of small flow voids ⇨ (due to high-flow vessels) within surrounding poorly defined hyperintense tissue about the patella.* **(Right)** *Longitudinal spectral Doppler US in the same patient shows abnormally low-resistance arteries within one of the clusters of vessels, typical of an arteriovenous malformation (AVM).*

(Left) *Axial PD (top) & 2D TOF (bottom) MR images in a 9-year-old with a painful blue finger show numerous enlarged vessels (flow voids on PD & flow-enhancement on TOF) ⇨ throughout the visualized digit.* **(Right)** *Arterial- (left) & early venous- (right) phase DSA images of the hand in the same patient show a nidus of abnormal tangled arteries ⇨ in the distal middle finger with enlargement of the supplying digital arteries ⇨. There is early visualization of enlarged draining veins ⇨, consistent with shunting in this AVM.*

TERMINOLOGY

Definitions

- Arteriovenous malformation (AVM): Congenital high-flow vascular lesion with abnormal direct connections between arteries & veins (i.e., no intervening capillary bed)

IMAGING

General Features

- Morphology: Cluster of abnormal high-flow vessels; variable (but often minimal) associated soft tissue mass; draining veins are enlarged > tortuous feeding arteries
- Location: Essentially anywhere; often transspatial
  - Up to 20% of extremity AVMs have bone involvement
- **Radiographs**: ± mass-like density of soft tissues without phleboliths, limb/bone overgrowth; rare bone destruction
- **US:** Often used for initial investigation of mass
  - Grayscale: Clustered anechoic tubular channels (high vessel density) ± adjacent soft tissue edema/distortion (but classically without well-defined mass)
  - Color Doppler: Channels all fill with color flow; artifactual flow in surrounding soft tissues due to vibration
  - Pulsed Doppler: Numerous low-resistance (high diastolic flow) arterial waveforms with spectral broadening; arterialized venous waveforms
- **MR**
  - Spin-echo: Tangle(s) of flow voids in lesion due to high flow; phase-encoding pulsation artifact of nidus; ± surrounding edema or soft tissue components (in up to 50%, especially multicompartmental AVMs)
  - Gradient-echo: High-flow vessels are typically bright before & after contrast
- **CTA/MRA**: Useful for characterizing lesion, determining involvement of adjacent tissues, & planning embolization or surgery through measurement & mapping of vessels
  - Rapid contrast enhancement of nidus
    - Time-resolved/dynamic MRA: "Contrast rise time" < 20 seconds is highly specific for high-flow lesions
  - Early enhancement of draining veins due to shunting
  - Enlargement of otherwise normal vessels supplying/draining lesion

DIFFERENTIAL DIAGNOSIS

Infantile Hemangioma

- Discrete, heterogeneous, typically subcutaneous, high-flow, benign soft tissue neoplasm in infant
- US shows patchy regions of ↑ & ↓ echogenicity
  - High vessel density by color Doppler (not grayscale)
  - Low-resistance arterial waveforms during proliferation (but no shunting)

Venous Malformation

- Discrete or infiltrating low-flow mass, often intramuscular
  - Multiple high-signal serpentine channels on T2 FS MR
  - ± fluid-fluid levels in stagnant channels
- Phleboliths in pediatric mass are virtually diagnostic

Arteriovenous Fistula

- Direct high-flow communication between artery & vein without surrounding tangle of abnormal vessels

Soft Tissue Sarcomas

- Typically well-circumscribed, firm, solid mass
- Most have low to intermediate levels of vascularity

PTEN Hamartoma of Soft Tissue

- Heterogeneous mass with variable soft tissue components, including myxomatous & fatty elements
- High-flow vessels are typical
- Phenotype of *PTEN* mutation: Macrocrania, skin lesions

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Warm, pulsatile mass with thrill/bruit, pain
- Other signs/symptoms
  - Congestive heart failure (< 2%), steal phenomenon, skin discoloration, ulceration, prolonged bleeding
  - Limb length discrepancy: Bone overgrowth
  - Associated capillary stains (CM-AVM) are often multifocal & surrounded by characteristic pale halo
    - Number ↑ with age
  - May rarely present in utero with hydrops

Demographics

- ~ 80% of superficial AVMs present in childhood
  - Large shunting lesions may present soon after birth
  - Hormonal stimulation of puberty or pregnancy → ↑ AVM size & symptoms in 2nd/3rd decades of life

Natural History & Prognosis

- Schobinger classification: Outlines progressive clinical course of untreated AVMs
  - Stage 1 (quiescence)
    - All progress with > 80% doing so before adulthood
  - Stage 2 (expansion): ↑ pulse & thrill
  - Stage 3 (destruction): Local destruction with pain, ischemia, necrosis
  - Stage 4 (decompensation): High-output cardiac failure

Treatment

- Cure is rarely achievable; main goal is clinical improvement
- Conservative management: Compression garments
- Transarterial embolization
  - 75% volume devascularization rates are reported in 47-94%
- Surgical excision
  - Resection is best < 24 hours after embolization
- Recurrence rate: > 80-90%

Fibromatosis

KEY FACTS

TERMINOLOGY

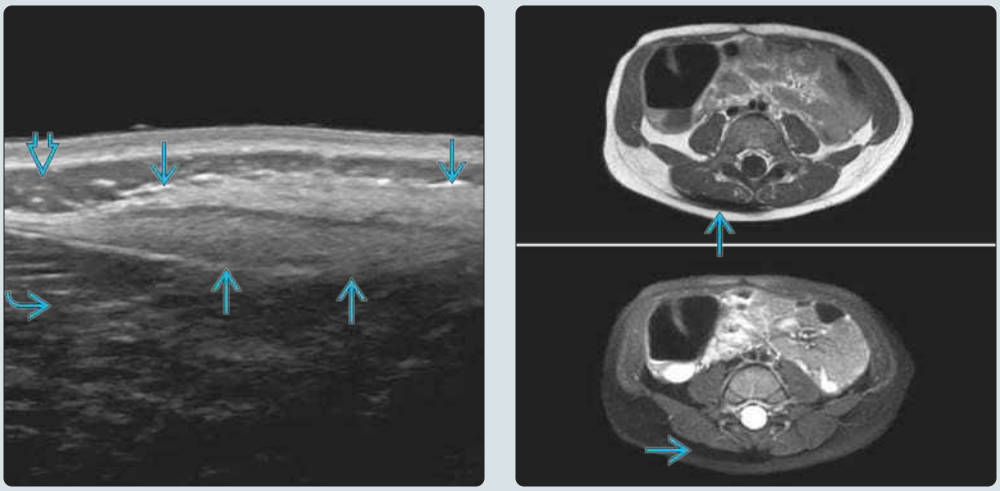
- Synonyms: Desmoid-type fibromatosis, aggressive fibromatosis, extraabdominal desmoid tumor, musculoaponeurotic fibromatosis
- Most common of fibrous tumors in children (60%)
- Locally aggressive with tendency to slowly infiltrate adjacent tissues
- Frequently recurs but lacks metastatic disease

IMAGING

- Homogeneous or heterogeneous with low T1 & T2 signal
  - Cellular components: T2 hyperintense/enhancing
  - Collagenous components: T2 hypointense/nonenhancing
- May be well defined or infiltrative
- Often in/adjacent to muscle; often multicompartmental
- Can remodel adjacent bone
- May arise at site of prior surgery or from preexisting Gardner fibroma
  - Gardner fibromas are typically plaque-like

PATHOLOGY

- Most are due to sporadic mutations activating β-catenin signaling pathway
- *APC* gene mutation (long arm of chromosome 5q21-22): Gardner syndrome



CLINICAL ISSUES

- Wait & see in some cases: May regress or stop growing
- Complete excision is often difficult due to infiltration
- Frequent local recurrence: 25-88%
  - Involvement of neurovascular bundle on baseline MR is greatest predictor for residual or recurrent disease

DIAGNOSTIC CHECKLIST

- Can mimic soft tissue sarcomas
- Due to slow growth, comparison to multiple prior exams is recommended to appreciate interval change

(Left) *Transverse ultrasound of the back in a 2-year-old with a palpable firm mass shows elongated echogenic tissue ⇨ at the interface of the subcutaneous fat ⇨ & muscle ⇨.* **(Right)** *Axial T1 (top) & T2 FS (bottom) MR images in the same patient show diffusely hypointense signal throughout the plaque-like mass ⇨, proven to be a Gardner fibroma in a patient with an APC mutation.*

(Left) *AP radiograph in a 14-year-old boy who injured his forearm 2 weeks prior shows subtle remodeling of the radius ⇨ & ulna ➡ with cortical scalloping.* **(Right)** *Axial T2 FS MR in the same teenager shows a lobulated hyperintense mass along the interosseous membrane between the radius & ulna. Note the cortical remodeling of the volar margin of the ulna ⇨ by this desmoid-type fibromatosis. With chemotherapy, increasing streaks of ↓ signal were noted in the lesion over time.*

TERMINOLOGY

Synonyms

- Desmoid-type fibromatosis, aggressive fibromatosis, extraabdominal desmoid tumor, musculoaponeurotic fibromatosis

Definitions

- Most common of fibrous tumors in children (60%)
- Locally aggressive with tendency to slowly infiltrate adjacent tissues
- Frequently recurs but lacks metastatic disease

IMAGING

General Features

- Location
  - Often in/adjacent to muscle; often multicompartmental
  - May arise at site of prior surgery or from preexisting Gardner fibroma
- Size
  - Varies widely; may be up to 20 cm (especially in Gardner syndrome)
- Morphology
  - Abdominal wall lesions tend to be more round/ovoid & well defined
  - Extremity lesions tend to be more elongated with nodular or tendril-like extensions
- **Desmoid-type fibromatosis (aggressive fibromatosis)**
  - 1st peak: 4-5 years old; 2nd peak: 25-35 years
  - F > M in younger patients
  - Erosions, scalloping, or bowing of bones
  - Nodular (more common in adults) or infiltrative (children) patterns
  - High potential for recurrence, locally aggressive
  - May spontaneously regress
- **Abdominal wall fibromatosis**
  - Most commonly in rectus abdominis muscles & adjacent fascia
  - Often related to recent pregnancy (in past year)
- **Gardner fibroma**
  - Mostly occur in 1st decade of life
  - Detection may be sentinel event leading to diagnosis of Gardner syndrome
  - Strong association with desmoid fibromatosis & Gardner syndrome
  - Plaque-like mass, typically hypointense T1 & T2 on MR with variable contrast enhancement
  - Common in trunk, paraspinal, head/neck, & extremities

Radiographic Findings

- Nondescript soft tissue mass
- ± periosteal reaction, scalloping, or erosions

CT Findings

- CECT
  - Soft tissue mass hyperdense to muscle
  - ± adjacent osseous changes, typically sparing medullary space

Ultrasonographic Findings

- Common 1st-line imaging modality for palpable mass
- Nonspecific soft tissue mass with variable echogenicity; may be well circumscribed or infiltrative & poorly defined

MR Findings

- T1WI
  - Typically hypointense to muscle; can be isointense
  - Frequently centered in intermuscular location with rim of surrounding fat (split fat sign)
- T2WI
  - Hyperintense or heterogeneous with bands of hypointense signal (fibrous components)
    - Depends on cellular compared (high signal) to collagen (low signal) components
  - Wide variability from diffusely low signal to diffusely high signal intensity
    - Significant portion of very hypointense signal is typical
    - Lesions with high signal at baseline are more likely to progress on therapy
  - Often insinuates slowly along fascial planes (fascial tail sign); may extend distance from main lesion
- DWI
  - Mean ADC value is higher than malignant soft tissue tumors
- T1WI C+
  - Variable enhancement depending on lesion activity

Nuclear Medicine Findings

- PET
  - Mild F-18 FDG uptake (with mean SUV of 3.1 in one study)

DIFFERENTIAL DIAGNOSIS

Infantile Myofibromatosis

- Most common in infancy but may occur in adults
- 90% in first 2 years of life, 50% in newborns
- ↑ in size & number to 1 year of age, then can regress
- 3 types: Solitary or multicentric involvement of soft tissues & bone, ± visceral involvement
  - Sharply defined bubbly lucent lesions of bone (metaphyseal > diaphyseal), often relatively symmetric
- MR: May have target appearance with nonenhancing center
  - ± Ca^{2+}

Congenital or Infantile Fibrosarcoma

- Typically presents < 2 years of age, commonly neonatal or congenital
- Can erode adjacent bone, rarely metastasize
- US: May be hypervascular with solid & cystic/hemorrhagic components
- MR: Heterogeneous enhancement, may be cystic
- Better prognosis than adults

Rhabdomyosarcoma

- Well-circumscribed solid soft tissue mass ± necrotic or hemorrhagic foci
- MR: Intermediate to high T2 signal, variable enhancement

Synovial Sarcoma

- Well-circumscribed soft tissue mass in close proximity to joint
- Amorphous Ca^{2+}

- MR: May be small & cystic-appearing before contrast

Venous Malformation

- Low-flow lesion with lobulated &/or tubular clusters
- MR: Fluid signal intensity ± phleboliths &/or thrombi, fluid-fluid levels, & patchy or diffuse enhancement

Plexiform Neurofibromas

- Clinical diagnosis of neurofibromatosis type 1 has often been established prior to imaging, but not always
- Elongated lobulated soft tissue lesions following course of nerve/nerves
  - With clustering of numerous lesions, may infiltrate/distort tissue planes & create bag of worms appearance
- MR: Typically T2 hyperintense; in cross section, individual lobules often have target appearance with central hypointensity

Fibrous Hamartoma of Infancy

- Neonates → young children (typically first 2 years of life, 1/4 are congenital)
- Subcutaneous or reticular dermis, 0.5 → 4 cm
- Axilla, shoulders, inguinal region, & chest wall are most common locations
- Excision is usually curative, excellent prognosis
- MR: Varying amounts of fibrous & fatty tissue
  - May have streaks of fat

Inflammatory Myofibroblastic Tumor

- Median age: 9 years old
- Most common in lung, mesentery, omentum
- May have inflammatory syndrome with fever, weight loss, abnormal lab values
- MR: Variable signal intensity depending on fibrous components

PATHOLOGY

General Features

- Etiology
  - β-catenin signaling pathway activation
- Genetics
  - Most are sporadic mutations
  - *APC* gene mutation (long arm of chromosome 5q21-22): Gardner syndrome
- Associated abnormalities
  - Familial adenomatosis fibromatosis (FAP) in 5% of Gardner syndrome patients
    - 1,000x greater risk of developing fibromatosis due to *APC* gene
    - Fibromatosis in 10-20% of FAP patients
  - Trisomies 7, 8, 14, 20

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Palpable mass
  - Firm, poorly circumscribed, slowly growing mass
  - Tends to extend beyond palpable limits
  - Flexion contractures
  - ± tenderness (related to nerve compression or infiltration)

Demographics

- Ethnicity
  - More common in White patients
- Epidemiology
  - 2-4/1 million per year

Natural History & Prognosis

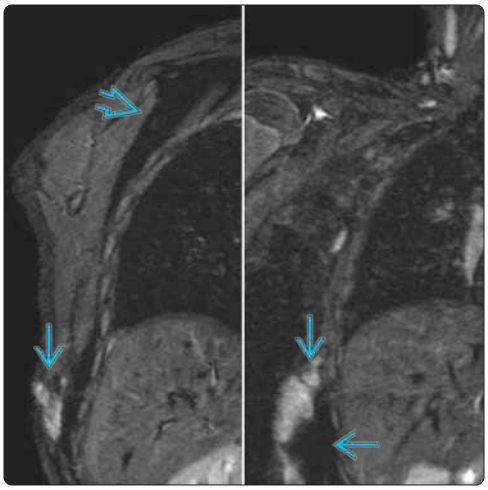
- Recurrence: 25-88% locally
  - Involvement of neurovascular bundle on baseline MR is greatest predictor for residual or recurrent disease
  - Larger lesions, < 30 years old, female predominance, location
  - Controversy over positive resection margin

Treatment

- With tissue confirmation: Wait & see; some lesions regress
- Surgical excision with wide margins; recurrence in 33-88%
  - For abdominal wall, symptomatic lesions, & progressive disease
  - Often wide excision is not feasible due to loss of function
- Chemotherapy, radiation therapy

DIAGNOSTIC CHECKLIST

Consider



- Can mimic soft tissue sarcomas

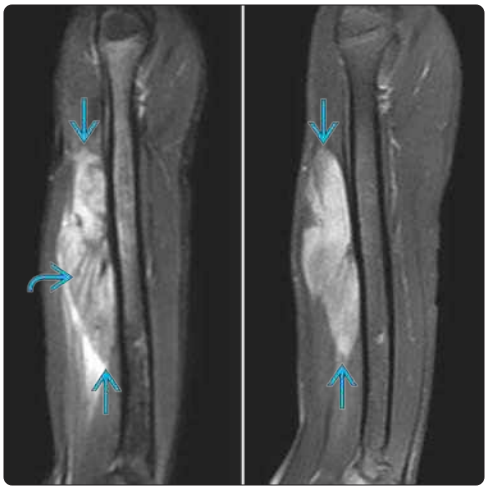


Image Interpretation Pearls

- Often contains regions of ↓ signal on T2 FS & T1 C+ FS MR
  - Inactive fibrous rather than active cellular components
- Due to slow growth, comparison to multiple prior exams is recommended to appreciate interval change

(Left) *Coronal STIR MR images in a 3-year-old with APC mutation-confirmed Gardner fibromatosis show 2 lesions: A stable, homogeneously low signal, plaque-like mass of the chest wall & a heterogeneous lobulated growing mass of the flank.* **(Right)** *Sagittal STIR (left) & T1 C+ FS (right) MR images in a 9-year-old show an elongated heterogeneous intramuscular mass proven to be desmoid fibromatosis. Note streaks of internal hypointensity. Due to progressive growth toward the chest, amputation was ultimately performed.*

(Left) *Coronal STIR MR of the forearm in a child just under 2 years of age shows a heterogeneous but predominantly hypointense ill-defined & infiltrative soft tissue mass. This was biopsied & proven to be desmoid-type fibromatosis.* **(Right)** *Axial T2 FS MR shows a heterogeneous, ill-defined soft tissue mass in the posterior right calf of a 16-year-old patient who had recurrent desmoid-type fibromatosis.*

(Left) *Axial T2 FS MR shows a heterogeneous mass within the left rectus abdominis muscle of a 25-year-old with Down syndrome & a history of multiple abdominal surgeries. Note the hypointense bands within this desmoid fibromatosis.* **(Right)** *Axial T2 FS MR shows a hyperintense subcutaneous mass extending to the anterior margin of the right rectus abdominis muscle in a 17-year-old boy. The mass was intensely enhancing (not shown) & proved to be a desmoid fibromatosis.*

Infantile Myofibroma/Myofibromatosis

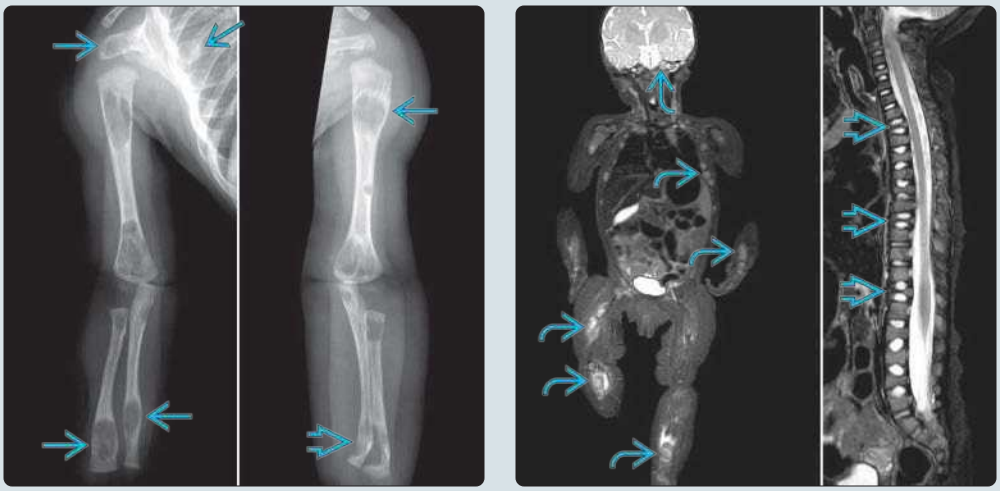
KEY FACTS

TERMINOLOGY

- Infantile myofibroma: Solitary, benign fibrous tumor of young children with high rate of spontaneous regression
- Myofibromatosis: Multicentric disease with soft tissue & bone lesions ± visceral involvement
  - Poorer prognosis with visceral lesions

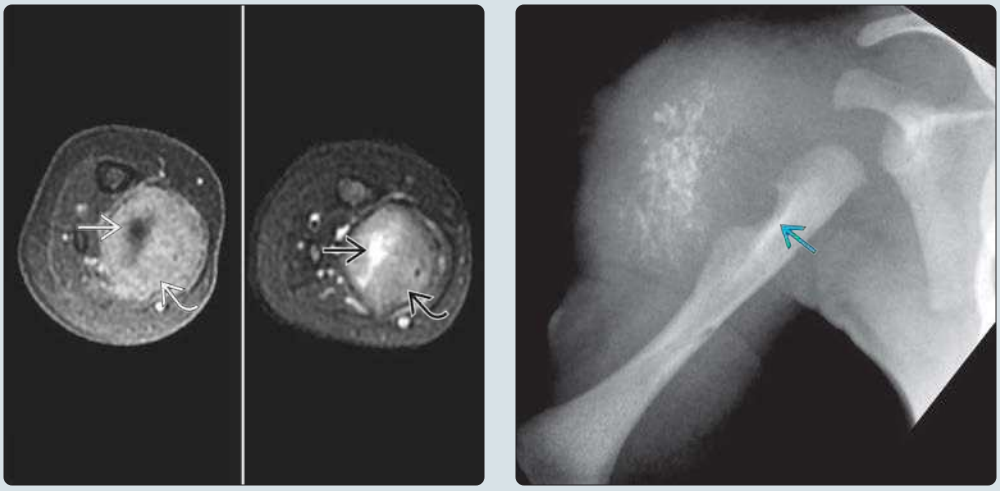
IMAGING

- Myofibroma: Solitary, solid soft tissue mass in infant
  - ± internal Ca^{2+}, bizarre adjacent bone remodeling
  - Hypovascular internally by Doppler
  - T2 FS MR: Variable internal signal intensity
  - T1 C+ FS MR: Peripheral/rim enhancement
  - Typical locations
    - Cutaneous, subcutaneous, muscular: 86%
    - Head & neck (50%) > trunk > extremities
- Myofibromatosis (25-55% of myofibroma cases)
  - Soft tissue masses
  - Relatively symmetric bony metaphyseal/metadiaphyseal lucent lesions ± remodeling, cortical loss
  - Visceral involvement in 25-37% of multicentric cases
    - Lungs > gastrointestinal tract > heart > liver



PATHOLOGY

- Peripheral clusters of spindled myofibroblastic cells
- Central cellularity & vascularity similar to hemangiopericytoma



CLINICAL ISSUES

- Presentations: Soft tissue mass ± red-purple skin nodules
  - Perinatal in 50%; 90% diagnosed by age 2
- Solitary/multicentric without visceral involvement: High rate of spontaneous regression over 1-2 years; 1% mortality
  - Observation vs. surgical resection
- Multicentric with visceral involvement: 48-75% mortality historically due to obstruction, organ failure
  - Favorable outcomes with low-dose chemotherapy

(Left) *AP radiographs of upper extremities in a 4-month-old with myofibromatosis show relatively symmetric, well-circumscribed lucent lesions of all visualized metadiaphyses. Many lesions demonstrate remodeling with expansion or bowing.* **(Right)** *Coronal (left) & sagittal (right) STIR MR images in the same patient show mild to moderate hyperintensity of the numerous skeletal lesions. There is deformity of many involved vertebral bodies, including several levels of vertebra plana. No visceral lesions were identified.*

(Left) *Axial T1 C+ FS (left) & axial T2 FS (right) MR images in a 4-month-old with multiple soft tissue masses show peripheral enhancement & T2 hypointensity with central nonenhancement & T2 hyperintensity of an infantile myofibroma.* **(Right)** *AP radiograph in a newborn with a large shoulder mass shows clustered speckled Ca^{2+} in the central necrotic portion of the mass. There is unusual remodeling of the adjacent humerus with expansion & focal surface scalloping. Myofibroma was confirmed on biopsy.*

TERMINOLOGY

Definitions

- Infantile myofibroma: Solitary, benign fibrous tumor of young children with high rate of spontaneous regression
- Myofibromatosis: Multifocal disease
  - Multicentric without visceral involvement: Soft tissue &/or bone lesions
  - Multicentric with visceral involvement (or generalized): Additional organ systems are involved with poorer prognosis

IMAGING

General Features

- Best diagnostic clue
  - Myofibroma: Solitary, solid, centrally nonenhancing soft tissue mass in newborn
    - Typically in skin & subcutaneous tissues
  - Myofibromatosis: Numerous, relatively symmetric, well-defined metaphyseal/metadiaphyseal lucent lesions ± remodeling, cortical loss
- Location
  - Cutaneous, subcutaneous, muscular: 86%
  - Solitary lesions: Head & neck (50%) > trunk > extremities
  - Multicentric disease in 25-55%
    - Visceral involvement in 25-37% of multicentric cases
      - Lungs > gastrointestinal tract > heart > liver
    - Uncommon forms
      - Large, extensive retroperitoneal/paraspinal lesions
      - Intracranial involvement, intra- or extraaxial

Radiographic Findings

- Soft tissue mass ± internal Ca^{2+}, bizarre adjacent bone remodeling
- Multifocal extensive, well-circumscribed, lucent metaphyseal & metadiaphyseal lesions of bone
  - Relatively symmetric distribution
  - ± cortical loss, expansile remodeling
  - Periosteal reaction is usually absent or solid
  - Can cause vertebra plana
  - Sclerosis may represent early healing

MR Findings

- T2 FS/STIR: Variable internal signal intensity
- T1 C+ FS: Peripheral/rim enhancement
  - Diffuse enhancement is less common
- DWI: Often restrict diffusion

Ultrasonographic Findings

- Heterogeneous, may be hypo- or isoechoic
- Hypovascular internally by Doppler

Nuclear Medicine Findings

- Bone scan: Lacks sensitivity
- PET/CT: Highly sensitive

DIFFERENTIAL DIAGNOSIS

Solitary Congenital/Neonatal Soft Tissue Mass

- Other fibrous lesions
  - Fibrosarcoma
  - Fibrous hamartoma of infancy
- Vascular anomalies
  - Neoplasm
    - Hemangioma, infantile or congenital
    - Kaposiform hemangioendothelioma
  - Malformation
    - Venous
    - Lymphatic
- Teratoma
- Neuroblastoma

Multifocal Infantile Lesions

- Langerhans cell histiocytosis
- Metastatic neuroblastoma
- Multifocal vascular anomalies
- Disseminated infection

PATHOLOGY

Microscopic Features

- Peripheral clusters of spindled myofibroblastic cells
- Central cellularity & vascularity are similar to hemangiopericytoma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Soft tissue mass ± red-purple skin nodules

Demographics

- Age: Perinatal in 50%; 90% diagnosed by age 2

Natural History & Prognosis

- Solitary/multicentric without visceral involvement: High rate of spontaneous regression over 1-2 years
  - May ↑ in size & number prior to regression
  - Overall 1% mortality
- Multicentric with visceral involvement: 48-75% mortality historically due to obstruction, organ failure

Treatment

- Solitary: Observation or surgical resection
  - 7-10% recurrence
- Multicentric with visceral involvement: Favorable outcomes with low-dose chemotherapy

Plexiform Neurofibroma

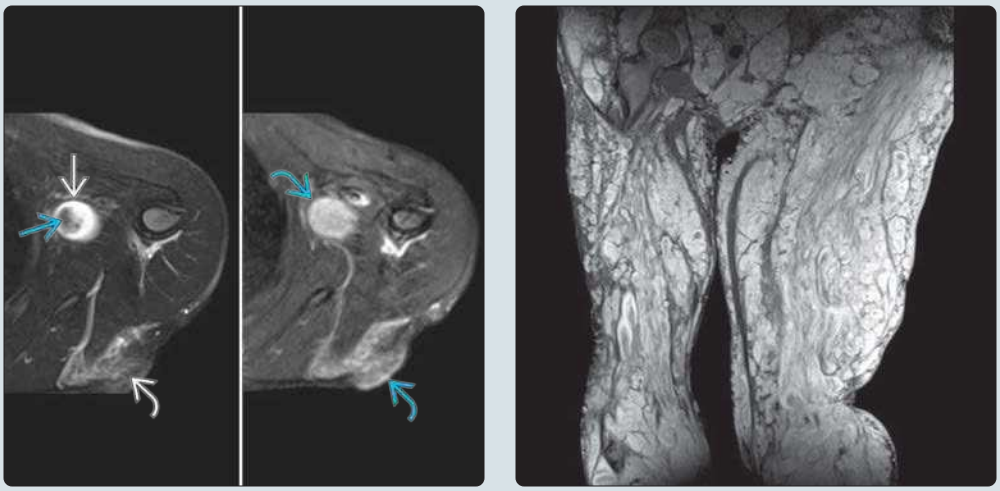
KEY FACTS

TERMINOLOGY

- Neurofibroma: Type of benign peripheral nerve sheath tumor with 3 subtypes (localized, diffuse, plexiform)
  - Plexiform subtype occurs almost exclusively in neurofibromatosis type 1 (NF1)
  - Extensive plexiform neurofibromas → massive enlargement of body part (elephantiasis neuromatosa)
- Malignant peripheral nerve sheath tumor (MPNST)
  - Plexiform neurofibromas are at ↑ risk → MPNST

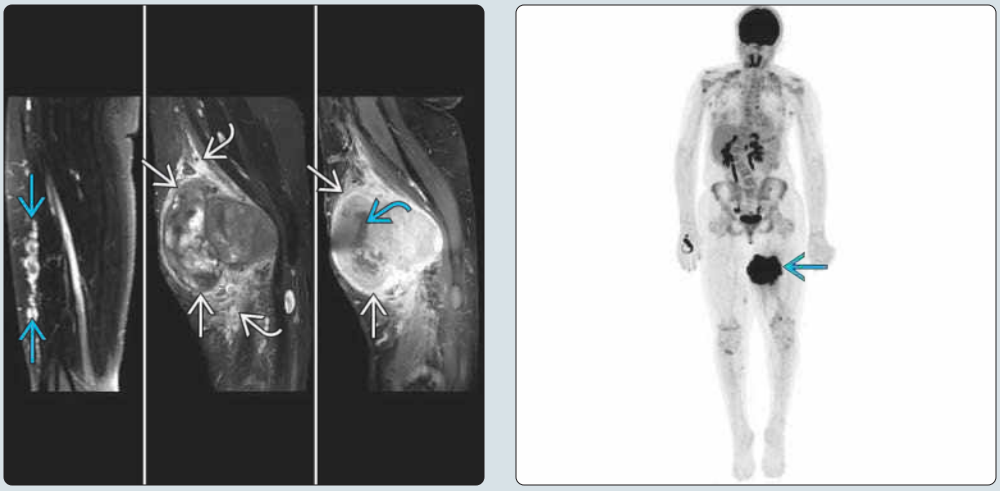
IMAGING

- Plexiform neurofibroma: Tortuous, lobulated expansion of long segments of nerves & branches ("bag of worms")
- Radiographs: Nonspecific soft tissue mass without Ca^{2+}; bony remodeling/erosions or mass effect on vital structures may occur from numerous adjacent neurofibromas
- T1 MR: Hypo- to isointense to skeletal muscle
  - Split fat sign: Rim of fat surrounding surrounding mass
- T2/STIR MR: Hyperintense lobules along nerve
  - Target sign: ↑ peripheral & ↓ central signal intensity
- T1 C+ MR: Heterogeneous or central enhancement
- MR features suggesting MPNST: ↑ size, cysts, peripheral enhancement, perilesional edema, heterogeneity on T1 (specific to NF1), ↓ ADC values
- FDG PET: SUVmax ≥ 3.5 is sensitive but not specific for MPNST



TOP DIFFERENTIAL DIAGNOSES

- Venous malformation, soft tissue sarcoma, MPNST, polyneuropathy



CLINICAL ISSUES

- Symptoms include pain, neurologic deficit, mass effect
- Treatment of plexiform neurofibroma is typically conservative due to inseparability of lesion & involved nerve
  - Surgery: For debulking symptomatic lesions & foci concerning for MPNST
  - Some chemotherapeutics shown to ↓ tumor bulk & symptoms

(Left) *Axial T2 FS MR (left) in a 14-year-old with neurofibromatosis type 1 (NF1) shows a localized neurofibroma in the left axilla with a target sign (high peripheral & low central signal). There is a poorly defined diffuse neurofibroma posteriorly. Axial T1 C+ FS MR (right) shows variable enhancement of the lesions.* **(Right)** *Coronal STIR MR in a 15-year-old with NF1 shows extensive plexiform neurofibromas with massive enlargement of both thighs (elephantiasis neuromatosa).*

(Left) *Initial sagittal T2 FS MR (left) in an NF1 patient shows a thin, elongated plexiform neurofibroma in the anterior thigh. Seven years later, this mass had rapidly enlarged with sagittal T2 FS (middle) & T1 C+ FS (right) MR images showing marked enlargement & heterogeneity of the mass with central nonenhancement from necrosis. Perilesional edema is also present.* **(Right)** *Coronal FDG PET in the same patient shows ↑ uptake (SUVmax of 13.7) within the mass. Pathology confirmed an MPNST.*

TERMINOLOGY

Definitions

- Neurofibroma: Type of benign peripheral nerve sheath tumor (BPNST)
  - 3 neurofibroma subtypes: Localized, diffuse, plexiform
- Malignant peripheral nerve sheath tumor (MPNST): Spindle cell sarcoma arising from nerve or BPNST
  - Plexiform neurofibromas have ↑ risk of MPNST

IMAGING

General Features

- Morphology
  - Plexiform type: Tortuous expansion of nerve(s) & branches by elongated lobules of varying size
    - May be relatively limited to courses of nerves vs. massive lobular proliferations engulfing & compressing adjacent tissues
      - Bag of worms appearance
      - Massive, disfiguring enlargement of body part (elephantiasis neuromatosa)
  - MPNST: ↑ heterogeneity with indistinct margins

Radiographic Findings

- Nonspecific soft tissue swelling without Ca^{2+}
- Large plexiform neurofibromas → bony remodeling from pressure erosions & mass effect on vital structures

Ultrasonographic Findings

- Predominantly hypoechoic lobular mass(es) along nerve(s)
  - May show ↑ echogenicity centrally

MR Findings

- T1WI
  - Hypo- to isointense to skeletal muscle
  - Split fat sign: Rim of fat surrounding tumor
- T2 FS or STIR
  - Predominately ↑ signal intensity
  - Target sign: ↑ peripheral, ↓ central signal intensity of lesion in cross section
- T1WI C+
  - Variable: Often heterogeneous & diffuse
- Whole-body MR
  - Used to evaluate neurofibromatosis type 1 (NF1) tumor burden, characterization, & treatment response

Nuclear Medicine Findings

- FDG PET/CT
  - SUVmax ≥ 3.5: Concerning for MPNST

Imaging Recommendations

- Best imaging tool
  - MR to characterize neurofibromas & evaluate depth & relationship to vital structures
  - FDG PET/CT is useful in differentiating MPNST vs. BPNST

DIFFERENTIAL DIAGNOSIS

Venous Malformation

- Low-flow vascular anomaly (localized or extensive)
- Numerous thin, low-signal septa in fluid-filled mass
  - ± fluid-fluid levels of stagnant blood
- Round, lucent-centered Ca^{2+} (phleboliths) are confirmatory
- Gradual patchy enhancement (often peripheral > central)

Soft Tissue Sarcoma

- Well-defined, solid, firm mass without entering/exiting nerve; no target sign or split fat sign
- Typically intermediate to high signal on T2/STIR MR; variable enhancement

Malignant Peripheral Nerve Sheath Tumor

- MR features favoring MPNST over plexiform neurofibroma (≥ 2: Specificity 90%, sensitivity 61%)
  - > 5 cm, cystic foci, peripheral enhancement, perilesional edema, heterogeneity on T1 (in NF1)
  - Also consider with preferential growth loss of target sign (if previously present), &/or ↓ ADC values

Polyneuropathy

- Various acute & chronic polyneuropathies cause diffuse enlargement of multiple adjacent nerves ± ↑ enhancement
- Nerve architecture is maintained without "target" lobules

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Plexiform type: Symptoms depend on location/extent
    - Pain & neurologic deficit vary with nerve involved
    - Symptoms from compression of adjacent structures
  - MPNST: ↑ pain, ↑ neurologic defect, & rapid growth

Natural History & Prognosis

- Neurofibromas (of all types) typically grow slowly
- Transformation of neurofibroma to MPNST
  - Lifetime risk of MPNST in patients with NF1: 8-13%
  - MPNST has poor prognosis with 5-year survival: 23-44%

Treatment

- Plexiform neurofibromas
  - Typically conservative management (as total resection → extensive neurologic deficit)
  - Surgery reserved for debulking of symptomatic lesions & masses concerning for MPNST
  - Some chemotherapeutics (e.g., tyrosine kinase inhibitors) ↓ tumor bulk & symptoms
- MPNST: Wide surgical excision + chemotherapy & radiation

Lipoblastoma

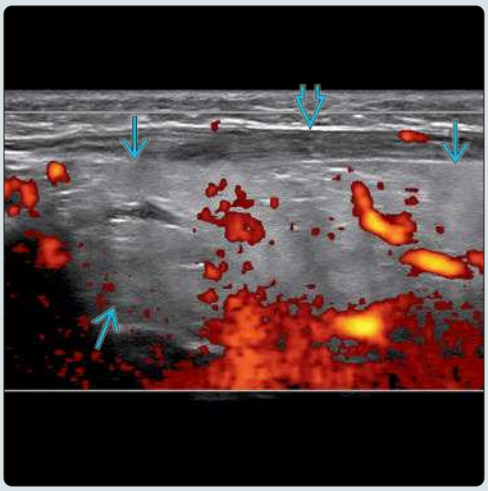
KEY FACTS

TERMINOLOGY

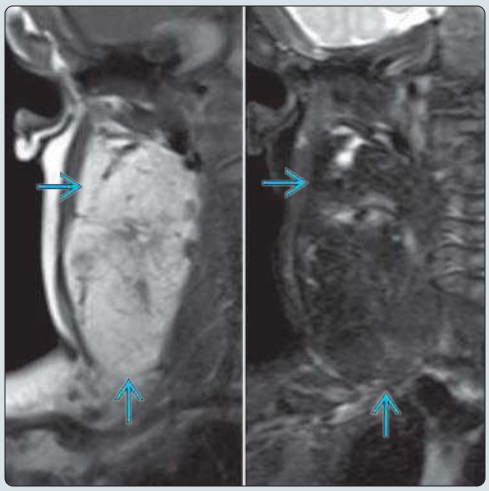
- Benign neoplasm of mature & immature adipocytes + myxoid stroma occurring in young children
- Termed lipoblastomatosis if lesion is poorly circumscribed or infiltrative

IMAGING

- Occurs at any soft tissue location: Extremities, trunk > head/neck; retroperitoneum in up to 5%
- Variable in size: 3-25 cm
- Imaging characteristic depend on percentage of fatty vs. myxoid components
  - Most commonly homogeneous & hyperechoic to muscle on ultrasound

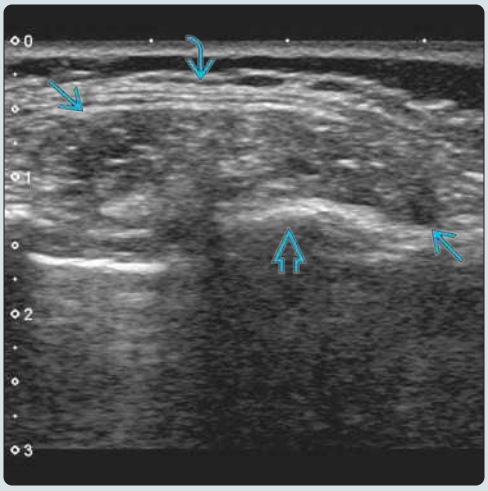


TOP DIFFERENTIAL DIAGNOSES



- Lipoma: Well-circumscribed soft lesion of only fat ± few thin internal septations
- Involuting infantile hemangioma: Gradually increasing fat content with decreasing size, vascularity, & enhancing soft tissue relative to proliferating phase
- Fibrous hamartoma of infancy: Streaks of fat in solid mass
- Liposarcoma: Not reported < 5 years of age
- Hibernoma: Rare tumor of brown fat
- Teratoma: Abundant soft tissue & cystic components ± fat & Ca^{2+}; occurs in characteristic locations
- *PTEN* hamartoma: Abundant fatty, solid, & high-flow vascular elements in hamartoma-forming syndrome due to *PTEN* mutation
- Angiolipoma: Tender subcutaneous lesion of teenagers

CLINICAL ISSUES



- Often asymptomatic palpable mass; may grow rapidly &/or exert mass effect on critical structures
- 90% occur < 3 years of age; mean of 16-17 months
- Resection is curative; recurrence in up to 25%

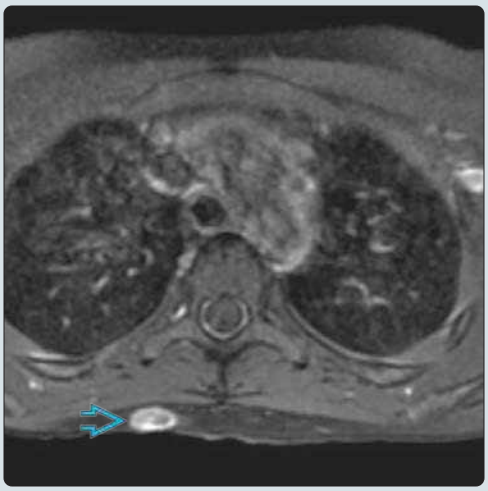
(Left) *Longitudinal power Doppler ultrasound in a 6-month-old with a neck mass shows an elongated, mildly lobulated echogenic mass deep to the sternocleidomastoid muscle with scattered internal vascularity.* **(Right)** *Coronal T1 & STIR MR images of the same patient show that the mass is predominantly of fat signal intensity with scattered internal vessels & patchy solid components that enhanced (not shown). Lipoblastoma was confirmed upon resection.*

(Left) *Transverse ultrasound of the chest wall in a 9-month-old shows an elongated, mildly heterogeneous hypoechoic mass overlying the ribs & displacing adjacent musculature.* **(Right)** *Axial T1 MR in the same patient shows a well-circumscribed, mildly heterogeneous but predominantly fatty mass of the right chest wall musculature. Lipoblastoma was confirmed at resection.*

KEY FACTS

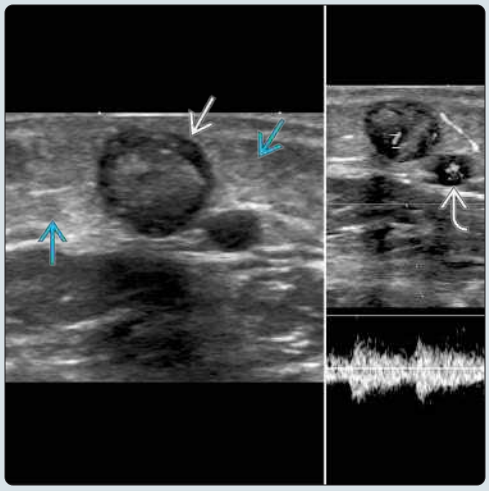
TERMINOLOGY

- Benign soft tissue neoplasm of hair follicle matrix cells
- a.k.a. pilomatricoma, calcifying epithelioma of Malherbe

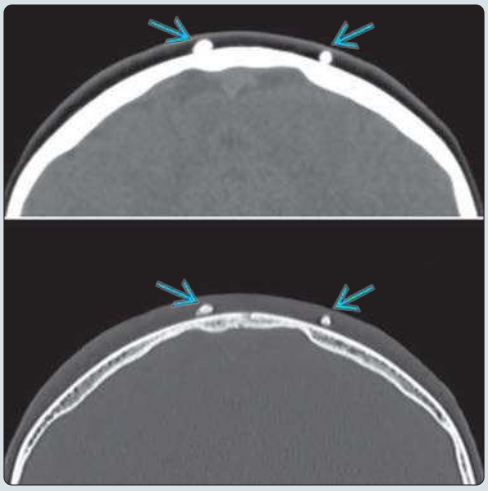


IMAGING

- Occurs in subcutaneous fat at junction with dermis
  - Head & neck > extremities & trunk
    - Midface & periauricular regions are most common
  - Multiple lesions in 2-10%
- Mean of 0.8 cm; rarely "giant" (> 5 cm)
- Ultrasound: Well-circumscribed subcutaneous nodule with hypoechoic rim & internal heterogeneity
  - Nodule may be predominantly hyper-, iso-, or hypoechoic
  - Most show internal Ca^{2+} as echogenic foci in patterns of arcs, clumps, or dots
    - ± posterior acoustic shadowing
  - Less commonly show cystic degeneration
  - ± ↑ peritumoral echogenicity (due to inflammation)
  - Color Doppler flow is more likely peripheral than central
- Radiographs: Ca^{2+} in up to 55%, of various morphologies
- CT: Nonspecific soft tissue nodule; Ca^{2+} in up to 81%, ranging from punctate/scattered to diffuse/complete
- MR: T2: Heterogeneously isointense to muscle with patchy & reticulated foci of ↑ signal; ± surrounding fat stranding
  - T1 C+ FS: Rim, patchy, or reticular enhancement



CLINICAL ISSUES



- Asymptomatic, mobile, firm nodule; often with reddish/blue skin discoloration
- Mean age at diagnosis: 16 years; range: 5 months to 97 years
- Various underlying syndromes have been reported (though most occur without syndrome)
- Rare recurrence status post excision
- Malignant degeneration rarely occurs in adults

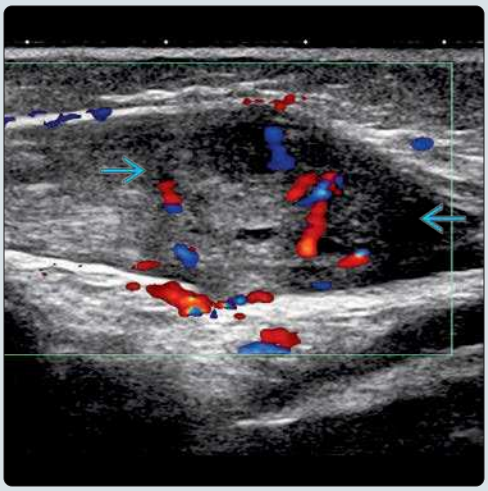
(Left) *Longitudinal ultrasound of the back soft tissues in a 12-year-old shows a well-circumscribed ovoid lesion of the subcutaneous fat with internal heterogeneity, posterior acoustic shadowing, & ↑ peritumoral echogenicity. **(Right)** Axial T1 C+ FS MR in the same patient shows predominantly peripheral enhancement of the lesion. Central low & peripheral high T2 signal intensity was also seen (not shown). Pilomatrixoma was confirmed upon resection.*

(Left) *Transverse grayscale & pulsed Doppler images of a 1-cm forearm mass in a 9-year-old show a round, well-circumscribed subcutaneous lesion with a peripheral hypoechoic rim & ↑ peritumoral echogenicity. A small amount of internal arterial flow is noted (as compared to the normal adjacent vein). Pilomatrixoma was confirmed at surgery. **(Right)** Axial NECT images in an 8-year-old show 2 heavily calcified pilomatrixomas. Note the normal underlying calvarium.*

KEY FACTS

TERMINOLOGY

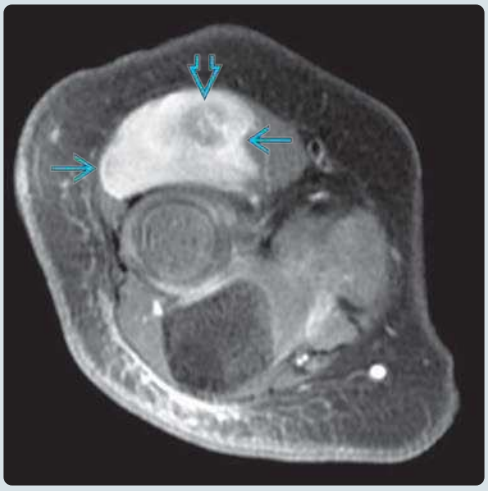
- Arises from rhabdomyoblasts (primitive muscle cells); lacks normal differentiation into skeletal muscle
  - Embryonal rhabdomyosarcoma (RMS): 60-70% of childhood RMS
    - Most common type in patients < 15 years old
    - Most commonly GU, head & neck, retroperitoneum
  - Alveolar RMS: 20% of RMS
    - Average age: 15 years old
    - Most commonly extremity, trunk, & perianal/perirectal
  - Undifferentiated RMS
    - 30-50 year olds; rarely in children



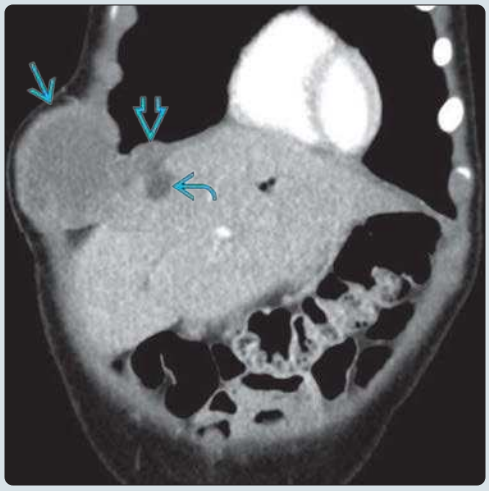
IMAGING

- Best clue: Solid, firm, mildly heterogeneous, intramuscular mass without significant surrounding soft tissue edema
- Usually round with well-circumscribed, lobular margins
  - May have tail of tumor extending proximal/distal
- Radiographs: Ca^{2+} is not typical
- US: Variable internal vascularity; not compressible
- MR: Moderately to markedly hyperintense (T2 FS/STIR) to skeletal muscle, ± heterogeneity (necrosis & hemorrhage)
  - Variable enhancement, ranging from minimal to diffuse, heterogeneous to homogeneous
  - Typically restricts diffusion
- US & MR features can strongly suggest sarcoma
- MR is better at defining deep extent & relationship to critical structures (e.g., neurovascular bundle, joints, etc.)
- PET is best for staging

CLINICAL ISSUES



- Most common soft tissue sarcoma in children
- Typically presents as enlarging, firm, painless mass
- 2 age peaks: 2-6 years, 14-18 years
- Prognosis is worse with alveolar subtype, tumor > 5 cm, metastatic disease at presentation (lung, bone marrow, & lymph nodes are most common)



(Left) *Longitudinal color Doppler US in a 12-month-old with weeks of arm swelling shows a heterogeneous, ovoid, intramuscular soft tissue mass ⇨ with moderate internal vascularity. The mass showed no significant deformation upon compression by the transducer.* **(Right)** *Coronal STIR MR in the same infant shows mild internal heterogeneity of the predominantly hyperintense mass ⇨, which involved the brachioradialis & extensor carpi radialis muscles.*

(Left) *Axial T1 C+ FS MR in the same infant shows nearly uniform enhancement of the forearm rhabdomyosarcoma (RMS) ⇨ with a central region of necrosis &/or hemorrhage ⇨. Diffusion restriction (not shown) was variable in the mass with ADC values ranging from 0.8-1.2 x 10^{-3} mm/s^2.* **(Right)** *Coronal CECT in a 21-month-old with an enlarging chest wall mass shows deep extension of the predominantly superficial mass ⇨ into the diaphragm ⇨ & liver ⇨. RMS was proven at biopsy.*

TERMINOLOGY

Definitions

- Mesenchymal sarcoma arising from rhabdomyoblasts (primitive muscle cells); lacks normal differentiation into skeletal muscle
  - Embryonal rhabdomyosarcoma (RMS): 60-70% of childhood RMS
    - Resembles skeletal muscle of 6- to 8-week fetus
    - Most common type in patients < 15 years old
    - Most common locations: GU, head & neck, retroperitoneum
    - Botryoid subtype (sarcoma botryoides): 10% of RMS
      - Grape-like polyploid masses or clusters protruding into lumen of vagina, bladder, biliary tree, or nasopharynx
  - Alveolar RMS: 20% of RMS
    - Resembles skeletal muscle of 10-week fetus
    - Average age: 15 years
    - Most common locations: Extremity, trunk, & perianal/perirectal
  - Undifferentiated RMS
    - 30- to 50-year-olds; rarely in children

IMAGING

General Features

- Best diagnostic clue
  - Well-circumscribed, solid, mildly heterogeneous intramuscular mass without significant surrounding soft tissue edema
- Location
  - Head & neck (28-40%)
    - Nasopharynx, sinuses, orbit, soft tissues (7%)
  - GU (20%)
    - Prostate, bladder, vagina, paratesticular
  - Extremities (15-20%)
    - Typically intramuscular
  - Truncal/retroperitoneal (11-17%)
- Size
  - Quite variable
- Morphology
  - Usually round with well-circumscribed, lobular margins
  - May have tail of tumor extending proximal/distal

Radiographic Findings

- Soft tissue fullness similar to muscle density on radiographs
- Rarely shows adjacent bone involvement
- Ca^{2+} is not typical

CT Findings

- Not used for primary mass investigation
- Lung CT for metastatic work-up

Ultrasonographic Findings

- Solid, firm, mildly heterogeneous soft tissue mass with variable amounts of internal vascularity
- Often round & well-circumscribed, though deeper infiltration is possible

MR Findings

- T1WI
  - Similar signal to skeletal muscle
- T2 FS/STIR
  - Moderately to markedly hyperintense to skeletal muscle
    - Not typically cystic
  - Can be heterogeneous with necrosis & hemorrhage
  - Typically minimal (if any) surrounding edema
- T1WI C+ FS
  - Variable enhancement, ranging from minimal to diffuse, heterogeneous to homogeneous
- DWI
  - Typically restricts diffusion; can ↑ conspicuity of primary & metastatic lesions
    - Mean ADC values reported from 0.7-1.2 x 10^{-3} mm/s^2
- MRA/MRV
  - May be helpful to determine relationship of mass to neurovascular bundle

Nuclear Medicine Findings

- PET
  - Intense FDG uptake by soft tissue tumor
  - Better than conventional imaging in staging disease (except for very small lung lesions)
  - May not predict event-free survival in intermediate- or high-risk RMS

Imaging Recommendations

- Best imaging tool
  - US & MR features can strongly suggests sarcoma
  - MR is better at defining deep extent & relationship to critical structures (e.g., neurovascular bundle, joints, etc.)
  - Extremity RMS: Important to image entire extremity, including lymph node drainage basins
- Protocol advice
  - Consider subtraction MR images of pre- from postcontrast T1 FS
    - Avoids pseudoenhancement postcontrast due to preexisting hemorrhage, protein, etc.

DIFFERENTIAL DIAGNOSIS

Other Soft Tissue Sarcomas

- Synovial sarcoma
  - Ca^{2+} in 1/3, may be small & cystic-appearing
  - Usually not intraarticular but near joint; often abuts bone
- Extraosseous Ewing sarcoma
  - Similar in appearance to RMS, usually 2nd-3rd decades
- Fibrosarcoma
  - Typically infantile in children
  - May be highly cystic or solid & highly vascular
  - Frequently infiltrative

Plexiform Neurofibroma

- Most common in neurofibromatosis type 1 (NF1)
- Lobular masses following course of nerve
- Classic target appearance in cross section on T2/STIR MR
  - Bright periphery, intermediate/dark center
- Loss of target appearance & disproportionate growth suggest malignant degeneration

Venous Malformation

- Patchy enhancement, fluid-fluid levels, ± phleboliths

Infantile Hemangioma

- Solid but soft subcutaneous mass of infants with mild lobulations, variable echogenicity
- Highly vascular on color Doppler US with > 5 vessels/cm²
  - Low-resistance arterial waveforms during proliferation

Myositis Ossificans

- Heterogeneous intramuscular mass in older children with prior acute trauma (2/3) or microtrauma history
- Marked inflammatory reaction of surrounding muscle
- Calcifies peripheral to central over weeks/months

Abscess

- Heterogeneous collection with thick, irregular wall & septations; swirling internal debris with compression
- Peripheral hyperemia/enhancement
- Moderate to marked surrounding edema

PATHOLOGY

General Features

- Genetics
  - Embryonal: Loss of chromosome 11 genomic material
  - Alveolar: Translocation of chromosomes 1 or 2 & 13
    - Translocation t(2;13) (q35;q14), results in *PAX3-FKHR* fusion gene (55%)
    - Translocation t(1;13) (p36;q14), results in *PAX7-FKHR* fusion gene (22%)
    - Better prognosis in *PAX7-FKHR* than *PAX3-FKHR* (more invasive)
- Associated abnormalities
  - Syndromes: NF1, Li-Fraumeni, Costello, Noonan, *DICER1*

Microscopic Features

- Embryonal RMS: Primitive with dense, spindle-shaped cells with hyperchromatic nuclei & cytoplasmic processes, strap cell appearance
- Alveolar RMS: Large oval cells separated into nests of "alveoli" separated by fibrous septa
- Central cells are necrotic & loosely arranged with peripheral cells arranged into well-organized picket fence appearance
- Immunohistochemical staining: MyoD1, myoglobin, myogenin, actin, & desmin

CLINICAL ISSUES

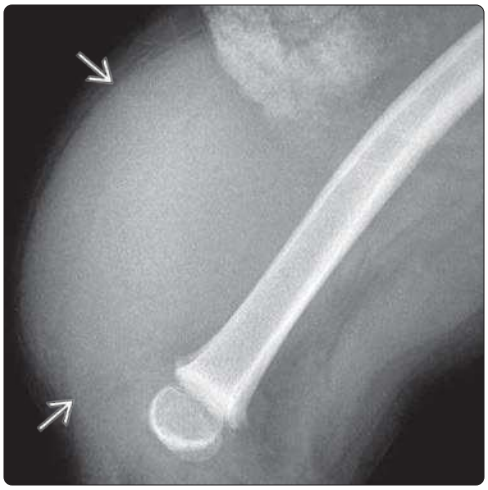
Presentation

- Most common signs/symptoms
  - Enlarging, firm soft tissue mass
- Other signs/symptoms
  - < 1/2 experience pain; symptoms depend on location

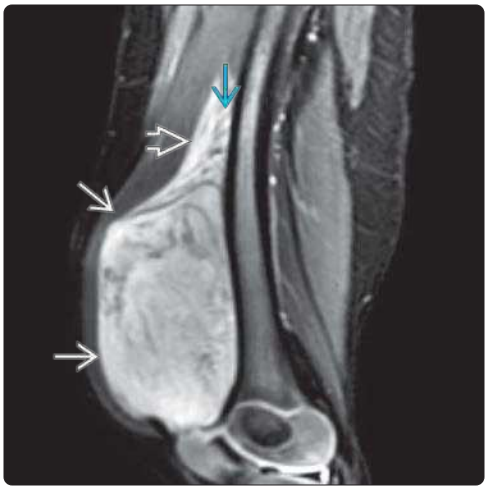
Demographics

- Age
  - 65% present < 6 years old
  - 2 age peaks: 2-6 & 14-18 years of age
    - Embryonal: < 15 years old; head & neck, GU
      - 46% occur in patients < 5 years old
    - Alveolar: Typically adolescents & young adults (extremity, paratesticular, & truncal)
      - Occurs at all ages
- Sex
  - Overall M > F (1.5:1), extremity: M < F (0.8:1), GU: M > F (3:1)
- Epidemiology
  - 5-10% of childhood malignant solid tumors overall
    - 4-6 cases/1 million per year
  - Most common soft tissue sarcoma in children

Natural History & Prognosis



- Prognosis depends on
  - Site of tumor
    - Orbit & nonparameningeal sites: More favorable
    - Extremity: Poorer prognosis, ↑ incidence of alveolar RMS, often lymph node (+), ↑ metastases at presentation
    - Chest: Poorer prognosis with 45% 5-year survival, tends to be alveolar RMS, ↑ metastases at presentation, location difficult for resection & radiation
  - Size: < 5 cm more favorable
  - Age: Alveolar ↓ prognosis < 1 year old & > 10 years old
  - Histiologic type: Embryonal is better than alveolar RMS
  - DNA component: Hyperdiploid (embryonal RMS) is better than diploid or tetraploid (alveolar RMS)
  - Tumor expression of p-glycoprotein gene: More likely multidrug resistant
  - Metastatic disease at presentation has much poorer prognosis: Lung, bone marrow, lymph nodes are most common



Treatment

- Neoadjuvant & adjuvant chemotherapy, surgery, radiation

(Left) *Lateral radiograph in 2-year-old patient shows a large soft tissue mass in the mid- & lower anterior thigh ➡ with mild saucerization of the outer anterior femoral cortex.* **(Right)** *Sagittal STIR MR in the same patient shows a heterogeneously hyperintense soft tissue mass ➡ within the thigh anteriorly. There is tumor ➡ & edema ⇨ extending proximally in this embryonal RMS.*

(Left) *Axial CECT shows massive enlargement & replacement of the left psoas muscle by a hypodense RMS ➡.* **(Right)** *Coronal STIR MR in a 10-year-old with an intramuscular gluteal mass (not shown) demonstrates numerous hyperintense osseous metastatic foci ➡ within the lower lumbar spine, pelvis, & femurs. Biopsy of the mass showed alveolar RMS.*

(Left) *Color Doppler US in a 6-month-old with a firm hand mass shows a mildly heterogeneous palmar soft tissue lesion ➡. Features that lead away from considering an infantile hemangioma include the lack of significant internal vascularity, the presence of deep extension ⇨, & firmness. Biopsy confirmed an RMS.* **(Right)** *AP radiograph in a 4-year-old with left knee pain shows multifocal lytic lesions throughout the pelvis & proximal femurs. This was biopsy-proven metastatic embryonal RMS of prostate origin.*

Nonrhabdomyosarcoma Soft Tissue Sarcomas (NRSTS)

KEY FACTS

TERMINOLOGY

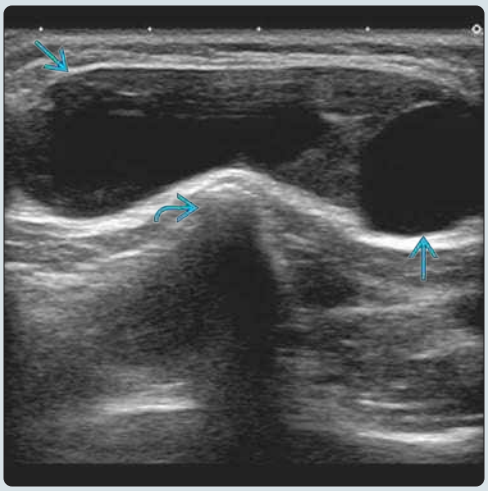
- Heterogenous group of malignant mesenchymal tumors
- Pediatric soft tissue sarcomas: ~ 40% are rhabdomyosarcoma, ~ 60% are nonrhabdomyosarcoma soft tissue sarcomas (NRSTS)

IMAGING

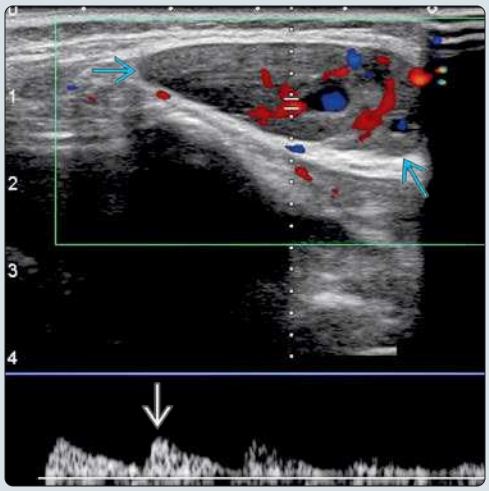
- Best clue: Well-circumscribed, round or ovoid, predominantly solid (firm) soft tissue mass without substantial surrounding edema
  - Overlaps many benign pediatric soft tissue masses
- Variable internal heterogeneity
  - Solid tumor components show variable enhancement
  - Intermixed nonenhancing foci: Hemorrhage, necrosis, Ca^{2+}
    - Some sarcomas may appear partially or entirely cystic until contrast is administered
- MR with IV contrast: Best study to characterize mass, determine local extent, & follow local therapy response

TOP DIFFERENTIAL DIAGNOSES

- Vascular anomalies
- Periarticular cysts or cyst-like lesions
- Myositis ossificans
- Benign fibrous or neurogenic tumors
- Abscess

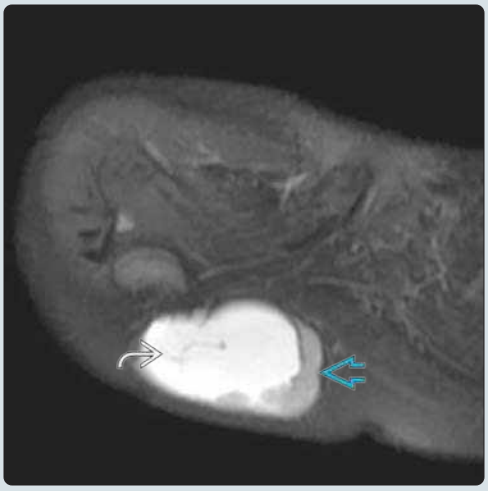


CLINICAL ISSUES

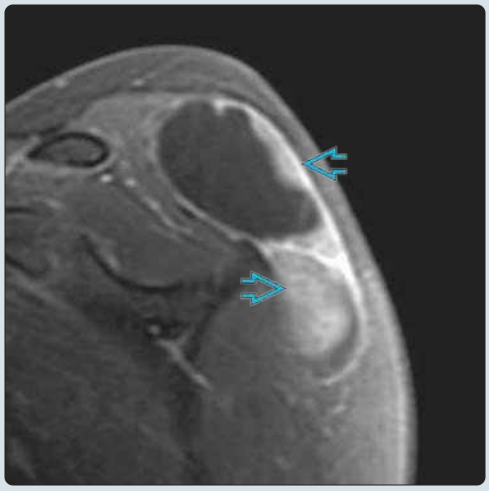


- Most common signs/symptoms: Palpable, firm mass

DIAGNOSTIC CHECKLIST



- Benign & malignant soft tissue masses overlap in appearances
- Without specific clinical & imaging features of benign process → biopsy required
- If specific features strongly suggest benign, self-limited or medically treatable process → close clinical & imaging follow-up
- Smaller focal lesions are frequently excised regardless



(Left) *Longitudinal ultrasound through a firm mass in the posterior right shoulder of a 5-year-old shows a mixed cystic & solid lesion overlying the scapula.* **(Right)** *Transverse pulsed Doppler ultrasound in the same patient shows a moderate amount of internal vascularity throughout the solid portions of the lesion, including several arterial waveforms. Spectral tracings (at several locations) are critical for characterizing flow within a lesion.*

(Left) *Axial T2 FS MR in the same patient shows nodular intermediate signal intensity components along the wall of the mass. Some of the cystic portions show thin internal septations.* **(Right)** *Sagittal T1 C+ FS MR in the same patient shows enhancement of the solid components of the mass. While some of the cystic features could be seen in a lymphatic malformation, the enhancing, solid components are concerning for malignancy. An extraskeletal Ewing sarcoma was confirmed with biopsy.*

TERMINOLOGY

Abbreviations

- Nonrhabdomyosarcoma soft tissue sarcomas (NRSTS)

Definitions

- Soft tissue sarcomas: Heterogenous group of malignancies arising in extraskeletal mesenchymal tissues
- In children: ~ 40% are rhabdomyosarcoma, ~ 60% are NRSTS
- > 40 subtypes of NRSTS (e.g., synovial sarcoma, infantile fibrosarcoma, malignant peripheral nerve sheath tumor, undifferentiated sarcoma, extraskeletal Ewing sarcoma, etc.)

IMAGING

General Features

- Best diagnostic clue
  - Well-circumscribed, round or ovoid, predominantly solid (firm) soft tissue mass without surrounding edema
    - Overlaps many benign pediatric soft tissue masses

MR Findings

- T1: Typically similar to muscle signal intensity ± bright foci of hemorrhage
- T2 FS/STIR: Relatively uniform intermediate to bright signal intensity of solid tissue
  - ± cystic/necrotic foci of very bright signal; purely cystic appearance is uncommon (but still requires contrast)
  - Typically lacks significant surrounding muscle edema
- T1 C+ FS: Wide range of enhancement patterns
  - Often intermediate- to low-level enhancement
    - ± nonenhancing foci of necrosis or hemorrhage
- DWI: Highly cellular tumors show restricted diffusion, typically with ADC values < 1.0 x 10^{-3} mm/s^2

Ultrasonographic Findings

- Grayscale ultrasound
  - Firm mass of variable internal echogenicity
    - Typically of intermediate- or low-level echoes
  - Rarely anechoic with posterior acoustic enhancement & compressibility → favors benign, fluid-filled process
    - Must look closely for solid nodular components
- Color Doppler
  - Variable internal vascularity
    - Frequently only mild to intermediate
    - Check for spectral waveforms to confirm true flow

Imaging Recommendations

- Best imaging tool
  - MR ± IV contrast: Best study to characterize mass, determine local extent, & follow local response during/after therapy
- Protocol advice
  - MR technique
    - T1 sequence in at least 1 plane
      - Axial images show relationship of mass to neurovascular bundle (normally encased by fat)
      - Additional T1 FS sequence may help evaluate etiologies of bright signal in mass & determine true enhancement after contrast administration
    - Multiplanar fluid-sensitive T2 FS or STIR sequences to highlight most pathologies
    - Contrast is critical for showing solid vs. necrotic foci
      - Subtraction of precontrast images is most accurate

DIFFERENTIAL DIAGNOSIS

Vascular Anomalies

- Infantile hemangioma
- Venous malformation
- Lymphatic malformation

Benign Fibrous/Fibrohistiocytic Tumors

- Fibrous hamartoma of infancy
- Myofibroma/myofibromatosis
- Nodular fasciitis
- Fibromatosis

Neurogenic Tumors

- Plexiform, localized, or diffuse neurofibroma
- Schwannoma

Fat-Containing Neoplasms

- Lipoma
- Lipoblastoma
- Hibernoma

Periarticular Cysts

- Ganglion vs. synovial or parameniscal cysts

Infectious/Inflammatory Masses

- Granuloma annulare
- Abscess

Posttraumatic Lesions

- Myositis ossificans
- Fat trauma/necrosis
- Hematoma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms: Palpable, painless, firm mass

Natural History & Prognosis

- Prognosis varies greatly based on subtype, staging, grade

Treatment

- Combination of surgery, chemotherapy, &/or radiation

DIAGNOSTIC CHECKLIST

Consider

- Benign & malignant soft tissue masses overlap in appearances; biopsy is often required
- Correlation with clinical history is important
  - Inflammatory & posttraumatic etiologies should be considered when pain & surrounding edema are present
  - Firm & painless or mildly tender mass is more concerning
  - Indolent growth does not exclude malignancy

Image Interpretation Pearls

- Soft tissue sarcomas often show well-defined margins

Pediatric Soft Tissue Malignancies

Tumor	Characteristic Imaging Features	Clinical Features	Prognosis
Rhabdomyosarcoma	Typical soft tissue sarcoma without specific features: Well-circumscribed, round/ovoid solid mass of intermediate/high T2 MR signal intensity with diffusion restriction & variable enhancement	Peak incidence overall: 2-6 years old; head/neck & genitourinary sites are more common than extremities; metastases in 15-20% at presentation	Overall 5-year survival: ~70%
Synovial sarcoma	30% show Ca^{2+}; often cystic-appearing; enhances with IV contrast; T2 MR triple sign (of intensities) is not specific; fluid-fluid levels in up to 25%; contiguity with bone is more common than remodeling or invasion	30% < 20 years old with median of 13-14 years in children; lower extremity is most common, often near joint (rarely in joint); slow growth is common	5-year survival: 36-76%; late recurrence is common
Extraskeletal Ewing sarcoma/PNET	No specific features overall; aggressive chest wall mass (Askin tumor) with pleural effusion & rib destruction is very suggestive	10-30 years old; most common in White patients; extraskeletal is less common than skeletal	Overall 5-year survival: ~ 61%
Infantile fibrosarcoma	Frequently infiltrative; often contains prominent cystic spaces; may be highly vascular	0-2 years old; 30-80% detected by/at birth; rapidly growing; skin involvement mimics vascular lesion; distal extremities are most common	5-year survival: 80% (better than adolescent/adult fibrosarcoma)
Undifferentiated sarcoma	No specific features	Multiple subtypes within this group	Varies by type, grade, stage
Extrarenal malignant rhabdoid tumor	No specific features overall; reported in virtually all anatomic sites (head/neck, trunk/viscera, limbs)	Older than renal rhabdoid patients with median < 4 years; ± concomitant CNS or renal rhabdoid tumors	5-year survival: 25-50%
MPNST	Features that can help distinguish from PN: Enlarging mass (> 5 cm) amidst stable PNs, loss of target sign on MR, ↑ activity on PET	~ 50% in neurofibromatosis type 1: 8-13% lifetime risk of MPNST	5-year survival: 23-69%
Dermatofibrosarcoma protuberans	Nodular, superficial mass with cutaneous elongation ± satellite nodules	Slow-growing, discolored skin mass	5-year survival: > 99%
Granulocytic/myeloid sarcoma (chloroma)	Background of diffuse marrow abnormalities	Acute myelogenous leukemia	5-year survival: 20-25%
Neuroblastoma	Typically small cutaneous & subcutaneous masses; ± discrete paraspinal primary mass; ± extensive marrow abnormalities	Wide range of clinical presentations; soft tissue metastases are most common < 18 months of age	Excellent in infant with metastases limited to liver, skin, & bone marrow; otherwise variable
Alveolar soft part sarcoma	Often brighter than muscle on T1 MR; typically shows prominent intra- & peritumoral vascularity, central necrosis, & infiltration	Head/neck is most common in children	5-year survival: 56-70%
Epithelioid sarcoma	Ca^{2+} in 20-30%; may have moderate surrounding edema with extension along fascia & tendon sheaths (uncommon for other sarcomas)	75% are 10-39 years old; distal upper extremity is most common, slow growth is frequent; proximal type is more aggressive	5-year survival: 50-70%
Angiosarcoma	Evidence of prior hemorrhage; tangles of high-flow vessels are uncommon	Typically de novo; rarely arise from preexisting vascular malformation	5-year survival: As low as 15%
Liposarcoma	Fat-poor myxoid subtype in 2nd decade of life	Extremely uncommon < 8-10 years old	Better than adult types

PNET = primitive neuroectodermal tumor; PN = plexiform neurofibroma; MPNST = malignant peripheral nerve sheath tumor.

- Significant surrounding edema favors (but does not confirm) infectious/inflammatory or posttraumatic etiology; consider close follow-up before biopsy

(Left) *Transverse ultrasound of the posterior calf in a 2-year-old girl with a palpable mass shows a well-circumscribed, heterogeneous, solid mass that was noncompressible. Internal vascularity was seen on Doppler (not shown).* **(Right)** *Sagittal T2 FS (left) & T1 C+ FS (right) MR images in the same patient demonstrate the full extent of the soft tissue mass ⇨ extending from the posterior upper thigh to the midleg. Biopsy showed an undifferentiated round cell sarcoma.*

(Left) *Transverse color Doppler ultrasound through a growing plantar soft tissue mass of the foot in a young infant shows a heterogeneous & highly vascularized lesion. The high-resistance waveforms (with reversed diastolic flow ⇨) & deep extent would be atypical for an infantile hemangioma.* **(Right)** *Sagittal T1 C+ FS MR in the same patient shows heterogeneous enhancement of the deep & infiltrative mass ⇨ that encases the flexor tendons ➡. An infantile fibrosarcoma was found upon biopsy.*

(Left) *Axial T2 FS MR in a 4-year-old with a firm mass shows a well-circumscribed, round, mildly heterogeneous, intermediate to bright intramuscular mass ⇨ directly abutting the posterior left humerus ⇨. Note the lack of surrounding edema.* **(Right)** *Axial T1 C+ FS MR in the same patient shows moderate heterogeneous enhancement throughout the mass ⇨. The overall appearance as a "solid soft tissue ball" is highly suggestive of a soft tissue malignancy. Biopsy confirmed a synovial sarcoma.*

Granuloma Annulare

KEY FACTS

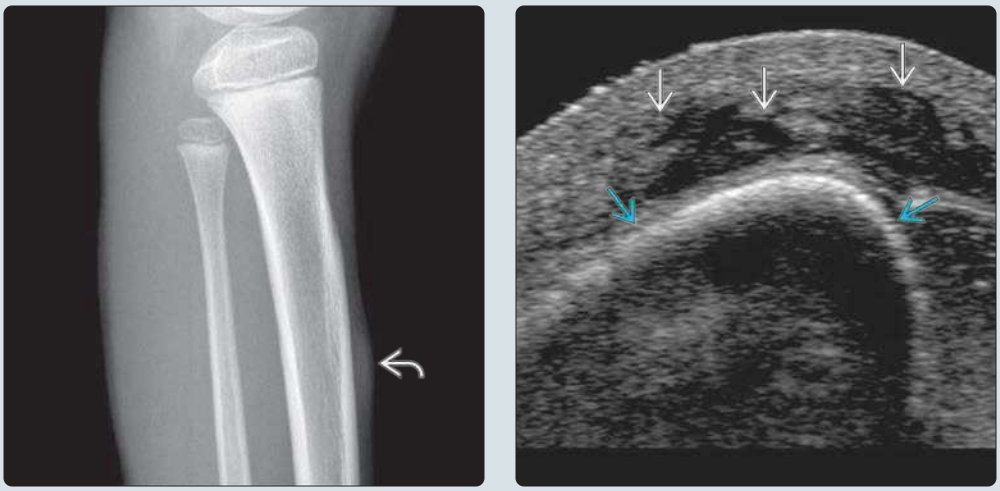
TERMINOLOGY

- Benign, inflammatory lesion of superficial soft tissues
- Cutaneous form is very familiar to dermatologists
- Subcutaneous granuloma annulare (SGA) is type most frequently encountered by radiologists due to
  - Deeper location
  - Nonspecific clinical appearance

IMAGING

- Subcutaneous lesion(s) of extensor surfaces of lower leg (pretibial), foot, & forearm/elbow or scalp
- Elongated, nodular, & poorly defined
- Radiography: Swelling without Ca^{2+} or bone involvement
- Ultrasound: Hypoechoic, mildly heterogeneous, infiltrating superficial lesion
- T2 FS MR: Heterogeneous with regions of ↓ & ↑ signal
  - Indistinct margins with surrounding edema is common
- T1 C+ FS MR: Homogeneous to mildly heterogeneous

TOP DIFFERENTIAL DIAGNOSES



- Trauma (contusion or fat necrosis)
- Chronic foreign body
- Microcystic lymphatic malformation
- Cellulitis
- Fibromatosis

PATHOLOGY

- Fine-needle aspiration is not adequate for diagnosis
  - May lead to mistaken diagnosis of malignancy
- Mucin staining is characteristic

CLINICAL ISSUES

- Typical presentation: Firm, painless, subcutaneous nodule in otherwise healthy young child
- Natural history: Spontaneous involution
- Lesions with characteristic history, location, & imaging: Consider observation vs. incisional biopsy for diagnosis
- May recur even after excisional biopsy

(Left) *Lateral radiograph of a 6-year-old girl presenting with a painless, firm bump at the anterior tibia shows a soft tissue mass without Ca^{2+} or underlying bony abnormality. A similar but smaller mass was present on the contralateral side (not shown).* **(Right)** *Transverse ultrasound in the same patient shows an elongated & lobulated hypoechoic mass with indistinct margins in the subcutaneous fat anterior to the tibial diaphysis. The mass proved to be subcutaneous granuloma annulare (SGA) on biopsy.*

(Left) *Knee radiograph (left) in a 3-year-old girl shows nonspecific soft tissue swelling anterior to the patellar tendon. On the sagittal T2 FS MR (right), the mass is poorly defined with areas of intermediate & high signal intensity.* **(Right)** *Axial T1 FS MR images were performed before (left) & after (right) contrast in the same patient. The mass is isointense to slightly hyperintense to skeletal muscle before contrast with heterogeneous enhancement after contrast. Biopsy confirmed SGA.*

TERMINOLOGY

Abbreviations

- Subcutaneous granuloma annulare (SGA)

Synonyms

- Benign rheumatoid nodule, pseudorheumatoid nodule, deep granuloma annulare, subcutaneous palisading granuloma, palisading granuloma nodosum, isolated subcutaneous nodule, isolated subcutaneous granuloma, necrobiotic granuloma

Definitions

- Benign inflammatory skin lesion of unknown etiology
- 4 clinically distinct subtypes
  - Localized
  - Generalized
  - Perforating
  - Subcutaneous: Subtype of concern to radiologists

IMAGING

General Features

- Location
  - Extension up to (but not deep to) investing fascia
    - Abnormal muscle signal is highly atypical
  - Distributed within feet, lower legs, fingers, hands, forearms, & scalp; can be multifocal & bilateral
    - Primarily affects extensor surfaces of extremities
    - Classic location: Pretibial (19-65%)
- Morphology
  - Elongated, mildly nodular mass with indistinct margins

Radiographic Findings

- Superficial soft tissue mass
  - No Ca^{2+} or bone involvement

Ultrasonographic Findings

- Hypoechoic, mildly heterogeneous nodular lesion

MR Findings

- T1WI
  - Iso- to slightly hyperintense to skeletal muscle
- T2WI FS
  - Heterogeneous with areas of ↓ & ↑ signal intensity
  - Reticular ↑ signal in surrounding subcutaneous fat
- T1WI C+ FS
  - Homogeneous to mildly heterogeneous enhancement

DIFFERENTIAL DIAGNOSIS

Trauma (Contusion or Fat Necrosis)

- Focally edematous soft tissue after trauma, often overlying bony protuberance
- May ultimately lead to focal fat thinning

Chronic Foreign Body

- Hyperechoic foreign body surrounded by poorly defined hypoechoic tissue or fluid

Microcystic Lymphatic Malformation

- Longstanding, poorly defined infiltrative lesion
- ± macrocysts (> 1 cm)
- Often has characteristic cutaneous blebs

Cellulitis

- Poorly defined, serpentine foci of fluid tracking through indurated fat
- Erythema & tenderness are typical

Nodular Fasciitis

- Benign rapidly growing lesion, often painful
- Frequently at subcutaneous fat-fascial interface

Muscle Hernia

- Superficial fascial defect with dynamic muscle protrusion

Fibromatosis

- Typically deeper & infiltrative but benign locally aggressive lesion
- Often has foci of ↓ & ↑ T2 signal intensity

PATHOLOGY

Microscopic Features

- Degenerating collagen with peripheral palisading histiocytes & surrounding reactive inflammatory cells
- Mucin staining is characteristic
- Fine-needle aspiration is suboptimal
  - May cause lesion to look aggressive (like malignancy)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Painless, firm subcutaneous nodules in extremities or scalp

Demographics

- Age
  - Subcutaneous form is almost exclusively seen in children
  - Classic range: 2-5 years; mean age: 4.3 years

Natural History & Prognosis

- Spontaneous involution is typical (over months to years)
- Recurrence in 19-75% of cases
  - May occur following incisional or excisional biopsy

Treatment

- Observation with typical clinical & imaging findings
- No proven efficacious medical treatment
- Incisional or excisional biopsy is diagnostic but not necessarily curative

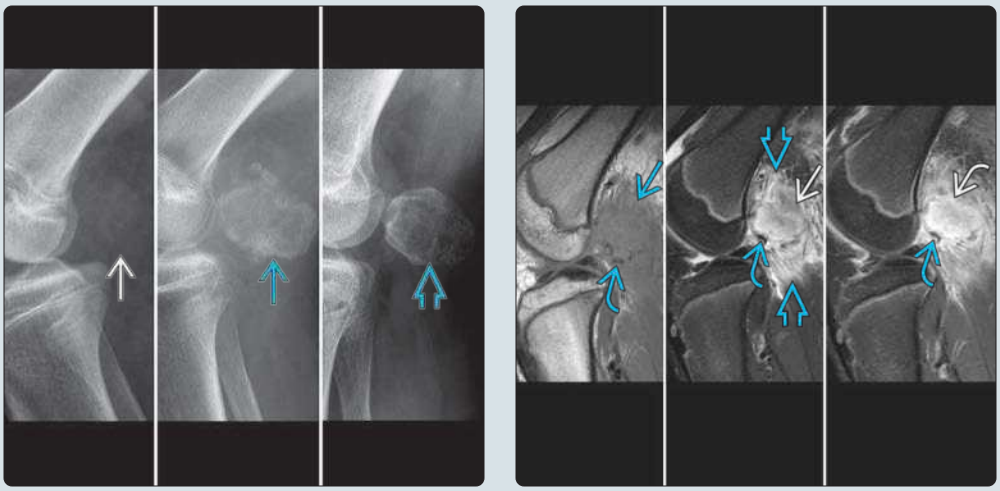
Myositis Ossificans

KEY FACTS

TERMINOLOGY

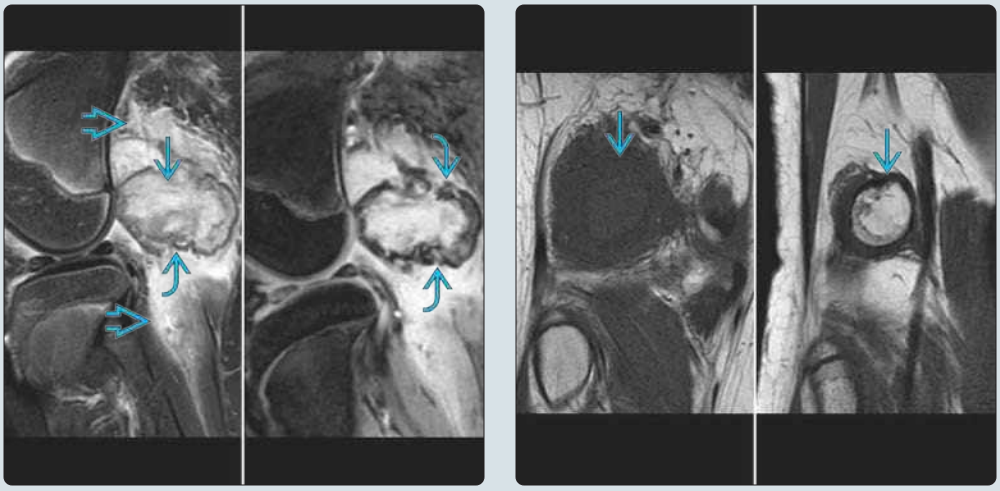
- Myositis ossificans (MO): Benign reactive ossifying soft tissue mass; clear history of trauma in 60-75%

IMAGING



- Best diagnostic clue: Heterogeneous intramuscular mass occurring after trauma with evolving imaging appearance
- Radiographic findings
  - 0-2 weeks: Nonspecific soft tissue swelling/mass
  - 2-6 weeks: Faint but increasing peripheral Ca^{2+}
  - 6-8 weeks: Sharply circumscribed osseous mass
  - 5-6 months: Ossified mass with ↑ maturity, ↓ size
- CT: Rim of mineralization by 4 weeks; cortical & trabecular bone ± fatty marrow within months
- MR appearance also varies with age of lesion
  - Early: T2 heterogeneity internally with mild peripheral mineralization + marked surrounding edema
    - Active areas show intense enhancement
  - Late (mature): Well-circumscribed mass with rim of low signal cortex & little surrounding edema
    - Internal foci of fatty yellow marrow on all sequences
  - GRE: Sensitive for mineralization (blooming artifact)

TOP DIFFERENTIAL DIAGNOSES



- Soft tissue sarcoma
- Hematoma
- Abscess
- Surface osteosarcoma

DIAGNOSTIC CHECKLIST

- Short-term radiographic follow-up or CT to demonstrate zonal ossification
- MR of early MO can mimic malignant soft tissue tumors
  - Marked surrounding edema is atypical in sarcomas
- Indeterminate lesions should undergo adequate biopsy
  - Pathologist to be aware if MO is being considered, as early MO may mimic malignancy under microscope

(Left) *Serial lateral radiographs in a 14-year-old dancer with a popliteal mass show an evolving lesion with only soft tissue edema present initially (left). A 6-week follow-up (middle) shows peripheral ossification with progressive maturation at 6 months (right).* **(Right)** *Initial sagittal MR in the same patient shows a mass that is isointense on PD (left), hyperintense on T2 FS (middle), & diffusely enhancing on T1 C+ FS (right). Small peripheral hypointense foci represent early ossification. Note adjacent edema.*

(Left) *Sagittal T2 FS (left) & GRE (right) MR images in the same patient 6 weeks later show heterogeneous internal signal in the mass with a peripheral hypointense rim that blooms on the GRE sequences. There is continued surrounding edema.* **(Right)** *Coronal T1 MR in the same patient at 6 weeks (left) & 1 year (right) of follow-up shows progressive maturation of the mass to an ossified lesion of fatty yellow marrow with no surrounding edema. The mass was then resected.*

TERMINOLOGY

Abbreviations

- Myositis ossificans (MO)

Definitions

- Benign ossifying soft tissue mass; reactive lesion typically occurring after muscle insult
  - Clear history of trauma in 60-75% of cases
  - Others: Repetitive microtrauma, inflammation, ischemia

IMAGING

General Features

- Best diagnostic clue
  - Heterogeneous intramuscular mass with peripheral mineralization developing within weeks
    - Appearance changes over time as lesion matures

Radiographic Findings

- 0-2 weeks: Nonspecific soft tissue swelling/mass
- 2-6 weeks: Faint Ca^{2+}, largely peripheral
- 6-8 weeks: Sharply circumscribed peripheral Ca^{2+}
- 5-6 months: More mature ossified mass with ↓ size

Ultrasonographic Findings

- Early: Heterogeneous lesion with ↓ central & ↑ peripheral echogenic zones
- Late: Peripheral zone shows posterior shadowing

CT Findings

- NECT
  - Low-attenuation mass without mineralization early
  - Rim of mineralization usually seen by 4 weeks
  - Gradual maturing ossification demonstrates cortical & trabecular bone ± fat attenuation of yellow marrow

MR Findings

- Early: Round, elongated, or poorly defined intramuscular mass + intense surrounding edema
  - T2 FS/STIR: Heterogeneous signal intensity
  - T1: Isointense to skeletal muscle
  - ± small areas of ↓ peripheral signal (mineralization)
- Intermediate: ↓ peripheral signal is more apparent
  - ± central areas of irregular low signal; ± fluid/fluid levels from hemorrhage
- Late (mature): Well-defined mass of variable heterogeneity with minimal, if any, surrounding edema
  - Internal foci that are isointense to fat (yellow marrow) on all sequences; confluent peripheral rim of low signal intensity
- GRE: Most sensitive for mineralization; exaggerated signal loss or blooming artifact
- T1 C+ FS: Heterogeneous to intense enhancement if active

Imaging Recommendations

- Best imaging tool
  - Radiographs: Short interval follow-up in 3-4 weeks (when MO is suspected) → new peripheral mineralization
  - CT: Earliest detection of zonal pattern of mineralization

DIFFERENTIAL DIAGNOSIS

Soft Tissue Sarcoma

- Typically well-circumscribed with little surrounding edema
- May contain disorganized Ca^{2+}

Hematoma

- Heterogeneous mass after trauma or with coagulopathy
- Subacute/chronic hematomas may develop Ca^{2+}

Venous Malformation

- Large phleboliths may occur in extensive lesions

Soft Tissue Abscess

- Clinical symptoms typically suggest infection
- Mass with thick, irregular enhancing wall & central nonenhancing fluid

Surface Osteosarcoma

- Underlying bone shows cortical scalloping, periosteal reaction

PATHOLOGY

Microscopic Features

- Early: Immature, highly cellular fibroblastic lesion
  - Differentiation from sarcoma may be difficult
- Late (mature): Distinct zonal pattern of ossification
  - Peripheral: Rim of mature lamellar bone

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Firm/hard soft tissue mass ± pain, tenderness
  - Clear history of traumatic event is absent in up to 40%

Treatment

- Surgical excision of symptomatic lesions

DIAGNOSTIC CHECKLIST

Consider

- Heterogeneous, solid, intramuscular mass in teenager/young adult with marked surrounding muscle edema → strongly consider MO, especially after trauma
  - Recommend short-term follow-up radiographs or CT rather than immediate biopsy
- If biopsy is required for indeterminate lesion → obtain core, incisional, or excisional biopsy; FNA may be inconclusive

Image Interpretation Pearls

- Earliest MR findings of MO: Mass with small peripheral areas of ↓ signal + marked surrounding edema
  - Recent study found that perilesional edema on MR > 2x size of central lesion favors early/intermediate MO vs. malignant soft tissue mass

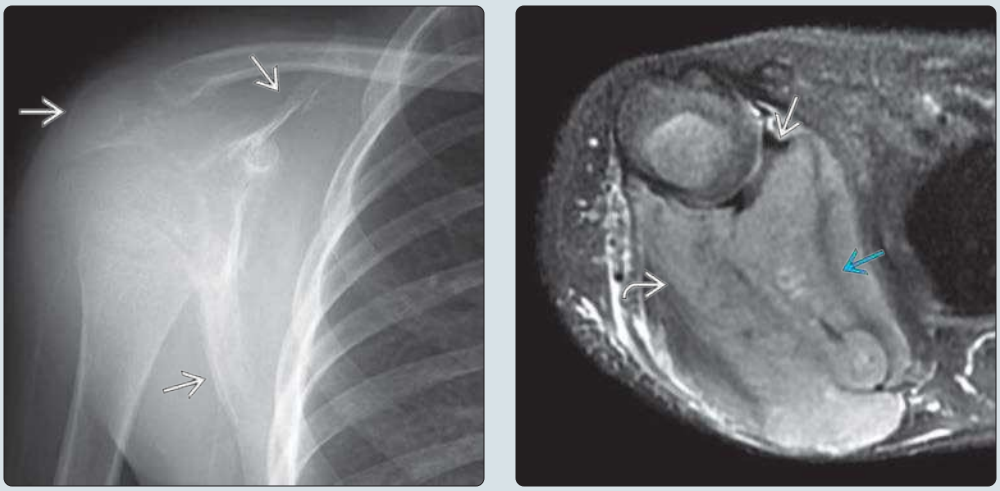
Ewing Sarcoma

KEY FACTS

TERMINOLOGY

- Ewing sarcoma family of tumors: Ewing sarcoma, primitive neuroectodermal tumor, Askin tumor, extraosseous Ewing sarcoma
- Aggressive small round blue cell tumor that typically arises in bone



IMAGING

- Highly aggressive appearance
  - Lucent, ill-defined, intramedullary lesion; poorly marginated; can show mild expansile remodeling
    - Sclerosis in up to 25% of cases (not beyond bone)
  - Permeative or moth-eaten cortical destruction
  - Aggressive periosteal reaction: Spiculated, sunburst, lamellated onion skin appearance, &/or Codman triangle
  - Associated soft tissue mass
    - Disproportionately larger than amount of bone destruction
- Greater propensity for flat bones (scapula, pelvis) than other primary bone malignancies
- Diaphyseal involvement is more common than with other bone malignancies
- MR for local evaluation: Intraosseous & soft tissue extent, relationship to joint & neurovascular bundle
  - Coronal/sagittal T1 MR best shows true tumor margin in bone: Sharp demarcation vs. adjacent fatty marrow
  - Early joint-to joint marrow sequence (coronal T1 &/or STIR) to look for intraosseous skip metastases before smaller field-of-view high-detail assessment
- Chest CT, PET/CT for staging

CLINICAL ISSUES

- 2nd most common primary bone malignancy in children after osteosarcoma
- Most common during 2nd decade of life

(Left) *AP radiograph in a 5-year-old with shoulder pain shows abnormal lucency, permeation, & expansion of the entire right scapula.* **(Right)** *Axial T2 FS MR in the same patient shows that the entire scapula has been replaced by a solid mass that extends into the surrounding soft tissues. A thin, low-signal rim of expanded & permeated cortex remains. Note the residual glenoid articular cartilage & labrum. Biopsy of the mass confirmed Ewing sarcoma.*

(Left) *Lateral radiograph in a 10-year-old with weeks of knee pain shows poorly circumscribed lucency & permeation of the mid to lower patella.* **(Right)** *Coronal T1 MR (left) in the same patient show a relatively sharp interface between the lesion & yellow marrow. Coronal T1 C+ FS MR (right) shows heterogeneous enhancement of the lesion with adjacent marrow & soft tissue signal abnormality. Ewing sarcoma was proven at biopsy.*

TERMINOLOGY

Synonyms

- Malignant primary bone tumor
- Ewing sarcoma (EWS) family of tumors: Ewing, primitive neuroectodermal tumor (PNET), Askin tumor, extraosseous Ewing

Definitions

- Aggressive small round blue cell tumor that typically arises in bone

IMAGING

General Features

- Best diagnostic clue
  - Central, diaphyseal, permeative lytic lesion with lamellated "onion skin" periosteal reaction
- Location
  - Can occur in any bone & soft tissue
    - Metaphyseal & diaphyseal: 94%
      - Diaphyseal involvement is more common than with other bone malignancies, tends to be central
      - Metaphyseal involvement tends to be eccentric
    - Greater propensity for flat bones (scapula, pelvis) than other primary bone malignancies
  - Lower extremity: 41%
  - Pelvis: 26%
  - Chest wall: 16%
  - Extraosseous: Chest wall & retroperitoneum or paravertebral are most common
  - Metastatic disease
    - Most commonly lungs, bones
- Morphology
  - Bone lesions classically (but not always) have large soft tissue mass relative to degree of bone change
  - Extraosseous EWS arises from soft tissues, not bone
    - Typically adjacent to or involving neurovascular bundles
    - Appears as nonspecific, well-circumscribed soft tissue mass

Radiographic Findings

- Radiography
  - Highly aggressive appearance overall
    - May sometimes show expansile remodeling but not without other more aggressive features
  - Ill-defined (wide zone of transition) intramedullary lesion
  - Mixed lytic & sclerotic intraosseous components
  - Permeative or moth-eaten appearance of cortical destruction
    - Infiltration of tumor through haversian canals of cortical bone
  - Cortical thickening, violation, or rarely, saucerization
  - Aggressive periosteal reaction, often interrupted
    - Spiculated
    - Lamellated onion skin appearance
    - Sunburst or hair standing on end patterns: Periosteal reaction laid down along Sharpey fibers (which attach periosteum to underlying cortical bone) in attempt to wall off tumor
    - Codman triangle: Interrupted elevation of periosteal new bone along margin of tumor
  - No ossified tumor matrix (i.e., no soft tissue osteoid) but can be sclerotic in flat bones
    - Bone necrosis, reactive sclerosis
  - Associated soft tissue mass, often disproportionately larger than amount of bone destruction
  - ± pathologic fracture

CT Findings

- NECT
  - Depicts aggressive periosteal reaction & bone destruction
  - May be helpful in complex anatomic areas (pelvis, spine, skull base)
  - Chest CT for pulmonary metastasis

MR Findings

- T1WI
  - Coronal/sagittal best shows true tumor margin in bone: Sharp demarcation vs. adjacent normal fatty marrow
  - Axial may be helpful for relationship of tumor to neurovascular bundle
- T2 FS/STIR
  - Heterogeneous mass of intermediate to high signal intensity
  - Surrounding marrow, periosteal, & soft tissue edema
- DWI
  - Typically restricts diffusion in cellular areas
  - ADC values are lower than osteosarcoma
  - ADC value may help in monitoring response to therapy
- T1WI C+ FS
  - Heterogeneous enhancement
  - Baseline for postchemotherapy response assessment

Nuclear Medicine Findings

- Bone scan
  - Intense uptake
  - Traditionally used for evaluation of metastatic bone disease
- PET
  - Lesions demonstrate F-18 FDG avidity
  - Useful in staging & monitoring response to therapy
    - More likely to detect osseous metastases than bone scan
  - Possible predictor of outcome

Imaging Recommendations

- Best imaging tool
  - MR for local evaluation: Intraosseous & soft tissue extent, relationship to joint & neurovascular bundle
- Protocol advice
  - Early joint-to-joint marrow sequence (coronal T1 &/or STIR) to look for intraosseous skip metastases
  - Then smaller field-of-view pre- & postcontrast sequences for high detail

DIFFERENTIAL DIAGNOSIS

Osteomyelitis

- May be difficult to differentiate from EWS as both can have very aggressive imaging appearances

- Typically has less enhancing soft tissue & more nonenhancing fluid pockets & surrounding inflammation than EWS
- More common in children < 5 years of age
- More rapid presentation of symptoms

Osteosarcoma

- Osteoid tumor matrix in 90%
- More commonly involves long bone metaphysis than diaphysis or axial skeleton

Metastatic Neuroblastoma

- More common in children < 3 years of age
- Multifocal permeative lucent lesions
- Calcified abdominopelvic mass

Langerhans Cell Histiocytosis

- Lytic bone lesion, often with sharp, punched-out margins & minimal to no periosteal reaction
- Homogeneously enhancing soft tissue mass in bone defect
- ± T2 MR hypointense rim, surrounding marrow edema > soft tissue edema

PATHOLOGY

General Features

- Genetics
  - EWS family of tumors: t(11;22)(q24;q12) (85%)

Microscopic Features

- Highly cellular with sheets of cells, little stroma
- Small round blue cell tumor

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Presents with pain & swelling
  - Tenderness/palpable mass
- Other signs/symptoms
  - May be associated with systemic symptoms/signs: Leukocytosis, fever, anemia, elevated sedimentation rate
    - Mimics osteomyelitis
  - Pathologic fracture (up to 15%)
    - Not considered adverse prognostic sign

Demographics

- Age
  - 2nd most common primary bone malignancy in children after osteosarcoma
  - Median age: 15 years
  - 80% are < 20 years old
  - Rare before 5 years of age
  - Extraosseous EWS is typically slightly older age group
- Sex
  - M > F (1.5-2:1)
- Ethnicity
  - White patients are 9x more common than Black patients

Natural History & Prognosis

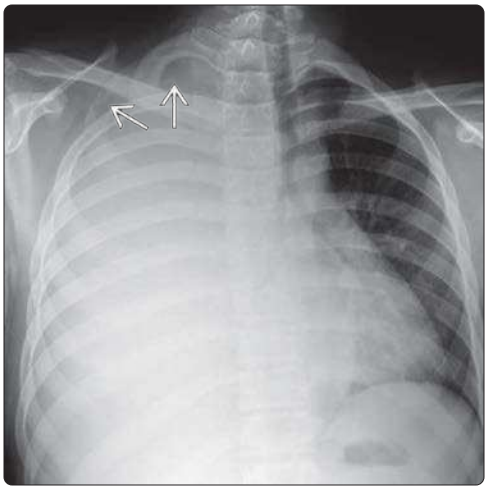
- Poorer prognosis in
  - Boys
  - Patients 15-18 years & older
  - Metastatic disease
  - Larger tumor volume
  - Pelvic location
  - Higher serum lactate dehydrogenase levels prior to treatment
  - Previous treatment of malignancy: EWS as 2nd malignancy
- Survival is better for lesions of extremities than those of axial skeleton
  - Pelvic lesions tend to be larger at presentation
- ↑ incidence of developing other future solid neoplasms
  - Treatment-related acute myeloid leukemia & myelodysplastic syndrome in 1-2% of patients
- Overall survival rate: 41%

Treatment

- Neoadjuvant & adjuvant chemotherapy
  - Vincristine, cyclophosphamide, doxorubicin, or actinomycin D
- Radiation therapy
- Resection of primary tumor
- Limb salvage procedures
- IGF-1R antibody
- Investigational: High-dose therapy followed by stem cell transplant for metastatic disease at presentation & patients with poor response to initial chemotherapy

DIAGNOSTIC CHECKLIST

Consider



- F-18 FDG PET in determining active residual/recurrent tumor from therapeutic changes

Image Interpretation Pearls

- May mimic osteomyelitis clinically or in laboratory findings

(Left) *Frontal radiograph in a 15-year-old boy shows a large mass & effusion filling the entire right hemithorax. Note the destructive right 2nd rib lesion due to Ewing sarcoma.* **(Right)** *AP radiograph in a 10-year-old with leg pain shows an aggressive-appearing lucent lesion of the midfibular diaphysis with permeation, wide zone of transition, & expansile remodeling. Biopsy confirmed Ewing sarcoma.*

(Left) *AP radiograph shows a large soft tissue mass displacing bowel from a permeated, mottled, & expanded left iliac bone with overlying periosteal reaction. Ewing sarcoma was proven on biopsy.* **(Right)** *Coronal STIR MR in the same patient confirms the large soft tissue component of the Ewing sarcoma emanating from an expanded & permeated iliac bone. This patient had innumerable lung metastases (not included).*

(Left) *AP radiograph in a 7-year-old who presented with soft tissue swelling shows an expanded & permeated lucent clavicle with aggressive periosteal reaction & a soft tissue mass from Ewing sarcoma.* **(Right)** *Axial NECT in bone (top) & soft tissue (bottom) windows from an 11-year-old with back pain shows L2 vertebral body permeation by a Ewing sarcoma. Note the overlying soft tissue expansion & epidural space infiltration.*

Osteosarcoma

KEY FACTS

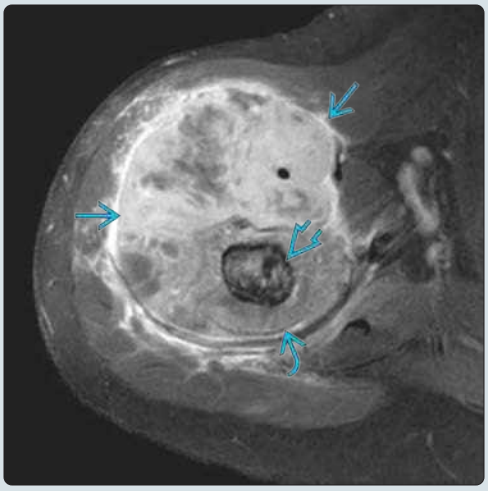
TERMINOLOGY

- Conventional high-grade intramedullary osteosarcoma (OS): 75-85%
- Less common OS subtypes (5% or less each): Telangiectatic, low-grade intramedullary, surface (low to high grade), multicentric, extraskeletal, secondary

IMAGING

- Aggressive metaphyseal/metadiaphyseal lesion with variable mix of bone destruction & bone production (cloud-like osteoid)
  - 55-80% around knee; axial skeleton < 20%
- Radiographs are often diagnostic or highly suggestive
- MR to characterize tumor + intra- & extraosseous extent
  - Large field of view joint-to-joint imaging
    - Look for skip metastases
    - T1 is best sequence for intraosseous tumor margin
  - High-detail focused imaging with surface coils
    - Heterogeneous signal intensity on all sequences
      - Mineralized tumor: Dark T2
      - Nonmineralized tumor: Intermediate to bright T2
      - Necrosis: Bright T2; extensive fluid-fluid levels (layering blood products) in telangiectatic subtype
    - Evaluate relationship to physis, joint, neurovascular bundle
- PET for distant metastases; chest CT for small nodules

CLINICAL ISSUES



- Most common malignant primary bone tumor in children/young adults
- Bimodal age distribution: 10-30 years, > 60 years
- Presentations: Pain, mass, recent trauma
- Treatment
  - Neoadjuvant chemotherapy → surgical resection → adjuvant chemotherapy
    - Improved survival if necrosis > 90% at resection
  - Lung nodule metastasectomy (if low-volume disease)

(Left) *Internal rotation radiograph in a 13-year-old with pain shows a mixed lucent & sclerotic lesion of the proximal humerus with many aggressive features, including a wide zone of transition & a Codman triangle ⇨ of periosteal reaction. The cloud-like osteoid in the overlying soft tissues ⇨ is diagnostic of osteosarcoma (OS).* **(Right)** *Sagittal T1 MR in the same patient shows the typical sharp margin ⇨ of bone tumors on T1 against normal yellow marrow. Note the large soft tissue ⇨ & subperiosteal ⇨ components.*

(Left) *Axial T1 C+ FS MR in the same patient shows cortical permeation ⇨ & periosteal elevation ⇨ by the OS with heterogeneous enhancement of the large soft tissue mass ⇨. Though not shown in this case, axial T1 without contrast or FS is particularly helpful for evaluating the relationship of the tumor to the neurovascular bundle.* **(Right)** *Lateral radiograph shows a poorly defined intramedullary sclerotic lesion ➡ within the right tibial diaphysis. There is no visible periosteal reaction or soft tissue mass in this osteoblastic OS.*

TERMINOLOGY

Definitions

- Osteosarcoma (OS): Malignant tumor with ability to produce osteoid directly from neoplastic cells

IMAGING

General Features

- Best diagnostic clue
  - Aggressive metaphyseal/metadiaphyseal lesion with mix of bone destruction & new bone formation
    - Sclerotic (cloud-like) osteoid density extending beyond margins of underlying bone is classic

Radiographic Findings

- Radiography
  - Conventional OS (75-85%)
    - Poorly defined, intramedullary mass
    - Extends through cortex: Frank lysis &/or moth-eaten destruction
    - Aggressive periosteal reaction: Codman triangle, sunburst appearance
    - Soft tissue mass with cloud-like osteoid matrix (90%)
  - Telangiectatic OS (< 5%)
    - Purely lytic geographic lesion; blown-out appearance
    - Cystic cavities filled with blood/necrosis
      - Fluid-fluid levels in 90% (may mimic aneurysmal bone cyst)
    - Enhancing nodular components
    - Pathologic fracture in 25%
  - Parosteal OS (3%)
    - Low-grade surface OS; better prognosis than conventional OS
      - > 90% 5-year survival
    - Age: 20-50 years (older than conventional OS)
    - Classically at distal posterior femoral metaphysis
    - Invasion of marrow in 25%
  - Periosteal OS (1%)
    - Intermediate- to high-grade surface OS
      - Metastatic disease in 15%
      - Recurrence rate as high as 70%
    - Attached to underlying cortex with thickening, scalloping, &/or saucerization of cortex
    - Usually diaphyseal with no medullary involvement
      - Medullary involvement may have poorer prognosis
    - Femur + tibia (85-95%); ulna + humerus (5-10%)
  - High-grade surface OS (1%)
    - Peak incidence in 2nd decade of life
    - Partially mineralized mass
    - Underlying cortex is often partially destroyed
    - Periosteal new bone along margins of lesion
    - May have minimal medullary involvement
  - Multicentric OS (1%)
    - Synchronous osteoblastic osteosarcomas at multiple sites (usually symmetric)
    - Exclusively in children (5-10 years)
    - Extremely poor prognosis
  - Secondary OS (5%)
    - Association with preexisting bone lesion: Paget disease, prior radiation, bone infarct

CT Findings

- Critical for detecting lung metastases

MR Findings

- T1WI
  - Very low signal: Mineralized tumor
  - Low/intermediate signal: Solid, nonmineralized tumor
  - High signal: Hemorrhage
  - Best sequence for determining true tumor margin
- T2 FS/STIR
  - Very low signal: Mineralized tumor
  - Intermediate/high signal: Nonmineralized tumor
  - High signal: Necrosis
    - Fluid-fluid levels with hemorrhagic components, especially telangiectatic OS
  - Tumor margin may blend with surrounding edema
- DWI
  - Highly cellular components restrict diffusion
    - Hemorrhage may also restrict diffusion
  - ADC values may help evaluate treatment response & help differentiate OS from Ewing sarcoma
- T1WI C+ FS
  - Heterogeneous, variable enhancement
    - Subtracted postminus precontrast images are helpful to determine true enhancement vs. T1 shortening due to hemorrhage
  - Changes in dynamic enhancement parameters reflect therapy response better than tumor volume changes

Nuclear Medicine Findings

- Bone scan
  - Much less sensitive for metastatic OS than PET
- PET
  - Intense metabolic activity in viable tumor
    - Differentiates from necrosis/posttherapeutic change
    - May help stage & predict/evaluate treatment response

Imaging Recommendations

- Best imaging tool
  - Radiograph: Primary investigative tool for bone pain
    - Often diagnostic in OS
  - MR to further characterize lesion, including extent in marrow, physis, joint, & soft tissues, including relationship to neurovascular (NV) bundle
  - CT of chest for pulmonary metastatic disease
- Protocol advice
  - Joint-to-joint T1 & STIR MR imaging to determine marrow extent & look for skip metastases
  - Targeted high-detail imaging of lesion to determine relationship to physis, joint, NV bundle

DIFFERENTIAL DIAGNOSIS

Ewing Sarcoma

- Aggressive long bone diaphyseal or flat bone lesion
- Often shows permeation, mild remodeled expansion, large soft tissue mass
- No osteoid production

Stress Fracture

- Linear sclerosis without bone destruction

- Often perpendicular to bone long axis
- Subtle, solid periosteal reaction or cortical thickening

Aneurysmal Bone Cyst

- Numerous fluid-fluid levels with septal enhancement
- No soft tissue mass, nodular enhancement, or sclerosis
- Bony expansion is more frequent than cortical disruption

Osteomyelitis

- Acute (most common): Typically presents prior to development of aggressive radiographic change
  - MR shows poorly defined marrow abnormalities ± subperiosteal & soft tissue fluid collections
- Chronic: Can show mixed sclerotic & lucent foci

Myositis Ossificans

- Reactive lesion, typically to muscle injury
- Marked edema often surrounds intramuscular mass
- Ca^{2+} is first seen at periphery of lesion within weeks

Bone Infarction

- Acute: May show only periosteal reaction & marrow edema
- Chronic: Classic serpentine/geographic sclerotic foci

PATHOLOGY

General Features

- Genetics
  - Most cases are sporadic
  - Predisposing syndromes
    - Li-Fraumeni (*TP53* mutation)
    - Hereditary retinoblastoma (*RB1* mutation)
    - Rothmund-Thomson (*RECQL4* mutation)

Microscopic Features

- Highly pleomorphic, spindle-shaped tumor cells producing different forms of osteoid
- 3 main histologic subtypes depending on sarcomatous component: Osteoblastic (50%), chondroblastic (25%), fibroblastic (25%)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, soft tissue swelling/mass
- Clinical profile
  - Pathologic fracture: 5-10% in conventional OS
  - Pulmonary metastases can cause pneumothorax (calcifying)
  - Less common metastases: Bone, lymph nodes, liver, brain

Demographics

- Age
  - Bimodal distribution: 10-30 years; over 60 years
- Sex
  - M ≥ F, 3:2 to 2:1
- Epidemiology
  - Most common malignant primary bone tumor in children/young adults
  - Incidence: 5/1 million children ≤ 19 years old

Natural History & Prognosis

- Prognosis depends on
  - Age, sex, extent of disease at diagnosis, time to 1st relapse, location, & stage
    - Better prognosis for extremity vs. axial tumors
    - 15-20% have metastatic disease at diagnosis
      - 80-85% to lungs; bone is 2nd most common
  - Best predictor: Degree of necrosis following neoadjuvant chemotherapy
    - Improved survival with > 90% necrosis
  - OS has ↑ incidence of secondary malignancies
- 5-year survival
  - Without metastases: 70-80%
  - With metastases at presentation: 20-30%
    - Pulmonary is more favorable than bone or other sites
  - With metastases > 2 years after chemotherapy: 40%

Treatment

- Neoadjuvant chemotherapy → surgical resection → adjuvant chemotherapy
- Limb salvage procedures (> 80% of cases)
- Pulmonary nodule metastasectomy in isolated or low-volume metastatic disease (can be curative)

DIAGNOSTIC CHECKLIST

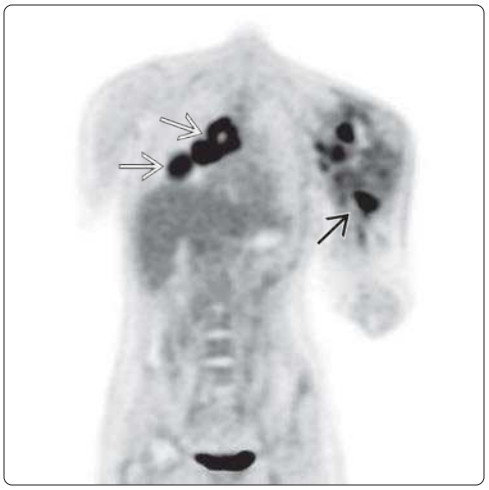


Image Interpretation Pearls

- Bone MR
  - Do not miss distinct skip or other metastatic lesions
    - Requires joint-to-joint imaging
  - Evaluate relationship to physis, joint, & NV bundle
    - Requires focused high-detail imaging
- Chest CT: Calcified & noncalcified pulmonary nodules must be presumed as metastatic until proven otherwise
  - Even in geographic locations with endemic granulomatous diseases (such as histoplasmosis)

(Left) *AP radiograph of a 12-year-old with leg swelling for 2 weeks shows an aggressive sunburst periosteal reaction within this distal femoral osteoblastic OS.* **(Right)** *Coronal PET/CT in a teenager with a left humeral OS shows ↑ metabolic activity in the primary mass ⇨ with an SUVmax of 8.7. Intense FDG accumulation is also seen within the right subcarinal/hilar & lung metastases ➡ with an SUVmax of 11.3. Metastatic lesions were also found in the brain & right adrenal gland (not shown).*

(Left) *AP radiograph in a 16-year-old presenting with back & leg pain shows sclerosis of the left iliac wing with aggressive sunburst periosteal reaction ⇨. Ring & arc chondroid Ca^{2+} ➡ are seen within the lateral soft tissues in this chondroblastic OS.* **(Right)** *Coronal oblique T2 FS MR in the same patient shows heterogeneity of the sacrum & left ilium due to tumor. Soft tissue components of the mass extend into multiple left neural foramina ⇨. Note the multiple tumor cartilage lobules ➡ in this chondroblastic OS.*

(Left) *AP radiograph of the knee in a 15-year-old with pain shows a lytic metaphyseal OS with a wide zone of transition ➡, overlying soft tissue mass ⇨, & no substantial osteoid production.* **(Right)** *Axial T2 FS MR in the same patient shows numerous fluid-fluid levels throughout the lesion, typical of layering blood products. The lateral cortex is completely absent with ballooning of the periosteum by tumor ⇨. A telangiectatic OS was confirmed histologically.*

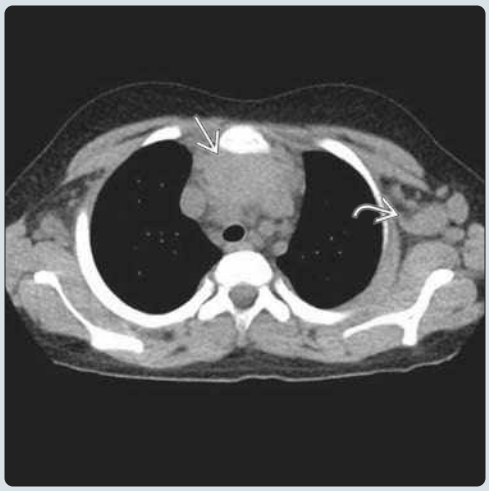
Leukemia

KEY FACTS

TERMINOLOGY

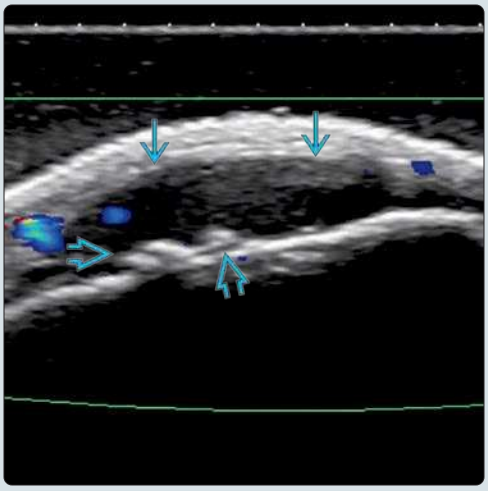
- Leukemia: Malignancy of hematopoietic stem cells diffusely infiltrating or replacing normal bone marrow
- Granulocytic sarcoma or chloroma: Soft tissue mass of leukemic cells typically found with AML

IMAGING



- Radiographs are often normal or have subtle findings
  - Diffuse osteoporosis
  - Leukemic lines
    - Radiolucent metaphyseal bands; zone of provisional calcification (ZPC) is often intact
  - Focal bone destruction
    - Poorly defined, metaphyseal osteolytic lesions with moth-eaten or permeative appearance
  - Aggressive periosteal reaction (lamellated, spiculated, interrupted), even if some components appear smooth
  - Pathologic fracture
  - Chloroma (granulocytic sarcoma)
  - ± chronic bone infarcts in treated patients
    - Osteonecrosis with subchondral collapse
- MR: Leukemia may completely replace normal fatty marrow
  - Discordance of signal between abnormal, infiltrated marrow & subcutaneous fat
  - ± superimposed acute infarction, fracture, or osteomyelitis causing focal symptoms

CLINICAL ISSUES



- Leukemia is most common childhood malignancy
  - Subtypes: ALL > 75%, AML 15-20%, CML < 5%
- Most common presentations
  - Bone or joint pain, limp, swelling
  - Fatigue (anemia), fever ± infection, petechiae, bleeding
  - Hepatosplenomegaly, lymphadenopathy > 60%
- ALL: 5-year survival > 85%; 60-80% for others
- Treatment: Chemotherapy with steroids ± radiation, GCSF (→ ↑ red marrow content), stem cell transplant

(Left) *PA radiograph of the wrist in a 9-year-old with acute lymphoblastic leukemia (ALL) presenting with bone pain for 1 month & periorbital ecchymosis shows permeative osteolytic changes of the distal radius & ulna.* **(Right)** *Axial NECT in the same patient shows lobular thymic infiltration/expansion & bilateral axillary lymphadenopathy. The largest axillary nodes on more superior images measured up to 2 cm in short axis. The spleen was also enlarged (not shown).*

(Left) *Transverse Doppler US shows a left temporal soft tissue mass with calvarial permeation & irregular periosteal reaction due to a granulocytic sarcoma in acute myelogenous leukemia (AML).* **(Right)** *AP radiograph in an anemic patient with cardiomegaly & splenomegaly shows transverse radiolucent lines in the femurs due to leukemia. Note the intact thin sclerotic zones of provisional Ca^{2+} abutting the physes (just proximal to the lucent lines), which help differentiate leukemia from rickets.*

TERMINOLOGY

Synonyms

- Acute lymphocytic (or lymphoblastic) leukemia (ALL), acute myelogenous leukemia (AML), myeloblastoma, chronic myelogenous leukemia (CML), chronic lymphocytic leukemia (CLL), juvenile chronic myeloid leukemia (JCML)

Definitions

- Leukemia: Malignancy of hematopoietic stem cells diffusely infiltrating or replacing normal bone marrow
- Granulocytic sarcoma or chloroma: Soft tissue mass of leukemic cells typically found with AML
- Extramedullary sanctuary sites: Sites of leukemia with barriers to systemic therapy (CNS & reproductive organs)

IMAGING

Radiographic Findings

- Radiography
  - Often normal or with very subtle metaphyseal findings
    - Only 40% have radiographic findings
  - Diffuse osteoporosis
    - Coarse trabeculae with abnormally well-visualized sclerotic rim due to intact zone of provisional calcification (ZPC) or subchondral bone
    - Multiple flattened, collapsed, or biconcave vertebrae
  - Leukemic lines
    - Radiolucent metaphyseal bands; ZPC is often intact
      - Stress of disease or leukemic infiltration
    - ± dense metaphyseal bands post therapy
  - Focal bone destruction
    - Poorly defined osteolytic lesions with moth-eaten or permeative bone destruction
  - Periosteal reaction
    - Usually has some aggressive features (lamellated, spiculated, interrupted) even if some components appear smooth
      - Subperiosteal infiltration by malignant cells through haversian canals
      - Subperiosteal hemorrhage is less common
  - Sclerotic foci
    - Typically in myelogenous leukemia
    - ± chronic bone infarcts in treated patients
  - Pathologic fracture
    - Usually metaphyseal
    - Can simulate nonaccidental trauma
  - Chloroma (granulocytic sarcoma)
    - Nonspecific soft tissue mass
    - Most commonly in head & neck, musculoskeletal soft tissues, GI system, lymph nodes, peritoneum, or bony mass
      - Can simulate meningioma or epidural hematoma
    - Poor prognosis
  - Late findings
    - Osteonecrosis (ON) with subchondral collapse
    - Endochondral ossification is rarely interrupted with persistence of unossified cartilage in metaphysis
  - Other organs: Splenomegaly, cardiomegaly, thymic infiltration

CT Findings

- Bone CT
  - Permeative bone destruction, periosteal reaction
  - ± soft tissue mass of chloroma
  - Sclerotic foci of ON

MR Findings

- T1: Confluent dark leukemic infiltrate replacing normal high-signal fatty yellow marrow
  - Marrow signal abnormally is abnormally discordant from signal of bright subcutaneous fat
    - Must be interpreted in light of normal red to yellow marrow conversion patterns in children
- T2 FS/STIR: Poorly defined patchy or diffusely bright marrow signal of visualized bones
  - Marrow signal is abnormally discordant from signal of dark subcutaneous fat
- T1 C+ FS: Intermediate to mildly bright enhancement of leukemic marrow diffusely
- DWI: May show restricted diffusion
- Special circumstances
  - Acute infarction or osteomyelitis
    - May present before, during, or after treatment
    - Focal regions of superimposed marrow heterogeneity with ↓ enhancement & overlying periosteal & soft tissue edema
  - Chloroma
    - Intermediate to bright T2 FS/STIR signal soft tissue mass with heterogenous or uniform enhancement
  - Recovery of normal marrow signal after treatment
    - Gradual process in setting of effective therapy
      - ↑ fat fraction, T1 shortening
  - Relapse after stem cell transplant
    - Numerous, round, well-circumscribed "dots" of leukemic infiltrate
    - T1 dark, T2 FS/STIR bright; enhance with contrast
    - May require targeted biopsy rather than blind iliac marrow aspiration to confirm recurrence

Nuclear Medicine Findings

- Bone scan
  - ↑ radiotracer uptake in tumor
    - May underestimate disease
- PET
  - Helpful to identify extramedullary disease with ↑ metabolic activity

Imaging Recommendations

- Best imaging tool
  - MR: T1, T2 FS/STIR, T1 C+ FS
    - Musculoskeletal symptoms with normal radiographs
    - Whole-body MR can screen for ON

DIFFERENTIAL DIAGNOSIS

Metastatic Neuroblastoma

- Bone involvement is similar to leukemia
  - Metaphyseal lucent bands
  - "Moth-eaten" bone destruction
  - Circumscribed or diffuse marrow replacement
  - Spiculated periosteal reaction of skull

- Look for primary retroperitoneal/suprarenal mass

Langerhans Cell Histiocytosis

- Focal/multifocal, punched-out lytic lesion(s)
- Intense marrow edema + homogeneous small soft tissue mass
- ± periosteal reaction, soft tissue edema

Osteomyelitis

- Symptoms similar to leukemia
- Adjacent, poorly defined soft tissue abnormalities
- Poorly defined metaphyseal-centric marrow process
  - ± drainable fluid collections

Congenital Syphilis

- Metaphyseal lucent bands
- Hepatosplenomegaly, lymphadenopathy, anemia, skin rash
- Wimberger corner sign: Focal destruction of medial proximal tibial metaphysis

Lymphoma

- Typically solitary, often sclerotic focus
- Older age group

Ewing Sarcoma

- Diaphyseal or flat bone lesion with aggressive periosteal reaction & permeative bone destruction
- Sharply circumscribed marrow interface on T1 MR
- Large soft tissue mass

Rickets

- Physeal lengthening/widening with loss of ZPC
- Metaphyseal fraying, cupping, & splaying

Physeal Stress Injuries

- Physeal lengthening/widening with loss of ZPC
- Isolated to painful extremity

PATHOLOGY

General Features

- Etiology
  - Arises from primitive stem cells either de novo or from preleukemic state
- Genetics
  - ↑ ALL risk in Down syndrome, Li-Fraumeni syndrome, Fanconi anemia, immunodeficiencies
  - CML translocation chromosome 9 & 22 is classic (Philadelphia chromosome)
- Associated abnormalities
  - Myelodysplastic syndrome (1/3 develop AML)
  - Long-term risk from low medical levels of diagnostic imaging ionizing radiation is debated
- Classified
  - Basis of cell maturity: Acute (blasts) or chronic (more mature cells)
  - Basis of cell type: Lymphocytic or myelogenous form

Microscopic Features

- Acute: Infiltration of bone marrow by poorly differentiated blast cells
  - ALL: Patternless sheets of small blue cells
  - AML: Wright stain or Giemsa preparation with lysosomal cytoplasmic structure (Auer rods)
- Chronic: Mature leukocyte infiltration
  - CML: Mature granulocyte with normal lymphocyte count, Philadelphia chromosome
  - CLL: Mature lymphocytes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Bone or joint pain, limp, swelling
    - Sharp, localized, recurrent arthralgias (75%)
  - Fatigue (anemia), fever ± infection, petechiae, bleeding
  - Hepatosplenomegaly, lymphadenopathy > 60%
- Other signs/symptoms
  - Chest radiographs are often obtained prior to sedated procedures
    - Mediastinal mass, tracheal deviation, lung opacities, cardiomegaly, humeral metaphyseal lucent bands
  - SVC syndrome, tachypnea, respiratory distress
  - ↑ ESR, thrombocytopenia, neutropenia

Demographics

- Age
  - ALL: Peak 2-10 years
  - AML: Peak > 65 years but accounts for 15-20% of childhood leukemias
  - CML: Peak 30-50 years
  - CLL: Median 60 years
- Epidemiology
  - Most common pediatric malignancy
    - ALL is most common form in children
      - ALL > 75%, AML 15-20%, CML < 5%

Natural History & Prognosis

- ALL: 5-year survival > 85%
- AML: 5-year survival ~ 60-70%
- CML: 5-year survival ~ 60-80%

Treatment

- Chemotherapy with steroids ± radiation
- Intrathecal chemotherapy for CNS disease
- CD19-directed chimeric antigen receptor (CAR) T cells for relapsed or refractory disease in ALL
- Granulocyte colony-stimulating factor (GCSF)
- Stem cell transplant

(Left) *AP radiograph in an 11-month-old shows pathologic fractures of the femoral, tibial, & fibular metaphyses at sites of underlying permeative osteolytic change. The patient was ultimately diagnosed with leukemia.* **(Right)** *Coronal STIR MR in a 3-year-old with arm pain & fever shows diffuse hyperintense marrow throughout the humerus, coracoid process, & ribs. The marrow was diffusely dark on T1 MR (not shown). The patient was eventually diagnosed with B-cell ALL.*

(Left) *Lateral chest radiograph in a 5-year-old with newly diagnosed ALL who had lucent metaphyseal bands on hip radiographs (not shown) demonstrates osteoporosis & compression fractures throughout the spine.* **(Right)** *Sagittal T1 MR in a 14-year-old with a history of ankle pain 2 years after a bone marrow transplant for ALL shows numerous round lesions in a background of normal yellow marrow. Recurrent leukemia was confirmed by biopsy.*

(Left) *Coronal T2 FS MR in a 10-year-old with history of T-cell ALL shows a bone infarct within the distal tibia as well as talar dome osteonecrosis with a hypointense subchondral fracture. Subchondral collapse of the talar dome was visible on 1-year follow-up radiographs (not shown).* **(Right)** *AP radiograph in a 12-year-old with relapsed ALL & bilateral shoulder pain shows humeral head osteonecrosis with a lucent subchondral fracture due to steroid therapy.*

Langerhans Cell Histiocytosis

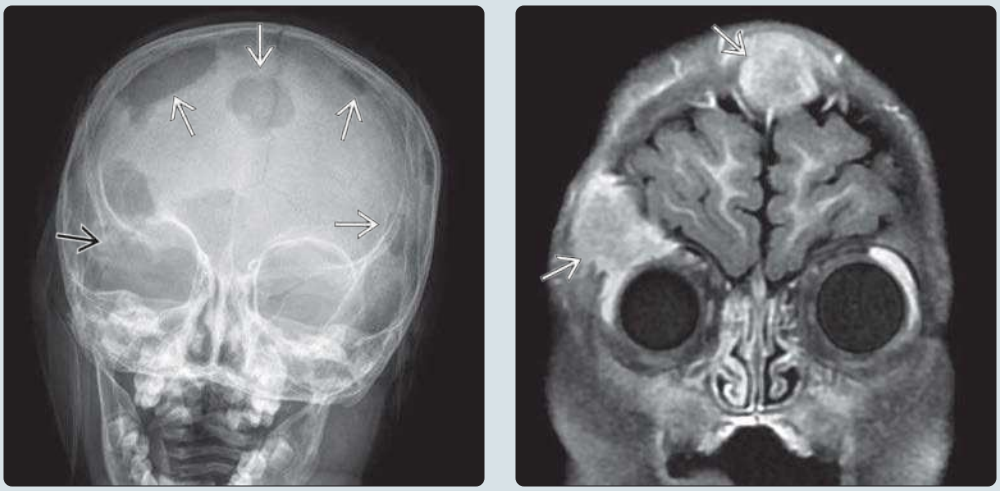
KEY FACTS

TERMINOLOGY

- Langerhans cell histiocytosis (LCH): Spectrum of disease caused by neoplastic clonal proliferations of CD1a, CD207, & S100 protein (+) dendritic cells
- Single system (SS) (unifocal or multifocal) vs. multisystem (MS) disease
  - Most frequently involved: Bone (80-90%) & skin (40-50%)
  - Risk organ (RO) involvement: Liver, spleen, marrow; confers worse prognosis (high risk)
  - Others: Lymph nodes, lung, pituitary, thymus, GI tract

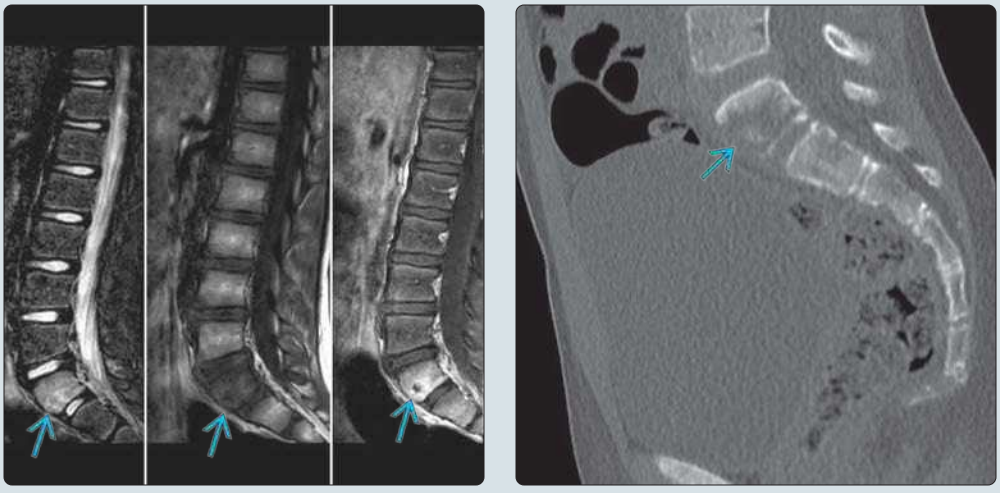
IMAGING

- Best clue: Well-defined, round or lobulated lytic punched-out skull lesion(s) without sclerotic rim
- Monostotic vs. multifocal involvement: 50-75% vs. 10-20%
- Affected sites: Flat bones (50%) vs. long bones (30%)
  - Skull > ribs > femur > pelvis > spine
  - Classic cause of vertebra plana & "floating tooth"
  - Typically lacks large soft tissue mass
- Sensitivity for LCH: FDG PET & whole-body MR > > radiographs > bone scan
  - FDG PET is better for active vs. healing disease



CLINICAL ISSUES

- Age: 90% of LCH cases are < 15 years at presentation
  - SS, unifocal (70% of cases); peak age: 5-15 years
  - SS, multifocal (20% of cases); peak age: 1-5 years
  - MS RO(+) disease (10% of cases); peak age: 0-2 years
- Spontaneous regression of unifocal bone disease is common; chemotherapy & steroids are used otherwise
- Mortality: SS or MS RO(-) disease < 5%; MS RO(+) disease 10-50%
- Disease reactivation &/or long-term sequelae in 25-75% (MS > SS)



DIAGNOSTIC CHECKLIST

- LCH should be considered for most lytic pediatric bone lesions due to variable appearances

(Left) *AP radiograph of the skull in a 1-year-old girl with palpable masses shows multiple punched-out lytic lesions of the calvarium. The superior & lateral walls of the right orbit are destroyed. An ultrasound performed at the same time (not shown) demonstrated hypovascular soft tissue filling these sites of complete bone absence (rather than bone permeation or spiculation).* **(Right)** *Coronal T1 C+ FS MR in the same patient shows enhancing soft tissue masses at the sites of the lytic bone lesions. LCH was confirmed at biopsy.*

(Left) *Sagittal (from left to right) STIR, T1, & T1 C+ FS MR images in an 8-year-old patient with 1 month of back pain show a heterogeneous poorly defined lesion of the S1 vertebral marrow. No soft tissue mass is seen.* **(Right)** *Sagittal bone CT in the same patient shows a lytic lesion of S1 with destruction of the anterior cortex. LCH was found at biopsy. A subsequent PET/CT (not shown) demonstrated no other foci of involvement.*

TERMINOLOGY

Definitions

- Langerhans cell histiocytosis (LCH): Spectrum of disorders caused by neoplastic clonal proliferations of CD1a, CD207, & S100 protein (+) dendritic cells
- Single system (SS) (unifocal or multifocal) vs. multisystem (MS) disease
  - Bone (80-90%) & skin (40-50%) are most frequently involved
    - Lung is most common SS site in adults
  - Risk organ (RO) involvement: Liver, spleen, marrow; confers worse prognosis (high risk)
    - Lung is no longer considered RO
  - Other organs: Lymph nodes, pituitary, thymus, GI tract
  - CNS-risk lesion: Skull base & many facial lesions
    - Diabetes insipidus (25% overall, 50% with MS disease), growth hormone deficiency (10%), parenchymal mass lesions (1%), & delayed neurodegenerative changes

IMAGING

General Features

- Best diagnostic clue
  - Well-defined, round or lobulated lytic punched-out skull lesion(s) without sclerotic rim
- Location
  - Monostotic involvement (unifocal SS): 50-75%
  - Multifocal SS involvement: 10-20%
  - Predilection for flat bones (> 50% of cases): Skull, ribs, pelvis, scapula
  - Long bones affected ~ 30% of cases
    - Metaphysis, diaphysis > epiphysis
  - Decreasing order of frequency: Skull, ribs, femur, pelvis, spine
- Morphology
  - Variable radiographic appearance of skeletal lesions depending on phase of disease ± therapy
    - Lucent/lytic > > sclerotic; well-defined vs. poorly defined borders; aggressive vs. nonaggressive vs. absent periosteal reaction

Radiographic Findings

- Radiography
  - Skull (50%)
    - Well-defined lytic lesion, most commonly solitary, without sclerotic rim
      - Sclerotic rim develops during healing phase (which may occur before therapy)
      - Coalescence of lesions: Geographic skull
    - Periosteal reaction is often absent in skull LCH
      - Does not produce radiating spicules of new bone as seen with metastases
    - ± beveled edge: Asymmetric involvement of inner vs. outer table of skull
    - ± button sequestrum: Sclerotic focus within lytic lesion
    - Small soft tissue mass may extend from lytic lesion
    - Floating tooth sign: Lesion in alveolar mandible → loss of dense lamina dura
  - Appendicular skeleton: Variable appearance
    - Lesions generally respect joint space & growth plate
  - Spine: Variable loss of height
    - Classic vertebra plana: Complete collapse of vertebral body ("wafer thin")
    - Height recovers to some degree over years

MR Findings

- T1WI
  - Intermediate- to low-signal lesion replacing marrow fat
- T2WI FS
  - Intermediate to high signal within focal lesion
    - ± hypointense lesion rim
    - Surrounded by ill-defined hyperintense marrow > soft tissue edema
    - Hyperintense signal deep to or overlying periosteum
  - Purely medullary lesion vs. cortical destruction with relatively small soft tissue mass extending beyond bone
  - Findings may change with phase of disease
- STIR
  - Whole-body STIR to assess for multifocal disease
    - Much more sensitive for skeletal & extraskeletal LCH than radiographs or bone scan
    - Limited ability to distinguish active vs. residual disease
- T1WI C+ FS
  - Diffuse enhancement of lesion & adjacent edema is typical

Nuclear Medicine Findings

- Bone scan
  - Lower sensitivity than radiographic survey or whole-body MR
- PET/CT
  - FDG PET is highly sensitive for active LCH (FDG avid)
    - Less sensitive than MR in vertebral disease
  - Also demonstrates healing before other modalities
  - Higher radiation dose than other modalities; radiation dose reduction can be achieved with
    - Low-dose lesion-selective CT technique
    - PET/MR fusion

Imaging Recommendations

- Best imaging tool
  - PET/CT vs. whole-body STIR MR

DIFFERENTIAL DIAGNOSIS

Osteomyelitis

- Cortical & marrow abnormalities are less well defined
- Moderate to marked soft tissue inflammation
- Rim-enhancing fluid collections are often present

Metastatic Neuroblastoma

- Lucent metaphyseal bands &/or lytic permeative metaphyseal lesions
- Radiating spicules of periosteal new bone formation are typical in permeative skull lesions
  - May also cause mild expansile remodeling

Leukemia

- Lucent metaphyseal bands &/or lytic permeative metaphyseal lesions
- ± diffusely abnormal background marrow

Ewing Sarcoma

- Permeative bone destruction, wide zone of transition, aggressive periosteal reaction; often with large soft tissue mass
- ± remodeling with expansion, saucerization
- May involve entire flat bone, but calvarium is uncommon

Congenital Syphilis

- Hepatosplenomegaly, lymphadenopathy, rash, lucent metaphyseal bands
- Wimberger sign: Lytic lesion of proximal medial tibia

Infantile Myofibromatosis

- Single or multifocal bone &/or soft tissue lesions
- Expansile bubbly lucent metadiaphyseal lesions, often relatively symmetric

PATHOLOGY

General Features

- Historic categorization
  - Letterer-Siwe (acute disseminated form): < 10%
  - Hand-Schüller-Christian (chronic disseminated form): 15-30%
  - Eosinophilic granuloma (isolated bone or lung involvement): 60-80%

Microscopic Features

- Active lesion: Granuloma of dendritic Langerhans cells > inflammatory cells
- Later stages: Macrophages > Langerhans cells + fibrotic & xanthomatous changes
- Birbeck granule: Classic "tennis racquet" organelle found by electron microscopy in up to 40% of Langerhans cells
  - Diagnostic importance is now diminished due to immunostaining of specific markers

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Localized bone pain, tenderness
  - Soft tissue swelling or mass
- Other signs/symptoms
  - Rash, limping, exophthalmos, hepatosplenomegaly, lymphadenopathy, otitis externa, mastoiditis, gingivitis
  - Fever, ↑ erythrocyte sedimentation rate, & leukocytosis may occur

Demographics

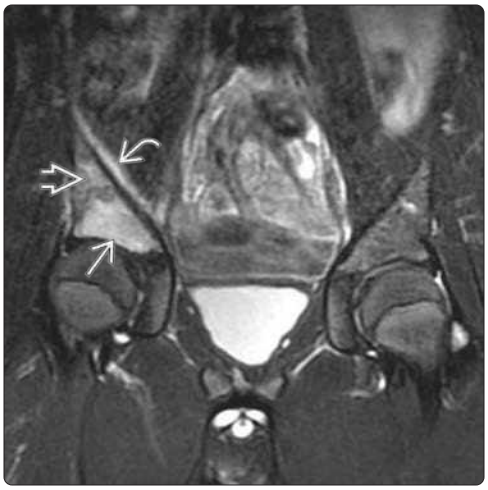
- Age
  - 90% of cases are < 15 years at presentation; median is 3 years of age at diagnosis
  - SS, unifocal (70% of cases); peak age: 5-15 years
  - SS, multifocal (20% of cases); peak age: 1-5 years
  - MS RO(+) (10% of cases); peak age: 0-2 years
- Sex
  - M:F = 1.2-3:1

Natural History & Prognosis

- Mortality
  - SS or no RO [MS RO(-)] disease: < 5%
    - Spontaneous regression of unifocal bone disease is common
  - MS disease + RO involvement [MS RO(+)]: 10-50%
    - Progressive disease on multiagent chemotherapy at 6 weeks: 40-80% mortality
  - Lung disease in adults: 25% at 5 years
    - Regresses with smoking cessation
- Disease reactivation
  - Unpredictable timeframe, number of episodes
  - Up to 25% in multifocal SS (bone) disease
  - 50-75% in MS disease
  - Bone is most frequent site of reactivation
- Long-term sequelae
  - 70% in MS disease, 25% in SS disease
  - Often related to destructive/fibrotic changes at site(s) of initial disease
  - Diabetes insipidus & CNS degeneration (which may be paraneoplastic) are most serious

Treatment

- SS disease
  - Unifocal bone disease: Watchful waiting vs. curettage & local steroid injection
  - Multifocal bone disease or CNS-risk lesion: Chemotherapy & steroids x 6-12 months
- MS disease (± RO): Multiagent chemotherapy x 12 months



DIAGNOSTIC CHECKLIST

Consider

- LCH should be considered in differential diagnosis for most pediatric bone lesions due to variable appearances
- If favoring LCH on initial targeted radiographs, consider whole-body survey (MR vs. PET) to help direct biopsy & determine disease extent

(Left) *Coronal T2 FS MR in a 10-year-old patient with right hip pain shows a homogeneously hyperintense lesion ➡ of the right iliac marrow without adjacent bone destruction. There is surrounding marrow ➡ & juxtacortical ➡ edema. LCH was confirmed with biopsy.* **(Right)** *Sagittal bone CT in a 12-year-old patient undergoing evaluation for a spinal deformity shows a wafer-like L4 vertebral body (vertebra plana) ⇨, ultimately proven to be secondary to LCH.*

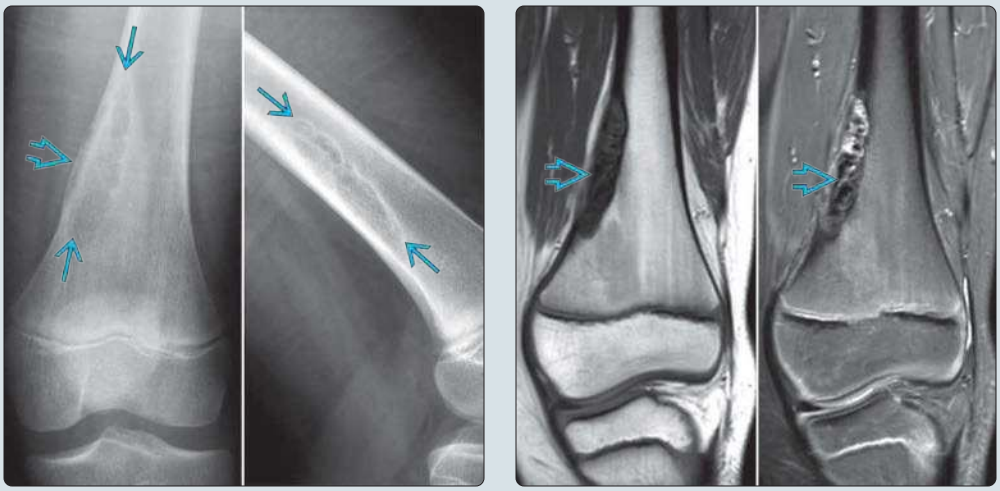
(Left) *AP radiograph in a 15-year-old boy with weeks of pelvic pain shows a lucent lesion ⇨ with intermediate zone of transition in the right ischium.* **(Right)** *Coronal T1 C+ FS MR in the same patient shows enhancing bone lesions arising from the right ischial tuberosity ➡ & left posterior acetabular wall ➡. Contiguous enhancing soft tissue masses ➡ overlie foci of cortical destruction, & there is adjacent soft tissue & marrow edema at each site.*

(Left) *Coronal FDG PET/CT in the same patient shows FDG avidity (or ↑ metabolic activity) in the lesions ⇨, typical of LCH. No other lesions were identified.* **(Right)** *Longitudinal ultrasound of the occipital calvarium in a 6-month-old patient with a palpable mass shows complete interruption of the bone ⇨ by a mildly heterogeneous ovoid mass ⇨, confirmed as LCH on biopsy.*

Nonossifying Fibroma

KEY FACTS

TERMINOLOGY



- Very common benign fibrous lesion of pediatric bone
- Terms fibroxanthoma & metaphyseal fibrous defect include
  - Nonossifying fibroma (NOF)
    - > 2- or 3-cm length; encroachment on medullary cavity
  - Fibrous cortical defect (FCD)
    - < 2- or 3-cm length
    - Essentially isolated to cortex

IMAGING

- Eccentric, elongated, & bubbly lucent lesion in long bone metaphysis/diaphysis with narrow zone of transition, lobular or smooth sclerotic margin, & no periosteal reaction
- Expected involution/healing → gradual sclerosis, resolution
- Typical locations
  - Metaphysis of long bone: Up to 93%
    - Distance from physis ↑ with age
  - Located around knee: 55-89%
- Radiographs are usually diagnostic
  - Atypical features should suggest other lesion or superimposed complication (such as pathologic fracture)

CLINICAL ISSUES

- May be developmental defect rather than neoplasm
- Usually asymptomatic & incidentally discovered
- Occurs in up to 35% of children
  - Peak age: 10-15 years (75% in 2nd decade)
- May develop symptoms (uncommon)
  - Acute pain with pathologic fracture
    - Classic predictors: > 50% of cortical thickness involved or > 3.3 cm in size in weight-bearing bone
  - Gradual pain with stress fracture of adjacent bone (very rare)
  - Paraneoplastic rickets/osteomalacia (extremely rare)
- Gradual healing with spontaneous regression of most cases in late adolescence
- Treatment is only required if patient is at high risk for pathologic fracture

(Left) *AP (left) & lateral (right) radiographs in a 9-year-old after an injury show a well-circumscribed, elongated, lucent & bubbly, eccentric lesion ⇨ of the distal femoral diaphysis with mild expansile remodeling ⇨.* **(Right)** *Coronal T1 (left) & STIR (right) MR images in the same patient show heterogeneous but predominantly low signal intensity ⇨ throughout the 6-cm lesion. Note the lack of adjacent marrow & soft tissue edema or periosteal reaction. The features are typical of a nonossifying fibroma (NOF).*

(Left) *AP radiograph in a 14-year-old after an injury shows an incidental, elongated, lucent & bubbly, eccentric lesion ➡ in the medial femoral metaphysis with a narrow zone of transition & sclerotic border, typical of an NOF or fibroxanthoma. There is mild expansile remodeling & endosteal scalloping without periosteal reaction.* **(Right)** *Coronal T2 FS MR in the same patient shows heterogeneous but largely hypointense signal of the lesion ➡ with normal adjacent marrow & soft tissues. (Note the torn lateral meniscus ⇨.)*

TERMINOLOGY

Abbreviations

- Nonossifying fibroma (NOF)

Synonyms

- Non-ossifying fibroma, fibrous cortical defect (FCD), metaphyseal fibrous defect, fibroxanthoma

Definitions

- Very common benign fibrous lesion of pediatric bone, usually asymptomatic
- Terms fibroxanthoma & metaphyseal fibrous defect include
  - NOF
    - > 2- or 3-cm length
    - Encroachment on medullary cavity
  - FCD
    - < 2- or 3-cm length
    - Essentially isolated to cortex

IMAGING

General Features

- Best diagnostic clue
  - Eccentric, elongated, & bubbly lucent lesion in long bone metaphysis/diaphysis with narrow zone of transition, sclerotic margin, & no periosteal reaction
- Location
  - Metaphysis of long bone involved in up to 93%
    - Distance from physis ↑ with age
  - Tibia (43%), femur (38%), fibula (8%)
    - Around knee: 55-89%
  - Less common in upper extremity: 8%
    - Humerus: 5%
  - Usually solitary in absence of syndrome
- Size
  - 0.5-7.0 cm
- Morphology
  - Elongated, lobular, eccentric lesion

Radiographic Findings

- Radiography
  - Eccentric, cortically based, lucent lesion
  - Lesion long axis parallels bone long axis
  - Narrow zone of transition
  - Scalloped, lobular, or smooth deep sclerotic margin
  - ± mild expansile remodeling of overlying cortex &/or endosteal scalloping
    - Cortex thinned but usually intact (not always)
  - No matrix Ca^{2+}
  - ± septation/trabeculation
  - No periosteal reaction without fracture or other complication
  - ↑ mineralization in healing stages

CT Findings

- Bone CT
  - Parallels radiographic findings
  - Attenuation of lesion matrix is slightly > bone marrow

MR Findings

- T1WI
  - Intermediate to low signal intensity centrally
  - Peripheral hypointense rim (reactive sclerosis)
- T2WI
  - Variable signal intensity centrally, most commonly low
    - T2-hypointense components are due to fibrous tissue ± hemosiderin
  - Visible internal septa
  - Peripheral hypointense rim (reactive sclerosis)
  - No overlying soft tissue mass
  - No adjacent marrow, periosteal, or soft tissue edema without superimposed complication
- T1WI C+
  - Variable enhancement centrally, may be avid

Ultrasonographic Findings

- Grayscale ultrasound
  - Expanded, thinned, or scalloped cortex filled with hypoechoic tissue
  - ↓ size, ↑ echogenic foci with healing
- Color Doppler
  - May show prominent internal blood flow

Nuclear Medicine Findings

- Bone scan
  - Almost all lesions show some degree of uptake
    - Mild to intense uptake in healing lesions
    - Faint to absent uptake in inactive or fully healed lesions
- PET/CT
  - Mildly to intensely ↑ metabolic activity (may mimic malignancy)
    - ↓ activity with healing, though FDG avidity of these lesions often differs from Tc-99m bone scan uptake
    - Correlation with CT appearance is critical (or radiographs if PET performed without CT)

Imaging Recommendations

- Best imaging tool
  - Radiographs are diagnostic in most cases
  - Usually no other imaging needed unless
    - Complications are suspected by clinical or radiographic features
    - Larger lesion is identified
      - May be less pathognomonic
      - Follow-up to evaluate growth & fracture risk
  - CT/MR is helpful in confirming underlying fibroxanthoma in atypical or complicated lesion or with unusual clinical symptoms

DIFFERENTIAL DIAGNOSIS

Distal Femoral Metaphyseal Irregularity

- Cortical undulation/irregularity/interruption by lucent lesion with concave sclerotic deep margin
- Always at posterior, medial distal femur near medial gastrocnemius or adductor magnus attachments
- Overlaps fibroxanthoma imaging & histology despite poorly applied term "cortical desmoid"

Aneurysmal Bone Cyst

- Lucent metadiaphyseal lesion with marked expansile remodeling of cortex ± internal septations

- CT/MR: Fluid-fluid levels + thin septal enhancement

Unicameral Bone Cyst

- Centrally located, well-defined metadiaphyseal lucent lesion without profound expansion or septations
- Fallen fragment sign is pathognomonic in cases of fracture
- Classic location: Proximal humerus

Fibrous Dysplasia

- Mildly expansile, medullary diaphyseal lesion
- Ground-glass (think frosted or smudged glass) appearance of matrix

Chondromyxoid Fibroma

- Eccentric, bubbly, lucent metadiaphyseal lesion
- ~ 90% are expansile
- Much less common than fibroxanthoma

Enchondroma

- Central diaphyseal bubbly lucent lesion with endosteal scalloping & mild expansile remodeling
- ± ring & arc chondroid matrix
- Most commonly found in hands & feet

PATHOLOGY

General Features

- Genetics
  - Vast majority of these lesions are sporadic
  - Multiple lesions are seen in
    - Neurofibromatosis type 1 (NF1)
    - Jaffe-Campanacci syndrome (may be NF1 subset)
      - Multifocal fibroxanthomas with extraskeletal manifestations in children
      - Café au lait spots, mental restrictions, hypogonadism, & cryptorchidism + cardiovascular, renal, & ocular abnormalities

Microscopic Features

- NOF & FCD are histologically identical
- Bundles of spindle-shaped fibroblasts, scattered multinucleated giant cells, & foamy histiocytes
- Arranged in storiform pattern

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually asymptomatic & identified incidentally
- Other signs/symptoms
  - Acute pain with pathologic fracture
    - Risk greatest if lesion is > 3.3 cm in size or causing loss of > 50% cortical thickness in weight-bearing bone
    - Recent literature touts 4 point scale for assessment of fracture risk by CT: Risk ↑ with more positive factors
      - > 50% width in sagittal plane
      - > 50% width in coronal plane
      - Breach of cortex
      - Lack of "neocortex" (i.e., sclerotic deep margin that is similar in thickness to true cortex)
  - Adjacent stress fractures are reported rarely with gradual pain onset
  - Rarely complicated by other processes (such as infection)
  - Oncogenic osteomalacia is extremely rare
    - Paraneoplastic syndrome where benign bone tumor releases factors, resulting in renal phosphate wasting with subsequent rickets/osteomalacia
    - Usually in adults (mean age: 35-40 years)

Demographics

- Age
  - 2-20 years; peak: 10-15 years
    - 75% are found in 2nd decade of life
    - Usually not seen after age 30
- Sex
  - M:F = 2:1
- Epidemiology
  - Most common fibrous lesion of bone
  - Occurs in up to 35% of children

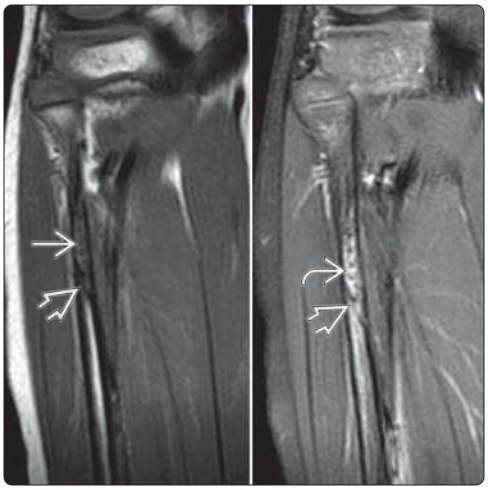
Natural History & Prognosis

- Benign lesion; no malignant transformation risk
  - More likely to be developmental defect than neoplasm
- Presents during childhood, usually disappears in late adolescence
  - Involution over 2-4 years
- Rarely grows rather than involutes

Treatment

- Usually not required
- Curettage with bone grafting of larger lesions at risk for fracture
- Conventional casting or internal fixation if fracture occurs
  - Lesion may heal after fracture

DIAGNOSTIC CHECKLIST



Consider

- No need to biopsy or treat if appearance is typical & fracture risk is low ("do not touch")
- MR to assess any atypical radiographic features

(Left) *AP radiograph shows a well-circumscribed, bubbly, lucent lesion eccentrically located in the proximal fibular diaphysis with a deep margin of sclerosis & mild expansile remodeling of the overlying cortex, typical of an NOF.* **(Right)** *Coronal T1 (left) & T1 C+ FS (right) MR images in the same patient show the low signal intensity rim of the lesion. The lesion shows intermediate signal intensity internally prior to contrast administration with heterogeneous enhancement after contrast.*

(Left) *Coronal FDG PET/CT in a teenager with nasopharyngeal carcinoma shows ↑ metabolic activity in an eccentric distal femoral lesion that has typical CT characteristics of an NOF.* **(Right)** *AP (left) & lateral (right) radiographs show an obliquely oriented pathologic fracture through a relatively large NOF in the distal tibia of this teenage patient who fell from a height of 12 feet.*

(Left) *AP radiograph (left) & coronal T2 FS MR (right) in a 10-year-old boy with knee pain show a large NOF with atypical periosteal reaction & edema of the surrounding soft tissues & marrow. No fracture was identified. Biopsy confirmed an NOF with superimposed osteomyelitis.* **(Right)** *AP radiograph of the knee in a 16-year-old girl shows a well-defined, crescentic, sclerotic lesion in the medial aspect of the distal femoral metadiaphysis, typical of a nearly healed fibroxanthoma/NOF.*

Osteoid Osteoma

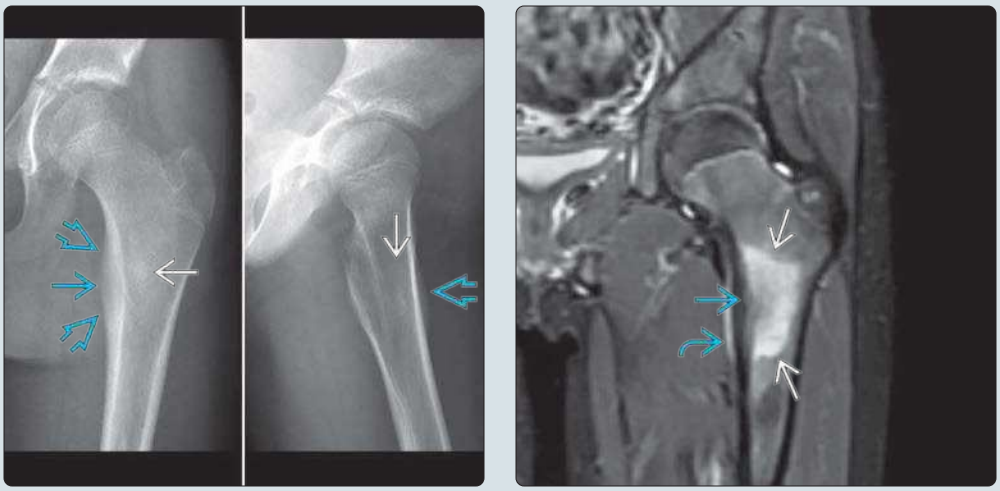
KEY FACTS

TERMINOLOGY

- Benign osteoblastic lesion characterized by < 2-cm nidus of osteoid/woven bone in fibrovascular stroma

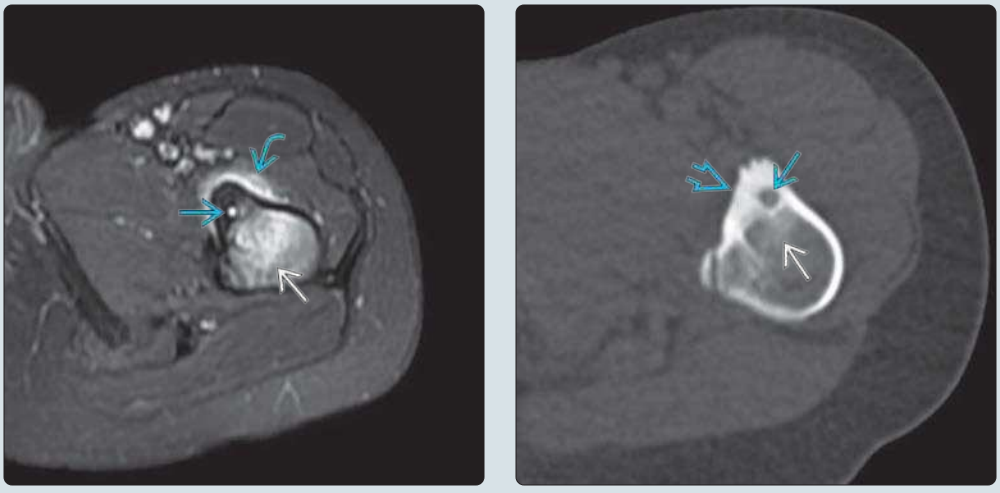
IMAGING

- Best clue: Well-defined, small, lucent lesion in tubular bone cortex with surrounding sclerosis & edema
- Locations
  - Cortical: 70-80%
    - Diaphyses > metaphyses of tubular bones
  - Medullary: 20-30%
    - Epiphyses or equivalents (intraarticular in 10%)
    - Spine posterior elements
- Radiographs/CT
  - Small, round, or ovoid lucent nidus ± central Ca^{2+}
  - Surrounding cortical thickening, solid periosteal reaction
  - Prominent cortical vessels near nidus
- MR
  - Variable nidus signal on T2 FS MR; may be "target"
  - Surrounding marrow, periosteal, & soft tissue edema
    - Joint effusion/synovitis if osteoid osteoma is intraarticular
  - Hyperenhancing nidus on early dynamic T1 C+ FS MR
- NM bone scan: Double density sign



TOP DIFFERENTIAL DIAGNOSES

- Osteomyelitis, Langerhans cell histiocytosis, stress injury, osteoblastoma, osteosarcoma



CLINICAL ISSUES

- Insidious pain, classically worse at night & relieved by NSAIDs
- Gradual spontaneous regression is accelerated by NSAIDs
- Surgery is curative if nidus is completely resected
- Image-guided percutaneous interventions are highly effective due to nidus visualization

(Left) *AP & lateral views in an 8-year-old with months of left hip pain show cortical thickening & medullary sclerosis at the medial & anterior proximal femur surrounding a subtle lucent focus.* **(Right)** *Coronal STIR MR in the same patient shows well-circumscribed edema (a.k.a. the half-moon sign) surrounding the subtle cortical lesion. Note the edema overlying the periosteum.*

(Left) *Axial T2 FS MR in the same patient shows hyperintense signal at the osteoid osteoma nidus with overlying soft tissue & periosteal edema + subjacent medullary edema.* **(Right)** *Axial NECT in the same patient at the time of radiofrequency ablation shows a tiny focus of calcification in the lucent nidus of this osteoid osteoma (OO). The characteristic adjacent cortical thickening & medullary sclerosis are again noted.*

TERMINOLOGY

Abbreviations

- Osteoid osteoma (OO)

Definitions

- Benign osteoblastic lesion characterized by < 2-cm nidus of osteoid/woven bone in fibrovascular tissue

IMAGING

General Features

- Best diagnostic clue
  - Small, well-defined, cortically-based lucent lesion of tubular bone with surrounding sclerosis & edema
- Location
  - Distribution in body
    - Femur, tibia: 53-60%
    - Hands & feet: 15-25%
    - Spine: 9-20%
      - Posterior elements: 90%
      - Vertebral body: 10%
      - Lumbar > cervical > thoracic > sacral
  - Distribution in bone
    - Cortical: 70-80%
      - Diaphyses > metaphyses of tubular bones
    - Medullary: 20-30%
      - Epiphyses or equivalents (10% are intraarticular)
      - Posterior vertebral elements
    - Subperiosteal

Radiographic Findings

- Radiolucent central nidus is usually < 1 cm
  - Nidus is often partly calcified
- Adjacent cortical thickening & medullary sclerosis are common
  - Less frequent with medullary/intraarticular OO
- Periosteal reaction: Solid > lamellated
  - Often distant from intraarticular OO
- Focal cortical bulge or scalloping may be present
- Joint effusion & synovitis with intraarticular OO
- ± osteoporosis, muscle atrophy distally

CT Findings

- Small, well-defined, round or ovoid hypoattenuating nidus surrounded by thickened cortex & medullary sclerosis
  - Elongated/eccentric nidus is more likely to have treatment failure
- Central Ca^{2+} of nidus is often present, may have target appearance
- Overlying nonaggressive periosteal reaction
- Prominent cortical vascular channels extending toward nidus

MR Findings

- T1WI
  - Low- to intermediate-signal nidus
  - ± adjacent muscle atrophy
- T2WI FS/STIR
  - Unmineralized nidus shows intermediate to high signal; mineralized nidus shows low signal
  - ± target appearance of nidus
    - Low signal centrally from nidus Ca^{2+}
    - Surrounding high signal of unmineralized nidus
    - Outer low-signal rim of sclerosis
  - Adjacent abnormal fluid signal
    - Marrow, periosteal, & soft tissue edema
      - Extensive marrow edema can obscure small nidus
      - Half-moon sign (or half-circle) of marrow edema may be suggestive of femoral neck OO (but is also seen with stress injuries)
      - "Pseudotumor" of surrounding soft tissue inflammation is reported at phalangeal OO
    - Joint effusion/synovitis if OO is intra/periarticular
- T1WI C+ FS
  - Dynamic imaging: Peak enhancement of nidus occurs during early arterial phase with subsequent partial washout
    - Slower enhancement of adjacent marrow edema
  - Reactive synovitis with intra/periarticular OO
- Post ablation (by radiofrequency)
  - ↓ nidus volume
  - T2 hypointense center with hyperintense band
  - ↑ ADC values of nidus
  - No dynamic enhancement

Ultrasonographic Findings

- Color Doppler
  - ↑ vascularity of superficial nidus
    - May be obscured by overlying thickened cortex
  - Can be used to localize lesion for biopsy

Nuclear Medicine Findings

- Bone scan
  - ↑ radiotracer uptake
    - Double density sign: Small focus of intensely ↑ activity (nidus) surrounded by larger area of less intensely ↑ activity (reactive sclerosis)
  - SPECT: ↑ sensitivity for subtle spine OO
    - Fusion with targeted CT at site of abnormal uptake provides optimal localization

Imaging Recommendations

- Best imaging tool
  - SPECT-CT (if OO suspected)
- Protocol advice
  - CT: Limit coverage to region of abnormality based on preceding imaging studies
  - MR: Dynamic postcontrast sequence is most helpful for localizing nidus

DIFFERENTIAL DIAGNOSIS

Osteomyelitis

- Chronic infection with Brodie abscess
  - Sclerosis & periosteal reaction ± lucent abscess cavity, necrotic bone sequestrum
    - Margins of abscess & sequestrum are more likely to be irregular
      - Peripheral enhancement of abscess
      - Penumbra sign of subacute/chronic intraosseous abscess: High T1 signal rim (precontrast) of granulation tissue lining sclerotic margin
    - Cloaca drainage tract may be present

- Acute infection
  - Poorly defined marrow edema, periosteal reaction
    - Intramedullary OO may be confused for early infection by MR if nidus not clearly seen
  - More likely to have osteolysis & fluid collections than OO

Langerhans Cell Histiocytosis

- Lytic lesion with well-defined or permeative margins ± lamellated periosteal reaction
- Sclerotic rim with healing

Stress Injury

- Radiolucency & sclerosis are more linear & perpendicular to cortex (rather than parallel)

Osteoblastoma

- Histologically similar but larger than OO (> 2-2.5 cm)
- More frequently involves spine
- Constellation of symptoms is less classic than OO
- Reactive bone formation is uncommon

Osteosarcoma

- Intramedullary location is most common
- Combination of aggressive bony destructive features & cloud-like osteoid matrix

PATHOLOGY

General Features

- Benign tumor consisting of osteoblastic mass (nidus) surrounded by zone of reactive sclerosis
  - Zone of sclerosis is not integral part of tumor: Represents reversible reactive change; not always present
  - Nidus has limited growth potential
- Prostaglandin E2 is elevated 100-1000x within nidus
  - May be cause of pain & vasodilation

Microscopic Features

- Nidus is composed of osteoid tissue or mineralized, immature bone surrounded by fibrovascular stroma
  - Variable amounts of osteoblasts & giant cells resembling osteoclasts
  - Unmyelinated nerve fibers are present
- Sclerosis surrounding nidus is composed of dense bone

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Local pain, worse at night; ↓ by aspirin/NSAIDs in < 30 minutes (75%)
    - Up to 5% of patients present without pain
- Other signs/symptoms
  - Local swelling, erythema, point tenderness
  - Symptoms may last weeks to years before presentation
  - Spinal involvement: Painful scoliosis with concavity of curvature toward side of lesion
    - Scoliosis improves/resolves if nidus is resected within 15 months of diagnosis
  - Intraarticular lesion
    - Pain, limp, ↓ range of motion, swelling
    - Some literature reports that intraarticular OO takes up to 3x as long as extraarticular OO due to variety of other joint pathologies considered in work-up
  - ↑ urinary excretion of major prostacyclin metabolite (6-keto-PGF1α)
    - Returns to normal after removal of nidus

Demographics

- Age
  - 5-35 years old; 50% between ages 10-20 years
- Sex
  - M:F = 2-4:1
- Epidemiology
  - 4% of primary bone tumors
  - 11-14% of benign bone tumors

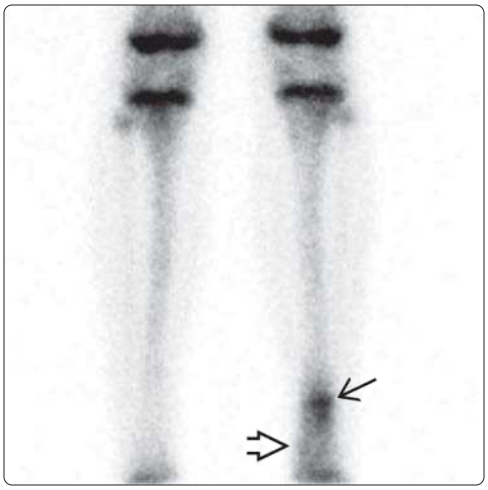
Natural History & Prognosis

- No malignant potential
- No growth progression
- Without treatment, lesion ultimately regresses in 6-15 years with symptom resolution
- Long-term bone growth disturbances can result from hyperemia of OO
  - Overgrowth, angular deformities

Treatment

- Medical: NSAIDs
  - Can expedite lesion healing/regression to < 3 years
- Surgical resection is curative if nidus is completely removed
  - Tetracycline with fluorescence or radionuclide labeling was used historically for lesion localization at surgery
- CT-guided percutaneous interventions
  - Radiofrequency ablation, laser photocoagulation, cryoablation, trephine/drill excision
- MR-guided high intensity focused ultrasound or other percutaneous interventions

DIAGNOSTIC CHECKLIST



Consider

- Image-guided therapy is often more successful than surgical resection due to nidus visualization

(Left) *AP radiograph of the left tibia in a 15-year-old girl with 1 year of lower leg pain shows a region of diaphyseal cortical thickening laterally ➡ with mild overlying solid periosteal reaction ➡ & a subtle lucent focus centrally ➡. (Right) Anterior Tc-99m nuclear medicine bone scan in the same patient shows focally ↑ uptake at the level of the nidus ⇨. This "hot" focus is superimposed on a background of mildly ↑ radiotracer activity in the distal tibia ⇨ (the double density sign, typical of OO).*

(Left) *Oblique radiograph in a 13-year-old boy with lateral foot pain shows a centrally calcified lucent focus ⇨ in the posterior cuboid. Note the medullary sclerosis surrounding the lesion.* **(Right)** *Sagittal bone CT in the same patient shows the hypoattenuating round nidus ⇨ of the cuboid OO with central Ca^{2-} & surrounding sclerosis.*

(Left) *Axial dynamic T1 FS MR images before (left), 1 minute after (middle), & 8 minutes after (right) contrast administration in an 11-year-old patient with an OO of the humeral cortex show early intense enhancement of the nidus ➡ with gradual vague enhancement of the adjacent marrow ⇨ & overlying tissues ⇨.* **(Right)** *Coronal oblique bone CT of the sacrum in an 8-year-old girl with pain shows a round, hypoattenuating nidus with central Ca^{2+} ⇨ & adjacent sclerosis ➡, consistent with an OO.*

Chondroblastoma

KEY FACTS

TERMINOLOGY

- Benign to intermediate-grade bone tumor with immature cartilage cells (chondroblasts) in heterogeneous matrix

IMAGING

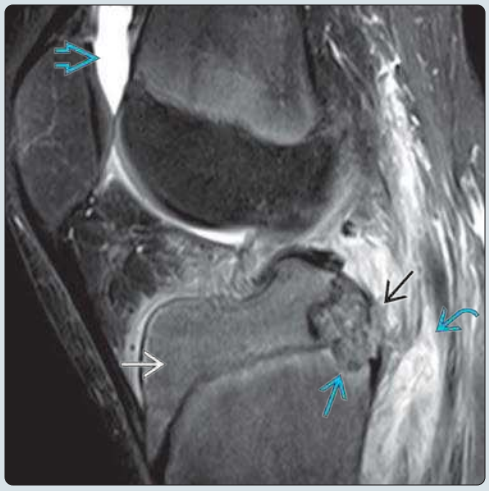
- Vast majority originate in epiphysis (85%), apophysis (12%), or other epiphyseal equivalent (tarsals, carpals, patella)
  - Up to 55% extend to adjacent metaphysis
  - Pure metaphyseal/diaphyseal location is uncommon
- Tubular bones are affected most frequently
  - Long bones in 75-80%
- Radiographs
  - Well-circumscribed, lucent epiphyseal lesion
  - Chondroid ring & arc Ca^{2+} in 30-50%
  - Solid periosteal reaction of adjacent metaphysis in 50-60%
- T2 FS MR
  - Heterogeneous internally with foci of low or intermediate T2 signal intensity
    - Distinct from most other cartilage tumors
  - Low signal intensity rim
  - Surrounding marrow, periosteal, & soft tissue edema
  - Reactive joint effusion in up to 50%
  - Secondary aneurysmal bone cyst in 23-33%

TOP DIFFERENTIAL DIAGNOSES

- Osteoid osteoma
- Osteomyelitis
- Langerhans cell histiocytosis
- Metastatic disease
- Giant cell tumor

CLINICAL ISSUES

- Presentations: Pain, tenderness, stiffness, swelling, limping
- Peak age: 15-20 years
- Treatment: Surgical curettage ± bone grafting vs. RFA; must consider risks to adjacent growth plate
  - Recurrence in 5-35%; rare lung metastases



(Left) *AP radiograph in a 14-year-old girl with right shoulder pain shows a well-circumscribed, round, lucent lesion of the humeral head. The adjacent growth plate appears intact.* **(Right)** *Axial STIR MR in the same patient shows nearly homogeneous low signal intensity throughout the round lesion with an even lower signal rim of sclerosis. Note the marked edema of the surrounding marrow of the humeral head (as compared to the normal scapular marrow), typical of a chondroblastoma.*

(Left) *Lateral knee radiograph in a 13-year-old girl with 1 year of pain shows a lobular, lucent lesion in the posterior tibial epiphysis. There is fullness & poor definition of the surrounding soft tissues, suggesting edema.* **(Right)** *Sagittal T2 FS MR in the same patient shows heterogeneous low signal intensity in the lesion with metaphyseal extension & cortical breach. There is surrounding marrow & soft tissue edema as well as a joint effusion. Chondroblastoma was confirmed at surgery.*

TERMINOLOGY

Definitions

- Benign to intermediate-grade bone tumor with immature cartilage cells (chondroblasts) in heterogeneous matrix

IMAGING

General Features

- Best diagnostic clue
  - Well-circumscribed, lucent epiphyseal lesion in teenager
- Location
  - Majority originate in epiphysis (85%), apophysis (12%), or other epiphyseal equivalent (tarsals, carpals, patella)
    - Up to 55% extend to metaphysis
    - Pure metaphyseal/diaphyseal location is rare
  - Tubular bones are affected most frequently
    - Long bones in 75-80%
      - Proximal tibia, distal & proximal femur, & proximal humerus are most frequent
    - Foot involved in 5-16%
      - Talus, calcaneus: ~ 40% each
  - Rare cortical disruption with extraosseous or intraarticular extension

Radiographic Findings

- Well-circumscribed, lucent epiphyseal lesion
- Mildly lobulated with sclerotic rim
- Chondroid ring & arc Ca^{2+} in 30-50%
- Solid periosteal reaction of adjacent metaphysis in 60%
- Bubbly expansile remodeling if aneurysmal bone cyst (ABC) develops

CT Findings

- ± chondroid Ca^{2+} (~ 44%)
- Cortical disruption (19%)
- Periosteal reaction of adjacent metaphysis

MR Findings

- T2WI FS
  - Heterogeneous internally with foci of low or intermediate T2 signal intensity
    - Ca^{2+} vs. hemosiderin vs. cellular regions
    - Distinct from most other high T2 signal intensity cartilage tumors
  - Low signal intensity rim
  - Surrounding marrow, periosteal, & soft tissue edema
  - Reactive joint effusion in up to 50%
  - Multiloculated component containing fluid-fluid levels due to secondary ABC (15-33%)
- T1WI C+ FS
  - Variable enhancement of lesion internally
  - Enhancement of edematous marrow & soft tissues

DIFFERENTIAL DIAGNOSIS

Osteoid Osteoma

- Cortical metaphysis/diaphysis is most common location (but can be epiphyseal)
- Adjacent edema & cortical thickening
- Lucent nidus is usually small
  - Enhances early on dynamic MR imaging

Osteomyelitis

- Metaphyseal origin is most common
- Typically presents early, often with only soft tissue edema on radiographs
- Abundant marrow & soft tissue edema on MR, usually without well-defined lesion
- Fluid collections are often present

Langerhans Cell Histiocytosis

- Cortical destruction with soft tissue mass
  - Typically well circumscribed
  - Often has uniform high T2 signal & enhancement
  - May have low T2 signal intensity rim
- Favors metadiaphysis or flat bones

Metastatic Disease

- Often multifocal with aggressive features & enhancement

Giant Cell Tumor

- Subchondral epiphyseal lesion without sclerotic rim
- Uncommon in skeletally immature patients but more likely to involve metaphysis

PATHOLOGY

General Features

- Closely packed immature cartilage cells (chondroblasts) with scattered mature cartilage & giant cells
- Intercellular Ca^{2+} (chicken wire) in 60%
- Frequency of secondary ABC depends on definition
  - "ABC-rich" form: 23-33%
  - Microcysts + hemorrhage: Up to 83%

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain, tenderness, stiffness, swelling, limping

Demographics

- 1% of primary bone tumors
- Peak age: 15-20 years; range: 3-85 years
- M:F = 1.6-3.5:1.0

Natural History & Prognosis

- Rare lung metastases

Treatment

- Surgical curettage ± bone grafting preferred over resection due to adjacent growth plate
  - Recurrence in 5-35%
    - More likely with skeletal immaturity
- Radiofrequency ablation (RFA) in some cases

Osteochondroma

KEY FACTS

TERMINOLOGY

- Common benign, developmental bony surface lesion resulting from displaced growth cartilage; not neoplastic

IMAGING

- Lobulated, sessile or pedunculated bony protuberance
  - Demonstrates flowing corticomedullary continuity with underlying (parent) bone
  - Covered by cap of hyaline cartilage
- Radiographs are usually diagnostic
- MR is typically reserved for pain/complications or if diagnosis is unclear
  - Fracture (± radiographic visibility) may occur at stalk
  - Mass effect may lead to
    - Friction/irritation of overlying soft tissues ± bursa formation
    - Compression neuritis leading to denervation
    - Vascular compression or rarely occlusion, pseudoaneurysm

TOP DIFFERENTIAL DIAGNOSES

- Osteosarcoma (parosteal)
- Myositis ossificans
- Periosteal chondroma

PATHOLOGY

- Solitary > > multiple
  - Hereditary multiple exostoses (HME) patients
    - Develop characteristic growth disturbances
    - Have 5-11% lifetime risk of malignant degeneration vs. < 1% risk for solitary osteochondroma (OC)
      - OC cartilage cap thickness > 2 cm in skeletally mature patient is more likely to harbor malignancy

CLINICAL ISSUES

- Most commonly found in ages 10-35 years
- Typically presents as painless hard mass
- Lesion growth should cease at skeletal maturity
  - Further ↑ suggests malignant degeneration

(Left) *AP radiograph of the lower extremities in a 13-year-old with hereditary multiple exostoses (HME) shows numerous osteochondromas (OCs) about the knees, ranging in morphology from pedunculated to sessile. Note the broadened metadiaphyses typical of HME.* **(Right)** *Subsequent lateral radiograph of the right knee in the same patient shows that the pedunculated OCs ⇨ point away from the joint. Note the characteristic corticomedullary continuity of the OCs with the underlying bones.*

(Left) *Axial T2 FS MR of the right thigh in a 14-year-old girl shows a pedunculated OC with a thin stalk ⇨ arising from the posteromedial femur. A thin high-signal cartilage cap is noted ⇨. The sciatic nerve is displaced laterally ⇨ & shows abnormal high T2 signal internally.* **(Right)** *Sagittal T2 FS MR in the same patient shows displacement & abnormal fluid signal of the sciatic nerve ⇨ due to mass effect from the adjacent OC ⇨.*

TERMINOLOGY

Definitions

- Osteochondroma (OC): Benign, developmental bony surface lesion arising from displaced growth cartilage
  - Not true neoplasm
  - Generally synonymous with exostosis
- Maintains corticomedullary continuity with underlying bone
- Covered by hyaline cartilage cap

IMAGING

General Features

- Best diagnostic clue
  - Lobulated, sessile or pedunculated bony protuberance demonstrating flowing corticomedullary continuity with underlying bone (parent bone)
- Location
  - Any bone that develops by endochondral ossification
    - Distal femur > proximal femur, proximal tibia, humerus
      - Metaphysis/metadiaphysis > diaphysis > epiphysis
    - Hands, feet, scapula, spine, pelvis, skull base < 10% each; cervical > thoracic > lumbar
      - C2 is most common spine site
  - > 80% solitary, < 20% multiple
- Morphology
  - Spectrum between extremes
    - Sessile: Broad base with underlying bone
    - Pedunculated: Narrow or bulbous mass with thin stalk of attachment to bone
      - Usually points away from joint due to traction

Radiographic Findings

- Sessile or pedunculated bony lesion arising from bone surface
- Corticomedullary continuity with underlying bone
- Chondroid Ca^{2+} may be seen in cartilage cap
- U-shaped rim of sclerosis if viewed en face

CT Findings

- CTA is useful for assessing vascular complications
  - Vessel compression, occlusion, arteriovenous fistula, or pseudoaneurysm (PSA) may result from mass effect by adjacent OC

MR Findings

- T1WI
  - Continuity of dark cortex & bright fatty marrow signal between lesion & underlying bone
- T2WI FS
  - Marrow & cortex signal similar to parent bone
    - Marrow edema due to contusion or fracture
  - Bright cartilage cap overlying ossified lesion
    - Cartilage cap thickness > 2 cm after skeletal maturity → ↑ ↑ likelihood of malignant transformation
    - Size of cartilage cap may be irrelevant prior to skeletal maturity, though some report risk if > 3 cm
  - Very sensitive for soft tissue complications
    - Friction/compression of overlying muscle & fat ± bursa formation
    - Nerve compression
    - Vascular compression & PSA formation
      - PSAs are very heterogeneous due to turbulent internal flow & layers of thrombus; pulsation artifact in phase-encoding direction
      - Popliteal artery is most common PSA location due to OC
    - Edema from fracture through stalk
- T1WI C+ FS
  - Enhancement of growth plate at osteocartilaginous junction
  - Variable enhancement of remaining cartilage cap
    - May show lobular septal & rim enhancement

Ultrasonographic Findings

- Can confirm cortical continuity, cartilage cap
- May be useful to evaluate surrounding soft tissues
  - Relationship of OC to nerve or vessel
    - Color Doppler to look for vascular complication
  - Bursa formation

Nuclear Medicine Findings

- Bone scan
  - ↑ activity at growth plate of cartilage cap
  - ↓ activity with skeletal maturity
  - ↑ activity beyond skeletal maturity: Concerning for malignancy
- PET/CT
  - FDG PET can help identify malignant change

Imaging Recommendations

- Best imaging tool
  - Radiographs are usually diagnostic
  - MR is excellent for soft tissue complications
- Protocol advice
  - T2 FS/STIR most sensitive MR sequence for complications
  - Contrast-enhanced MR is rarely needed

DIFFERENTIAL DIAGNOSIS

Osteosarcoma (Parosteal)

- Most common surface osteosarcoma
- Ossified soft tissue mass arising from outer periosteum
- May have broad base vs. cleavage plane with bone
  - Lacks "flowing" corticomedullary continuity of OC
- Most common at posterior distal femoral metaphysis
- Peak incidence: 20-40 years of age

Myositis Ossificans

- Initially, noncalcified soft tissue mass overlying bone
- Typically shows marked surrounding muscular edema by MR
- Develops peripheral Ca^{2+} within weeks, progressing to center
- Trauma history is often (but not always) present

Periosteal/Juxtacortical Chondroma

- Uncommon cartilaginous surface lesion
- Partially interrupted & layered or scalloped cortex deep to cartilage focus (rather than corticomedullary continuity)

PATHOLOGY

General Features

- Etiology
  - Displaced physeal cartilage herniates through periosteal bone cuff
  - Endochondral ossification of this cartilage yields growing bony protuberance
  - Growth of OC is expected to cease at skeletal maturity
    - Continued growth or pain is concerning for malignant transformation
  - ↑ OC incidence with prior radiation (up to 24% develop exostoses)
    - Mean latency of 5-12 years
- Associated abnormalities
  - Hereditary multiple exostoses (HME)
    - Numerous OCs with resulting growth disturbances
      - Valgus tibiotalar tilt, limb length discrepancy, pseudo-Madelung deformity, coxa valga
    - Autosomal dominant with incomplete penetrance
      - Mutations of exostosin tumor suppressor genes on chromosomes 8 (*EXT1*), 11 (*EXT2*), & 19 (*EXT3*)
    - ↑ likelihood of malignant transformation to chondrosarcoma
      - 5-11%; typically after skeletal maturity
  - Dysplasia epiphysealis hemimelica (Trevor disease)
    - Classically considered to be epiphyseal (or equivalent) OCs
      - Now seen as epiphyseal cartilage overgrowth
    - Multiple bones of single extremity are often involved on either medial or lateral side (not both)
    - Lower extremity (particularly foot/ankle) is much more commonly affected than upper
    - Mechanical symptoms & limb deformities are common
  - Metachondromatosis
    - Very rare disease of multiple OCs & enchondromas
  - Subungual exostosis
    - Lesion deep to nailbed
  - Bizarre parosteal osteochondromatous proliferation (BPOP or Nora lesion)
    - Phalanges involved in 70% of cases
      - Middle phalanx is most common
      - Hands > > feet
    - Ossified pedunculated lesion attached to (but not flowing from) cortex
    - Most common in 20-30 year olds
    - May grow rapidly

Gross Pathologic & Surgical Features

- Lobulated cartilage cap with shiny bluish-gray surface
  - Thickness is typically on order of several mm but up to 2 cm is acceptable
    - > 2 cm in skeletally mature patient is more likely to harbor malignancy

CLINICAL ISSUES

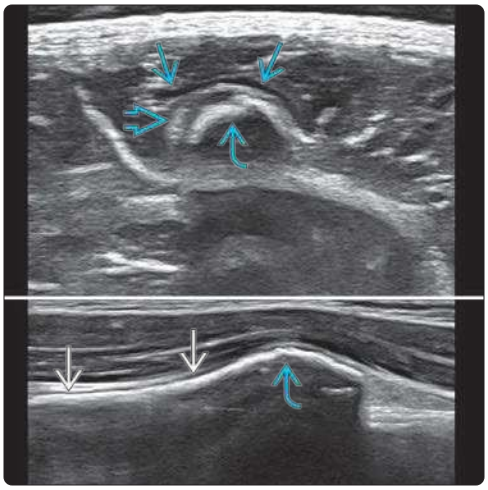
Presentation

- Most common signs/symptoms
  - Hard painless mass with deformity
- Other signs/symptoms
  - Pain secondary to
    - Soft tissue friction or bursitis
    - Nerve or vessel compression
    - Fracture of exostosis stalk
    - Malignant transformation (uncommon in pediatrics)
      - Chondrosarcoma is most likely
  - Spinal cord compression from vertebral lesion
  - Hemo-/pneumothorax from rib lesion
  - Hip pain in HME can also be from labral or chondral injury or ischiofemoral impingement

Demographics

- Age
  - 10-35 years of age for solitary lesion
  - Most HME patients are diagnosed by age 10
- Epidemiology
  - Most common bone "tumor"
    - Solitary OC in 1-2% of population
    - Up to 15% of all bone tumors
    - Up to 50% of benign bone tumors

Natural History & Prognosis



- Lesion growth should cease at skeletal maturity
  - Spontaneous regression has been reported
- Continued growth suggests malignant transformation
  - Extremely rare in skeletally immature
  - Solitary exostosis lifetime risk: < 1%
  - HME lifetime risk: 5-11%

Treatment

- Surgical resection for symptomatic lesions or lesions growing beyond skeletal maturity
  - Entire cartilage cap & perichondrium must be removed to prevent recurrence
- Additional procedures are often required in HME to correct deformities

(Left) *Transverse (top) & longitudinal (bottom) ultrasounds in a 14-year-old with a hard bump for 3 years along the upper arm show flowing cortical continuity of the humerus ➡ to the osseous excrescence ⇨. Note the overlying cartilage cap ⇨ & small bursa ⇨.* **(Right)** *External rotation radiograph in the same patient confirms the typical OC ⇨ pointing away from the joint & demonstrating flowing corticomedullary continuity with the underlying bone.*

(Left) *Longitudinal ultrasound of the upper chest in a 10-year-old with a newly noted palpable mass shows a lobulated bony protuberance ⇨ at the superior margin of the left clavicle ⇨.* **(Right)** *Sagittal T2 FS MR in the same patient shows an OC protruding from the anterior 1st rib ⇨ deep to the clavicle ⇨. Note the hyperintense cartilage cap ⇨ & deformation of the adjacent subclavian vein ➡.*

(Left) *Lateral radiograph of the right knee in a patient with recently diagnosed leukemia & subsequent onset of acute knee pain shows a sessile OC ⇨ of the distal femur.* **(Right)** *Sagittal T1 C+ FS MR in the same patient shows homogeneous, diffusely abnormal marrow enhancement of the proximal tibia ⇨ due to leukemic infiltration. Heterogeneous enhancement of the distal femoral marrow ⇨ (with overlying soft tissue edema ➡) was due to superimposed acute infarction with extension into the OC ⇨.*

Developmental Hip Dysplasia

KEY FACTS

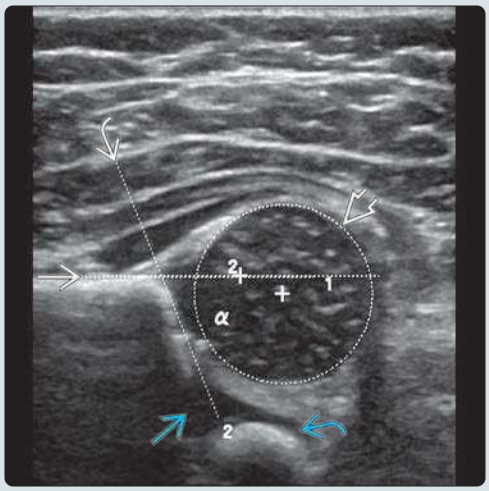
TERMINOLOGY

- Developmental dysplasia of hip (DDH): Spectrum of hip abnormalities, including dysplastic acetabulum & femoral head malpositioning
- Risk factors: Female, 1st-born infant, breech positioning, oligohydramnios, White patients, family history, swaddling
- Ligamentous laxity contributes to DDH

IMAGING

- US is modality of choice for infants 1-4 months old
- Radiographs necessary after 4-5 months
  - Proximal femoral epiphysis ossifies, blocks ultrasound beam, limits evaluation

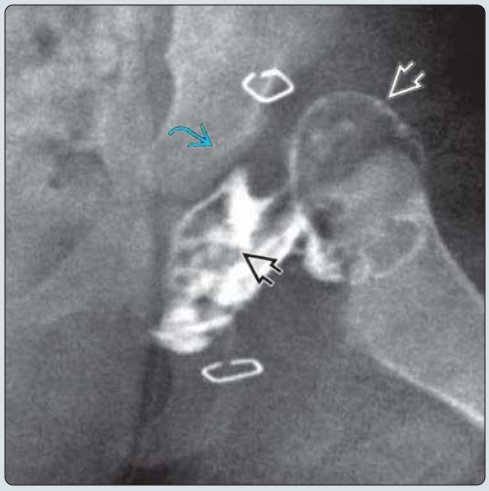
PATHOLOGY



- Normal
  - α angle ≥ 60°, coverage ≥ 50%, no instability
- Immature hip (applies only to infants < 3 months of age)
  - α angle 50-59°, coverage 45-50%, no instability
  - Small risk of delayed DDH; follow-up recommended to confirm normal development
- Mild hip dysplasia
  - α angle 50-59°, coverage 40-50%
  - May observe, repeat US in 1 month, especially if ≤ 2 months; older infants usually treated with harness
- Moderate hip dysplasia
  - α angle ≤ 50°, coverage ≤ 40%, any instability
  - Treated with harness; repeat US q4 weeks until normal
- Severe hip dysplasia
  - Grossly dysplastic acetabulum, dislocated hip
  - No improvement in harness by 4 weeks → operative management

CLINICAL ISSUES

- Treat with Pavlik harness to flex, abduct, & externally rotate hips
- Frequently repeat US to evaluate progression
- Occasionally surgical hip reduction & casting are required



(Left) *The US transducer is placed over the lateral hip with slight posterior obliquity to obtain a coronal flexed image. Note the use of 2 hands (& the foot pedal to save images).* **(Right)** *Coronal flexed US in the same patient shows the unossified femoral head, the straight segment of the iliac bone, & a line drawn along the acetabular roof. The α angle is measured between these lines & should be ≥ 60°. The iliac line should cover the femoral head by ≥ 50%. Note the triradiate cartilage & ischium.*

(Left) *Frontal radiograph in a 6-month-old boy with a left hip clunk reveals severe left developmental dysplasia of the hip. The acetabular roof is quite steep, & the ossified femoral head is small with superolateral dislocation.* **(Right)** *An intraoperative arthrogram shows contrast outlining a dysplastic, mostly unossified left femoral head. Note that the acetabular roof is quite steep. The femur is dislocated from the severely dysplastic & shallow joint space. This child required an osteotomy.*

TERMINOLOGY

Synonyms

- Congenital dislocation of hip (archaic)

Definitions

- Developmental dysplasia of hip (DDH): Spectrum of progressive hip abnormalities developing during infancy & resulting in acetabular dysplasia with femoral head malpositioning
  - Ranges from mild subluxation → dislocatable hip → fixed hip dislocation

IMAGING

General Features

- Best diagnostic clue
  - Abnormal position & delayed ossification of femoral head with abnormally steep & shallow acetabulum

Ultrasonographic Findings

- Grayscale ultrasound
  - Sonography directly visualizes cartilaginous & osseous components of hip
  - Static (anatomic) & stress (dynamic) imaging evaluates
    - Acetabular morphology
    - α angle (normal ≥ 60°)
    - Coverage of femoral head (normal ≥ 50%)
    - Dynamic subluxation during stress maneuvers
- Color Doppler
  - May be helpful in assessing femoral head perfusion, especially in patients abducted in Pavlik harness

Radiographic Findings

- Radiography
  - Hilgenreiner (horizontal) line
    - Drawn through bilateral triradiate cartilages
  - Perkin (perpendicular) line
    - Drawn from superolateral rim of acetabulum through line of Hilgenreiner
    - Should intersect lateral femoral metaphysis with femoral head mostly medial to line
      - Femoral head begins ossification by 3-6 months
  - Acetabular angle
    - Angle between line drawn along acetabular roof & Hilgenreiner line
      - Mathematically complementary to α angle of US
    - ↓ as hip matures
      - Normal < 30° in 1st year of life
      - Normal < 24° in 2nd year of life
  - Shenton line
    - Drawn along superior aspect of obturator foramen & medial femoral neck
    - Normally represents contiguous arc
    - If noncontiguous, suggests hip subluxation (DDH)

CT Findings

- NECT
  - Limited CT scans are sometimes performed to confirm hip position after open surgical reduction & spica casting

MR Findings

- Used only in difficult cases & casted/postoperative patients
  - Contrast may be used to look for ↓ femoral head perfusion

Nonvascular Interventions

- Arthrogram
  - Occasionally performed intraoperatively

Imaging Recommendations

- Best imaging tool
  - US is modality of choice for infants 1-4 months of age
    - Screening hip US is not recommended < 4 weeks of age due to presence of physiologic laxity
    - However, US should be performed early if clinical exam suggests dislocation or significant instability
  - Radiographs are necessary after 4-5 months
    - Proximal femoral epiphysis ossifies, blocks ultrasound beam, limits evaluation
- Protocol advice
  - Important to examine both hips
  - Careful US technique is mandatory; use high-frequency transducer (7-9 MHz), MSK settings, foot pedal
  - Coronal view
    - Infant at rest, in supine or lateral decubitus position
    - Transducer is parallel to lateral aspect of hip; may need to angle transducer 10-15° posteriorly into oblique coronal plane
    - Normal: α angle ≥ 60°, ≥ 50% femoral head coverage
    - Image should show
      - Straight segment of iliac wing
      - Center of femoral head (maximal diameter)
      - Deepest part of acetabulum (should see triradiate cartilage & ischium posteriorly)
  - Transverse flexion view
    - Infant's hip is held in 90° flexion
    - Place transducer over posterolateral hip in anatomic transverse plane
    - Image should show
      - Femoral metaphysis, femoral head, ischium (posterior acetabulum)
      - Femoral head should rest on ischium
    - Considered unstable if head slips or pistons beyond ischium on stress maneuvers
  - Posterior lip view
    - Stay in coronal flexed position, slide transducer posteriorly, remove 10-15° obliquity
    - Image should show
      - Ilium, ischium, & intervening triradiate cartilage: Posterior acetabular lip
      - Should **not** see femoral head
    - If normal, gently push thigh posterior to check stability
    - If subluxed, gently pull to determine if head can be easily reduced

DIFFERENTIAL DIAGNOSIS

Cerebral Palsy, Congenital Coxa Valga, Neuromuscular Disease

- Abnormal muscular tension causes subluxation/abnormal alignment

- Other radiographic findings of neuromuscular disease are often present
  - Gracile long bones, muscle wasting, coxa valga, "windswept pelvis"

Septic Arthritis

- Acute: Joint fluid may displace femoral head
  - Clinical/laboratory findings of infection are present
- Chronic: Abnormally small & misshapen femoral head & acetabulum

Proximal Focal Femoral Deficiency

- Rare congenital anomaly characterized by varying degrees of proximal femoral hypoplasia/aplasia; acetabulum may be normal

PATHOLOGY

General Features

- Etiology
  - Cartilaginous components on both sides of hip joint must be closely apposed to develop properly
  - DDH is likely multifactorial, includes ligamentous laxity
    - Effect of maternal hormones (especially relaxin)
    - Intrinsic acetabular/femoral head deficiency
    - Reduced in utero space
      - Breech position (extreme hip flexion, knee extension)
      - Oligohydramnios
      - 1st-born child or multiple gestation pregnancy
      - Large for gestational age, twins

Staging, Grading, & Classification

- Graf staging is based on single, static coronal image
- Most recommendations now include description of femoral head coverage & require stress imaging
- Simpler US classification includes normal, immature, & abnormal (with mild, moderate, severe modifier)
- Normal
  - Sometimes called Graf type 1
  - α angle ≥ 60°, coverage ≥ 50%
  - Requires no treatment
- Immature hip
  - Sometimes called Graf type 2a
  - Applies only to infants < 3 months of age
  - α angle 50-59°, coverage 45-50%
  - Small risk of delayed DDH
    - Recommend follow-up to confirm normal development
    - Requires no treatment
- Mild hip dysplasia
  - α angle 50-59°, coverage 40-50%
  - May be observed by orthopedists with repeat US in 1 month, especially if < 2 months of age
  - Older infants usually treated with harness
- Moderate hip dysplasia
  - α angle ≤ 50°, coverage ≤ 40%
  - Unstable on stress imaging or clinical exam
  - Treated with Pavlik harness with repeat US every 4 weeks until normal
- Severe hip dysplasia
  - Grossly dysplastic acetabulum with dislocated hip
  - Can treat with Pavlik harness for no more than 4 weeks
    - If no improvement in Pavlik harness by 4 weeks, continue to operative management

CLINICAL ISSUES

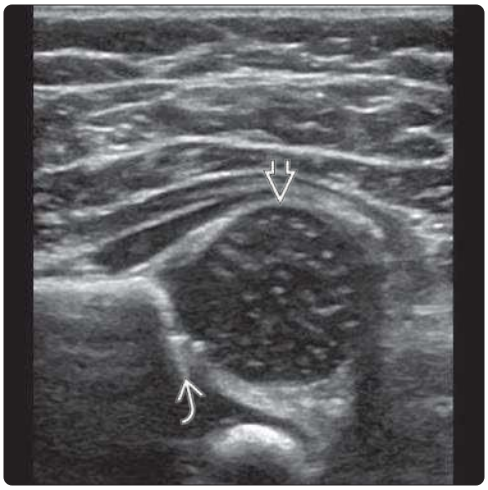
Presentation

- Most common signs/symptoms
  - Asymmetric skin or gluteal folds
  - Leg length discrepancy
  - Palpable click or clunk during stress maneuvers: Ortolani & Barlow
- Other signs/symptoms
  - Delayed ambulation or limp in toddlers

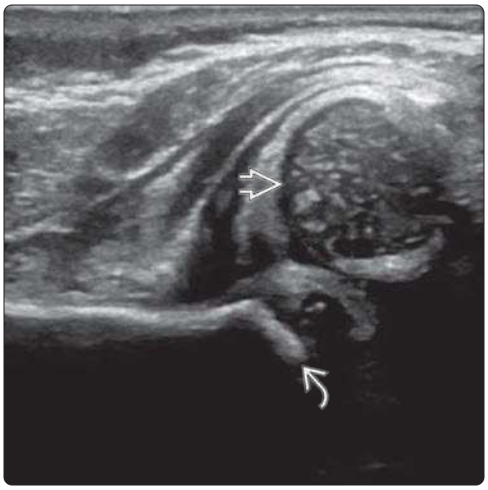
Demographics

- Sex
  - M:F = 1:5-8
- Epidemiology
  - Incidence: 2-20 per 1,000 births

Natural History & Prognosis



- Mild hip dysplasia may resolve spontaneously & never cause clinical problems
  - 60-80% of abnormalities found by clinical exam resolve spontaneously
  - 90% of abnormalities found by US resolve spontaneously
- Moderate or severe dysplasia can cause long-term disability, limb shortening, ↓ range of motion, degenerative change, avascular necrosis
  - Some patients may eventually require hip replacement
- Excellent prognosis when diagnosed & treated early with Pavlik harness
- Some authors recommend follow-up radiographs at 6 months for breech presentation, even after normal screening US
- Delayed diagnosis or treatment can result in irreversible dysplasia requiring iliac osteotomy/shelving procedure



Treatment

- Pavlik harness to flex, abduct, & externally rotate hips
  - Increases femoral head engagement with acetabulum
  - Overabduction can cause femoral head ischemia
- Occasionally, surgical hip reduction & casting are required
  - Salter osteotomy, Steele triple osteotomy, Pemberton or Chiari procedure, femoral osteotomy

(Left) *Coronal flexed US of a normal right hip shows ≥ 50% coverage of the unossified femoral head. The acetabular roof is normal with an a angle ≥ 60° (measurement not shown).* **(Right)** *Similar image of the left hip in the same patient shows dislocation of the femoral head & a steep acetabular roof (with an a angle of 40°). As is customary, the image is rotated 90° counterclockwise from the anatomic position, so a radiographically steep acetabular roof appears as a "shallow" angle on US.*

(Left) *Transverse flexed stress view shows a normal, stable right hip. Note how the femoral metaphysis, triradiate cartilage, & ischium form a U-shaped concavity in which the unossified femoral head rests. Even with stress, a stable hip will remain resting against the ischium & posterior labrum.* **(Right)** *In contradistinction, the unstable left hip (in the same patient) is dislocated on this transverse flexed stress view. The femoral head lies posterior & lateral, no longer resting in a U-shaped concavity.*

(Left) *The posterior lip US view is useful to determine stability but is often misunderstood. The unossified cartilage between the iliac bone & ischium is actually the posterior lip of the acetabulum, not the femoral head. If a hip is unstable, the femoral head will be seen rising over the convex margin of the acetabular cartilage with stress.* **(Right)** *In this already dislocated hip, the femoral head is seen just above (posterior & lateral) the posterior lip of the acetabulum.*

Proximal Focal Femoral Deficiency

KEY FACTS

TERMINOLOGY

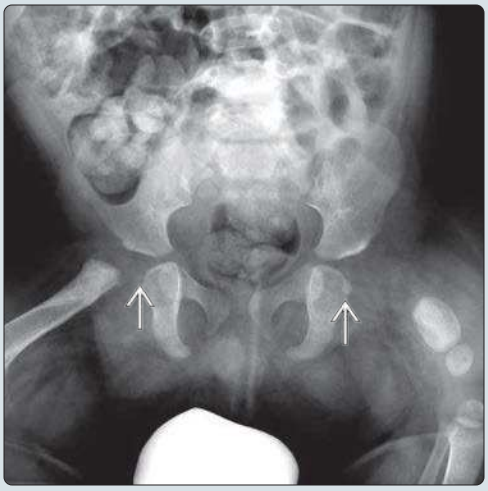
- Proximal femoral focal deficiency: Malformation in which complete growth & development of upper femur fails to occur

IMAGING

- Often difficult to classify with radiographs at early age (due to delayed ossification)
- Can classify earlier with MR

PATHOLOGY

- Aitken classification
  - Class A (38%)
    - Femoral head is present, & acetabulum is normal
    - All parts of femur are connected by bone
    - Subtrochanteric varus is common
  - Class B (32%)
    - Femoral head is present within acetabulum; acetabulum is adequate or moderately dysplastic
    - Bone does not connect femoral head & shaft
    - Pseudoarthrosis is often present but does not heal at skeletal maturity
  - Class C (17%)
    - Femoral head is absent or represented by ossicle
    - Femur tapers proximally
    - Acetabulum is severely dysplastic
  - Class D (13%)
    - Both femoral head & acetabulum are absent
    - Distal femoral segment is shortened & deformed
    - Obturator foramen of pelvis is enlarged
- Associations: Ipsilateral fibular hemimelia in ~ 50%, unstable knee, tarsal coalition, ↓ number of foot rays; abnormal contralateral extremity in 26%



CLINICAL ISSUES

- 4 major biomechanical problems: Hip instability, malrotation of thigh with flexed knee, deficient proximal musculature, & leg length discrepancy

(Left) *AP radiograph in a 6-month-old shows bilateral (right worse than left) proximal femoral focal deficiency (PFFD). Note the right-sided fibular hemimelia, anterior tibial bowing, 4 rays of the right foot, & severely dysplastic acetabulum.* **(Right)** *AP radiograph in a 2-year-old shows a short right femur with small right femoral head ossification center ➡ & developing proximal femoral pseudoarthrosis ➡. This is best classified as Aitken class B.*

(Left) *AP radiograph in a 4-month-old shows bilateral tiny femoral head ossification centers ➡ with left worse than right PFFD changes.* **(Right)** *Coronal T2 FS MR in the same child at 20 months of age shows no connection of the right femoral head ➡ to the remainder of the femur. There is continuity of the left femoral head & neck, which eventually developed pseudoarthrosis 1 year later (not shown), effectively making this bilateral Aitken class B.*

TERMINOLOGY

Abbreviations

- Proximal femoral focal deficiency (PFFD)

Definitions

- Malformation in which complete growth & development of upper femur fails to occur
- Spectrum ranging from mild shortening & varus deformity of otherwise normal femur to absence of all but distal femur
- Accompanied by varying degrees of acetabular dysplasia, thigh muscular hypoplasia, fibular & foot maldevelopment, & shortened lower extremity length

IMAGING

Radiographic Findings

- At 2 years of age, radiographs are more accurate in classifying Aitken type
- Pelvis
  - Obturator foramen: Enlarged
  - Acetabulum: Supraacetabular bump of Court, horizontal or small/shallow/dysplastic roof
  - If detached femoral head is fixed in acetabulum, then supraacetabular bump, enlarged obturator foramen, horizontal acetabular roof, & pencil-pointing of upper end of detached distal femur are common
- Femur
  - Short femur; delayed appearance or nonappearance of femoral capital ossification center
    - Average age of appearance in PFFD is 25 months vs. 3-6 months in normal patients
  - Misshapen femoral head & neck, coxa vara
  - Upper end of disconnected distal femur: Either bulbous or pencil-pointed

MR Findings

- Shows cartilage structure of acetabulum & upper femur in infants to assist prognosis & treatment planning
  - More accurate than radiographic evaluation for classification of PFFD
    - Radiographs tend to overestimate degree of deficiency prior to complete ossification of cartilaginous femur
- Presence or absence of unossified femoral head & neck & their degree of connection to shaft can be identified
- Hip joint poorly forms when femoral head is fixed in acetabulum
- Sartorius muscle is enlarged, which may explain flexion, abduction, & external rotation of hip

PATHOLOGY

General Features

- Etiology
  - Embryology
    - Developmental insult: PFFD occurs at 4-6 weeks during limb bud formation, growth, & differentiation
    - Acetabulum & proximal femur develop from common anlage in embryo
- Associated abnormalities
  - Ipsilateral fibular hemimelia (absence) in ~ 50%
  - Knee is often unstable & may dislocate
    - Absent or hypoplastic cruciate ligaments & menisci
  - Ball-&-socket ankle, clubfoot, tarsal coalition, ↓ number of foot rays
  - Abnormal contralateral extremity in 26%

Staging, Grading, & Classification

- Goals: Predict limb function & treatment planning
- Aitken classification (1968)
  - Class A (38%): Femoral head is present, & acetabulum is normal; short femur with all parts of femur connected by bone; subtrochanteric varus is common
  - Class B (32%): Femoral head is present within acetabulum, & acetabulum is adequate or moderately dysplastic; bone does not connect femoral head & shaft
  - Class C (17%): Femoral head is absent or represented by ossicle; acetabulum is severely dysplastic
  - Class D (13%): Both femoral head & acetabulum are absent; distal femoral segment is shortened & deformed; obturator foramen of pelvis is enlarged

CLINICAL ISSUES

Demographics

- Epidemiology
  - Incidence: 1.1-2 per 100,000 live births
  - Bilateral PFFD in 10-15%, often Aitken class D

Treatment

- 4 major biomechanical problems
  - Hip instability, malrotation of thigh with flexed knee, poor development of proximal musculature, & leg length discrepancy
- Treatment is highly individualized; options include (when PFFD is unilateral): Prosthesis, limb lengthening, hip reconstruction, Van Ness rotationplasty, & Syme amputation
- Bilateral PFFD: Most ambulate well on shortened legs
  - Usually not treated surgically without severe foot deformities
  - Children ambulate at home without prostheses; prostheses may be used in social settings to achieve stature closer to that of peers

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- If radiographs show normal acetabulum at birth, normal cartilaginous femoral head is likely

KEY FACTS

TERMINOLOGY

- Symptomatic growth disturbance of capital femoral epiphysis due to idiopathic osteonecrosis

IMAGING

- Radiographic flattening & fragmentation of sclerotic capital femoral epiphysis ± "cystic" metaphyseal changes
- ↓ perfusion of femoral head acutely
  - Photopenia on nuclear medicine bone scan
  - ↓ enhancement on MR: Sagittal plane detects early anterior involvement
- Gradual coxa magna, coxa plana, & coxa brevis with femoral head extrusion, femoroacetabular impingement, labral tears, joint degeneration

TOP DIFFERENTIAL DIAGNOSES

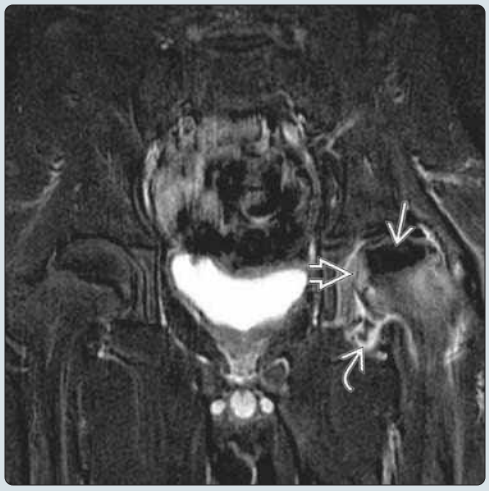
- Septic arthritis
- Transient synovitis
- Juvenile idiopathic arthritis
- Slipped capital femoral epiphysis
- Epiphyseal dysplasias

CLINICAL ISSUES

- Limp due to groin, thigh, or referred knee pain
- Age: 4-12 years; peak: 4-8 years
- 10-20% bilateral, usually asynchronous
- Worse prognosis: > 8 years old at onset, greater femoral head + lateral pillar involvement, subchondral fracture, metaphyseal changes, physeal arrest, aspherical femoral head with joint incongruence
- Surgical interventions: Femoral head containment with joint congruence is key to maintaining femoral head shape & preventing accelerated joint degeneration

DIAGNOSTIC CHECKLIST

- Anterior femoral head is most frequently affected: Include sagittal MR plane
- Subtracted pre- from postcontrast T1 FS: Most sensitive MR sequence for acute ischemia & revascularization



(Left) *AP radiograph in a 10-year-old boy with left hip pain shows flattening, broadening, & sclerosis of the left femoral head. The left hip joint is widened, & the acetabular roof is flattened. The femoral neck is short & broad with a lateral metaphyseal lucency.* **(Right)** *Frog leg lateral radiograph in the same patient shows similar left hip findings with better definition of the cystic-appearing femoral neck lucency. The constellation of findings is typical for Legg-Calvé-Perthes (LCP) disease.*

(Left) *Coronal T2 FS MR in the same patient shows fluid within a subchondral fracture of the flattened & hypointense left femoral head. There is hyperintense marrow edema in the femoral neck with an adjacent joint effusion.* **(Right)** *Subtracted T1 C+ FS MR in the same patient shows no enhancement of ~ 80% of the left femoral head (as compared to the normal right) with the medial ~ 20% showing hyperenhancement. Adjacent reactive synovitis is noted.*

TERMINOLOGY

Abbreviations

- Legg-Calvé-Perthes (LCP) disease

Synonyms

- Legg-Perthes or Perthes disease
- Juvenile idiopathic osteonecrosis

Definitions

- Idiopathic osteonecrosis of femoral head in children

IMAGING

General Features

- Best diagnostic clue
  - Sclerosis, fragmentation, & flattening of capital femoral epiphysis in child 4-8 years old
  - ↓ perfusion of femoral head (earliest stage) in otherwise healthy child with pain
    - Photopenia on Tc-99m nuclear medicine bone scan
    - ↓ enhancement on MR
- Morphology
  - Proximal femoral configuration depends on extent & severity of involvement & timing of imaging

Radiographic Findings

- Radiography
  - Does not depict earliest stages of insult or repair
  - Active early: Sclerosis, subchondral fracture (lucency), early fragmentation of femoral head
  - Active late: Late fragmentation (± reossification) with flattening (asphericity), extrusion of femoral head, metaphyseal irregularity or "cystic" change
    - Hinge abduction: Medial joint space widening with abnormal lateral femoral head rotating on superolateral acetabular rim
  - Healed: Reossification completed with absence of sclerotic avascular bone
    - Coxa magna (enlarged femoral head), coxa plana (flattened), coxa irregularis (irregular), coxa brevis (short neck, greater trochanter overgrowth), hip joint incongruence
  - Waldenström classification: Radiographic reflection of LCP natural evolution; developed in 1922
    - Initial/necrotic stage (lasts 6 months to 1 year)
    - Fragmentation stage (lasts 2-3 years)
    - Reparative/healing/reossification stage (lasts 1-2 years)
    - Growing/remodeling stage (changes up to skeletal maturity)
    - Definite stage (final shape with congruent or incongruent joint)

MR Findings

- T1WI
  - Patchy hypointensity replacing fatty marrow signal due to necrosis
  - Returning fatty marrow signal intensity with revascularization
- T2WI FS
  - Patchy femoral head ↑ signal (edema) or ↓ signal (sclerosis)
  - Hyperintense joint effusion & synovitis
- T2* GRE
  - Cartilage & osteochondral disturbances: Epiphyseal thickening, metaphyseal abnormalities, physeal bone bridge, articular surface degeneration
- DWI
  - Restricted diffusion immediately after ischemic event
  - Days to hours after event: ↑ diffusion & ADC values
- T1WI C+ FS
  - Acute ischemia: ↓ enhancement
    - Subtraction of unenhanced T1 FS from T1 C+ FS (perfusion): Earliest detection/extent assessment
    - Sagittal images show early anterior involvement
  - Adjacent marrow edema, synovitis: ↑ enhancement
  - Revascularized bone: ↑ enhancement
    - Improved prognosis with lateral pillar perfusion; may predict radiographic maintenance of lateral pillar
- MR arthrogram
  - Long-term sequelae include joint degeneration & femoroacetabular impingement with labral tears
- Advanced techniques
  - Delayed gadolinium enhancement, T1rho, & T2 mapping detect cartilage degeneration prior to conventional sequences

Ultrasonographic Findings

- Some studies propose using ultrasound to evaluate femoral head lateral containment

Nuclear Medicine Findings

- Bone scintigraphy
  - Photopenia from ischemia
    - In correct clinical setting, associated joint effusion must be sampled to exclude septic arthritis
  - ↑ uptake with revascularization

Imaging Recommendations

- Best imaging tool
  - MR or nuclear medicine bone scan for early changes of ischemia & revascularization
    - MR better delineates location of involvement
- Protocol advice
  - MR: FS postcontrast images are key
    - Subtraction is most helpful (perfusion)
    - Sagittal plane is most sensitive for early changes
    - Specific thresholds of ↓ enhancement & ↑ ADC values may predict worse outcomes
  - Nuclear medicine bone scan: Pinhole hip images

DIFFERENTIAL DIAGNOSIS

Septic Arthritis

- Fever, leukocytosis, ↑ erythrocyte sedimentation rate
- Hip held in flexion, abduction, external rotation
- Joint effusion ± marrow edema
  - Reduced perfusion of femoral head due to large effusion
- May yield long-term ossific abnormalities or joint destruction

Transient Synovitis

- Self-limited acute synovitis in ages 3-10 years
- Significant effusion & capsular distention

- No long-term femoral head changes

Juvenile Idiopathic Arthritis

- Synovitis predominates over bone findings early
- ± rice bodies in joint fluid

Slipped Capital Femoral Epiphysis

- Posterior, medial displacement of femoral head
- Older patients (age 10-15 years), often obese

Osteoid Osteoma

- Local pain worse at night, ↓ by salicylates
- Uncommonly epiphyseal; more commonly in femoral neck
- May have sclerosis, marrow/soft tissue edema, effusion

Juvenile Osteonecrosis

- Osteonecrosis due to known cause: Sickle cell anemia, steroids, Gaucher, after hip dislocation

Epiphyseal Dysplasias

- Multifocal: Spondyloepiphyseal & multiple epiphyseal dysplasias
- Limited to hips: Meyer dysplasia
  - Age 2-4 years, bilateral in 60%, asymptomatic

Juvenile Idiopathic Chondrolysis

- Band area of ↑ T2 signal/enhancement in central femoral head
- Often has adjacent ill-defined acetabular marrow edema
- ± mild synovitis & minimal effusion

PATHOLOGY

Staging, Grading, & Classification

- Prognostic staging during radiographic evolution
  - Catterall classification (originated in 1971; 1st widely used system): Based on extent of epiphyseal involvement
  - Salter-Thompson scheme (originated in 1984): Based on extent of subchondral fracture
  - Herring system (originated in 1992): Based on lateral pillar (lateral 1/3 of femoral head) involvement by AP view
    - Most reliable, reproducible
- Prognostic staging of final morphology at maturity
  - Stulberg classification based on shape & congruency of femoral head
- Radiographic systems may miss window of opportunity for intervention while waiting to predict outcomes at (or beyond) midfragmentation stage; perfusion MR allows assessment during initial stage

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Limping with groin, thigh, or referred knee pain
- Clinical profile
  - No specific history of trauma
  - ↓ range of motion with loss of abduction & internal rotation

Demographics

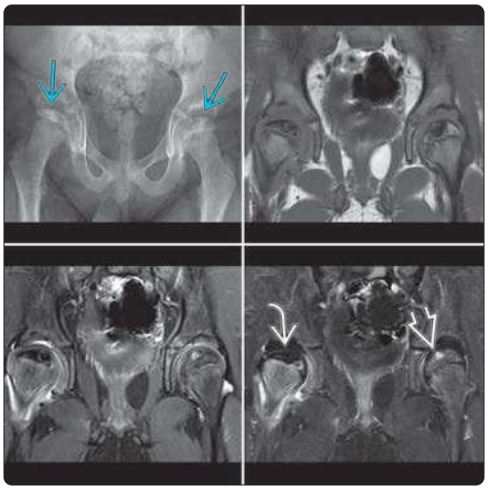
- Age
  - 4-12 years; peak: 4-8 years
- Sex
  - M:F = 4-5:1
- Epidemiology
  - Prevalence: 0.4 to 29/100,000 in children < 15 years old
  - 10-20% bilateral, usually asynchronous

Natural History & Prognosis

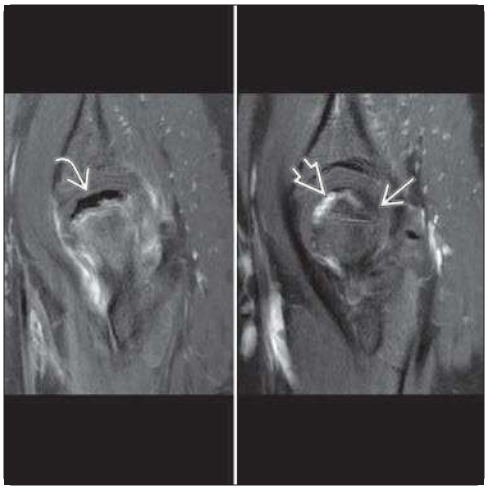
- Worse prognosis
  - > 8 years old at onset
  - Greater extent of femoral head involvement
  - Necrosis/height loss of lateral pillar
  - Subchondral fracture
  - Metaphyseal changes
  - Premature physeal closure
  - Aspherical femoral head
  - Lateral subluxation with joint incongruence
- 21-77% with premature physeal closure at hip
  - 3.5 years earlier than unaffected side
  - High percentage develop limb length discrepancy > 1 cm

Treatment

- Conservative
  - Bed rest, abduction stretching, bracing
  - Best nonoperative outcomes in patients < 6 years old
- Surgical
  - Femoral/pelvic osteotomies, shelf acetabuloplasty
    - Femoral head containment with joint congruence is key to maintaining femoral head shape & preventing accelerated joint degeneration
  - Greater trochanter epiphysiodesis to prevent overgrowth with abnormal gait & instability



DIAGNOSTIC CHECKLIST



Consider

- MR & nuclear medicine bone scan detect early ischemia & revascularization
- Anterior femoral head is most frequently affected → include sagittal MR plane

(Left) *Images (clockwise from upper left: AP radiograph, coronal T1, subtracted T1 C+ FS, & T2 FS MR) in an 8-year-old boy show bilateral LCP with regions of bilateral femoral head sclerosis. Most of the right femoral head is of low signal intensity on all sequences & is nonenhancing. Note the focal hyperenhancement of the left femoral head.* **(Right)** *Sagittal T1 C+ FS MR from the same exam shows the nonenhancement (necrosis) of the right femoral head vs. left hyper-(revascularization) & normal enhancement.*

(Left) *AP radiograph in a 4-year-old boy with left hip pain shows left femoral head flattening & sclerosis, consistent with LCP. Note the central femoral notch in the otherwise normal right femoral head, a normal variant.* **(Right)** *Pinhole images from a Tc-99m MDP bone scan show ↓ radiotracer uptake in the left femoral head as compared to the normal right side, consistent with ischemia.*

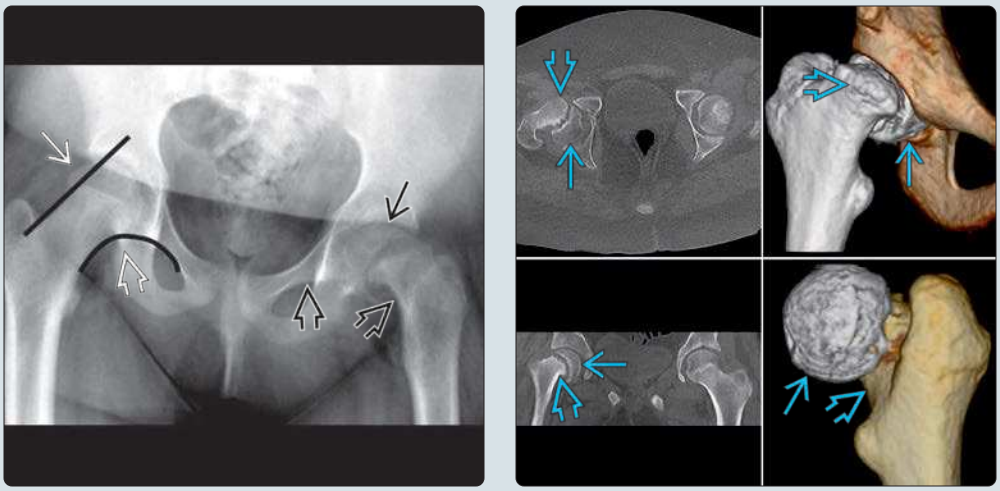
(Left) *AP radiograph in an 18-year-old with a history of left hip LCP & chronic pain shows a dysplastic left acetabulum with coxa magna, plana, & breva of the proximal femur.* **(Right)** *Axial oblique PD MR arthrogram in the same patient shows chronic LCP findings of coxa magna, plana, & breva with an anterior femoral head protuberance that is causing femoroacetabular impingement. The anterior superior labrum is torn & replaced by para- & intralabral cysts. Articular cartilage degeneration is noted.*

Slipped Capital Femoral Epiphysis

KEY FACTS

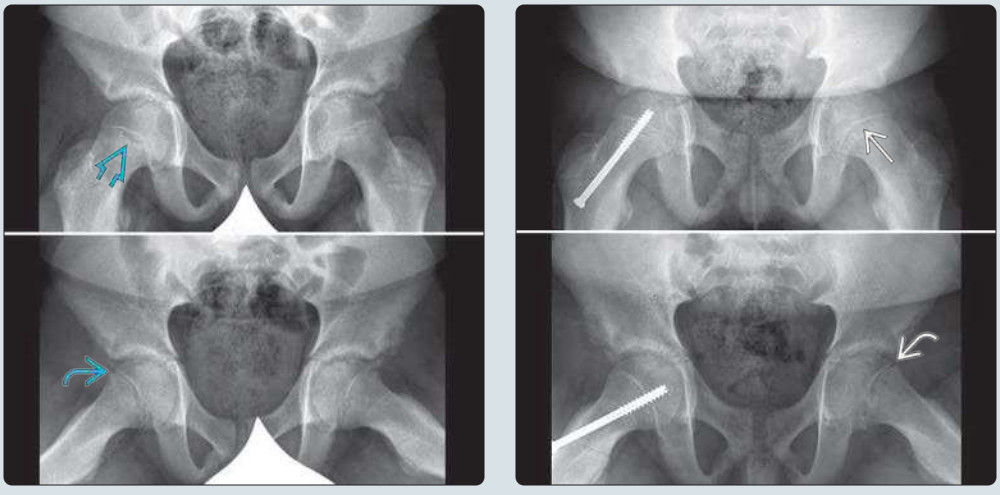
TERMINOLOGY

- SCFE: Salter-Harris I fracture of subcapital femoral physis due to chronic stress of weight bearing
  - Femoral head slips posterior & medial to metaphysis



IMAGING

- AP view: Subcapital femoral physis is abnormally smooth, lucent, & elongated ("wide")
  - Visible before medial femoral head displacement
- Frog leg lateral view (essential for diagnosis): Posterior displacement of femoral head relative to metaphysis
  - Femoral head-neck angle for severity assessment
- CT/MR more accurately determine severity of slip
- MR is more sensitive than radiographs for diagnosis & complications
  - "Preslip" physeal elongation ("widening") on T1
  - ± marrow edema, synovitis with slip on T2 FS/STIR
  - Long term: Femoroacetabular impingement, labral tear, articular cartilage damage, osteonecrosis (ON)
- Incidence of bilateral SCFE varies widely: 18-80%
  - At initial presentation: 9-22%
  - Contralateral slip usually occurs in 18 months



CLINICAL ISSUES

- Limp, pain, limited motion; symptoms are often mild for weeks with acute worsening
  - Pain in hip, groin, or proximal thigh in 85%
  - Distal thigh or knee pain in 15%
- Girls average 11-12 years, boys average 13-14 years
- Major predisposing factor: Obesity
- Prognosis is poorer for unstable (unable to bear weight) SCFE: ↑ ON risk
- Most common treatments
  - Percutaneous single screw in situ fixation without femoral head manipulation (stable & mild unstable SCFE)
  - Open surgical hip dislocation with capital realignment (↑ use in moderate & severe unstable SCFE)
  - Prophylactic contralateral fixation is controversial

(Left) *AP radiograph in an obese 10-year-old girl with left hip pain shows intersection of the lateral right femoral head ➡ by the line of Klein (normal). Such a line would not intersect the slipped left femoral head ⇨. A normal continuous Shenton arc can be drawn on the right ➡ but not the left ⇨.* **(Right)** *Axial (top left) & coronal (bottom left) 2D & posterior (bottom right) & anterior (top right) 3D surface-rendered CT images in a 12-year-old show a chronic SCFE with a posteromedial slip of the right femoral head ⇨ relative to the neck ⇨.*

(Left) *AP (top) & frog leg lateral (bottom) radiographs in an obese 12-year-old patient with right hip pain show an abnormally smooth & lucent right subcapital physis ⇨ with offset of the femoral head-neck junction ⇨, consistent with a SCFE.* **(Right)** *Follow-up radiographs 1 month later in the same patient status post right SCFE pinning demonstrate interval development of an abnormally smooth & lucent left subcapital physis ➡ with mild head-neck offset on the frog leg lateral view ➡, consistent with a left SCFE.*

TERMINOLOGY

Abbreviations

- Slipped capital femoral epiphysis (SCFE)

Definitions

- Salter-Harris I fracture of subcapital femoral physis due to chronic stress of weight bearing
  - SCFE term is not used for acute trauma
- Capital femoral epiphysis = femoral head
- Subcapital physis = proximal femoral growth plate

IMAGING

General Features

- Best diagnostic clue
  - Posterior displacement of femoral capital epiphysis relative to femoral neck on frog leg lateral view
- Location
  - Rates of bilateral SCFE vary widely: 18-80%
    - At initial presentation: 9-22%
    - 88% of contralateral SCFE occurs within 18 months
- Morphology
  - Femoral head slips posterior, inferior, & medial relative to metaphysis

Radiographic Findings

- Wide (elongated), smooth, & lucent subcapital femoral physis
  - May occur before visible femoral head displacement
- AP view: Medial displacement of femoral head relative to metaphysis
  - Klein line: Straight line drawn along lateral femoral neck normally intersects outer 15-20% of femoral head
    - Slipped femoral head lies medial to Klein line
    - ↑ sensitivity if > 2-mm difference in amount of femoral head lateral to line vs. contralateral side
  - Shenton arc: Normally continuous smooth curve drawn along undersurface of superior pubic ramus & medial femoral neck
    - SCFE disrupts arc as slipped femoral head displaces femoral neck laterally & superiorly
  - Dense medial femoral metaphysis due to normal overlap with ischium
    - Lost in SCFE due to lateral & superior displacement of femoral neck
- Frog leg lateral view: Posterior displacement of femoral head relative to metaphysis
  - Appears medial relative to acetabulum, pelvis
  - More sensitive for slip than AP view
  - Staging on frog leg lateral view
    - Percentage of epiphyseal displacement: Mild 0-33%, moderate 34-49%, severe > 50%
- Metaphysis: Scalloping, irregularity, sclerosis, & posterior beaking if chronic
- Valgus SCFE (lateral & superior slip of epiphysis) is very uncommon
  - Typically has posterior component revealed on lateral view (as Klein line is insensitive)

CT Findings

- Axial oblique & sagittal planes best reveal maximum displacement
- Osteoporosis & ↓ muscle bulk if chronic

MR Findings

- Physeal elongation ("widening") of "preslip" is best seen on coronal T1
- ± marrow edema, synovitis with slip on T2 FS/STIR
- Severity of slip angle is more accurate than radiographs
- Periosteal disruption confirms instability
- Chronicity is suggested with remodeling, osteoporosis, ↓ muscle bulk
- Long term: Femoroacetabular impingement (FAI), labral tear, & articular cartilage damage are likely ↑ with greater degree of slip & residual head-neck offset

Nuclear Medicine Findings

- Bone scan
  - Acute SCFE: ↑ uptake at physis (fracture)
  - Chondrolysis: ↑ uptake on acetabular & femoral sides of joint (synovitis)
  - Osteonecrosis (ON): ↓ uptake in femoral epiphysis (infarct)

Imaging Recommendations

- Best imaging tool
  - AP & frog leg lateral radiographs of both hips
    - Frog leg view: Abducted, externally rotated femurs
    - Do not use force to secure frog leg lateral position (may worsen slip)
- Protocol advice
  - SCFE may be subtle on radiographs; consider urgent MR to include coronal T1 if any doubt exists

DIFFERENTIAL DIAGNOSIS

Legg-Calvé-Perthes Disease

- Idiopathic ON of hip, classically 5-8 years old
- Marrow edema, synovitis/effusion, ↓ femoral head enhancement early on MR
- Subsequent radiographic sclerosis & collapse of femoral head ossification center, coxa magna

Juvenile Idiopathic Arthritis

- Nonspecific joint effusion & synovitis, often insidious
- ± multiple joints, characteristic rash, systemic symptoms

Renal Osteodystrophy

- Generalized bony sclerosis with "fuzzy" margins
- Subperiosteal & subsymphyseal resorption
- Multifocal physeal elongation ("widening"): ↑ SCFE risk

Traumatic Salter-Harris I Fracture

- Unequivocal history of acute trauma in adolescence
- Rarely in newborns with difficult delivery

Septic Arthritis

- ↑ WBC, ESR, fever, & failure to bear weight
- Marrow & soft tissue edema often surround effusion

Transient Synovitis

- Limp & pain without systemic findings

- Lack of marrow & soft tissue edema surrounding effusion

Idiopathic Chondrolysis

- Accelerated hip joint cartilage destruction in preadolescent without clear etiology
- Early: Geographic ↑ T2 signal & enhancement centrally in femoral head ± synovitis
- Late: Joint space loss & degenerative change

PATHOLOGY

General Features

- Associated abnormalities
  - ON may be due to
    - Vessel injury acutely at time of slip
    - Vascular compression from operative reduction
    - ↑ intracapsular pressure by effusion reducing flow
  - Residual head-neck offset post therapy can result in cam-type FAI & premature joint degeneration

Microscopic Features

- Physeal architectural distortion before fracture
- Fracture occurs in zone of hypertrophic chondrocytes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Limp, pain, limited motion
    - Pain in hip, groin, or proximal thigh in 85%
    - Distal thigh or knee pain in 15%
- Other signs/symptoms
  - Clinical staging
    - Stable: Able to bear weight (even with crutches)
      - More likely to have delayed presentation
    - Unstable: Unable to bear weight
    - Timing of symptoms: Acute < 3 weeks, chronic > 3 weeks
      - Acute on chronic: Gradual onset, suddenly worse (most common)

Demographics

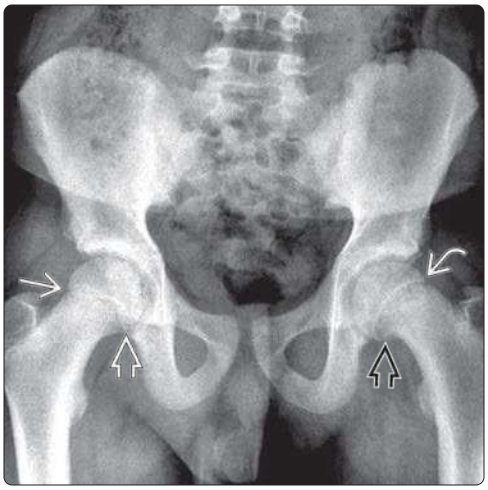
- Age
  - Girls: Range 8-15 years, average 11-12 years
  - Boys: Range 10-17 years, average 13-14 years
  - Can see at younger age with endocrine/metabolic disorder
- Sex
  - M:F = 2.5:1:0
- Ethnicity
  - Nearly 4:1 = Black patients:White patients
- Epidemiology
  - Most common hip disorder in adolescents
  - Incidence: 0.7-10.8 per 100,000
- Predisposing factors
  - Obesity is most significant factor
  - Adolescent growth spurt
  - Endocrine: Primary hypothyroidism, hypogonadism
  - Renal rickets, radiation therapy, chemotherapy

Natural History & Prognosis

- Prognosis is poorer for unstable SCFE → 10-60% develop ON
  - ↑ risk with slip severity, younger age, manual reduction, ↑ intracapsular pressure
    - Some advocate surgery within 24 hours to ↓ risk
- Chondrolysis from SCFE is most frequently due to persistent (not transient) joint penetration by pin
- Joint degeneration secondary to incongruity, residual head-neck offset → cam-type FAI

Treatment

- Percutaneous screw/pin fixation of epiphysis to femoral neck through physis
  - In situ fixation (no attempted reduction due to ↑ risk of ON with manual reduction)
    - Placement of threaded screw across physis
      - Traditional placement promotes growth arrest (growth-restricting method) → ↑ stabilization
      - Also promotes continued deformity of femoral-head neck junction → FAI & joint degeneration
      - Up to 45% of patients with SCFE need total hip replacement 50 years after slip
    - Newer (growth-sparing) techniques
      - Use nonthreaded fixation or gliding/telescoping screw techniques
      - Allow for continued growth & remodeling (improvement of α angle)
      - Goal: ↓ late complications of FAI & degenerative joint disease
- Surgical hip dislocation (open reduction + internal fixation)
  - Used for unstable severe slip & chronic slip
    - Capsulotomy advocated to ↓ risk of ON
    - Modified Dunn procedure with capital realignment ± osteochondroplasty
      - ↓ FAI & ON
- Prophylactic contralateral fixation is controversial; strongly considered in
  - Predisposing disease
  - Girls < 10 years old, boys < 12 years old



DIAGNOSTIC CHECKLIST

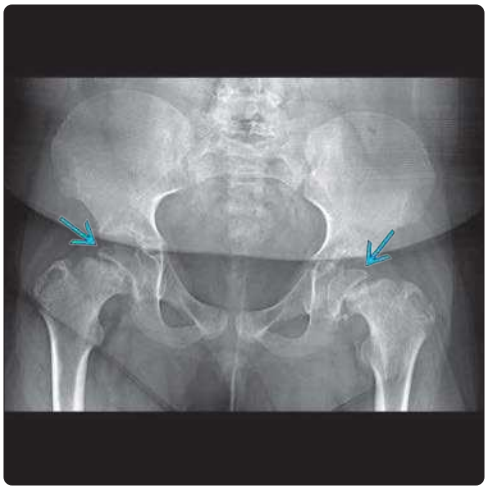


Image Interpretation Pearls

- Frog leg lateral view is essential
- Beware comparison to contralateral side
  - Up to 22% have contralateral SCFE at presentation
- Bilateral SCFE below typical age range should raise suspicion for underlying disorder

(Left) *AP radiograph in an obese 15-year-old boy shows slight posterior slippage of the left femoral head with an abnormally smooth, widened, & lucent physis. The left medial femoral metaphyseal corner does not overlap the ischium. Note the normal undulating right physis & normal metaphyseal/ischium relationship.* **(Right)** *AP radiograph in an obese 13-year-old girl with hip pain & hypothyroidism shows bilateral SCFE with widened physes & metaphyseal irregularities.*

(Left) *AP radiograph in a 14-year-old boy with left hip pain shows slightly ↑ smoothness & lucency to the left femoral physis relative to the right.* **(Right)** *Coronal T1 MR (top) of the same patient shows periphyseal foci of fatty marrow signal loss with poor definition of the subcapital femoral physis, suggesting a "preslip". No physeal abnormality can be seen on the corresponding T2 FS MR (bottom). Note the normal right side.*

(Left) *AP (top) & frog leg lateral (bottom) radiographs in an 11-year-old with hip pain show an abnormally smooth & wide right subcapital physis with femoral head-neck offset, consistent with SCFE. The left subcapital physis appears normal with questionable head-neck offset.* **(Right)** *Coronal T1 (top) & T2 FS (bottom) MR images of the same patient show an abnormal right subcapital physis & associated joint effusion from SCFE. However, the left subcapital physis is normal.*

Achondroplasia

KEY FACTS

TERMINOLOGY

- Most common nonlethal skeletal dysplasia

IMAGING

- Symmetric shortening of all long bones
  - Proximal are most affected (rhizomelic)
- Upper extremity shortening
  - Humerus is barely longer than ulna
  - Short metacarpals & phalanges with trident hand configuration: 3 forks = thumb, digits 2 & 3, digits 4 & 5
- Lower extremity shortening
  - Femur is barely longer than tibia
  - Ice cream scoop shape of proximal femurs in infants
  - Lower femoral & proximal tibial epiphyses/metaphyses have cone or chevron shapes
  - Relatively elongated fibulae
- Pelvis: Squared iliac wings, narrowed sacrosciatic notches, horizontal acetabular roofs, overall coupe-type champagne glass configuration
- Spine: Gibbus deformity of thoracolumbar junction, anterior vertebral body beaking or wedging (bullet-shaped), posterior vertebral body scalloping, progressive narrowing of interpediculate distances from L1-L5
- Skull base: Keyhole foramen magnum, narrow jugular foramina → venous hypertension → ventriculomegaly

PATHOLOGY

- Autosomal dominant; 80% are sporadic
- Mutation at chromosome 4p16.3: Fibroblast growth factor receptor-3 gene (*FGFR3*)
  - Other mutations of same gene cause mild hypochondroplasia or lethal thanatophoric dysplasia
- Fetal cell-free DNA from maternal plasma is replacing amniocentesis for prenatal diagnosis

CLINICAL ISSUES

- ↑ risk of sudden death from cervicomedullary compression
- Otherwise, lifespan is near normal

(Left) *Sagittal T2 MR in a 2-month-old with achondroplasia shows narrowing of the craniocervical junction with cervicomedullary compression ⇒. Note the enlarged lateral ventricles & subarachnoid spaces (due to jugular foramen stenosis with venous hypertension & impaired CSF resorption).* **(Right)** *Sagittal T2 MR in a 4-year-old shows lumbar spinal canal stenosis with scalloping of the posterior vertebral bodies. A bullet configuration with anterior vertebral body wedging is seen at T12-L2.*

(Left) *AP radiograph shows inferiorly decreasing interpediculate distances of the lower lumbar spine, squared iliac wings, narrow sciatic notches, & horizontal acetabular roofs characteristic of achondroplasia.* **(Right)** *PA radiograph shows a trident hand configuration in a newborn with achondroplasia. The fingers are of approximately equal length & diverge from one another in 2 pairs + the thumb (i.e., there is splaying of the middle & ring fingers). The metacarpals & phalanges are short & broad.*

TERMINOLOGY

Definitions

- Mutations of fibroblast growth factor receptor-3 gene (*FGFR3*) at chromosome location 4p16.3 underlie achondroplasia & related dysplasias (FGFR3 group)
  - Achondroplasia (ACH)
    - Most common nonlethal skeletal dysplasia
    - Large cranium; small face & chest; short limbs
  - Hypochondroplasia
    - Milder skeletal dysplasia affecting similar sites
      - Usually not recognized until child is > 2 years old
      - Severe forms overlap with achondroplasia
    - Milder changes of hands & spine
    - Fibular overgrowth
  - Thanatophoric dysplasia
    - Most common lethal bone dysplasia
    - Lungs cannot fully develop/ventilate due to short ribs; micromelia

IMAGING

Radiographic Findings

- Radiologic evaluation begins with skeletal survey
- Skull, face, & brain
  - Calvarium is enlarged with frontal bossing, megalencephaly
  - Flat nasal bridge
  - Skull base is small with narrow foramen magnum
    - Concern for brainstem compression
  - Petrous pyramids are closer to midline than normal
  - Basal angle is low: 85-120°; steep clivus
  - Basilar impression
  - Narrow jugular foramina may cause ventriculomegaly via venous hypertension
  - Short petrous carotid canals
  - Mastoids are underpneumatized
  - Midface hypoplasia, dental crowding
  - Choanal atresia: Occasional
- Spine
  - Spinal canal stenosis is seen as short pedicles on lateral view with ↓ interpediculate distances on AP view
    - Interpediculate distances become progressively smaller lower in lumbar spine (opposite of normal)
  - Vertebral bodies: Short, bullet-shaped in early life; concave posterior surfaces (scalloping)
    - Vertebral heights are normal
  - Transverse processes are short
  - Thoracolumbar gibbus or kyphosis in infancy
  - ↑ lumbar lordosis after infancy with horizontal sacrum
  - Cervical instability
- Chest
  - Short ribs & sternum
  - Cup-shaped anterior rib ends
  - Clavicles: Musk ox horn shape, relatively long
- Pelvis
  - Champagne glass shape (coupe type of glass, not tulip or flute) of inner margin
    - Pelvic cavity broad & short
  - Small, squared iliac wings with horizontal acetabular roofs & rounded iliac crests (tombstone or elephant ear appearance)
  - Narrowed sacrosciatic notches
- Lower extremity
  - Rhizomelic shortening: Femur is barely longer than tibia
  - Femoral necks are short with coxa vara
  - Hemispheric femoral head
  - Ice cream scoop shape of proximal femurs in infants
  - Flared (widened) metaphyses capped by large epiphyses
  - Diaphyseal widths are normal but appear broadened due to shortening
  - Distal femoral & proximal tibial metaphyses/epiphyses are cone or chevron in shape
  - Bowlegs: Genu varum (> 90%)
  - Delayed ossification of tibial epiphysis
  - Fibula is longer than tibia
  - Posteroinferior calcaneal pseudospurs before ossification of calcaneal apophysis
  - Joint laxity
- Upper extremity
  - Rhizomelic shortening: Humerus is barely longer than ulna
  - Outward lateral bulging of humerus at deltoid insertion
  - Concave medial distal radial metaphysis
  - Hand: Delayed bone age
  - Metacarpals & phalanges are short & broad
  - "Trident hand" with 3 forks: Thumb, digits 2 & 3, digits 4 & 5
    - Splaying of middle & ring fingers

Ultrasonographic Findings

- Prenatal studies may be normal on early scan with long bone shortening not detected until 22- to 24-weeks gestation
  - Foreshortening of limbs (< 3rd percentile)
  - ↑ biparietal diameter (> 95th percentile)
  - Flat nasal bridge
  - Collar hoop sign: Overgrowth of periosteum with small, echogenic hook at proximal femoral metaphyseal-epiphyseal junction
  - Rounded metaphyseal-epiphyseal interface
  - Possible temporal lobe abnormalities

Other Modality Findings

- MR: Herniated nucleus pulposus
- CT/MR: Narrowed foramen magnum, enlargement of convexity subarachnoid CSF spaces & ventricles

DIFFERENTIAL DIAGNOSIS

Hypochondroplasia

- Milder short-limbed dwarfism with similarly affected sites
  - Hands & feet are short & broad
  - Midface hypoplasia
  - Foramen magnum is small
  - Lumbar spine: ↓ interpediculate distance
  - Vertebral bodies: Posterior scalloping
- Often not clinically apparent until 2 years of age

Pseudoachondroplasia

- Normal skull; severe epiphyseal findings

Metatropic Dysplasia

- Dumbbell-shaped femurs
- Kyphoscoliosis, caudal appendage (tail)

Other Conditions With Endochondral Growth Slowing

- Homozygous achondroplasia (lethal), Ellis van Creveld syndrome, thanatophoric dysplasia (lethal), Morquio disease

PATHOLOGY

General Features

- Etiology
  - ↓ rate of endochondral ossification
- Genetics
  - Defect on chromosome 4p16.3
    - Fibroblast growth factor receptor-3 (*FGFR3*) gene
      - > 98% are due to G1138A (glycine to arginine substitution at nucleotide 1138)
    - Prenatal diagnosis by next-generation sequencing of cell-free fetal DNA from maternal plasma
      - Traditional methods: Amniocentesis or chorionic villus sampling
  - Autosomal dominant
    - 80% of cases are new (de novo) mutations
    - Heterozygous: Common
    - Homozygous: Rare, lethal

Microscopic Features

- Histology of epiphyseal & physeal growth cartilage is normal

CLINICAL ISSUES

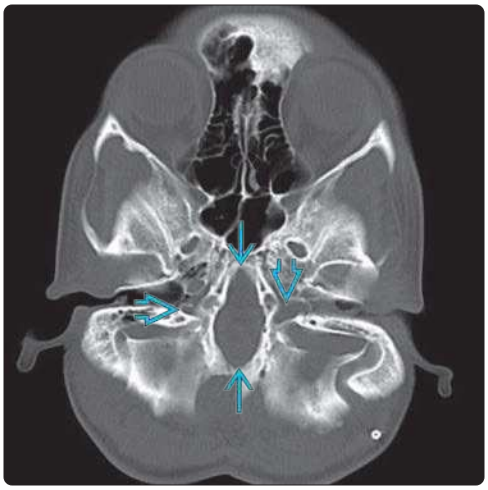
Presentation

- Most common signs/symptoms
  - Characteristic face with midface hypoplasia, saddle nose, & macrocephaly with frontal bossing
  - Rhizomelic limb shortening
  - Limited elbow extension
  - Trident hand
  - Thoracolumbar gibbus or kyphosis
  - Lumbar lordosis is exaggerated
    - Buttocks prominent & abdomen protuberant after walking begins
  - Hypermobility of joints, especially knees
  - Hypotonia
- Clinical profile
  - At birth, physical appearance commonly makes the diagnosis

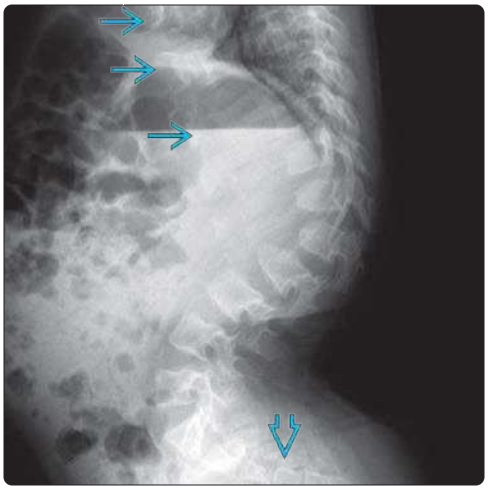
Demographics

- Epidemiology
  - Heterozygous achondroplasia
  - Incidence: 1:10,000-40,000 live births
  - Increasing incidence with advancing paternal age

Natural History & Prognosis



- 2-5% risk of sudden death due to cervicomedullary compression
  - Suspect with central hypopnea, ↓ arousal state, small foramen magnum, hypotonia, hyperreflexia
- Lifespan is near normal without craniocervical junction stenosis
- Obesity is common
- ↑ incidence of orthopedic & neurologic complications
  - Cervical instability in infancy
  - Basilar impression, Chiari 1, syringomyelia
  - Lumbosacral stenosis
  - Tibial bowing in 42%
    - Tibial osteotomy is required in 22%
- Upper airway obstruction/obstructive sleep apnea
- Otitis media in 60% of infants & 93% of toddlers
  - Myringotomy tubes in 80% over lifespan
  - Conductive hearing loss in 40%
- Normal intelligence but delayed motor & speech development
- Average adult height is 4 feet



Treatment

- Available for most complications
  - Cervicomedullary decompression surgery in 17%
    - Potentially urgent to prevent sudden death
  - Cardiorespiratory & sleep dysfunction
    - Mild midface hypoplasia & relative adenotonsillar hypertrophy: Treat with tonsillectomy & adenoidectomy
    - Upper airway obstruction: Nocturnal, continuous positive airway pressure
    - Upper airway obstruction associated with hypoglossal canal stenosis: Various options, including foramen magnum decompression
    - Ventriculomegaly from jugular foramen stenosis: Treat with shunt as needed clinically
- Limb lengthening: Controversial
  - Ilizarov procedure with average length gain of 20.5 cm
    - High complication rate includes fracture, infection, joint stiffness, contractures
  - Magnetically driven intramedullary nail

(Left) *Axial bone CT in a teenager with achondroplasia & shunted hydrocephalus shows a typical keyhole foramen magnum ⇨ with jugular foramen hypoplasia ⇨.* **(Right)** *Lateral radiograph in a 5-year-old shows thoracolumbar kyphosis (or gibbus deformity) with multilevel anterior wedging & an exaggerated lumbar lordosis. There is ↑ concavity of the posterior vertebral bodies. Note the nearly horizontal sacrum ⇨ & rib shortening with anterior flaring ⇨.*

(Left) *External rotation radiograph in a child with achondroplasia shows a prominent deltoid insertional irregularity ⇨ of the proximal humerus.* **(Right)** *AP radiograph shows ice cream scoop configurations ➡ of the proximal femurs in this infant with achondroplasia. Also note the elephant ear configurations of the iliac wings ⇨ with small sciatic notches ⇨.*

(Left) *AP radiograph in an infant with achondroplasia shows horizontal acetabular roofs ⇨, metaphyseal flaring, & chevron or upside-down chevron deformities of the knees ➡ with long fibulae.* **(Right)** *AP radiograph in a 7-year-old with knee pain & achondroplasia shows metaphyseal flaring with chevron or upside-down chevron deformities of the distal femoral & proximal tibial epiphyses bilaterally ➡. The fibulae are elongated.*

Mucopolysaccharidoses

KEY FACTS

TERMINOLOGY

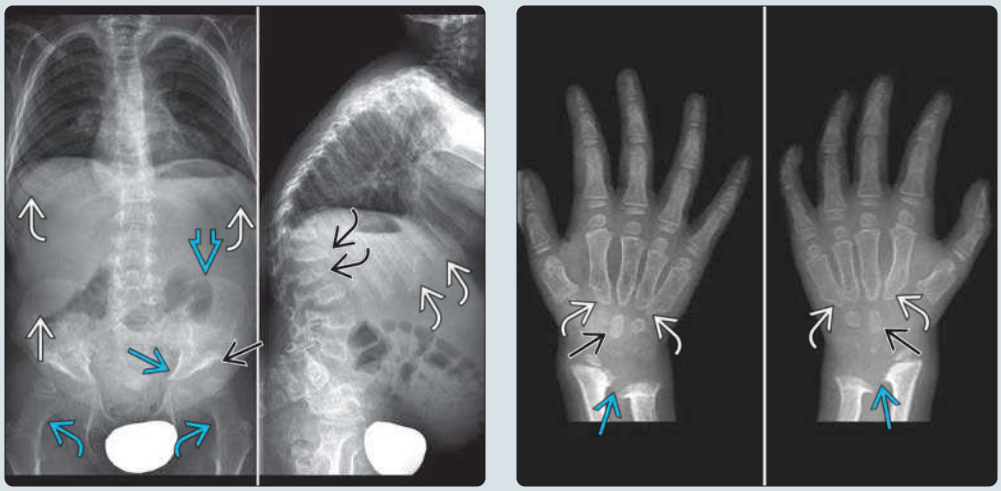
- Heterogeneous group of lysosomal storage diseases due to deficiency of enzymes that degrade glycosaminoglycans (GAGs)
- Dysostosis multiplex: Constellation of bone dysplasia features seen variably in mucopolysaccharidoses (MPS)

IMAGING

- Thoracolumbar gibbus (sharply angled kyphosis) with anteriorly beaked vertebral bodies
- Oar-shaped ribs (thin proximally, wide distally)
- Short, thick clavicles
- Pelvis: Ilia small & tapered inferiorly, steep acetabular roofs, hip subluxation, coxa valga, ± femoral head avascular necrosis
- Pointed proximal 2nd-5th metacarpals
- Diaphyseal widening of tubular bones
- Odontoid hypoplasia & other C1/C2 abnormalities → atlantoaxial subluxation → cord compression

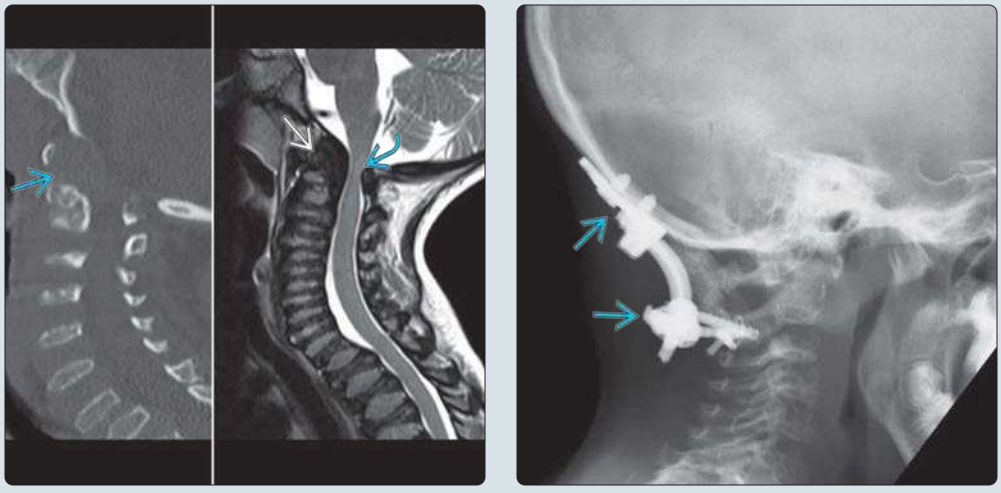
TOP DIFFERENTIAL DIAGNOSES

- Legg-Calvé-Perthes disease
- Sickle cell disease
- Gaucher disease
- Spondyloepiphyseal dysplasia
- Multiple epiphyseal dysplasia
- Spondylometaphyseal dysplasia



PATHOLOGY

- GAGs are ubiquitous in connective tissues throughout body
- GAGs accumulate in lysosomes in bone marrow & multiple viscera → dysfunction



CLINICAL ISSUES

- Stem cell transplantation by unrelated donor umbilical cord blood: MPS I-H, VI
  - Best done when < 2 years old, no CNS disease
- Enzyme replacement therapy: MPS I, II, VI

(Left) *Frontal (left) & lateral (right) radiographs in a 6-year-old girl with MPS IV show thoracolumbar kyphosis, small irregular vertebrae, beaked vertebrae, wide ribs, hepatomegaly, coxa valga deformities, steep acetabula, & rounded iliac wings with inferiorly tapered ilia.* **(Right)** *Frontal radiographs of the hands in the same child show short, wide 2nd-5th metacarpals with pointed proximal ends, small, irregular carpal bones, & irregular, centrally-sloped metaphyses of the distal radius & ulna.*

(Left) *Sagittal CT (left) & T2 MR (right) images show the C-spine in the same child. The odontoid is hypoplastic with dark soft tissue filling the expected location of odontoid. There is also narrowing of the spinal canal at the craniocervical junction with cord compression.* **(Right)** *Lateral radiograph shows the same child after craniocervical junction decompression & fusion from the occiput to the C2 level. Cord compression in MPS can lead to cervical/brainstem myelopathy & respiratory failure.*

TERMINOLOGY

Abbreviations

- Mucopolysaccharidosis/mucopolysaccharidoses: MPS
- MPS I-H: Hurler syndrome
- MPS I-S: Scheie syndrome
- MPS I-H/S: Hurler-Scheie syndrome
- MPS II: Hunter syndrome
- MPS III: Sanfilippo syndrome
- MPS IV: Morquio syndrome
- MPS V: Nonexistent, now classified as MPS I-S
- MPS VI: Maroteaux-Lamy syndrome
- MPS VII: Sly syndrome or β-glucuronidase deficiency
- MPS VIII: Nonexistent
- MPS IX: Natowicz syndrome or Hyaluronidase deficiency

Definitions

- Heterogeneous group of lysosomal storage diseases due to deficiency of glycosaminoglycan (GAG)-degrading enzymes
  - GAGs were formerly called mucopolysaccharides
- Dysostosis multiplex (DM): Constellation of bone dysplasia features seen variably in MPS
- DM group: Includes all storage diseases that lead to skeletal dysplasia
  - MPS, mucolipidoses, others (Gaucher, Niemann-Pick, gangliosidosis, fucosidosis, mannosidosis, sialidosis)

IMAGING

Radiographic Findings

- Key features
  - Thoracolumbar gibbus (sharply angled kyphosis) with anteriorly beaked vertebral bodies
  - Oar-shaped ribs (thin proximally, wide distally)
  - Short, thick clavicles
  - Pelvis: Ilia are small & tapered inferiorly with steep & poorly formed acetabular roof, hip subluxation, coxa valga, femoral head deformities ± avascular necrosis (AVN)
  - Pointed proximal 2nd-5th metacarpals
  - Diaphyseal widening of small tubular bones

Other Modality Findings

- MPS I-H typifies DM features seen in other MPS types
- MPS I-H, Hurler syndrome: Severe DM
  - Brain: Abnormal white matter; delayed myelination; ↑ size of perivascular spaces, sulci, ventricles
  - Neurocranium: Enlarged; early closure of sagittal & lambdoid sutures; thickened skull base; J-shaped (elongated) sella
  - Face: Mandibular condyles flat/concave ± TMJ ankylosis; underpneumatized mastoids
  - Craniocervical junction: Spinal cord compression
  - Spine: Hypoplastic dens with C1/C2 subluxation; C3/C4 subluxation; thoracolumbar gibbus; anterior mid to inferior vertebral beak
    - May lead to spinal canal stenosis ± syringohydromyelia
  - Chest & shoulders: Trachea narrow; ribs wide & oar-shaped; clavicles short & thick; scapulae elevated with dysmorphic glenoid fossae
  - Pelvis & hips: Ilia small & taper inferiorly; steep, poorly formed acetabula; femoral head subluxation & developmental deformity ± AVN; coxa valga
  - Knees: Genu valgum
  - Arms: Humeral neck varus (hatchet-shaped humerus); wide humeral midshaft; distal radial & ulnar physes tilt toward each other
  - Wrists: Carpals small & irregular
  - Hands: Wide & short metacarpals with proximal pointed ends at 2-5; wide proximal & middle phalanges; synovitis & claw deformity, trigger finger
  - Cardiovascular: Cardiomyopathy; arterial narrowing; mitral/aortic stenosis
- MPS I-S: Scheie syndrome
  - Mild DM
- MPS II: Hunter syndrome
  - Mild to severe DM
- MPS I-H/S: Hurler-Scheie syndrome
  - Mild to moderate DM
- MPS IIIA-D: Sanfilippo syndrome
  - Mild or absent DM
  - Attenuated (mild) form: Intellectual disability, no DM
- MPS IVA-B: Morquio syndrome
  - Type A: Severe DM
    - Cord compression at C1/C2 level due to ≥ 1 of following
      - Transverse ligament laxity
      - Dural thickening from deposition of GAGs
      - Odontoid hypoplasia ± anterior soft tissue mass of unossified fibrocartilage & reactive changes
      - Indentation of posterior arch of C1
      - Chronic subluxation at C1/C2 → ligamentous hypertrophy → further narrowing at craniocervical junction → additional cord compression
      - Cervical cord compression can lead to myelopathy & respiratory failure
    - Cord compression at thoracic/thoracolumbar level from gibbous formation due to vertebral malformations; generalized platyspondyly; anterior vertebral beak (typically midportion)
    - Narrow; soft trachea collapses during neck flexion
    - Pectus carinatum
    - AVN of femoral heads
    - Ribs wide but not oar-shaped
  - Type B: Moderate DM
- MPS VI: Maroteaux-Lamy syndrome
  - Mild to severe DM
  - Severe form may have cervical & thoracic cord compression similar to type IV
- MPS VII: Sly syndrome
  - Mild to severe DM
    - Femoral head: AVN
- MPS IX: Hyaluronidase deficiency
  - Mild DM: Extremely rare

Imaging Recommendations

- Best imaging tool
  - Most findings are made on radiographs
    - Brain & spine MR may be needed

DIFFERENTIAL DIAGNOSIS

Legg-Calvé-Perthes Disease

- Idiopathic AVN of femoral head
- Isolated to hip without other MPS/DM features

Sickle Cell Disease

- Hemoglobinopathy
- Widespread marrow hyperplasia & osteonecrosis with H-shaped vertebral bodies

Gaucher Disease

- Storage disorder (not MPS) under DM group
- Osteoporosis with medullary expansion, undertubulation
- Osteonecrosis, H-shaped vertebral bodies

Spondyloepiphyseal Dysplasia

- No clinical or lab features of MPS
- Platyspondyly & abnormal epiphyses

Multiple Epiphyseal Dysplasia

- No clinical or lab features of MPS
- Findings at multiple epiphyses

Spondylometaphyseal Dysplasia

- No clinical or lab features of MPS
- Findings in spine & metaphyses

PATHOLOGY

General Features

- Etiology
  - Enzymatic deficiencies prevent GAG degradation
  - GAGs accumulate in lysosomes in bone marrow & multiple viscera → dysfunction
- Genetics
  - All MPS have autosomal recessive genetic abnormality (except MPS II: X-linked recessive)
    - MPS I-H, I-S, & I-H/S have same biochemical defect with spectrum of phenotypic severity
  - MPS I-H/S: > 110 gene mutations reported

CLINICAL ISSUES

Presentation

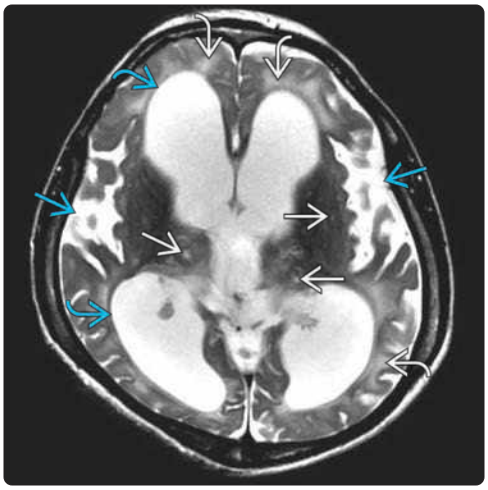
- Most common signs/symptoms
  - Many USA states are now screening newborns for MPS I
  - Spectrum of phenotypes (mild to severe)
    - Most common: Organomegaly, DM, intellectual disability/developmental delay
  - Brain: Regression of speech & learning skills → intellectual disability (not in MPS IV & VI)
  - Head/face: Large head, coarse hair & facial features, proptosis, corneal opacification, recurrent otitis media, flared nostrils, protruding tongue, ↓ hearing
  - Neck: Adenotonsillar enlargement, snoring, sleep apnea, tracheobronchomalacia
  - Spine & chest: Thoracolumbar gibbus (age 6-14 months in MPS I-H), scoliosis, spondylolisthesis in adults with MPS III, pectus carinatum
  - Respiratory: Frequent pneumonia
  - Cardiovascular: Valvular thickening, stenosis, insufficiency; cardiomyopathy, heart failure
  - Abdomen: Protuberant due to hepatosplenomegaly, umbilical/inguinal hernia, intestinal pseudoobstruction, idiopathic diarrhea
  - General: Short (except MPS I-S), claw hand, trigger finger, thick skin, carpal tunnel syndrome, ↓ joint mobility
  - Hydrops fetalis: MPS IV, VII
  - General anesthesia: ↑ risk due to redundant supraglottic tissue, ↓ airway size & stability, unstable C1/C2 joints in MPS I, II, IV, VI, & VII

Demographics

- Age
  - Clinical onset usually < 6 years old
  - Radiographic onset: May be at birth
- Epidemiology
  - Overall incidence of all types of MPS ~ 1 in 20,000 live births

Natural History & Prognosis

- Varies depending on type & severity
- Life span without treatment: MPS I-H < 10 years, MPS II roughly 15 years
- Near-normal lifespan: MPS I-S



Treatment

- Prevention of CNS damage: Perinatal screening → earliest possible treatment
- Stem cell transplantation using unrelated donor umbilical cord blood
  - Replacing conventional bone marrow transplant
  - Most primitive stem cells in cord blood have proliferative advantage & ↓ frequency & severity of graft-vs.-host disease (GVHD)
  - Early transplant is beneficial: MPS I-H (but does not arrest bone dysplasia), MPS VI
    - Best if performed when < 2 years old & no CNS disease
  - Transplant is not beneficial: MPS II, MPS III
    - Fails to arrest encephalopathy
- Enzyme replacement therapy: MPS I, II, VI
- Surgery
  - Hydrocephalus: Ventriculoperitoneal shunt (fewer complications prior to stem cell transplant)
  - Corneal opacity: Corneal transplant
  - Spine: C1/C2 stabilization, craniocervical junction decompression, fusion of progressive kyphosis
  - Airway obstruction or eustachian tube obstruction: Tonsillectomy & adenoidectomy
  - Valvular heart disease: Valve replacement
  - Carpal tunnel decompression
  - Hernia repair

5. Rasalkar DD et al: Pictorial review of mucopolysaccharidosis with emphasis on MRI features of brain and spine. Br J Radiol. 84(1001):469-77, 2011

(Left) *Sagittal NECT shows the thoracolumbar spine in a 9-year-old girl with MPS II (Hunter syndrome). There is gibbus deformity with anterior beaking of the L1 vertebral body. (Right) Axial T2 brain MR in the same patient shows enlarged ventricles & sulci. There is also ↑ signal within the periventricular white matter with a few enlarged perivascular spaces.*

(Left) *AP radiograph in a 10-year-old girl with MPS II (Hunter syndrome) shows thickened clavicles bilaterally. The ribs have a characteristic oar shape with narrowing medially but progressive broadening anterolaterally. Note the poorly formed glenoid fossae bilaterally. (Right) Bilateral frontal radiographs of the hands in a girl with MPS VI show short, wide metacarpals. There is also irregularity of the metaphyses of the distal radius & ulna & slight irregularity of the distal radial epiphyses.*

(Left) *Sagittal bone CT in a 5-year-old boy with Hurler's syndrome (MPSI-H) shows macrocephaly with an elongated, J-shaped sella turcica. (Right) Frontal (left) & lateral (right) radiographs of the spine in a 15-year-old girl with MPS VI show focal kyphosis with anterior beaking of the L1 & L2 vertebrae. There is underdevelopment of the acetabula. The femoral heads are broad with lateral uncovering. Lucency & sclerosis in the right femoral head suggests avascular necrosis (AVN).*

Osteogenesis Imperfecta

KEY FACTS

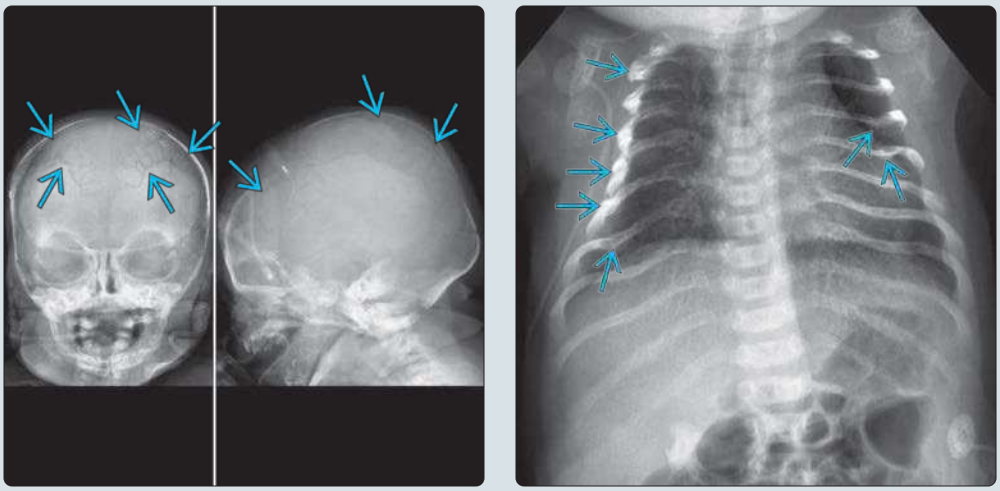
TERMINOLOGY

- Osteogenesis imperfecta (OI): Group of clinically heterogeneous genetic disorders, most often caused by type I collagen alterations
- ↑ bone fragility → frequent fractures → malunion & bowing
  - ↑ likelihood of subsequent fractures

IMAGING

- Numerous in utero or perinatal fractures of short, poorly mineralized bones (OI type II)
- Other OI types: Multiple fractures in thin, overtubulated long bones + vertebral fractures + osteoporosis
- Radiographs are generally sufficient to suggest diagnosis
- CT or MR for axial skeleton complications

PATHOLOGY



- Nosology & Classification of Genetic Skeletal Disorders (2019) identifies 5 clinical forms
  - Type I: Nondeforming with persistently blue sclera
  - Type II: Perinatal lethal form
  - Type III: Progressively deforming type; most severe form that survives infancy
  - Type IV: Moderate form
  - Type V: Similar to type IV + interosseous membrane Ca^{2+} &/or hypertrophic callus
- Currently 20 genetic types of OI

CLINICAL ISSUES

- Severity of OI (mild → severe)
  - Type I < IV < III < II
- Type II: Lethal in perinatal period
- Type III: Premature death
- Treatment: Intravenous bisphosphonates, surgery

DIAGNOSTIC CHECKLIST

- Wide range of radiographic features across OI types
- Radiographic appearance alone does not classify OI

(Left) *Frontal & lateral radiographs of the skull in a 1-day-old girl with multiple fractures seen on fetal ultrasound shows numerous (> 10) wormian bones throughout the skull. The patient was subsequently diagnosed with type III osteogenesis imperfecta (OI).* **(Right)** *Frontal radiograph of the chest in the same patient shows deformities & healing fractures of multiple bilateral ribs. Intrauterine fractures can be seen in OI, particularly in types II & III.*

(Left) *Frontal radiographs show the right & left upper extremities in the same patient. There are healing fractures of the right humerus, right radius, & right ulna, as well as multiple healing fractures of the left ulna.* **(Right)** *Frontal radiographs show the right & left lower extremities in the same patient with OI type III. There are healing fractures of the right & left femurs. Bowing deformities of both the right & left tibias/fibulae (secondary to healing fractures) are also noted.*

TERMINOLOGY

Abbreviations

- Osteogenesis imperfecta (OI)

Definitions

- Group of clinically heterogeneous genetic disorders most often caused by type I collagen alterations
- ↑ bone fragility → frequent fractures → malunion & bowing
  - Further ↑ likelihood of subsequent fractures
- Dentinogenesis imperfecta: Soft, cracked, discolored teeth

IMAGING

General Features

- Best diagnostic clue
  - Multiple in utero/perinatal fractures of short, poorly mineralized bones (OI type II)
  - Other OI types: Multiple fractures in thin, overtubulated long bones + vertebral fractures + osteoporosis

Radiographic Findings

- Radiography
  - Skull
    - Macrocranium
    - Frontal bossing, wide fontanelles, & sutures
    - Multiple wormian bones (≥ 10)
    - Platybasia & basilar impression/invagination
  - Spine
    - Kyphoscoliosis, biconcave or flattened vertebral bodies (platyspondyly), compression fractures
      - High rates of scoliosis progression in types III, IV, & V
      - Lower rate of progression in type I
    - Spondylolisthesis due to pedicle elongation
  - Chest
    - Thorax deformity → respiratory insufficiency
    - Sternum/manubrium bowing (convex outward)
    - Cardiac anomalies
  - Pelvis & hips
    - Coxa vara, protrusio acetabuli
  - Long bones
    - Diaphyseal overtubulation (thin, gracile)
    - Thin cortex
    - Bowing
    - "Popcorn Ca^{2+}" in epiphyses, metaphyses
      - Most common with type III
      - Especially knee & ankle
      - Typically resolves with physeal closure
    - Hyperplastic callus formation &/or interosseous membrane Ca^{2+} (type V)
      - Radioulnar interosseous membrane Ca^{2+} → radial head dislocation
      - Tibiofibular interosseous membrane Ca^{2+} (less common)
    - Zebra sign with bisphosphonate therapy
      - Sclerotic metaphyseal bands paralleling growth plates
      - Number of bands = number of treatments
  - Feet
    - Flatfoot & skewfoot (forefoot adduction, heel valgus, navicular abduction on talus)

Ultrasonographic Findings

- Fetal US may detect more severe types (II & III)
  - ↓ echogenicity of skull, spine, & long bones
    - Unusually well-visualized brain
  - Small thorax ± rib fractures
  - Long bones: Short, bowed multiple fractures ± callus
    - "Crinkled" or "crumpled" or "accordion" long bones

CT Findings

- Bone CT
  - Can help evaluate complications in axial skeleton
    - Cervical spine: Basilar invagination
    - Temporal bone: Otic capsule abnormalities resembling otospongiosis; stapes crura fractures & footplate fixation
    - Lumbar spine: Pedicle elongation + spondylolisthesis
  - Fetal CT done at some institutions if type II OI suspected
    - ↓ skull ossification, ↓ thorax size, bowed long bones with multiple fractures
- CTA
  - Rare: Aortic & carotid or vertebral artery dissection

MR Findings

- T2WI
  - Assess brainstem & spinal cord in basilar invagination

Nuclear Medicine Findings

- Bone scan
  - ↑ uptake with fractures

Imaging Recommendations

- Best imaging tool
  - Radiographs are usually sufficient to suggest diagnosis
  - CT or MR for axial skeleton complications

DIFFERENTIAL DIAGNOSIS

Child Abuse

- Fractures, retinal hemorrhages, intracranial injury, bruises
- No wormian bones, osteoporosis, or blue sclera

Diseases That Cause Bone Bowing

- Neurofibromatosis type 1
- Fibrous dysplasia
- Hyperparathyroidism
- Rickets
- Many bone dysplasias

Diseases With Fragile Bones

- Bruck syndrome
  - Fragile bones with congenital joint contractures
- Osteoporosis-pseudoglioma syndrome
  - Fragile bones with congenital blindness
- Cole-Carpenter syndrome
  - Fragile bones with craniosynostosis & ocular proptosis
- Idiopathic juvenile osteoporosis
  - No extraskeletal abnormalities

Hyperplastic Bone Formation

- Stress injury
- Myositis ossificans/heterotopic ossification
- Osteosarcoma

- Chronic osteomyelitis

Increased Wormian Bones

- Cleidocranial dysplasia
- Hypophosphatasia
- Hypothyroidism
- Pyknodysostosis
- Menkes syndrome

PATHOLOGY

General Features

- Genetics
  - Type I collagen is composed of triple helix
    - 2 α-1 chains (*COL1A1* gene)
    - 1 α-2 chain (*COL1A2* gene)
  - > 800 type I collagen mutations are known
  - 20 genetic types of OI are currently recognized
  - OI types I-IV: Mutations in *COL1A1* or *COL1A2*
    - OI type I: ↓ amount of type I collagen
    - OI types II-IV: Type I collagen folding, secretion, &/or mineralization abnormality
  - OI types V-XX involve mutations other than *COL1A1* or *COL1A2*
  - Screening for OI biochemical abnormalities
    - DNA sequencing is most sensitive
    - Cultured skin fibroblast test is rarely used now
- Associated abnormalities
  - Hearing loss (usually as adults), thin skin with subcutaneous hemorrhages, cardiac disease, hernias

Staging, Grading, & Classification

- Original Sillence classification (1979) included types I-IV
  - Based on clinical & radiologic manifestations & inheritance
  - Subsequent types were based on mutations outside type I collagen ± different phenotypes, inheritance
- OI type I: Mild, not deforming
  - Sclerae: Blue in most
  - Fractures: Spectrum of none (in 10%) → numerous; less common after puberty
  - Stature: Often normal, 20% with mild kyphoscoliosis in adults
  - Dentinogenesis imperfecta: Usually not present
- OI type II (subtypes A-C): Perinatal lethal
  - Sclerae: Blue
  - Beaded ribs, "accordion" femurs
  - Myriad of prenatal fractures
  - Poor to no ossification of skull
  - Intracranial hemorrhage, lung hypoplasia → death
- OI type III: Deformation severe
  - Triangular face due to underdeveloped facial bones
  - Sclerae: Gray
  - Kyphoscoliosis, chest deformity, bowed bones
  - Stature: Short
  - Usually wheelchair bound
- OI type IV: Deformation moderate
  - Sclerae: White
  - Bowing of long bones, vertebral fractures
  - Dentinogenesis imperfecta: In some but not all
  - Stature: Short
  - Walk with braces or crutches
- OI type V: Deformation moderate
  - Similar to type IV + interosseous membrane Ca^{2+} &/or hypertrophic callus
  - Dentinogenesis imperfecta: Absent
- OI type VI: Deformation moderate to severe
  - Sclerae: White or faintly blue
  - Stature: Moderately short
  - Vertebral compression fractures
  - Distinct histologic features
- Nosology & Classification of Genetic Skeletal Disorders (2019) identifies 5 clinical forms
  - Type I: Nondeforming with persistently blue sclera
    - Mildest form
  - Type II: Perinatal lethal
  - Type III: Progressively deforming
    - Most severely affected patients that survive infancy
  - Type IV: Moderate form
  - Type V: Similar phenotype to type IV + intramembranous ossification &/or hypertrophic callus

CLINICAL ISSUES

Demographics

- Epidemiology
  - All types: Incidence 1:10,000-20,000
  - OI type I: Incidence ~ 1:30,000
  - OI type II: Incidence ~ 1:60,000
  - Other types are rarer

Natural History & Prognosis

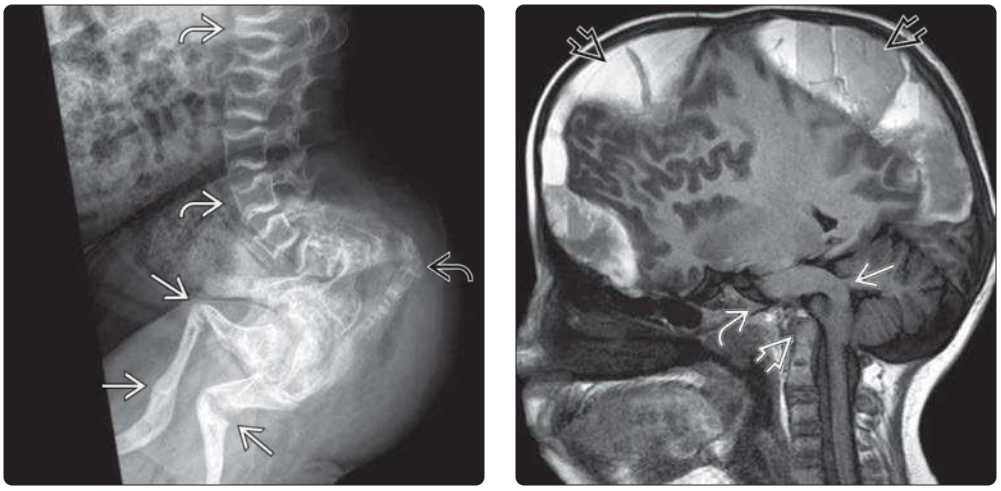
- Severity of OI (mild → severe)
  - Type I < IV < III < II
- Type II: Lethal in perinatal period
- Type III: Premature death

Treatment

- Intravenous bisphosphonates
  - Inhibit osteoclasts, ↑ bone mass/mineralization
  - ↓ bone pain & fractures
  - ↓ rate of scoliosis progression in type III if started < 6 years
  - Jaw osteonecrosis is not reported in this population
- Physical therapy, orthopedic surgery

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls



- Wide range of radiographic features across OI types
- Radiographic appearance alone does not classify OI
  - Family history, clinical features, histology, & genetic screening all contribute

(Left) *AP (left) & lateral (right) radiographs in an 11-year-old OI patient show a gracile, bowed appearance of the right humerus with the apex at the site of a prior fracture. Sclerotic metaphyseal lines are seen in the proximal humerus secondary to episodes of bisphosphonate therapy. Rods are seen in the radius & ulna.* **(Right)** *AP (left) & lateral (right) radiographs of the lower leg in the same patient show osteoporotic, gracile, & bowed bones with a prior fracture & hardware.*

(Left) *Lateral lumbar radiograph in a 16-year-old with OI shows diffuse demineralization, biconcave/flattened vertebral bodies, severe sacral kyphosis, & bilateral femur fractures with malunion & bowing.* **(Right)** *Sagittal T1 brain MR in a child with OI shows the dens protruding into the foramen magnum with a horizontal clivus & brainstem angulation. Large subdural hematomas are present. Patients with OI are predisposed to intracranial hemorrhages after minor trauma.*

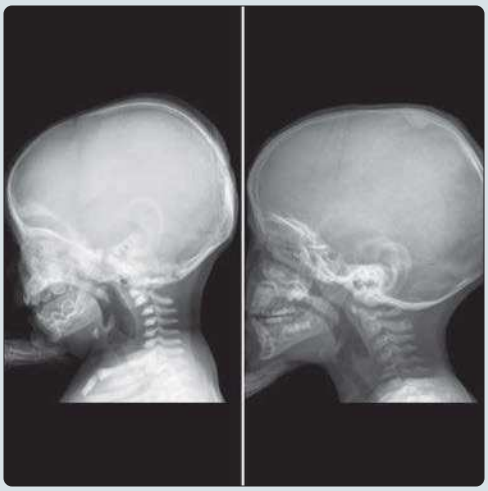
(Left) *Frontal radiographs of the right (left) & left (right) elbows in a 14-year-old girl with OI type V show a gracile appearance of the long bones & chronic bilateral radial head dislocations.* **(Right)** *Lateral radiographs of the right (left) & left (right) elbows in the same patient shows bilateral, volar radial head dislocations & ossification of the interosseous membranes. OI type V can have features of intramembranous ossification &/or hypertrophic callus formation.*

Osteopetrosis

KEY FACTS

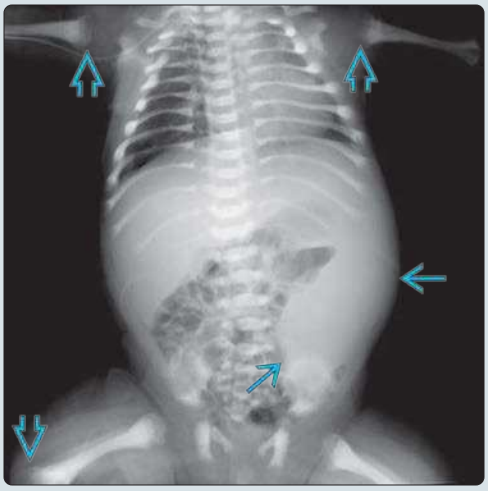
TERMINOLOGY

- Heterogeneous group of genetic disorders with ↑ bone density due to impaired bone resorption by osteoclasts
  - Osteopetrosis, autosomal recessive (ARO)
    - > 50% due to mutation of *TCIRG1* → infantile malignant osteopetrosis (IMO)
      - Typically presents in 1st year of life with macrocephaly, progressive blindness > deafness, hepatosplenomegaly, recurrent infections, severe anemia, fractures
      - Uniformly fatal without stem cell transplant
    - Other forms of ARO range from mild to severe
  - Osteopetrosis, autosomal dominant type 1
    - Not true osteopetrosis (unrelated to osteoclasts)
  - Osteopetrosis, autosomal dominant type 2
    - Most common form of osteopetrosis
    - More likely to present incidentally or due to pathologic fracture later in life

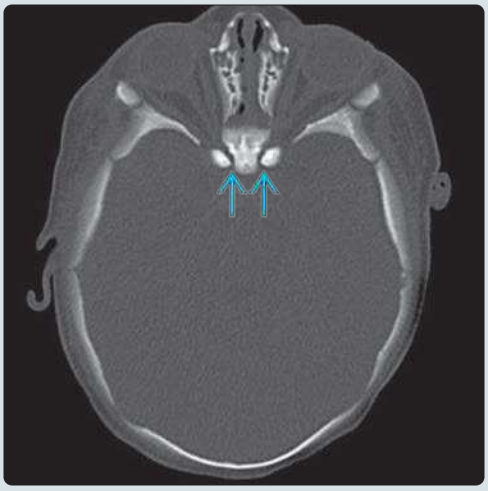


IMAGING

- Generalized osteosclerosis ± alternating radiolucent bands in metaphyses
  - Loss of corticomedullary definition
  - Undertubulated Erlenmeyer flask deformity of metaphyses, especially distal femurs
  - Bone-in-bone appearance of flat or small bones
  - ± pathologic fractures
- Thick, dense skull base &/or calvarium
- Well-defined sclerotic borders at vertebral endplates (sandwich vertebrae) vs. diffuse sclerosis



PATHOLOGY



- Defective bone remodeling results in effacement of marrow cavity & abnormal bone structure, impairing
  - Hematopoiesis → anemia, recurrent infections
  - Foraminal development → cranial nerve compression
  - Bone strength → pathologic fractures

(Left) *Bilateral lower extremity radiographs in a 6-month-old with fever show ↑ sclerosis of all visualized bones. The distal femurs show undertubulation (Erlenmeyer flask deformity) with loss of normal corticomedullary interfaces. Genetic testing confirmed autosomal recessive osteopetrosis (ARO).* **(Right)** *Lateral skull radiographs in an ARO patient taken at 6 months of age (left) & 2 years after bone marrow transplant (right) show interval restoration of normal bony mineralization.*

(Left) *AP radiograph in a 4-month-old with optic nerve atrophy, anemia, & thrombocytopenia shows diffusely ↑ bone density with marked splenomegaly. Genetic testing confirmed ARO. Note the irregular metaphyses with fraying & cupping due to superimposed rickets ("osteopetrorickets").* **(Right)** *Axial NECT in the same patient with ARO shows diffusely ↑ density & thickening of the skull with severely narrowed optic foramina.*

TERMINOLOGY

Definitions

- Heterogeneous group of genetic disorders characterized by ↑ bone density due to impaired bone resorption by dysfunctional osteoclasts
  - Osteopetrosis, autosomal recessive (ARO)
    - > 50% due to mutations of *TCIRG1* → infantile malignant osteopetrosis (IMO)
      - Severe anemia, hepatosplenomegaly, recurrent infections, fractures, macrocephaly, progressive blindness > deafness, ± hydrocephalus, coxa vara
    - Other forms of ARO range from mild to severe
  - Osteopetrosis, autosomal dominant type 1 (ADO1)
    - Not true osteopetrosis
      - *LRP5* mutation → enhanced osteoblast activity → high bone mass
  - Osteopetrosis, autosomal dominant type 2 (ADO2)
    - Albers-Schönberg disease, osteoclast rich
    - Most common form of osteopetrosis
    - *CLCN7* mutation in most → ↓ of chloride channel 7
      - Variable penetrance & expressivity; 20-40% are asymptomatic
  - Osteopetrosis, X-linked recessive (very rare)
    - *IKBKG* mutation → osteopetrosis, lymphedema, anhidrotic ectodermal dysplasia, immunodeficiency (OL-EDA-ID)

IMAGING

General Features

- Location
  - Skull, brain, face
    - Thick, dense skull base &/or calvarium
    - Macrocrania with frontal bossing
    - Neural: Narrowed foramina, including foramen magnum
    - Mandible: Frequent site of osteomyelitis
  - Axial skeleton
    - Vertebrae: Well-defined sclerotic borders at endplates (sandwich vertebrae) in ADO are classic; however, uniform sclerosis may be present
      - Bone-in-bone appearance
      - Osteomyelitis, scoliosis, fractures
    - Pelvis: Bone-in-bone appearance
  - Appendicular skeleton
    - Dense skeleton: Generalized sclerosis vs. radiolucent bands in metaphyses
      - Loss of corticomedullary definition
      - Bone-in-bone (endobone) appearance
    - Metaphyseal widening/flaring caused by defective tubular remodeling
      - Erlenmeyer flask deformity of distal femur, proximal humerus & tibia
    - Pathologic fractures
    - Coxa vara
    - ± osteopetrorickets (in ARO)
      - ↓ gastric acidity → ↓ calcium absorption; most commonly in *TCIRG1* mutation
      - Metaphyseal widening, cupping, & fraying superimposed over findings of osteopetrosis

PATHOLOGY

General Features

- Genetics
  - Different mutations affect osteoclasts in various ways
    - Osteoclast poor forms: ↓ number
    - Osteoclast rich forms: ↓ functionality
  - Mutations found in > 90% of cases

Microscopic Features

- Primary spongiosa persists & fills medullary cavity (rather than being removed during normal growth)
  - Leaves no room for hematopoietic marrow
  - Prevents development of normal mature trabeculae that provide strength to bone

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - ARO/IMO: Impaired hematopoiesis → thrombocytopenia, anemia, infection, & extramedullary hematopoiesis; cranial nerve compression → impaired vision, sensorineural hearing loss
  - ADO: Nontraumatic fractures, cranial nerve palsy, osteoarthritis of hip, mandibular osteomyelitis

Demographics

- Age
  - ARO/IMO typically presents < 1 year old
  - ADO2 typically presents in late childhood or adolescence

Natural History & Prognosis

- IMO: Uniformly fatal if untreated
- ADO: Can be completely asymptomatic

Treatment

- Hematopoietic stem cell transplant: Only cure for ARO
  - Addresses bone marrow failure & underlying bone resorption abnormality
    - Successful engraftment is indicated by changes in
      - Platelet & neutrophil counts
      - Calcium & phosphate levels
      - Bone morphology & mineralization (improving by 3-12 months)
- Fracture fixation: Unique problems are encountered due to abnormal bone density & fragility, lack of medullary canal, & ↓ vascularity with impaired healing & infection risks

Osteochondroses

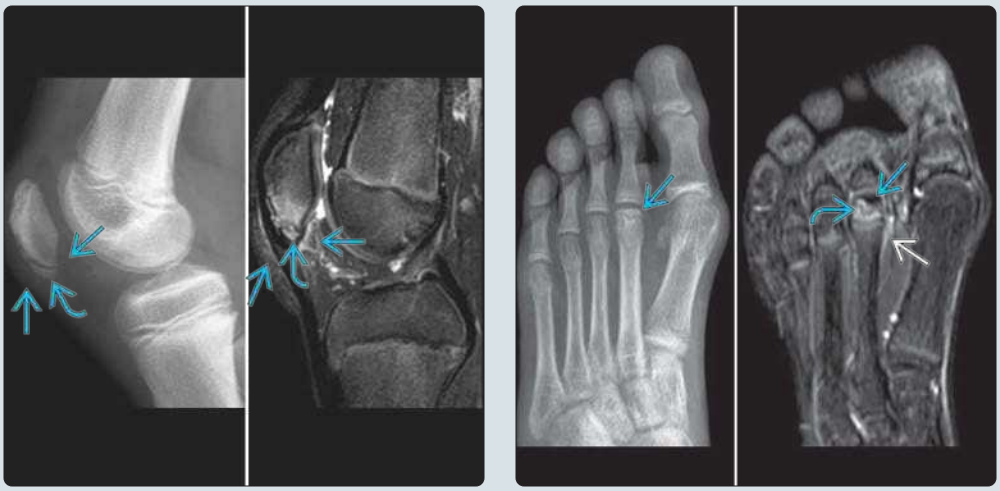
KEY FACTS

TERMINOLOGY

- Collection of poorly understood "disorders" of immature skeleton
  - > 70 entities, many with eponyms
- Many are symptomatic growth disturbances with elements of idiopathic osteonecrosis &/or overuse injury
- Symptoms vary: Asymptomatic → pain → long-term growth disturbances
- Outcomes vary: Resolution of self-limited process → permanent deformity if untreated

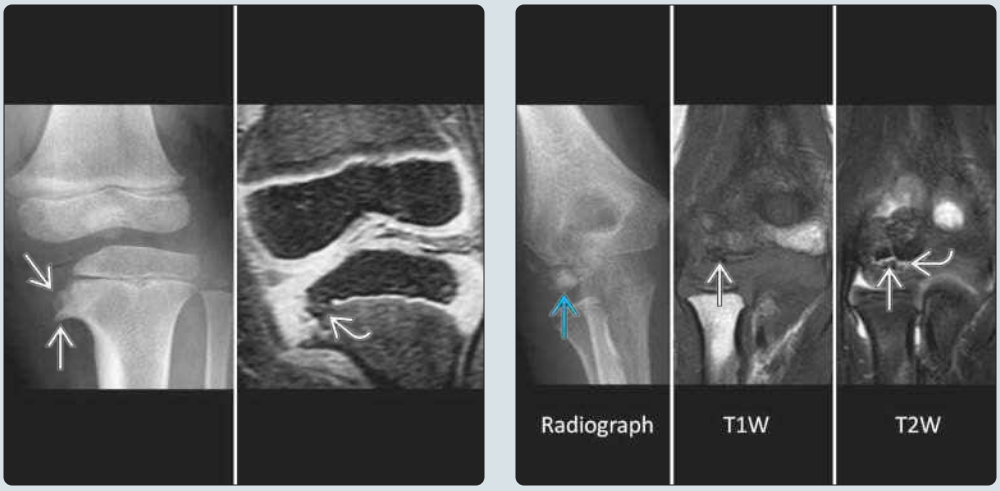
IMAGING

- Affect certain sites where bone growth occurs by endochondral ossification (epiphyses, apophyses > metaphyses)
- Radiographs: Fragmentation, sclerosis, flattening
  - Depending on location, symptoms, & patient age, such findings do not necessarily indicate disease
  - Normal variants of irregular epiphyseal ossification can occur at certain locations
- MR: Marrow & soft tissue edema typically correlate with symptoms
  - Subtracted pre-/postcontrast T1 FS images may show ↓ enhancement in setting of ischemia/necrosis
  - DWI/ADC may also reflect ischemia



CLINICAL ISSUES

- Conservative therapy with rest is effective for many
- Certain entities (e.g., Blount, Legg-Calvé-Perthes) often require surgical intervention to preserve long-term function



DIAGNOSTIC CHECKLIST

- Not every irregular ossification center is abnormal
  - Correlate with site, patient age, & symptoms
    - Helpful to know locations where irregular ossification normally occurs vs. never occurs
  - MR is useful adjunct for determining source of pain

(Left) *Lateral radiograph (left) & sagittal T2 FS MR (right) of a 12-year-old boy with anterior knee pain show fragmentation of the inferior pole of the patella with adjacent soft tissue swelling. The findings are consistent with Sinding-Larsen-Johansson syndrome.* **(Right)** *Oblique radiograph (left) & T2 FS MR (right) of the left foot in a 13-year-old girl with Freiberg disease show flattening & sclerosis of the 2nd metatarsal head. Additionally, the MR shows adjacent marrow & soft tissue edema.*

(Left) *AP radiograph (left) shows downsloping, beaking, & irregularity of the medial tibial metaphysis (Blount disease). Coronal GRE MR (right) shows abnormal ossification of the medial tibial epiphysis & metaphysis with an osseous bridge crossing the physis.* **(Right)** *AP radiograph (left) of an 8-year-old girl with Panner disease shows fragmentation & sclerosis of the capitellum. There is associated low signal intensity at this level on the T1 (middle) & T2 FS (right) MR images with interspersed ↑ signal intensity.*

TERMINOLOGY

Synonyms

- > 70 entities, many with eponyms

Definitions

- Collection of poorly understood "disorders" of immature skeleton
- Many entities reflect symptomatic growth disturbances with elements of idiopathic osteonecrosis &/or overuse
- Symptoms range from asymptomatic → pain → chronic manifestations of growth disturbances
- Outcomes range from resolution of self-limited process → permanent deformity if untreated

IMAGING

General Features

- Best diagnostic clue
  - Radiographic fragmentation, sclerosis, flattening
    - Depending on location, symptoms, & patient age, such findings do not necessarily indicate disease
    - Normal variants of irregular epiphyseal ossification can occur at certain locations
  - Bone marrow & soft tissue edema by MR
    - Typically correlate with symptoms
- Location
  - Affect certain sites where bone growth occurs by endochondral ossification (epiphyses, apophyses > metaphyses)
  - > 1 osteochondrosis can occur at some locations with differing clinical implications
  - Most frequent sites
    - Thoracic spine: Scheuermann disease
    - Capitellum: Panner disease, osteochondritis dissecans (OCD)
    - Lunate: Kienbock disease
    - Hip: Legg-Calvé-Perthes (LCP), Meyer dysplasia
    - Inferior patella: Sinding-Larsen-Johansson syndrome
    - Proximal, medial tibia: Blount disease
    - Tibial tubercle: Osgood-Schlatter disease
    - Calcaneal apophysis: Sever disease
    - Tarsal navicular: Köhler disease
    - 2nd or 3rd metatarsal head: Freiberg disease

Radiographic Findings

- Irregularity, fragmentation, sclerosis, flattening at site of endochondral ossification
  - Chronic changes may lead to deformity (e.g., LCP) &/or osteoarthritis (e.g., Freiberg)
- Bony bridges may rarely form across physes in this setting, leading to angular deformities or limb length discrepancy (e.g., Blount)
- ± adjacent soft tissue edema

MR Findings

- Abnormal sclerosis: Low T1 & T2 signal
- Marrow & soft tissue edema: Poorly defined high T2 signal
- Fragmentation/collapse: Discrete linear fluid signal intensity
- Osteonecrosis: Variable depending on stages
  - Subtracted pre-/postcontrast T1 FS images show earliest findings of ischemia & necrosis (↓ enhancement) & subsequent revascularization (↑ enhancement)
  - DWI can show early ischemia

Imaging Recommendations

- Best imaging tool
  - Radiographs correlated with specific symptoms
  - MR is useful adjunct if clinically uncertain

DIFFERENTIAL DIAGNOSIS

Normal Developmental Variants

- Asymptomatic
- Radiographic findings only with essentially normal MR
  - No marrow edema
- Characteristic locations (e.g., humeral trochlea)

Osteonecrosis of Systemic Disorders

- Sclerosis, fragmentation, collapse of epiphyses
- Often widespread with predisposing conditions

Spondyloepiphyseal Dysplasia

- Epiphyseal dysplasias may or may not involve spine
- Epiphyses are affected throughout body

Septic Arthritis

- Joint effusion, synovitis, marrow & soft tissue edema
- Fever, leukocytosis, & altered weight bearing

Juvenile Idiopathic Arthritis

- Swelling, pain, joint effusion, synovitis acutely
- Epiphyseal overgrowth, erosions, joint space loss chronically

CLINICAL ISSUES

Presentation

- Site dependent: Pain, limp, or limb deformity possible

Treatment

- Conservative therapy with rest is effective for many
- Certain entities (e.g., Blount, LCP) often require surgical intervention to preserve long-term function

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Not every irregular ossification center is abnormal
- Helpful to know locations where irregular ossification
  - Occurs normally (e.g., trochlea of humerus)
  - May occur normally without symptoms or with symptomatic osteochondrosis (e.g., calcaneal apophysis: Sever disease)
  - Does not normally occur (e.g., capitellum of elbow)
- MR is useful adjunct for determining source of pain

Rickets

KEY FACTS

TERMINOLOGY

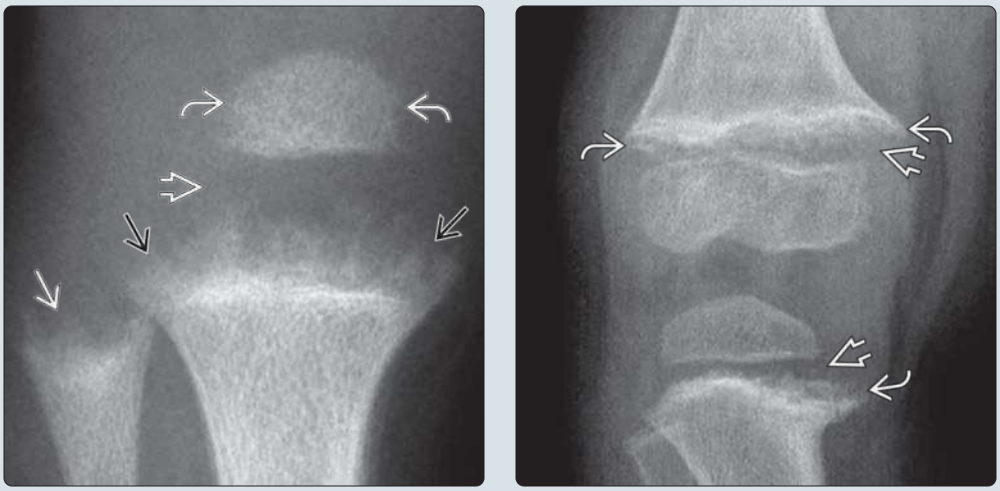
- Failure to mineralize cartilage & osteoid at growth plates (physes) of immature skeleton in setting of low ion concentrations (calcium or phosphorous)
  - Lack of phosphate (ultimate problem in all rickets) → failure of chondrocyte apoptosis → disruption of endochondral ossification
- Most common cause: Nutritional vitamin D deficiency

IMAGING

- Loss of normally thin, dense, well-defined zone of provisional Ca^{2+} at interface of physis & metaphysis
- Metaphyseal cupping, splaying, & fraying with lengthening ("widening") of adjacent radiolucent physis
- All sites of endochondral bone formation are affected
  - Most pronounced at long bone metaphyses with greatest linear growth
- Sites of membranous bone growth are less affected

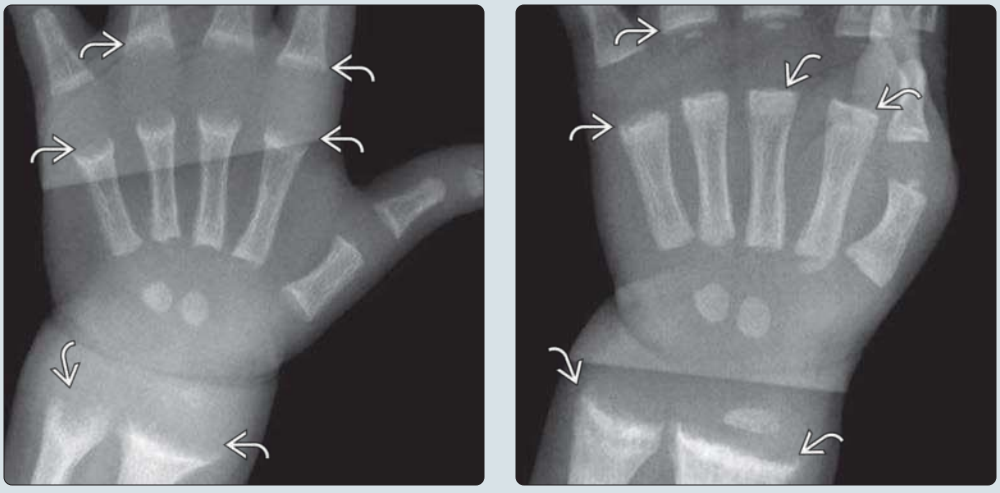
TOP DIFFERENTIAL DIAGNOSES

- Newborn stress demineralization
- Leukemia or metastatic neuroblastoma
- Congenital syphilis
- Metaphyseal fracture of child abuse
- Physeal stress injury
- Physeal fracture
- Metaphyseal chondrodysplasias
- Hypophosphatasia



CLINICAL ISSUES

- Peak age for dietary rickets: 3 months to 2 years
- Most rickets responds to vitamin D therapy ± calcium



DIAGNOSTIC CHECKLIST

- Unexplained physeal widening at 1 site (i.e., without acute or chronic trauma) merits survey at other sites of rapidly growing long bones (knees, wrists)
  - Multisite physeal widening → get metabolic work-up

(Left) *AP radiograph in a young child with rickets shows fraying, cupping, & splaying of the proximal tibial & fibular metaphyses. There is loss of the normally dense, well-defined zones of provisional Ca^{2+} (ZPC) that should be seen at the metaphyseal-physeal junctions. The radiolucent tibial physis is lengthened. The epiphyseal ZPC is also lost with poor bony margin definition.* **(Right)** *AP knee radiograph in a 3-year-old with rickets shows typical metaphyseal fraying, cupping, & splaying, as well as physeal lengthening.*

(Left) *PA wrist radiograph in this young child with rickets shows fraying, cupping, & splaying of every visualized metaphysis. The normal ZPCs are lost.* **(Right)** *PA radiograph in the same child 9 weeks after initiation of therapy shows that endochondral ossification has resumed with improved bone formation at all the growth centers. The visualized metaphyses are normalizing in shape & density as compared to the prior study.*

TERMINOLOGY

Definitions

- Failure to mineralize cartilage & osteoid at growth plates (physes) of immature skeleton in setting of low ion concentrations
  - Initial deficiency may be considered as calcipenic or phosphopenic
  - Lack of phosphate becomes ultimate problem
    - Underlying factor in all rickets: Failed apoptosis of hypertrophic chondrocytes
      - Key enzyme (caspase-9) is dependent on phosphorylation
      - Failure of apoptosis disrupts endochondral ossification
- Most common cause: Nutritional vitamin D deficiency
  - ↓ dietary vitamin D &/or ↓ exposure to sunlight
  - Primary calcium deficiency is uncommon
- Many other causes, including
  - Prematurity
    - < 28-weeks gestational age, birth weight < 1,000 g
    - 80% of fetal bone mineralization occurs in 3rd trimester
      - Typical neonatal nutrition is not sufficient
      - Exacerbated by medications used for chronic lung disease of prematurity, including steroids & calcium-excreting diuretics
  - Prenatal factors
    - Maternal medical problems → severe vitamin D deficiency
  - Malabsorption: Binding with malabsorbed fatty acids → ↓ calcium & vitamin D absorption
  - Liver disease: ↓ formation of 25-hydroxy vitamin D; unconjugated bilirubin interferes with osteoblasts
    - Chronic liver disease
    - Anticonvulsant therapy
  - Vitamin D-dependent types 1A, 1B, 2A, 2B
    - Various genetic disorders of vitamin D metabolism
  - Hypophosphatemic rickets: Renal loss of phosphates
    - > 10 phenotypes with FGF-23-dependent & -independent forms, including
      - X-linked, autosomal dominant & recessive forms
      - Syndromes, including neurofibromatosis type 1, McCune-Albright
    - Chemotherapy: Ifosfamide renal-tubule toxicity
  - Oncogenic rickets: Rare paraneoplastic syndrome caused by ↑ production of FGF-23
    - Phosphaturic mesenchymal tumor
    - Nonossifying fibroma
    - Hemangiopericytoma
    - Osteoblastoma
    - Linear sebaceous nevus syndrome
  - Chronic renal disease: Renal osteodystrophy with secondary hyperparathyroidism
    - ↓ glomerular function → phosphorus retention → hypocalcemia
    - Tubular dysfunction → ↓ synthesis of 1,25-dihydroxy vitamin D → hypocalcemia
    - Hypocalcemia → hyperparathyroidism

IMAGING

General Features

- Best diagnostic clue
  - Loss of normally thin, dense, well-defined zone of provisional Ca^{2+} (ZPC) at interface of physis & metaphysis
  - Metaphyseal cupping, splaying, & fraying with lengthening ("widening") of adjacent physis
- Location
  - All sites of endochondral bone formation are affected
    - Most pronounced at long bone metaphyses with greatest linear growth
      - Distal femur, proximal tibia, proximal humerus, distal radius
  - Sites of membranous bone growth are less affected

Radiographic Findings

- Axial skeleton
  - Costochondral junctions: Cupping, widening of anterior rib ends ("rachitic rosary")
  - Spine: Scoliosis, biconcave vertebral bodies
  - Skull, face (largely membranous growth, except skull base)
    - Widened sutures, delayed sutural & fontanel closure
    - Postural molding, frontal bossing, platybasia
    - Delayed eruption of teeth, enamel hypoplasia
- Appendicular skeleton
  - Epiphyses: Loss of dense outline (ZPC) of secondary ossification centers → irregular margins
  - Physes: Lengthening (longitudinal "widening") of radiolucent growth plates (due to ↑ unossified cartilage)
  - Metaphyses: Fraying, splaying/transverse widening, & cupping with loss of normal dense ZPC
    - Loss of metaphyseal collar of Laval-Jeantet
  - Diaphyses: Bowing, osteoporosis, tunneling, fractures
    - Looser zones: Transversely oriented lucencies of insufficiency fractures in severe cases
  - Pelvis: Inward migration of sacrum, acetabula → triradiate appearance; causes dystocia in adulthood
  - Hip: Coxa vara, protrusio acetabuli
  - Knees: Genu valgum or varum
  - Periosteal reaction: Occult fracture or subperiosteal accumulation of unmineralized osteoid
- Renal osteodystrophy with secondary hyperparathyroidism
  - Subperiosteal bone resorption
    - Distal clavicle, distal radius + ulna, middle phalanges of hands, medial femoral neck, medial proximal tibia
    - Lamina dura of teeth
  - Resorption at phalangeal tufts, pubic symphysis
  - Subchondral, subtendinous, subligamentous resorption
  - Endosteal bone resorption → lacy pattern of inner cortex (cortical tunneling)
  - Lengthened ("widened") physes (subphyseal resorption, fibrous tissue deposition)
    - ↑ risk for slipped capital femoral epiphysis
  - Bone margins unsharp, hazy
  - Sclerosis with "smudged" trabeculae
  - Soft tissue Ca^{2+}
- Healing rickets after vitamin D therapy
  - ↑ density at ZPC after treatment in 2-3 weeks with nutritional rickets, 2-3 months with renal rickets

MR Findings

- Elongated cartilaginous physes with ↑ PD/T2 signal
- Absence of normal thin, low signal intensity ZPC

DIFFERENTIAL DIAGNOSIS

Newborn Stress Demineralization

- Metaphyseal lucent bands with intact ZPC in first 2 months after delivery

Leukemia or Metastatic Neuroblastoma

- Metaphyseal lucent bands with intact ZPC
- ± osteoporosis, permeative lesions, periosteal reaction

Congenital Syphilis

- Serrated lucent metaphyses
- Focal destruction of upper medial tibial metaphyseal cortex (Wimberger corner sign)

Metaphyseal Fracture of Child Abuse

- Classic metaphyseal corner injury (or bucket-handle fracture) due to fracture through primary spongiosa
- Only at sites of injury (not diffuse)
- ZPC & bony mineralization are normal

Physeal Stress Injury

- Repetitive microtrauma to growth plate causes focal or diffuse longitudinal physeal widening & irregularity without transverse metaphyseal widening or cupping
  - Likely due to chronic metaphyseal vasculature injury impairing endochondral ossification in high-level athletes
- Single site is usually affected (e.g., distal radius of "gymnast wrist" or proximal humerus of "Little Leaguer shoulder")
- Non-weight-bearing long bones (e.g., fibula, ulna) are typically spared

Physeal Fracture

- Acute growth plate widening in Salter-Harris injuries
  - ± displacement of epiphysis + metaphyseal fragment
- Overlying soft tissue swelling
- Clear history of trauma is usually present

Metaphyseal Chondrodysplasias

- Widespread abnormal metaphyseal configurations
- Varying etiologies & associated anomalies

Hypophosphatasia

- Wide spectrum of disease severity; due to inactive enzyme despite normal mineral concentrations
- In milder forms, metaphyseal disturbances may be focal rather than uniform
- Bowdler spurs are characteristic

PATHOLOGY

General Features

- Etiology
  - Normal bone development requires adequate calcium + phosphorus (facilitated by vitamin D)
    - Essential for formation of hydroxyapatite crystals
    - Rickets is due to ↓ availability of these substances
      - Also need adequate blood supply & cartilage for endochondral ossification
  - Vitamin D
    - ↑ absorption of calcium from intestine
    - ↑ calcium resorption in renal proximal tubules
    - Regulates apoptosis of chondrocytes, cartilage matrix mineralization, & metaphyseal angiogenesis
- Associated abnormalities
  - Fractures due to vitamin D deficiency do occur in mobile patients with radiologic manifestations of rickets
  - Findings **not** attributable to rickets that must prompt child abuse evaluation
    - Fractures in nonmobile infants
    - Fractures otherwise typical of child abuse (e.g., classic metaphyseal lesion or corner fracture, etc.)
    - Subdural hematoma or retinal hemorrhage

Microscopic Features

- Normal physis consists of 4 zones of cartilage
  - Germinal/resting cartilage cells (near epiphysis)
  - Proliferating cartilage cells
  - Hypertrophic columns of cartilage cells
  - Provisional Ca^{2+} of cartilage (ZPC)
    - First 3 zones: Radiolucent
    - ZPC: Thin, dense, undulating line at metaphyseal edge
- Metaphyseal spongiosa adjacent to ZPC: Cartilage matrix replaced by osteoid with remodeling & Ca^{2+} leading to spongy bone occupying marrow cavity
  - Rickets: Ca^{2+} of cartilage & osteoid does not occur → physeal/metaphyseal abnormalities

CLINICAL ISSUES

Demographics

- Peak age for dietary rickets: 3 months to 2 years

Treatment

- Most rickets responds to vitamin D therapy ± calcium

DIAGNOSTIC CHECKLIST

Consider

- Unexplained physeal widening at 1 site (i.e., without acute or chronic trauma) merits survey at other sites of rapidly growing long bones (knees, wrists)
  - If widening is present at multiple sites, including non-weight-bearing long bones, suspect metabolic disease

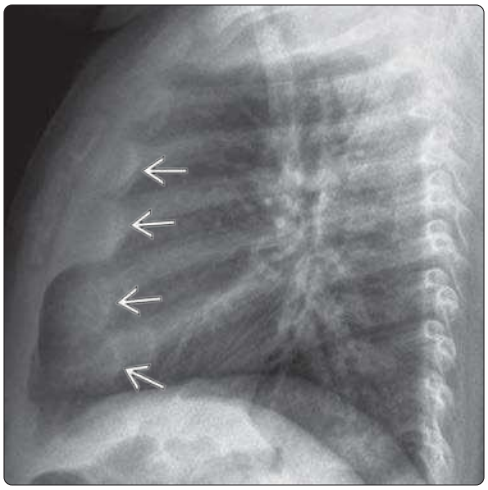


Image Interpretation Pearls

- Be sure to look at growth centers of proximal humeri & femurs on neonatal chest & abdominal radiographs

8. Shore RM et al: Rickets: part II. Pediatr Radiol. 43(2):152-72, 2013

(Left) *Lateral radiographs of the forearm in a 2-year-old child with linear nevus sebaceous syndrome & associated paraneoplastic hypophosphatemic rickets show severe demineralization with periosteal reaction, cortical tunneling, & cupped, frayed metaphyses.* **(Right)** *Lateral radiograph in a 7-month-old boy with failure to thrive shows the widened & cupped anterior ribs typical of the "rachitic rosary."*

(Left) *AP radiograph of a 15-year-old with knee pain shows loss of the normal dense ZPCs with partial mineralization of hypertrophied physeal cartilage. The metaphyses appear mildly frayed & cupped.* **(Right)** *Sagittal T2 FS MR in the same patient shows mild physeal lengthening ("widening") with abnormally hyperintense metaphyses that are partially mineralized. The thin, low-signal line represents an aberrant ZPC in this patient with nutritional rickets.*

(Left) *Sagittal CT reconstruction in a 12-year-old boy with ankle pain shows a lengthened ("widened") distal tibial physis with metaphyseal cupping & irregularity. This finding was present bilaterally at the tibias & fibulas.* **(Right)** *AP radiograph in the same patient, who was found to be in renal failure, shows typical changes of renal osteodystrophy & renal rickets with proximal femoral physeal lengthening, widened & irregular pubic symphysis & sacroiliac joints, & diffuse "smudging" of trabeculae.*

Sickle Cell Disease

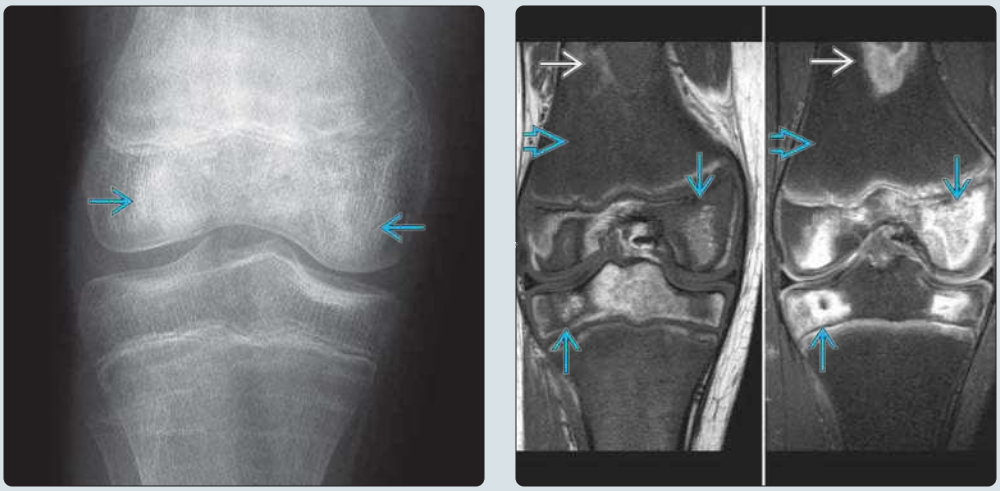
KEY FACTS

IMAGING

- Vertebrae
  - Infarctions: Central endplate depressions (H-shape or Lincoln log morphology)
  - Marrow hyperplasia with bone softening: Biconcave endplates (fish mouth)
- Ribs: Infarction is part of acute chest syndrome (chest pain, dyspnea, cough + pulmonary consolidation)
- Long bone infarctions
  - Acute/subacute: Poorly defined marrow, soft tissue, & periosteal edema ± fluid collections
    - Not easily distinguished from osteomyelitis
    - Dactylitis (hand-foot syndrome): Hand & foot small tubular bone infarcts, usually at age 6-24 months
  - Chronic: Lucent or sclerotic medullary cavity
    - Diaphysis, metaphysis
    - Epiphyseal infarction is most common in humeral & femoral heads: Sclerosis, subchondral collapse

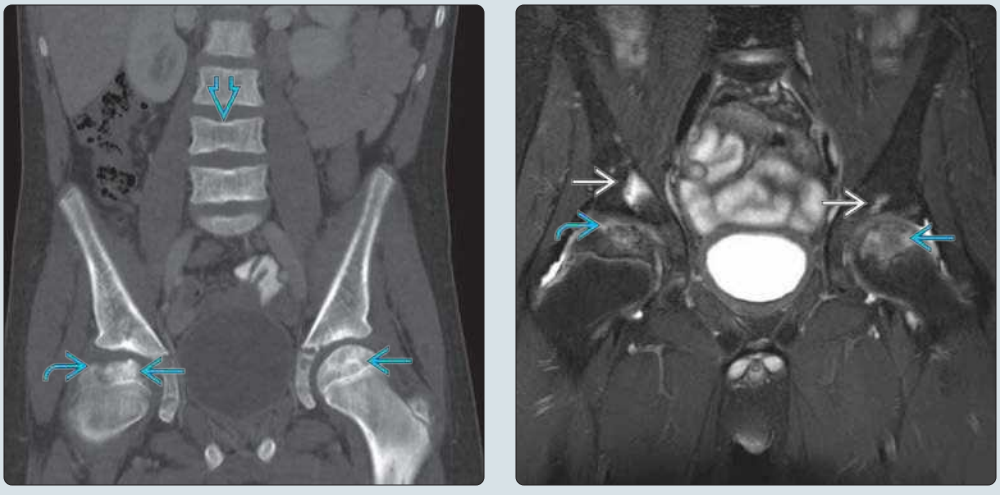
PATHOLOGY

- Bony manifestations result from
  - Chronic anemia → red marrow hyperplasia
  - Immunocompromise & altered blood flow → osteomyelitis
  - Vasoocclusion → medullary infarction



CLINICAL ISSUES

- Typical presentation: Pain due to vasoocclusive crisis involving any organ, most commonly bone
- Patients of African descent are most commonly affected
- Mean survival: 42 years



DIAGNOSTIC CHECKLIST

- Differentiation of acute bone infarct vs. osteomyelitis in SCD is very difficult
  - Episodes of vasoocclusion > > osteomyelitis in SCD
  - Cortical disruption & fluid collections (especially larger) favor osteomyelitis

(Left) *AP radiograph of the right knee in a patient with sickle cell disease (SCD) & pain shows patchy sclerosis of the femoral condyles, suggesting bone infarcts.* **(Right)** *Coronal T1 (L) & T2 FS (R) MR images in the same patient show heterogeneous, geographic foci with serpiginous margins in the femoral & tibial epiphyses & femoral diaphysis, typical of bone infarcts. The abnormally low T1 & T2 signal intensity of the visualized metadiaphyses is due to ↑ red marrow & iron overload.*

(Left) *Coronal CECT in the same patient shows heterogeneous sclerosis of the femoral heads, consistent with avascular necrosis (AVN). There is subchondral collapse & fragmentation on the right with associated acetabular dysplasia. Central depressions are seen at several vertebral body endplates.* **(Right)** *Coronal T2 FS MR in the same patient shows articular cartilage loss on the right at the site of fragmentation. Infarcts are also seen in the left femoral head & bilateral iliac bones.*

TERMINOLOGY

Abbreviations

- Sickle cell disease (SCD); hemoglobin SS (Hb SS, Hgb SS)

Definitions

- SCD: Hb SS (homozygous) → severe anemia
- Sickle cell-hemoglobin C disease: Hb SC → mild anemia
- Sickle cell-α thalassemia: Hb S-α thal → severe anemia
- Sickle cell-β thalassemia: Hb S-β thal → mild to severe anemia
- Sickle cell trait: Hb SA (heterozygous gene carrier)
- Normal: Hb AA

IMAGING

General Features

- Best diagnostic clue
  - H-shaped vertebrae
  - Bone marrow infarctions with sclerosis
- Location
  - Percentage of all bone infarcts found in individual bones: Femur 16%, tibia 15%, humerus 13%, spine 11%, radius 10%, ulna 8%, pelvis 8%, others 19%

Radiographic Findings

- Skull
  - Expanded diploic space; hair-on-end appearance is rare
  - Extramedullary hematopoiesis (EMH): Middle ear, paranasal sinuses
  - Mandible: Coarse trabeculae; condyle infarction
  - Orbital wall infarction → subperiosteal hemorrhage → proptosis (orbital compression syndrome)
- Spine
  - Vertebral infarctions
    - Central endplate depression (superior + inferior endplate → H-shape or Lincoln log morphology)
    - ± compensatory enlargement of adjacent vertebra (tower vertebra)
    - ↓ height → kyphosis, lordosis
  - Smooth endplate concavities from marrow hyperplasia → osteoporosis with bone softening → insufficiency fractures (fish mouth appearance formed by adjacent inferior & superior endplates)
  - EMH: Paraspinal/intraspinal masses
- Chest
  - Rib & sternal infarction: Part of acute chest syndrome (chest pain, dyspnea, cough + pulmonary consolidation)
    - Bone infarctions → lucent or sclerotic foci
  - EMH: Posterior mediastinal masses
  - Soft tissue findings provide useful clues
    - Enlarged heart (chronic anemia)
    - Absent splenic shadow (infarction)
    - Cholecystectomy clips (pigment gallstones)
- Pelvis
  - Osteomyelitis, protrusio acetabuli, infarction
- Extremities
  - Diametaphyseal infarction: Lucent or sclerotic serpiginous/geographic foci with healing (months)
  - Epiphyseal infarctions (avascular necrosis) are most common in humeral & femoral heads
    - Sclerosis, subchondral fracture, coxa magna
  - Dactylitis (hand-foot syndrome): Hand & foot small tubular bone infarcts, usually at age 6-24 months
    - Soft tissue edema, solid periosteal reaction, cortical mottling, sclerosis
  - Infarctions up to physis → growth disturbances
    - Cone-shaped epiphyses of metacarpals, phalanges
    - Premature physeal fusion
  - Osteomyelitis: Femur, tibia, & humerus are most common
  - Marrow hyperplasia: Osteoporosis, thinned cortex, widened medullary spaces, coarsened trabeculae

MR Findings

- T1WI
  - Marrow hyperplasia: Bright yellow marrow replaced by darker red marrow (↓ fat, ↑ water content)
  - Variable appearance of infarctions
    - Serpiginous low signal intensity foci if chronic
- T1WI FS
  - Bright, patchy foci can favor infarction but not reliable for differentiating from infection
- T2WI FS
  - Poorly defined bright marrow, periosteal, & soft tissue edema from acute infarction or osteomyelitis
  - Soft tissue or subperiosteal collections or joint fluid seen in either process
    - Larger collections favor infection
  - Interrupted dark signal cortex favors infection
  - Double-line sign: Alternating bright + dark T2 serpiginous foci of chronic infarctions throughout medullary cavities & epiphyses
  - ↓ marrow signal of iron overload from numerous transfusions
- T1WI C+ FS
  - Enhancement in infarction & infection is variable
    - ↓ marrow enhancement (± fluid) in regions of acute infarction or ↑ pressure from infection/abscess
      - Thin rim enhancement favors infarct
      - Thick rim enhancement favors infection
  - Extensive geographic regions of ↓ marrow enhancement: Bone marrow necrosis
    - Preservation of trabeculae

Ultrasonographic Findings

- Fluid collections (especially larger) favor osteomyelitis
- Imaging guidance is useful for sampling fluid for culture

Nuclear Medicine Findings

- Bone scan
  - Symmetric expansion of hematopoietic marrow involving femur, calvaria, small bones of hands/feet
  - Bone marrow infarction: Photopenic defect initially; may show ↑ activity with healing & revascularization
  - Bone infarction vs. osteomyelitis
    - Infarction: Tc-99m MDP bone scan shows ↑ activity; Tc-99m sulfur colloid marrow scan shows ↓ activity
    - Osteomyelitis: Bone scan shows ↑ activity; sulfur colloid marrow scan shows normal activity
- Tc-99m sulfur colloid
  - Can confirm masses as EMH

DIFFERENTIAL DIAGNOSIS

Langerhans Cell Histiocytosis

- Vertebra plana (flat vertebral body)
- Punched-out lytic bone lesions

Leukemia

- Osteoporosis, metaphyseal lucent bands, pathologic fractures
- May have more aggressive bone lesions & periosteal reaction

Thalassemia

- Changes of bone marrow expansion are similar to SCD but exaggerated
  - H-shaped vertebra
  - Hair-on-end appearance of skull diploic space
  - Avascular necrosis is less common than SCD
  - Paravertebral masses: EMH

PATHOLOGY

General Features

- Etiology
  - Normal human hemoglobin A contains 4 globin chains: 2 α + 2 β chains
    - Hb SS: Abnormal β chains twist (polymerization) → RBC distortion
    - RBC distortion is exaggerated with deoxygenation → irreversible sickling (banana-shaped RBCs)
      - Sickled RBCs occlude vessels → infarction
      - Sickled RBCs are quickly removed → anemia
  - Bony manifestations result from
    - Chronic anemia → red marrow hyperplasia → medullary cavity expansion, bone softening
    - Immunocompromise + abnormal blood flow → osteomyelitis
      - Osteomyelitis 2:1 *Salmonella*:*Staphylococcus*
    - Vasoocclusion → medullary infarction
- Genetics
  - Abnormal β globin gene on short arm of chromosome 11 → valine substituted for glutamic acid at β globin position 6 → Hb S

Microscopic Features

- Normally, red/cellular marrow of appendicular skeleton converts to yellow/fatty marrow during childhood
  - Begins in epiphyses & central diaphyses, gradually spreading toward metaphyses
  - Red marrow persists in normal adult axial skeleton
- Expansion of red marrow throughout skeleton in SCD

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pain due to vasoocclusive crisis involving any organ, most commonly bone
    - Infarction dactylitis is often 1st manifestation
    - Painful chest/abdominal crises begin at age 2-3 years
  - Skeletal pain due to marrow infarction > > osteomyelitis
    - Fever, pain, swelling, ↓ motion, leukocytosis, ↑ inflammatory markers in either diagnosis
      - C-reactive protein tends to be much higher in osteomyelitis
    - Osteomyelitis is 10-50x less common than bone infarction in SCD
  - Splenomegaly initially, then splenic atrophy
    - Autosplenectomy by progressive infarction
  - Hemolytic anemia: Jaundice, gallstones
    - 50-70% have gallstones by adulthood
  - Marrow, liver, pancreas hemosiderosis (transfusions)
  - Stroke in 11% before 20 years old

Demographics

- Age
  - Typically detected on newborn genetic screening
  - Painful crisis of bone in 50% by age 5
    - Most common cause of hospitalization
      - Acute chest syndrome is 2nd most common
- Epidemiology
  - Incidence: 1 in 375-650 Black Americans have SCD
    - 8% of Black Americans carry *HbS* gene
      - Up to 40% in some African tribes
  - Incidence: 1 in 2,000 Hispanic individuals from Caribbean, Central America, South America

Natural History & Prognosis

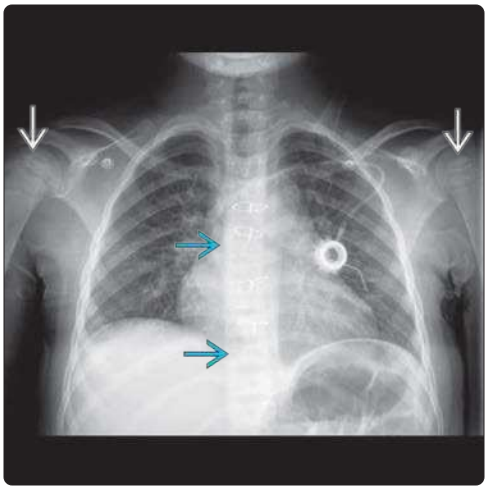
- Mean survival: 42 years
- Acute chest syndrome: Most common cause of death
- Frequency of vasoocclusive crises may predict presence of bone infarcts on imaging

Treatment

- Sickle cell crisis: Oxygen, hydration, pain management, blood transfusion
- Hydroxyurea to prevent vasoocclusive crises
- Autologous stem cell implantation at site of osteonecrosis may improve symptoms & prevent joint degeneration
- Prophylactic penicillin + pneumococcal & *Haemophilus influenzae* vaccines to prevent infection

DIAGNOSTIC CHECKLIST

Consider



- Differentiation of acute bone infarcts vs. osteomyelitis in SCD is very difficult clinically & radiologically
- Episodes of vasoocclusion > > osteomyelitis (up to 50:1)

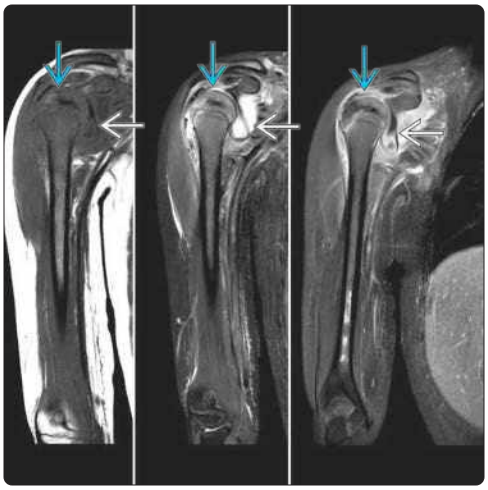


Image Interpretation Pearls

- Cortical disruption &/or fluid collections favor osteomyelitis

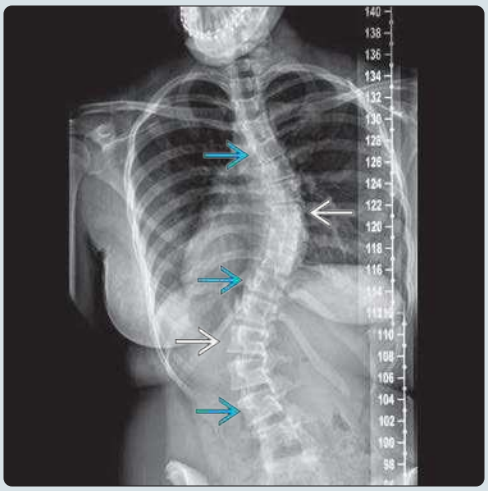
(Left) *AP chest radiograph in a 7-year-old with SCD shows sclerosis of the humeral heads, consistent with AVN. Vertebral endplate concavities & central depressions are noted at multiple levels.* **(Right)** *Coronal T1 (L), STIR (M), & T1 C+ FS (R) MR images in the same patient show heterogeneous epiphyseal marrow, a moderate joint effusion, & surrounding soft tissue edema. These findings can be seen with acute bone infarction or osteomyelitis in SCD.*

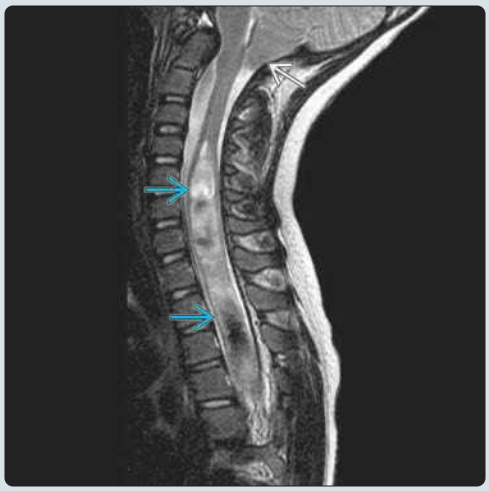
(Left) *PA radiograph of the hand in an 11-month-old SCD patient with swelling shows medullary sclerosis & periosteal reaction of the 2nd, 4th, & 5th metacarpals, typical of dactylitis.* **(Right)** *Coronal T1 C+ FS MR in an SCD patient with recently diagnosed pelvic osteomyelitis, septic arthritis, & soft tissue abscesses shows an unusual complication: Complete slip of the capital femoral epiphysis from the femoral neck.*

(Left) *Coronal T1 C+ FS MR in a 14-year-old boy with SCD shows heterogeneous enhancement of the distal left femur with periosteal edema (due to infection vs. acute infarction). The bilateral knee synovitis could be reactive from either process or from septic arthritis. Subacute infarction is seen in the right femoral shaft.* **(Right)** *Sagittal STIR MR shows biconcave vertebral bodies at each level, typical of bone softening. There is also high signal intensity in multiple spinous processes from recent infarctions.*

Scoliosis

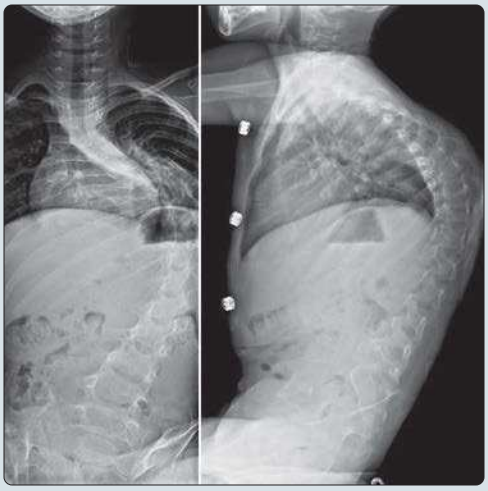


KEY FACTS



TERMINOLOGY

- Lateral curvature(s) of spine with Cobb angle of ≥ 10°
- Flexible: Nonstructural; corrects with ipsilateral bending
  - Usually does not progress; need not be included in fusion
- Rigid: Structural; does not correct with ipsilateral bending
  - Cobb angle remains ≥ 25° on ipsilateral bending
  - Included in spinal fusion
- Curve etiologies
  - Some diagnoses span categories
  - Idiopathic: Most common; 70-85% of all scoliosis
    - Classified according to time of onset
    - Infantile: < 3 years of age
      - Mostly develops during first 6 months of life
      - Typical: Convex left thoracic curve (70%)
      - M > F
    - Juvenile: 4-9 years
      - Typical: Convex right thoracic curve
      - Most likely to progress
    - Adolescent: > 10 years
      - Most common type: Convex right thoracic curve
      - M < < F
  - Congenital: 10%
    - Osteogenic: Segmentation anomaly
    - Neuropathic: Syrinx, tethered cord, diastematomyelia
  - Neuromuscular (neuropathic or myopathic)
    - Single long curve
    - Neuropathic: Chiari 1, cerebral palsy
    - Myopathic: Muscular dystrophies, spinal muscular atrophy
  - Developmental (skeletal dysplasia or dysostosis)
  - Tumor associated
    - Osteoid osteoma, cord neoplasm, neurofibromas



CLINICAL ISSUES

- Younger patients presenting with severe curves are more likely to progress than older children with less severe curves
- Progression is most likely during adolescent growth spurt

(Left) *PA radiograph of a 13-year-old during follow-up for adolescent idiopathic scoliosis shows 47° convex right thoracic & 47° convex left thoracolumbar curvatures. The terminal ⇨ & apical ➡ vertebrae for each curve are noted. The image is displayed from the perspective of the examining/operating orthopedist.* **(Right)** *Sagittal T2 MR shows a large syrinx ⇨, which extended to T10 (not shown). Note the Chiari 1 configuration of the cerebellar tonsils ➡. The patient was imaged due to a rapidly progressive curve.*

(Left) *Frontal (L) & lateral (R) radiographs of the spine in a 4-year-old with an uncommon form of muscular dystrophy show a severe apex left curve of the thoracolumbar spine with marked kyphosis.* **(Right)** *Anterior 3D bone CT in the same patient shows the severe thoracic deformity from the rotary as well as the sagittal & coronal components of the curvature.*

TERMINOLOGY

Definitions

- Presence of lateral curvature(s) of spine with Cobb angle of ≥ 10°, often associated with vertebral rotation
- 2 types
  - Flexible: Nonstructural, corrects with ipsilateral bending, usually does not progress
  - Structural: Rigid, does not demonstrate correction with ipsilateral bending
    - Cobb angle remains ≥ 25° on ipsilateral bending

IMAGING

General Features

- Idiopathic: No clear cause by clinical exam or radiographs
  - Most common: 70-85% of all scoliosis
  - Classified according to time of onset
    - Infantile: ≤ 3 years of age
      - Most develop during first 6 months of life; M > F
      - 1/4 are associated with hip dysplasia
      - Typical: Convex left thoracic curve (70%)
    - Juvenile: 4-10 years
      - Typical: Convex right thoracic curve, progressive
    - Adolescent idiopathic scoliosis (AIS): > 10 years
      - Most common type: Convex right S-shaped thoracic
      - Compensatory left convex lumbar; ↑ rapidly with growth spurts; M < < F
    - Adult: Curve begins after maturation
  - Note that other categories may cause similar curves
- Congenital: 10%
  - Result of vertebral anomalies: Hemivertebrae (45%), occult spinal abnormality (15-40%)
  - Typical: Thoracic or thoracolumbar curve
  - Progressive scoliosis (3/4)
  - If curve is progressive or surgery is planned, image with MR; fine osseous detail may be better seen on CT
  - Associated with
    - Spinal dysraphism: Lipoma, diastematomyelia, syringohydromyelia, tethered cord
    - Genitourinary anomalies (6%), cardiac anomalies (15%), rib anomalies
- Neuromuscular (neuropathic or myopathic)
  - Chiari 1
  - Cerebral palsy, muscular dystrophy, spinal muscular atrophy, poliomyelitis
- Developmental (skeletal dysplasia or dysostosis)
  - Neurofibromatosis, achondroplasia, osteogenesis imperfecta
- Tumor associated: Osteoid osteoma, cord neoplasm, neurofibroma

Radiographic Findings

- Imaging evaluation depends on cause of scoliosis
  - Initial erect anteroposterior view from chin to greater trochanter
    - Posteroanterior on follow-up (less breast radiation)
  - Lateral for clinical concern of excessive kyphosis or lordosis
  - Cobb method of measuring scoliosis angle
    - Parallel lines to superior terminal vertebra superior endplate & inferior terminal vertebra inferior endplate
      - If endplates are not seen, use pedicles
    - Perpendicular intersecting lines then yield Cobb angle
    - Same vertebral bodies are used for follow-up measurements
    - Curve progression is present when > 5° between studies
- Lateral bending films to assess flexibility prior to surgery
- Skeletal maturity assessment (to determine potential curvature progression & timing of surgery)
  - Iliac crest apophysis ossification center appearance/fusion on scoliosis study
    - Iliac crest is divided into 4 quadrants; Risser grade is given according to ossification of iliac apophysis
    - Risser 0: No ossification; Risser 1: Only lateral 1/4 is ossified; Risser 4: All 4 quadrants are ossified; Risser 5: Fused iliac apophysis
    - At skeletal maturity, scoliosis unlikely to progress if < 30°
  - Posteroanterior view of left hand/wrist for bone age
- Assessment of balance
  - Central sacral vertical line (CSVL): Vertical line drawn on frontal view perpendicular to imaginary tangential line across top of iliac crests, bisects sacrum
  - Plumb line: Center of C7 parallel to radiographic edges extending distally
  - Coronal balance on standing frontal image: Distance between CSVL & plumb line: > 2 cm is abnormal
  - Sagittal balance: Distance between posterosuperior aspect of S1 vertebral body & plumb line: > 2 cm is abnormal
- Vertebral rotation
  - Nash-Moe method: Percentage of pedicle on convex side of curve displaced in respect to vertebral body width
- **Findings by curve types**
  - Idiopathic
    - Prevalence of typical curvature: Convex right thoracic curve > right thoracic & left lumbar > right thoracolumbar > right lumbar
    - Vertebral rotation is often present; lower lumbar spondylolysis may be present
  - Congenital
    - Failure of vertebral formation (wedge vertebra, hemivertebra)
    - Failure of segmentation (pedicle bar, block vertebra)
  - Tumor associated
    - Look for osseous remodeling or destruction
  - Neurofibromatosis
    - Many lack distinctive diagnostic features
    - Classic: High thoracic acute curvature, kyphosis, rib & pedicle anomalies, posterior vertebral scalloping, ± paraspinal mass
  - Neuromuscular
    - Tethered cord, syrinx, Chiari 1
    - Single long curve
- EOS system: Biplanar x-ray imaging
  - Several times ↓ radiation dose compared to conventional radiographs
  - ↑ artifacts

CT Findings

- NECT
  - Coronal, sagittal, & 3D reconstruction for surgical planning
  - Evaluates congenital vertebral anomalies
  - May be used to size pedicles for screws
  - Assess for pseudoarthrosis following spinal fusion

MR Findings

- Indications for MR
  - Congenital scoliosis
  - Neuropathic cause
  - Juvenile onset: 4-10 years
  - Suspected adolescent idiopathic but with atypical feature
    - Rapid progression of curve
    - Unusual curves: Convex left thoracic, long right thoracolumbar curve, double thoracic
    - Widened spinal canal or foramina, osseous lesion, foot deformity
    - Pain, headache, neck pain, neurologic deterioration
    - Debatable utility of MR without other indications; some literature reports 1/7 will have neuraxis abnormality

Ultrasonographic Findings

- Several papers report curve measurements by US
- 3D imaging for measuring vertebral rotation
- Measuring lengthening in magnetically controlled rods

Nuclear Medicine Findings

- Bone scan
  - SPECT imaging for pseudoarthrosis following spinal fusion surgery

DIFFERENTIAL DIAGNOSIS

Other Causes for Scoliosis

- Differentiated by clinical history, radiographic findings, & MR
  - Osteoid osteoma
  - Paraspinal tumor
  - Inflammation, infection
    - Many etiologies
  - Limb length discrepancy

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Usually asymptomatic
    - Idiopathic scoliosis usually detected during physical exam
  - Pain from progressive curvature or degenerative disc & facet disease

Demographics

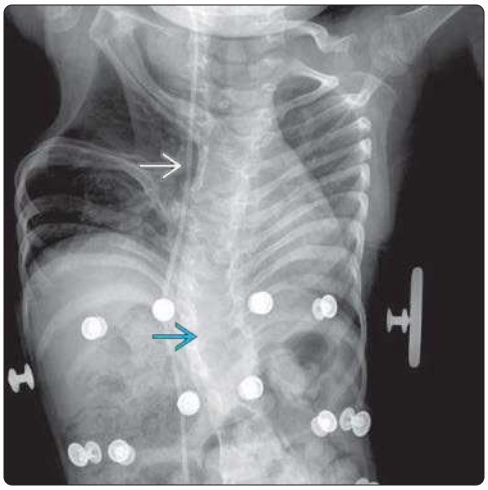
- Epidemiology
  - 0.2-0.5% of population in USA
- Sex: AIS: Female predilection
  - Girls tend to progress more than boys in idiopathic scoliosis

Natural History & Prognosis

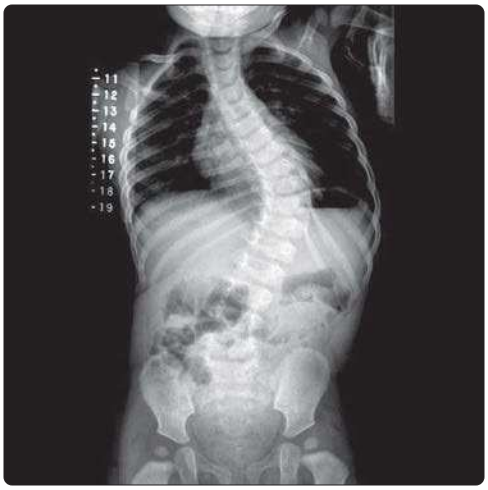
- Worsening curve in 10-25% of cases
  - During adolescent growth spurts
    - Younger patients with more severe curves at presentation are much more likely to progress than older children with less severe curves
  - Curves > 40-50° after skeletal maturity
  - Cardiopulmonary complications from severe scoliosis

Treatment

- Mehta casting for infantile scoliosis
- Idiopathic
  - Observe if < 20° in adolescent or < 30° in skeletally mature at presentation
  - Brace (orthotics)
    - ≥ 10 years
    - 25-45° at presentation (Risser 0-2)
    - > 25° with progression
  - Surgical
    - Curves > 45°
    - Progressive curves that fail bracing
    - Posterior spinal fusion with engagement of all 3 spinal columns (as by pedicle screw)
- Congenital
  - Observation
  - Surgical: With progressive curve
    - In situ fusion, anterior & posterior epiphysiodesis, hemivertebrae resection, reconstructive osteotomies
- Neuromuscular
  - Typical: Anterior & posterior spinal fusion
- Complications of surgery
  - Rod, screw, or wire breakage; slippage of hook; infection; spondylolysis; neurologic injury; superior mesenteric artery syndrome; pseudoarthrosis



DIAGNOSTIC CHECKLIST



Consider

- Atypical/painful scoliosis: MR to exclude spinal pathology

(Left) *AP radiograph shows numerous vertebral & rib anomalies throughout the spine. In addition to segmentation anomalies, there are multiple thoracolumbar levels with dysraphic bony elements ⇨ + a ventriculoperitoneal shunt ➡, suggesting a neurologic component to the curve as well.* **(Right)** *Frontal radiograph shows ~ 60° of convex leftward scoliosis of the spine from T7 to L2. This is a 1-year-old with the infantile type of idiopathic scoliosis.*

(Left) *Frontal radiograph (displayed from the orthopedic perspective) in a 12-year-old with back pain, café au lait spots, & neurofibromatosis type 1 (NF1) shows a short-segment, convex, right upper thoracic curvature. This dystrophic curvature is frequently associated with paraspinal plexiform neurofibromas.* **(Right)** *Axial T1 C+ FS MR in the same patient with NF1 shows lobular, enhancing paraspinal & intraspinal infiltrative lesions ➡ of plexiform neurofibromas.*

(Left) *Longitudinal US in a 4-year-old with infantile idiopathic scoliosis & magnetically controlled growing rod shows a 5-mm distance between the housing unit ⇨ & the neck of the extended part ⇨. This was performed in ultrasound prior to lengthening.* **(Right)** *Longitudinal US in the same child performed 5 minutes later (status post 3 mm of lengthening) shows that the distance between the housing ⇨ & neck ⇨ of the extending part now measures 8 mm, confirming success of the manipulation by the magnet.*

Tarsal Coalition

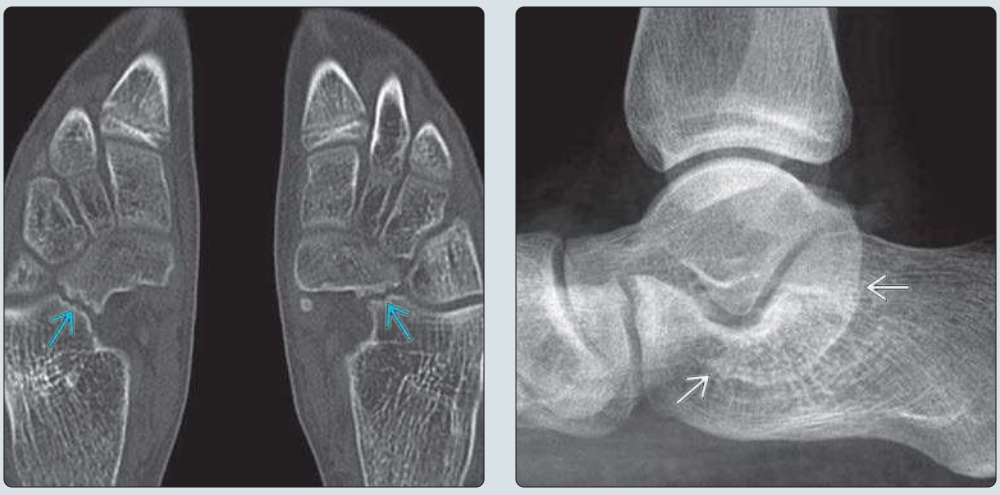
KEY FACTS

TERMINOLOGY

- Congenital or acquired abnormal fusion of ≥ 2 tarsal bones; fusion may be osseous, cartilaginous, or fibrous

IMAGING

- Tarsal coalitions
  - Calcaneonavicular (CN)
  - Talocalcaneal (TC)
  - Uncommon: Talonavicular, calcaneocuboid, cubonavicular
- CN coalition
  - 45° internal oblique foot radiograph view (Slomann view)
  - Anteater nose sign = elongation of anterosuperior calcaneus on lateral view
  - ± hypoplastic talar head
- TC coalition
  - Most common: Middle facet in up to 70%; posteromedial (posterior to middle facet) in up to 1/3; less common involvement of anterior or posterior facets
    - Extraarticular posteromedial TC coalitions lack classic indirect radiographic findings
  - Harris-Beath (axial) & lateral radiographic views are best
    - Difficult to see actual coalition, CT is often needed; many indirect signs
      - Talar beak
      - C sign: Continuous uninterrupted sclerotic line formed posteriorly by talar dome & sustentaculum tali on lateral view
      - Rounding of lateral talar process
      - Narrowing of posterior subtalar joint
      - "Ball-&-socket" ankle joint



CLINICAL ISSUES

- Recurrent sprains, midfoot pain, limited subtalar motion, peroneal spastic flatfoot
- 90% of all coalitions: TC or CN
- Up to 50% are bilateral
- Look for > 1 coalition in same foot (rare)

(Left) *Lateral radiograph in a 10-year-old girl with foot pain for 1 year shows elongation of the anterior process of the calcaneus (anteater nose sign) ➡. The oblique view (not shown) confirmed a calcaneonavicular (CN) coalition.* **(Right)** *Oblique foot radiograph in a 10-year-old shows narrowing of the CN articulation ⇨ with sclerosis & irregularity of the apposed navicular & calcaneus, consistent with a nonosseous coalition.*

(Left) *Coronal oblique bone CT images in the same patient confirm bilateral nonosseous CN coalitions with narrowing, irregularity, & sclerosis at the CN articulations ⇨.* **(Right)** *Lateral radiograph in a 15-year-old that presented with limited talar motion on physical examination shows a continuous C sign ➡ of a talocalcaneal coalition. The C-shaped line is formed superiorly by the medial talar dome & outline of the sustentaculum tali inferiorly.*

TERMINOLOGY

Synonyms

- Tarsal fusion

Definitions

- Congenital or acquired abnormal fusion of ≥ 2 tarsal bones
  - Union may be osseous, cartilaginous, or fibrous

IMAGING

General Features

- Best diagnostic clue
  - Close apposition or fusion of tarsal bones at/posterior to middle facet of talocalcaneal (TC) joint or calcaneonavicular (CN) joint at anterior process of calcaneus to navicular
- Location
  - Most common: CN, TC
    - Up to 1/3 of subtalar coalitions are at extraarticular posteromedial location (posterior to middle facet)
  - Uncommon: Talonavicular, calcaneocuboid, or cubonavicular
- Morphology
  - Synostosis = ossific bar
  - Synchondrosis = cartilaginous bar
  - Syndesmosis = fibrous union

Radiographic Findings

- Radiography
  - CN coalition
    - 45° internal oblique view (Slomann view) of foot
      - Ossific bar connects anterior process of calcaneus to dorsolateral navicular
      - Irregularity, sclerosis, or narrowing of CN space (fibrous or cartilaginous coalition)
    - Anteater nose sign: Elongation of anterosuperior calcaneus on lateral view
    - Broadening of medial aspect of anterosuperior calcaneus in close apposition to navicular
    - ± hypoplastic talar head
    - Radiography is typically diagnostic; other imaging may not be needed
  - TC coalition
    - Harris-Beath (axial) & lateral views
    - Difficult to see; CT is often needed
    - Most commonly at middle facet, though posteromedial extraarticular location may represent 1/3 of subtalar cases; less common involvement of anterior or posterior facets
    - Talar beak: Impaired subtalar motion → elevation stress at insertion of TC ligament → cycles of osseous repair → beak immediately adjacent to dorsal aspect of talonavicular joint (not specific for coalition)
    - Rounding or blunting of lateral talar process
    - C sign: Continuous uninterrupted sclerotic line formed by medial talar dome & sustentaculum tali on lateral view (50%)
      - False positive in some due to pes planus & abnormal positioning
    - Absent middle facet sign: Middle facet may be inapparent on lateral view
    - "Ball-&-socket" ankle joint: Concave surfaces of tibia & fibula, domed talus (convex proximal margin); uncommon & nonspecific
    - Narrowing of posterior subtalar joint
    - Normal middle & posterior facets are parallel to each other on Harris-Beath view; middle facet slants inferomedially in fibrous or cartilaginous coalition (bar in ossific coalition)
    - Extraarticular posteromedial TC can not be diagnosed by classic indirect radiographic signs
      - Prominence of posterior subtalar joint
- CT findings
  - Axial, coronal, & sagittal reformats
  - CN coalition
    - Joint space narrowing or reactive sclerosis
    - Widening of medial aspect of anterosuperior calcaneus
    - ± bony bridge
    - Best seen on axial or sagittal planes
  - TC coalition
    - Ossific bar (best on coronal images)
    - Downward (may be horizontal) orientation/sloping of sustentaculum along middle facet (normally slopes upward medially)
    - Reactive subchondral sclerosis & narrowing with cystic & hypertrophic changes of TC joint (especially middle facet)
    - ± broadening or hypoplasia of sustentaculum
      - Middle facet is shorter in posteromedial coalition

MR Findings

- T1WI
  - CN coalition
    - Sagittal & axial images are best for detecting coalition
    - Hypointense reactive changes
  - TC coalition
    - Most commonly at middle facet
    - Coronal image is best for detecting coalition
    - Osseous: Bar with marrow signal connection
    - Fibrous & cartilaginous: Hypointense signal connection with hypointense subchondral marrow changes
- T2WI
  - Ossific: Bone marrow contiguity across either TC or CN coalition
  - Cartilaginous: Hyperintense fluid signal connection with reactive, hyperintense subchondral bone marrow edema
  - Fibrous: Intermediate-signal connection with reactive, hyperintense subchondral bone marrow edema
  - Cartilaginous & fibrous: ↓ joint space

Imaging Recommendations

- Best imaging tool
  - Bone CT or 3-plane MR: TC coalition
  - 45° oblique radiograph: CN coalition

DIFFERENTIAL DIAGNOSIS

Subtalar Fractures

- Talar fractures
- Calcaneal fractures

Osteomyelitis

- Poorly defined marrow hyperintensity ± erosion or sinus tract
- Pain, fever, erythema; ↑ C-reactive protein, sedimentation rate, leukocytosis

Osteochondritis Dissecans

- Osteocartilaginous change at medial talar dome ± cysts, edema, sclerosis, fissuring, detached fragment
- Mostly adolescents, M > F

Juvenile Idiopathic Arthritis

- Synovitis with effusions, ± cartilage or bone erosions
  - Can eventually lead to ankylosis
- Reactive marrow edema
- ± tenosynovitis

PATHOLOGY

General Features

- Etiology
  - Congenital failure of segmentation & differentiation of primitive mesenchyme
  - Acquired: Trauma, infection, arthritis, or surgery
- Genetics
  - Autosomal dominance with high penetrance
- Associated abnormalities
  - Apert
  - Hand-foot-uterus syndrome
  - Proximal focal femoral deficiency
  - Hereditary symphalangism
  - Nievergelt syndrome

Staging, Grading, & Classification

- TC coalition classification scheme is based on 3D CT reconstruction (Rozansky et al.)
  - Type I: Linear coalition
  - Type II: Linear coalition with posterior hook
  - Type III: Shingled coalition
  - Type IV: Complete osseous coalition
  - Type V: Posterior coalition

Gross Pathologic & Surgical Features

- Osseous, fibrous, or cartilaginous connection

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Often asymptomatic in 1st decade of life
  - May lead to recurrent sprains, chronic midfoot pain, limited subtalar motion
- Other signs/symptoms
  - Commonly asymptomatic, discovered after imaging for trauma
  - Pes planus + heel valgus
  - Flattening of medial arch
  - Pain with activity
  - Peroneal spastic flatfoot
    - Rigid valgus deformity, pain, & peroneal muscle spasm
    - Tarsal coalition most common cause
    - Other causes: Fracture, arthritis, & some tumors
  - TC: Limited subtalar motion & prominence inferior to medial malleolus (double medial malleolus sign)

Demographics

- Age
  - Symptoms occur as coalition ossifies
    - Talonavicular (3-5 years)
    - CN (8-12 years)
    - TC (12-16 years)
- Sex
  - M > F
- Epidemiology
  - 1% incidence
  - 90% of all coalitions are TC or CN
  - Bilateral: 25-50%
  - Other tarsal coalitions are uncommon

Natural History & Prognosis

- Coalitions at birth may be fibrous or cartilaginous & later ossify
- Symptoms are more severe when coalition ossifies
- ↓ hindfoot motion makes child prone to ankle sprains
- Commonly discovered after imaging for ankle injuries

Treatment

- Initially conservative
  - Nonsteroidal antiinflammatory medication, arch supports, steroids, trial of casting, orthotics, & physical therapy
- Open surgical or arthroscopic resection
  - CN: Resection of bony bridge or arthrodesis
    - Fat autograft interposition, extensor digitorum brevis interposition
  - TC: Resection of middle facet bony bridge with fat interposition
  - If excision fails or if there is severe degenerative disease: Fusion or triple arthrodesis

DIAGNOSTIC CHECKLIST

Consider

- TC coalition: Coronal NECT or MR
- CN coalition: 45° internal oblique radiograph

Reporting Tips

- CT: Location & size of coalition; presence of other coalitions (bilateral or in same foot) or degenerative changes

(Left) *Coronal bone CT in a 12-year-old with bilateral ankle pain shows partial osseous bridging on the left & close apposition on the right at the posteromedial aspects of the middle facets with broadening & downsloping of each sustentaculum tali.* **(Right)** *Oblique radiograph of the foot shows an uncommon nonosseous coalition between the cuboid & navicular, evident by sclerosis, irregularity, & joint space narrowing.*

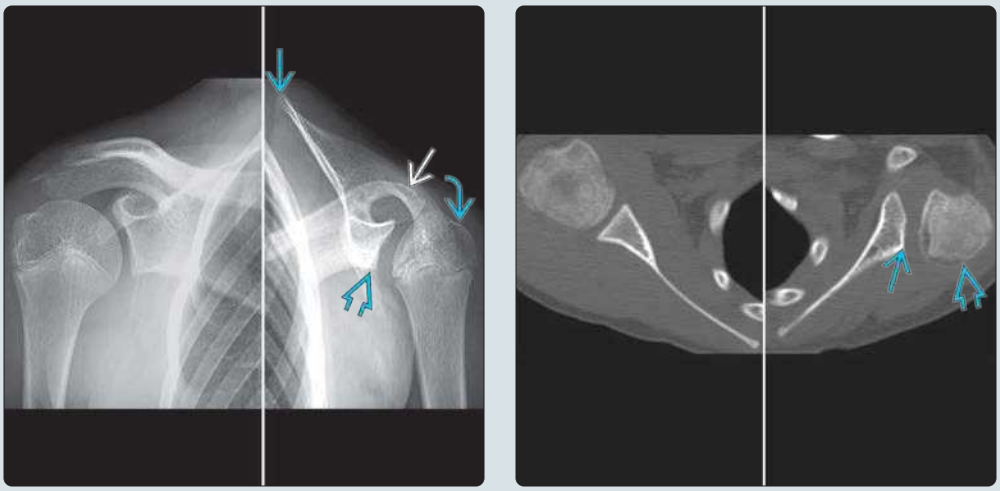
(Left) *Sagittal T1 MR in a 16-year-old with ankle pain shows a large osseous TC coalition of the middle facet. Note the talar beaking, a common secondary finding that is the result of impaired talar motion.* **(Right)** *Sagittal T1 MR in an 11-year-old with acute-on-chronic ankle pain shows irregularity & narrowing of the CN joint, indicating a nonosseous coalition. No other coalitions were found.*

(Left) *AP radiograph of the ankle in a 15-year-old after a football injury shows a lateral process fracture of the talus. Additionally, there is abnormal enlargement & orientation at the middle subtalar facet.* **(Right)** *Medial view of a 3D bone CT in the same patient shows the large posteromedial coalition with a largely intact middle facet.*

Brachial Plexopathy

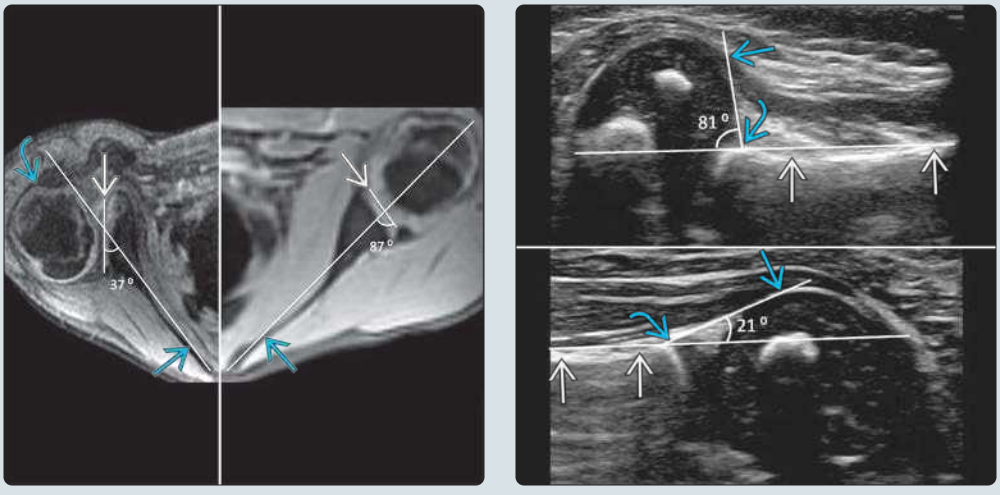
KEY FACTS

TERMINOLOGY



- Brachial plexopathy: Injury to ≥ 1 brachial plexus nerve roots, trunks, or cords → upper extremity contracture
- Glenohumeral dysplasia: Sequelae of brachial plexopathy on developing glenoid & humeral head

IMAGING



- Affected & unaffected shoulders imaged for comparison
- Radiographs
  - Dysplastic glenoid, winged scapula, hooked coracoid
  - Humeral head is small & ovoid
- Ultrasound
  - Uses posterior axial approach to glenohumeral joint
  - Can assess humeral head prior to ossification
  - α angle = angle between posterior scapular margin & tangent to humeral head from posterior edge of glenoid (normal ≤ 30°)
  - Percentage of humeral head posterior to scapular margin; humeral head ossification center should lie anterior to posterior scapular margin
- MR
  - Cartilage-sensitive GRE & PD FS sequences show unossified & ossified portions of glenoid & humeral head
    - Angle of glenoid version
      - ↑ retroversion with ↑ glenohumeral dysplasia
      - > 5° difference to unaffected side is abnormal
    - Percentage of humeral head anterior to scapular line
      - ~ 50% normally; ↓ with ↑ glenohumeral dysplasia
  - T1 shows fatty atrophy of shoulder musculature

CLINICAL ISSUES

- Shoulder traction at delivery → nerve injury → muscle imbalance → unopposed internal rotation → posterior glenoid/anterior humeral head cartilage loading → glenohumeral dysplasia → posterior subluxation
- Most deficits recover by 3 months; 20-30% are permanent

(Left) *Frontal radiographs of the normal right shoulder (left) & abnormal left shoulder (right) in a 12-year-old with glenohumeral dysplasia secondary to a left brachial plexopathy show a small, ovoid left humeral head, winging of the left scapula, a hooked coracoid, & a dysplastic left glenoid.* **(Right)** *Axial NECT images of the right (left) & left (right) shoulders in the same girl show that the small left humeral head is posteriorly displaced, articulating with a false glenoid.*

(Left) *Axial GRE MR of abnormal right (left) & normal left (right) shoulders shows a low right glenoscapular angle (between the scapular & glenoid lines) with the humeral head posterior to the scapular line.* **(Right)** *Posterior axial US of the left shoulder (top) in an infant with left brachial plexopathy shows a high α angle (between the posterior scapular margin & a tangent to the humeral head from the posterior glenoid), indicating posterior subluxation. The right α angle (bottom) is normal.*

TERMINOLOGY

Synonyms

- Neonatal/perinatal brachial plexus palsy, birth palsy, brachial plexus birth injury (BPBI), shoulder contracture

Definitions

- Brachial plexopathy: Injury to ≥ 1 brachial plexus nerve roots, trunks, or cords → upper extremity contracture
- Glenohumeral dysplasia: Sequelae of brachial plexopathy on developing glenoid & humeral head

IMAGING

General Features

- Best diagnostic clue
  - Retroverted glenoid + posteriorly displaced humeral head

Radiographic Findings

- Small & ovoid humeral head
- Dysplastic glenoid, winged scapula, hooked coracoid

Ultrasonographic Findings

- Assesses humeral head prior to ossification
- Uses posterior axial approach to glenohumeral joint
- Measurements made with neutral, internal, & external rotation of humerus
- α angle: Angle between posterior scapular margin & tangent to humeral head from posterior edge of glenoid
  - Normal ≤ 30°
- Percentage of humeral head posterior to posterior scapular margin
  - Humeral head ossification center normally lies anterior to posterior scapular margin
    - Posterior position indicates posterior subluxation

MR Findings

- GRE & PD FS: Cartilage-sensitive sequences show unossified & ossified portions of glenoid & humeral head
- T1: Shows fatty atrophy of shoulder musculature
- Measurements on axial images
  - Glenoscapular angle (GSA): Posterior angle between scapular & glenoid lines
    - Scapular line: Line connecting medial most scapula & midglenoid cartilage
    - Glenoid line: Line parallels glenoid articular cartilage
  - Glenoid version angle = GSA -90°
    - Negative number = glenoid retroversion
    - > 5° more retroversion vs. unaffected side indicates glenoid dysplasia
  - Percentage of humeral head anterior to scapular line (PHHA)
    - Normal ~ 50%; ↓ with ↑ glenohumeral dysplasia
- Recent papers show abnormal scapular position of affected shoulder → inaccurate measurement of GSA & PHHA
  - Corrected by measuring on reconstructed images truly axial to scapula (from 3D data set)
  - Another study found "modified Friedman method" to give similar values to 3D reformatted method

Imaging Recommendations

- Best imaging tool
  - MR provides best overall articular & soft tissue evaluation
- Protocol advice
  - Compare affected vs. unaffected shoulders

DIFFERENTIAL DIAGNOSIS

Pseudoparesis of Upper Extremity

- Due to birth trauma → clavicular or humeral fracture

Arthrogryposis

- Infant born with ≥ 2 joint contractures

Cervical Spinal Cord Injury

- Affects bilateral extremities + bladder & bowel function

PATHOLOGY

General Features

- Etiology
  - Shoulder traction at delivery → nerve injury → muscle imbalance → internal rotation → posterior glenoid/anterior humeral head cartilage loading → glenohumeral dysplasia → posterior subluxation
    - Subluxation develops gradually in 1st year of life in infants with more severe birth injuries

Staging, Grading, & Classification

- Birch glenoid classification: Concave-flat, convex, biconcave
- Waters classification system: Glenoid version, humeral head coverage/position, ± pseudoglenoid

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Depends on level of injured nerves (C5-T1)

Demographics

- Epidemiology: 1-3 per 1,000 live births in USA

Natural History & Prognosis

- Most BPBI patients have temporary injuries & recover by 1-3 months of age; persistence depends on
  - Type of nerve injury
  - Number of roots involved
- 20-30% have residual neurologic deficits at 3 years
  - Posterior humeral head subluxation in up to 33% of permanent BPBI

Treatment

- Conservative: Physical therapy, Botox injections, & closed reduction
- Surgical: Anterior soft tissue release ± tendon transfers

Hemophilia

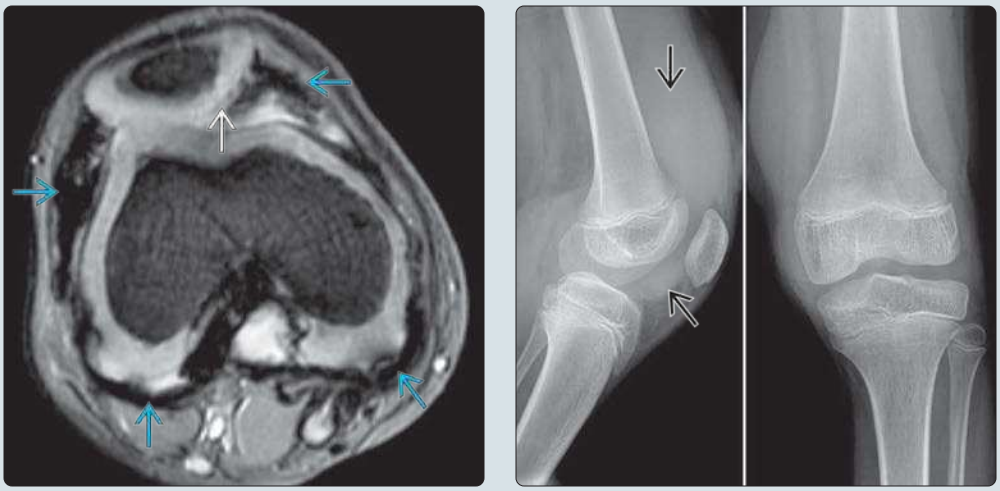
KEY FACTS

TERMINOLOGY

- X-linked recessive bleeding disorder resulting from clotting factor deficiencies
  - Hemophilia A (> 80% of cases): Factor VIII deficiency
  - Hemophilia B (< 15% of cases): Factor IX deficiency
- Hemophilic arthropathy: Progressive joint destruction due to recurrent hemarthrosis, synovitis, & erosions

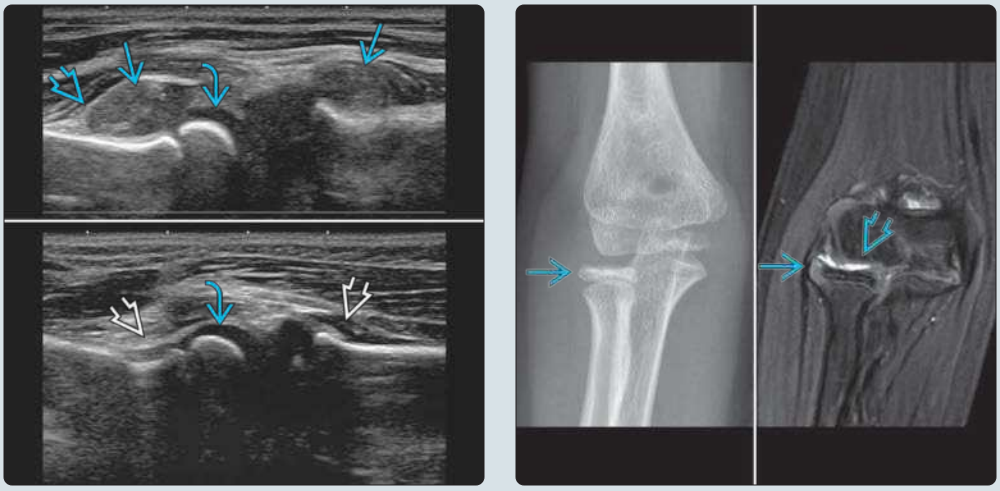
IMAGING

- Location of arthropathy: Ankle > knee, elbow > shoulder
- Radiographs
  - Distention of joint capsule by effusion & synovitis with eventual cartilage damage, erosions, & subchondral cysts
- MR
  - Variable signal intensity & heterogeneity of effusions due to blood products of different ages
  - Chronic hemosiderin deposits line synovium
    - Low signal intensity on all sequences with characteristic blooming of signal loss on T2* GRE
  - Eventual development of osteocartilaginous erosions
- US
  - Effusion of variable echogenicity/complexity
  - Synovial thickening with hyperemia by Doppler
  - Thinning, irregularity of hypoechoic cartilage



TOP DIFFERENTIAL DIAGNOSES

- Synovial venous malformation
- Pigmented villonodular synovitis
- Juvenile idiopathic arthritis



CLINICAL ISSUES

- Prevention: Early initiation of aggressive prophylaxis regimen with clotting factors
  - Significantly ↓ joint bleeds & chronic degeneration
- Acute hemarthrosis: Factor replacement + joint aspiration
- Chronic hemarthrosis: Synovectomy (surgical or radiosynovectomy); arthroplasty

(Left) *Axial T2* GRE MR of the knee in a 7-year-old with hemophilia A shows extensive blooming (exaggerated signal loss) along the joint capsule due to prior episodes of hemarthrosis. Early cartilage irregularity is seen at the patellar medial facet.* **(Right)** *Lateral & AP knee radiographs in the same patient 6 years later at a time of swelling show a large dense joint effusion. The epiphyses are mildly large & irregular due to repeated hemarthroses & synovitis causing local hyperemia & cartilage damage.*

(Left) *Sagittal US of the right (top) & left (bottom) elbows in a child with hemophilia A & right arm swelling shows a complex effusion anterior to the distal right humerus & radial neck. There is anterior fat pad displacement. No effusion is seen on the left. Normal hypoechoic humeral capitellar cartilage is seen bilaterally.* **(Right)** *AP radiograph (left) & T2 FS MR (right) in the same patient 3 years later show overgrowth & irregularity of the radial head with associated cartilage loss at the radiocapitellar articulation.*

TERMINOLOGY

Synonyms

- Hemophilia A: Factor VIII deficiency
- Hemophilia B: Factor IX deficiency, Christmas disease

Definitions

- Hemophilia: X-linked recessive bleeding disorder due to clotting factor deficiencies
- Hemophilic arthropathy: Spontaneous bleeding into joint → inflamed & friable synovium → recurrent bleeding → pain & loss of function with accelerated joint degeneration
- Hemophilic pseudotumor: Nonneoplastic mass from focally recurrent intraosseous, subperiosteal, or soft tissue bleeds

IMAGING

Radiographic Findings

- Hemophilic arthropathy: Historically common; substantially ↓ now due to aggressive factor replacement regimens
  - Distention of joint capsule by effusion & synovitis
  - Hyperemia leads to
    - Overgrowth (ballooning) of epiphyses
    - Premature physeal fusion → limb shortening
  - Inflammatory synovitis → cartilage destruction, erosions, subchondral cysts, recurrent bleeds
- Hemophilic pseudotumor (very uncommon)
  - Intraosseous: Large expansile or lytic bubbly lesion with mass effect on adjacent tissues
  - Subperiosteal or soft tissue: Extrinsic scalloping of bone

Ultrasonographic Findings

- Effusion (hemorrhage) showing variable complexity
  - Simple fluid & hemorrhagic fluid are not reliably differentiated by US
- Synovial thickening with hyperemia by Doppler
  - ↑ power Doppler signal of synovium → ↑ bleeding risk
- Thinning & irregularity of hypoechoic cartilage ± bone erosions at margins of joints
  - US is limited at central articular surfaces

MR Findings

- Hemophilic arthropathy
  - Variable signal intensity & heterogeneity of effusions due to blood products of different ages
  - Chronic hemosiderin lines synovium
    - Low signal intensity on all sequences with characteristic blooming of signal loss on T2* GRE
    - Hypertrophied enhancing synovium
  - Eventual development of osteocartilaginous erosions

Imaging Recommendations

- US for acute hemarthrosis
- MR provides superior assessment of entire joint

DIFFERENTIAL DIAGNOSIS

Pediatric Arthropathies

- Synovial venous malformation
  - Blood-filled intraarticular mass → hemarthrosis, synovitis, erosions, degeneration
  - Infiltrating or discrete lobular &/or tubular fluid signal intensity masses with septations
    - ± fluid-fluid levels, thrombi
- Pigmented villonodular synovitis
  - Diffuse intraarticular form: Intermixed hemosiderin deposits & enhancing proliferative synovium often have radiating frond-like appearance
- Juvenile idiopathic arthritis
  - Joint effusion ± rice bodies; blood products are rare
  - Synovitis → erosions & growth disturbances
    - Similar chronic radiographic appearance to hemophilia

PATHOLOGY

General Features

- Etiology
  - Sites of bleeds depend on clotting factor levels
    - Musculoskeletal system (exposed to repetitive mild trauma) accounts for up to 90% of sites
      - Joints: 70-80%; muscles: 10-20%

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Acute hemarthrosis: Tense, swollen, red, painful joint occurring spontaneously or with minor trauma
  - Subacute or chronic hemarthrosis: Degenerative arthrosis, ↓ range of motion, contractures

Demographics

- Age
  - 1st episode of joint hemorrhage by 2-3 years of age
- Epidemiology
  - Hemophilia A (> 80% of cases): 1 in 5,000 male patients
  - Hemophilia B: 1 in 30,000 male patients

Natural History & Prognosis

- Hemarthrosis classically occurs in 70-90% of cases
  - Substantial reduction in modern era by early initiation of aggressive prophylactic replacement of synthetic clotting factors
    - Patients may develop antibodies (inhibitors) to replacement clotting factors: Up to 30% of severe A vs. 2% of B

Treatment

- Hemophilic arthropathy
  - Acute bleed: Clotting factor, joint aspiration
  - Chronic: Synovectomy (surgical vs. radiosynovectomy); intraarticular hyaluronic acid; if end stage → arthroplasty

Overview

This 4th edition of *Diagnostic Imaging: Pediatrics* presents another great opportunity to expand & update the neuroradiology sections. As in the 3rd edition, we continue to add new diagnoses to the book. Length constraints mean that many diagnoses are only 1 or 2 pages long. We hope readers will see the increased number of diagnoses as outweighing the decreased in length & will explore the additional material in the Elsevier eBook & Expert Consult, where they will find expanded descriptions, case examples, & selected references to support the printed text.

The most difficult task in organizing the Brain section is deciding what to include & what to leave out. The brain section is divided into 6 subsections: Normal Developmental Variation, Congenital Malformations, Phakomatoses, Cysts & Neoplasms, Traumatic & Vascular Lesions, & Metabolic, Infectious, & Inflammatory Disorders. The included diagnoses are not meant to be all-encompassing but were selected to be the most helpful to the pediatric radiology practitioner. Some topics, such as pineal cyst & enlarged perivascular spaces, are included because they are so common. Conversely, metabolic brain diseases are rarely encountered but are complex entities that may be overwhelming to approach without a resource to provide direction. Some diagnoses that are not exclusively pediatric, such as cerebral venous sinus thrombosis, often get overlooked in specialty texts but have been included here because they constitute an important pathology for which we can provide a unique pediatric perspective.

As in the transition from the 2nd edition to the 3rd edition, there have been a number of changes to the neoplasm diagnoses in this edition. With an increasingly rapid evolution of our understanding of the molecular & genetic underpinnings of pediatric CNS tumors, we have seen previous diagnoses (e.g., CNS PNET) disappear from the WHO tumor classification lexicon, while others (e.g., embryonal tumor with multilayered rosettes) have grown up in their place. Not unexpectedly, the new 2021 WHO CNS classification increasingly relies on the molecular & genetic profile of tumors with a trend towards subgrouping of tumors, which previously represented a single diagnosis. Some tumors, which were once considered to be similar because they looked similar under the microscope, are now understood to represent remarkably unique tumors molecularly & genetically. Possibly the best example of this is ependymoma, which was previously addressed in the 3rd edition as a single chapter but is now split into posterior fossa ependymoma & supratentorial ependymoma. This change reflects the recent advances that show these tumors to be distinct entities based upon their genetic & molecular profiles. Posterior fossa ependymomas are subdivided into PFE-A & PFE-B with unique clinical & prognostic profiles. Supratentorial ependymomas are divided into those with *RELA* fusion & those without (e.g., *YAP1* fusion). The trend towards increased molecular subtyping of CNS tumors has driven forward remarkably targeted therapies. A great example of this is the targeting of the RAS-MAPK pathway in low-grade glial tumors with *BRAF* mutations. As radiologists, we have come to discover a number of important imaging markers that correlate well with molecular subtypes in pediatric CNS tumors, including both medulloblastoma & ependymoma. It is expected that radiogenomics, or the correlation of imaging & molecular data, will be a major area of research & clinical interest in the coming years.

Terminology

There is a constant process in science & medicine of renaming entities to more accurately reflect new knowledge gained. This can make understanding, teaching, & researching these disease processes difficult. When a disease has many names, a comprehensive literature search becomes significantly more difficult to confidently perform. For this reason, we have made every effort to be comprehensive in listing the synonyms used both in the past & present to describe certain disease processes. We have also updated the titles of certain diagnoses (e.g., white matter injury of prematurity rather than periventricular leukomalacia, & hypoxic-ischemic encephalopathy rather than perinatal asphyxia) to reflect evolving descriptions found in recent medical literature.

Normal Development

One of the great challenges in pediatric neuroimaging is understanding the dynamic development of the human brain from the fetus to the adult. Understanding this normal development allows for accurate identification of normal vs. abnormal & gives the imaging professional a conceptual framework to understand many CNS diagnoses, especially the congenital malformations. For instance, when evaluating a fetal MR of the brain, it is critical to know the expected sulcation pattern for a given gestational age in order to identify possible malformations of cortical development. A delayed sulcation pattern may suggest a malformation of cortical development on the spectrum of lissencephaly or gyral simplification, whereas the presence of too many sulci for gestational age may suggest polymicrogyria.

During the first 2 years of life, an understanding of the normal myelination pattern allows for accurate identification of conditions associated with delayed myelination (e.g., Pelizaeus-Merzbacher disease). Because understanding normal myelination is so critical, this edition includes a 4-page chapter dedicated to the topic. Another important point regarding myelination is that certain diseases have very different imaging characteristics during the 1st year of life compared with later years. A prime example of this can be seen in tuberous sclerosis in which cortical tubers & radial migration lines are T1 hyperintense & T2 isointense prior to myelination & exactly the opposite (T1 hypointense & T2 hyperintense) following myelination. Tuberous sclerosis is just one of many diagnoses with such dynamic imaging characteristics over time.

One final example of the importance of understanding normal CNS development can be found in the pituitary, which undergoes both age- & sex-specific changes in size & signal characteristics with time. The anterior pituitary in the newborn is very T1 hyperintense, often equal to that of the posterior pituitary. This is normal & should not be mistaken for hemorrhage or other pathology. This hyperintensity is presumed to be related to maternal hormones, as the same finding is not seen in early premature infants when imaged at term-equivalent age. The anterior pituitary slowly decreases in T1 signal intensity & becomes isointense to the pons after the 1st few months of life. Regarding pituitary size, the normal pituitary often has a convex superior margin at birth, slowly becoming flat or concave over the ensuing weeks, an appearance that is typically maintained in male patients throughout life & in female patients until puberty. The imaging professional should not be alarmed to see an enlarged pituitary with a convex superior border in a teenage

girl. This is a normal appearance in this age & sex should not in & of itself raise suspicion for a pituitary lesion.

Hydrocephalus

Hydrocephalus is a distressingly common entity in pediatrics, the consequence of a multitude of primary pathologies that result in alterations in the production, distribution, & resorption of CSF. Traditional views of intracranial fluid management as related to the choroid plexus, ventricles, subarachnoid space (SAS), arachnoid granulations, pia, arachnoid, & dural sinuses to manage the flow & distribution of interstitial fluid (ISF) have recently expanded to include the glymphatic system, which is a network of perivascular channels involved in fluid, nutrient, & metabolite exchange between the CSF & ISF.

Obstruction within the ventricular system will prevent egress of intraventricular CSF into the SAS, & increased pressure within the ventricles will cause ISF to accumulate in the periventricular white matter (transependymal edema). Elevated pressure in the dural sinuses will prevent the transmission of CSF from the SAS into the sinuses, as will alteration in arachnoid granulation function caused by inflammation or metabolic disorders (communicating hydrocephalus).

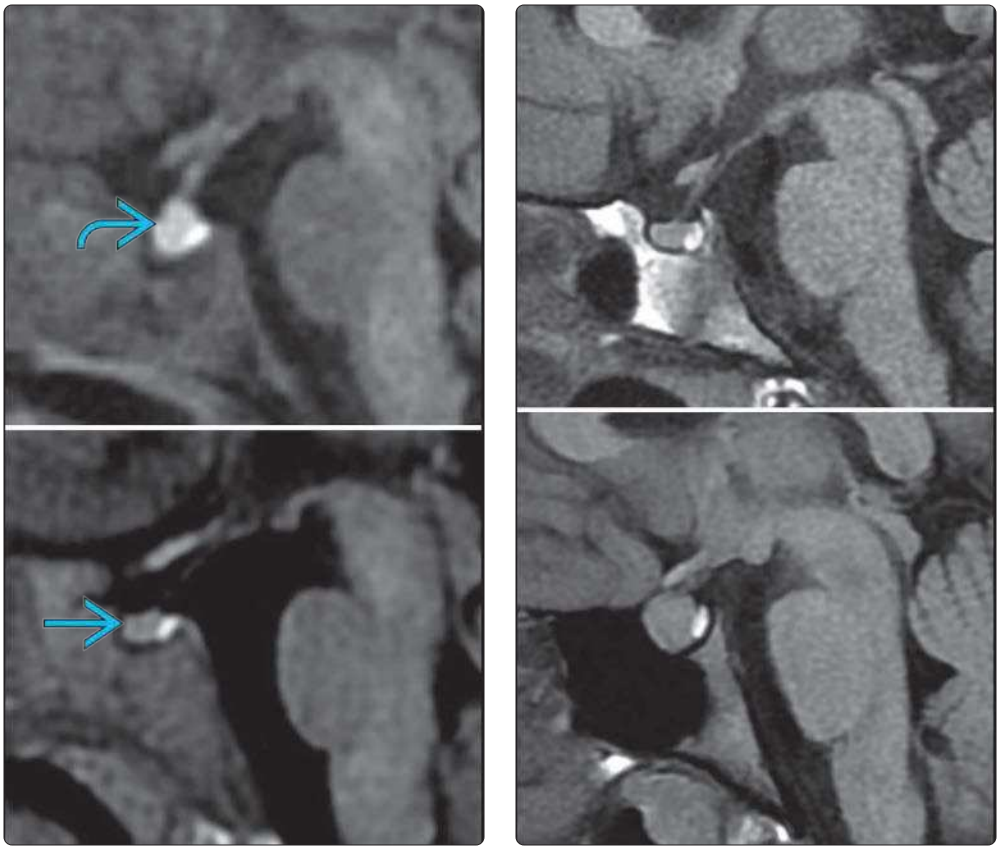
Cerebral Edema

A common & important neuroimaging finding is the development of brain edema, of which 4 basic types are recognized. Vasogenic edema reflects expansion of the ISF compartment in response to an irritating stimulus, such as tumor or inflammation. Cytotoxic edema is due to expansion of the intracellular fluid compartment secondary to failure of the sodium-potassium pump regulation of the cell membrane. In transependymal edema, increased hydrostatic pressure in the ventricular system prevents the normal progression of ISF into the ventricles & causes congestion in the periventricular white matter. Perhaps the least understood is posttraumatic edema, in which diffuse brain swelling is caused by a combination of cytotoxic & vasogenic edema resulting from a cascade of events that include sodium-potassium pump failure, diminished cerebral perfusion & autoregulation, & loss of integrity of the blood-brain barrier. Posttraumatic cerebral edema typically sets in several hours after the initial injury & can lead to rapid increase in intracranial pressure & death. Clinical management of traumatic brain injury usually includes imaging reassessment within the first 12 hours after presentation to look for progression of initially identified injuries, such as contusions & intracranial hemorrhage. The radiologist must be diligent in looking for signs of increased brain swelling at this time also; such signs include effacement of previously identifiable sulci at the vertex & decrease in size of basal cisterns. The presence of these signs should lead to more aggressive monitoring & management of intracranial pressure. Waiting until clinical signs develop is too late to effectively combat the cycle of reduced cerebral perfusion & progressive cellular injury. Diffuse cerebral edema is the leading cause of death from cases of child abuse, & the traumatic nature of the insult may not be readily apparent at first presentation. Nontraumatic insults, such as acute encephalitis & status epilepticus, can also lead to this potentially fatal complication.

Imaging Protocols

The development & use of high-quality indication-specific imaging protocols are essential to the practice of pediatric neuroradiology. For CT imaging in the age of the Image Gently campaign, much of the focus has been appropriately on the reduction of radiation exposure to the patient. When an indicated CT exam is performed, it is imperative that we extract the maximum information from this study. One of the best ways to do so is to perform multiplanar reconstructions (MPR) in coronal & sagittal planes. MPRs have been shown to ↑ the detection of small intracranial hemorrhages & reduce the number of false-positives by accurately characterizing some findings as artifactual. The same can be said for the detection of skull fractures, which is improved with MPR as well as 3D surface rendering.

Brain MR protocols for the neonate should be adjusted to confidently identify perinatal injuries, congenital malformations, & metabolic derangements. For the infant younger than 3 years, a focus on myelin maturation is key with T1 included in all protocols. Conversely, FLAIR sequences are typically avoided in the child under 24 months, as these may cause confusion in the incompletely myelinated brain. For the child over 24 months, adult-type sequences can be employed but should be specifically tailored to answer the clinical question at hand.



Volumetric MR is becoming increasingly important in pediatric imaging with most weightings (e.g., T1, T2, PD, FLAIR, & SSFP) now available on most platforms. Volumetric imaging is optimal for tumor follow-up, giving the imaging professional confidence in tumor size measurements from one exam to the next. Volumetric FLAIR has become a critical sequence in seizure protocols to increase sensitivity for the often subtle findings of focal cortical dysplasia. 3D SSFP (e.g., FIESTA, CISS) images remove CSF flow artifact & provide high spatial resolution for the optimal evaluation of masses with a CSF interface. Finally, volumetric imaging is helpful because it allows reconstruction in multiple planes with no penalty in exam length.

Pediatric radiologists should be eager to employ advanced MR techniques, such as diffusion tensor imaging (DTI), susceptibility weighted imaging (SWI), arterial spin labeling (ASL), & vessel wall imaging. DTI provides high-quality DWI & ADC derivatives, & the ability to perform tractography is very helpful in preoperative tumor & epilepsy planning. SWI provides highly sensitive detection of hemorrhagic foci in the brain parenchyma & important insight into the vascular supply to tumors & malformations. ASL provides the opportunity to acquire brain perfusion information without the need for contrast administration, opening the door for perfusion imaging in the routine setting. Finally, vessel wall imaging is becoming an increasingly important technique for identifying inflammatory arteriopathies in children.

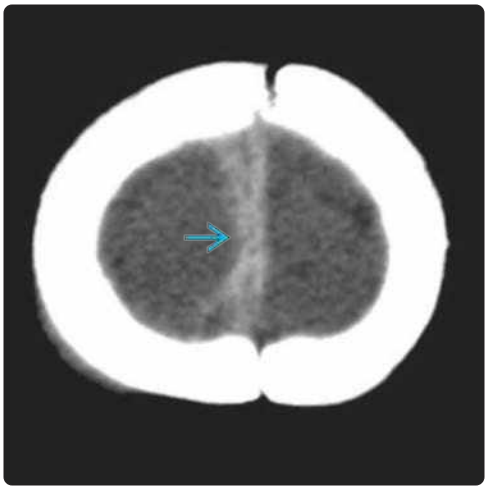
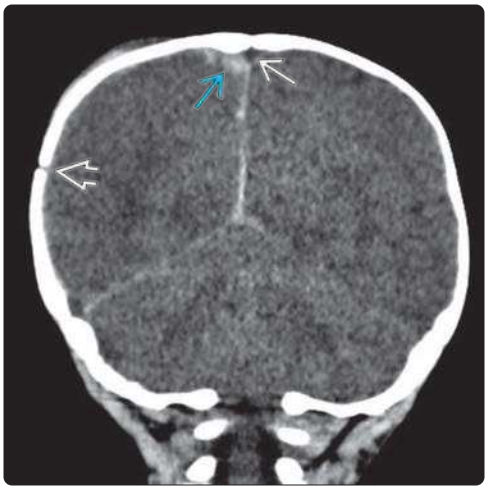
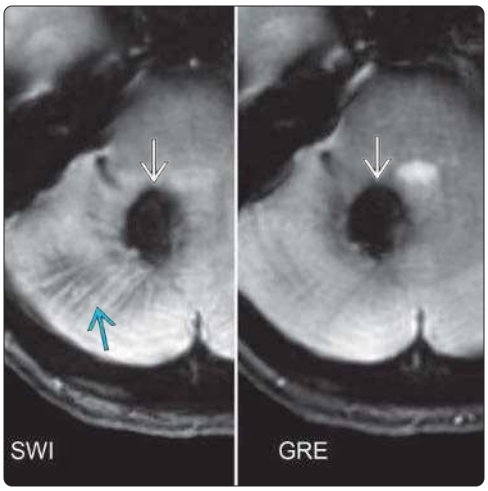
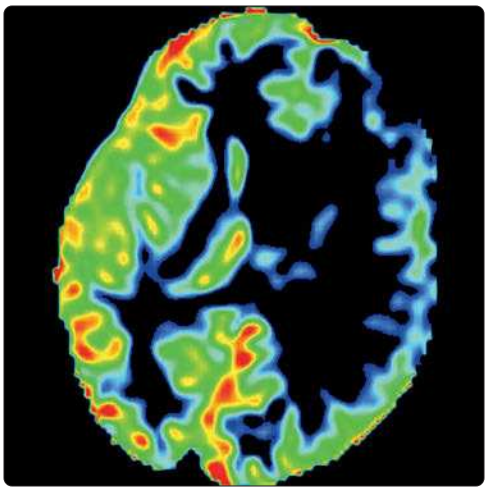
(Left) *Sagittal T1 MR images in a 7-day-old infant (top) & a 2-month-old infant (bottom) show the typical imaging evolution of the neonatal anterior pituitary, which is often very hyperintense (sometimes equal to the posterior pituitary) early with a superior convex border. This signal & morphology are presumably related to maternal hormones, as early premature infants imaged at term-equivalent ages do not have this appearance. Over the 1st few weeks of life, the anterior pituitary becomes isointense to the pons with a flat or concave superior border.* **(Right)** *Sagittal T1 MR images in a 6-year-old girl (top) & a 17-year-old girl (bottom) show typical appearances of the anterior pituitary at these ages. An enlarged (up to 9-mm vertical) anterior pituitary with a convex, superior border in a teenage girl should not raise concern.*



(Left) *Sagittal T1 MR images at 2, 4, 7, & 10 months (top to bottom, respectively) show development of the corpus callosum during the 1st year of life. Progressive myelination & thickening of the corpus callosum begin with the posterior body & splenium. The posterior 1/2 of the corpus callosum continues to thicken as the anterior body, genu, & rostrum begin to myelinate at 4 months. By the end of the 1st year of life, the corpus callosum is completely myelinated with uniform signal intensity.* **(Right)** *Axial T1 MR images in a patient with tuberous sclerosis complex at 3 months (top) & 10 months (bottom) show that, prior to significant myelination, the cortical tubers & radial migration lines are hyperintense. Following myelination, these lesions show varying degrees of hypointensity compared with adjacent white matter.*







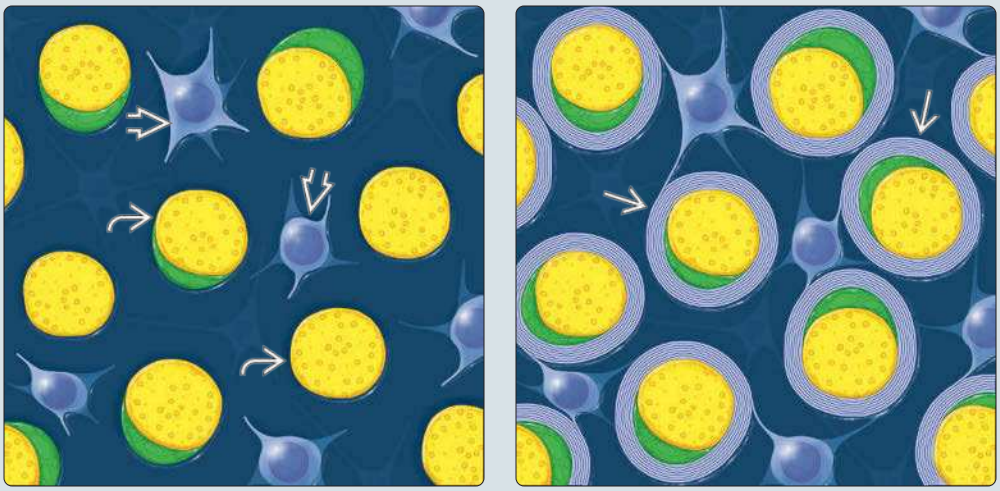
(Left) *Midline sagittal T2 MR in a 6-year-old child with a tectal mass shows obstruction of the cerebral aqueduct with mass effect on the midbrain. Treatment is an endoscopic 3rd ventriculostomy, which appears patent as evidenced by the dark flow artifact across the floor of the 3rd ventricle.* **(Right)** *Axial FLAIR MR in a 19-year-old man with a pineal germinoma shows ventriculomegaly with transependymal edema in the frontal & occipital regions (where hydrostatic pressure of interstitial fluid is highest).*

(Left) *Axial NECT in a 6-month-old infant with nonaccidental trauma shows hyperdensity in the region of the superior sagittal sinus. With axial images alone, it can be difficult to distinguish subdural hemorrhage from venous sinus thrombosis.* **(Right)** *Coronal NECT in the same patient clearly delineates the superior sagittal sinus from the adjacent subdural hemorrhage. Also note the axially oriented right parietal bone fracture, which was difficult to see on axial images.*

(Left) *Axial SWI (L) & T2* GRE (R) MRs in a patient with a cavernous malformation show the ↑ conspicuity of the associated developmental venous anomaly on SWI compared with GRE.* **(Right)** *Axial ASL in a 10-year-old boy with Sturge-Weber syndrome shows substantially ↓ perfusion within the left frontal lobe (which was severely affected with pial angiomatosis & parenchymal atrophy). ASL is a perfusion technique that does not require contrast administration.*

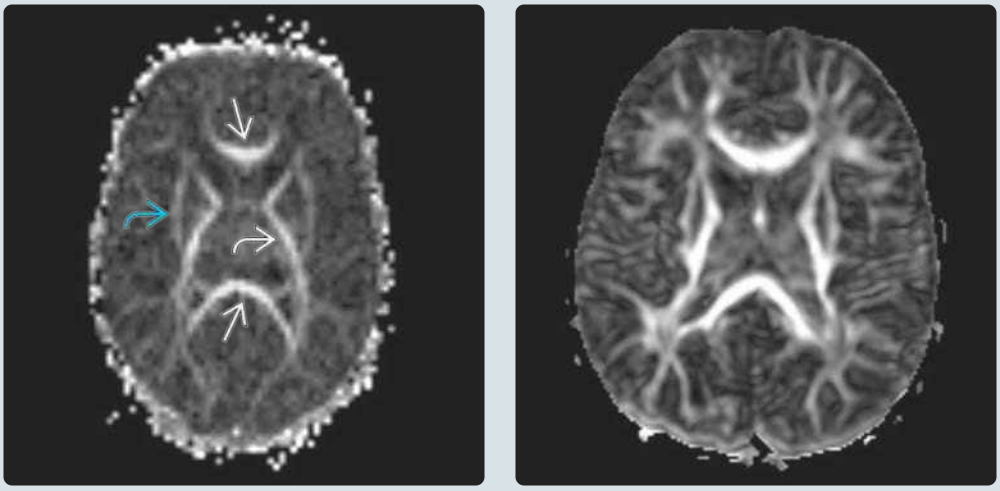
Normal Myelination

KEY FACTS



IMAGING

- T1 is key sequence in assessing myelination < 1 year
  - Bright signal reflects presence of proteolipid protein (PLP)
  - Extent of bright signal on T1 reflects distribution of myelinating oligodendrocytes in infant brain
- T2 is key sequence in assessing myelination in children 1-2 years of age
  - As myelin sheaths thicken, surrounding interstitial (extraaxonal) water is displaced
  - Less interstitial water → darker signal on T2
  - Drop in T2 signal lags considerably behind presence of bright T1 signal
- PD/intermediate echo images are especially valuable < 24 months
  - Very helpful in distinguishing gliosis from lack of myelination
  - Gliosis is brighter than terminal zones
- Difficult to distinguish pathology from normal in infant on FLAIR
- Presence of myelin has significant effect on ability of water to diffuse
  - Fractional anisotropy (FA) ↑ with brain maturation



DIAGNOSTIC CHECKLIST

- MR demonstration of normal myelination closely parallels developmental functional milestones
  - Assessment of myelination is essential aspect of interpreting MR in children
    - Analogous to documentation of developmental milestones by pediatrician
- Know gestational age before assigning myelination stage
  - Normal myelination milestones are based upon postconception age, regardless of degree of maturity at delivery

(Left) *Oligodendrocytes lie in proximity to axons after migration. The presence of proteolipid protein in the oligodendrocytes results in T1 shortening (T1 bright signal) on MR, but the large amount of interstitial water (dark blue background) results in T2 prolongation (T2 bright signal) on MR.* **(Right)** *With time, the oligodendrocytes lay down multiple layers of myelin around each axon. As it thickens, the hydrophobic myelin drives out the interstitial water, causing reduced T2 signal (or T2 shortening) on MR.*

(Left) *Axial fractional anisotropy (FA) map in a newborn shows bright signal in the corpus callosum & internal & external capsules, reflecting the relatively dense axonal population & early myelination in these regions. FA maps can demonstrate white matter tracts prior to their delineation on conventional MR sequences.* **(Right)** *Axial FA map in a 9-month-old shows extension of bright signal throughout the brain, reflecting the greater structural organization resulting from myelination.*

TERMINOLOGY

Synonyms

- Myelin maturation, white matter (WM) development

Definitions

- Process of myelin sheath development around axons throughout CNS
  - Begins in 5th fetal month & continues throughout life

IMAGING

General Features

- Best diagnostic clue
  - Appearance of myelination on imaging reflects presence of proteolipid & its effect on interstitial water
  - Myelin development correlates with functional milestones
- Location
  - In general, myelin maturation proceeds caudal to rostral, central to peripheral, dorsal to ventral
- Size
  - WM tracts, especially corpus callosum, ↑ in size with myelin formation
- Morphology
  - Diffusion tractography can demonstrate morphology & integrity of developing tracts

CT Findings

- NECT
  - Gray matter (GM)-WM differentiation is accentuated in neonate due to high water content of WM
    - Unmyelinated WM is hypodense relative to GM & to myelinated WM
      - Reflects high ratio of interstitial water:axons
  - Density ↑ with myelination is relatively subtle, making CT insensitive to detecting delays in myelination

MR Findings

- T1WI
  - Key sequence in assessing myelination < 1 year
  - Bright signal reflects presence of proteolipid protein (PLP)
    - PLP is expressed by mature (myelinating) oligodendrocytes as they start laying down myelin sheath
    - Extent of bright signal on T1 reflects distribution of myelinating oligodendrocytes in infant brain
  - Detection of myelination (represented by hyperintense signal) progresses in predictable fashion
    - By term
      - Dorsal brainstem
      - Dentate nucleus
      - Optic tracts
      - Anterior commissure
      - Posterior limb of internal capsule
      - Rolandic & perirolandic gyri
      - Pyramidal tracts
    - By 2 months
      - Splenium of corpus callosum
      - Anterior limb internal capsule
      - Early optic radiations
    - By 4 months
      - Genu of corpus callosum
      - Optic radiations become more apparent
      - Peripheral rami in pyramidal tracts (perirolandic gyri)
    - By 6 months
      - Genu & splenium are equally hyperintense
      - Peripheral rami in parietal & occipital lobes become hyperintense
    - By 8 months
      - All but most peripheral rami of frontal gyri are hyperintense
    - By 10-12 months
      - Adult appearance of myelin is achieved on T1
- T2WI
  - Key sequence in assessing myelination in children 1-2 years of age
  - As myelin sheaths thicken, surrounding interstitial (extraaxonal) water is displaced
    - PLP is hydrophobic
    - Less interstitial water → darker signal on T2
  - Drop in T2 signal lags considerably behind presence of bright T1 signal
    - Process starts immediately after oligodendrocytes begin laying down myelin sheath
    - Sheath has to thicken considerably before enough water is displaced to reduce signal
  - Detection of myelination (represented by hypointense signal) progresses in predictable fashion
    - By term
      - Dorsal brainstem
      - Part of posterior limb of internal capsule
      - Perirolandic gyri
    - By 4 months
      - More hypointense signal in rolandic & perirolandic gyri
      - Splenium of corpus callosum
      - More anterior extension in internal capsule
    - By 8 months
      - Genu & splenium of corpus callosum
      - Anterior limb of internal capsule
      - ↓ signal in centrum semiovale & optic radiations
      - ↓ signal in basal ganglia & thalamus
    - By 12 months
      - External capsule hypointense signal becomes apparent
      - Expansion of centrum semiovale hypointensity
      - Clearly defined peripheral rami around central sulcus & in occipital poles
    - By 16 months
      - Better definition of deep nuclei in brainstem & basal ganglia
      - Peripheral rami in parietal lobes become hypointense
    - By 18 months
      - All but most peripheral frontal WM rami are now hypointense

        - Some residual hyperintense signal around trigones of lateral ventricles (terminal zones) due to greater hydrostatic pressure in this region from confluence of WM tracts
      - By 36 months
        - Adult appearance of myelin achieved on T2
- PD/intermediate
  - Very helpful in distinguishing gliosis from lack of myelination
    - Gliosis is brighter than terminal zones
- FLAIR
  - Relatively "flat" images in immature brains
  - Signal changes associated with myelination (hyperintense to hypointense) are similar to T2
    - Tend to occur 2-3 months after changes visible on T2
      - Smaller amounts of interaxonal water may exert greater influence on FLAIR sequences
  - Difficult to distinguish pathology from normal in infant
- DWI
  - ADC values predate T1/T2 signal changes
  - Presence of myelin has significant effect on ability of water to diffuse
    - Fractional anisotropy (FA) ↑ with brain maturation
    - Diffusion perpendicular to myelin sheaths is restricted with ↓ in extraaxonal water
    - Diffusivity along axon ↑
  - Diffusion tractography (DTI) can elucidate fiber tracts as they become myelinated
    - Correlates with functional milestones
    - May allow more specific identification of developing functional tracts
    - Mean diffusivity & FA measurements can be used to assess integrity of tracts
- MRS
  - Changes in relative metabolite concentrations in first 2 years of life may reflect myelination
  - Myoinositol & choline are high in neonate
    - Choline ↓ with myelination
  - NAA ↑ with myelination in 1st year of life

Imaging Recommendations

- Best imaging tool
  - Use both T1 & T2 to assess myelination
    - T1 < 12 months
    - T2 from 12-24 months
- Protocol advice
  - IR may ↑ sensitivity to T1 shortening
  - FSE sequences may minimize appearance of abnormal hyperintensity
  - Conventional double spin-echo sequences are preferred for T2
    - PD/intermediate echo images are especially valuable < 24 months

PATHOLOGY

General Features

- Etiology
  - Oligodendrocyte precursors proliferate in germinal matrix
  - Immature oligodendrocytes (prooligodendrocytes) migrate throughout brain
    - Follow distribution of neurons
    - Mature to myelinating oligodendrocytes after reaching destination
    - Neuron induces myelinization by electrical impulse
- Genetics
  - 2 major structural proteins of myelin: Myelin basic protein (MBP) & PLP
    - *MBP* gene encoded on chromosome 18q
    - *PDXP* gene encoded on chromosome Xq21-q22
- General path comments
  - Oligodendrocytes form & maintain axon myelin sheath
  - 1 oligodendrocyte may invest up to 50 axons

Staging, Grading, & Classification

- Myelination is assessed as "appropriate" for age or delayed
- Delay in myelination should prompt investigation for possible causes

Gross Pathologic & Surgical Features

- Premyelinated brain is "soft" due to high water content
  - Presence of myelin is required for fixation

Microscopic Features

- Myelin sheath is formed of multiple layers wrapped around axon
  - Forms protein-lipid-protein-lipid-protein stack

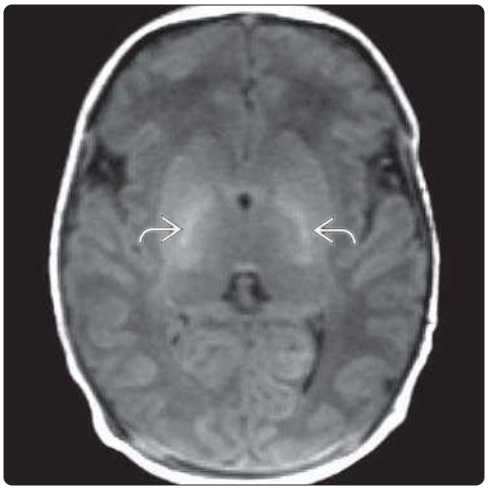
CLINICAL ISSUES

Demographics

- Age
  - All children should achieve adult appearance of WM by 36-40 months
- Sex
  - No significant male/female difference

DIAGNOSTIC CHECKLIST

Consider



- MR demonstration of normal myelination closely parallels developmental functional milestones
- Assessment of myelination is essential aspect of interpreting MR in children
- Know gestational age before assigning myelination stage
  - Normal myelination milestones are based upon postconception age, regardless of degree of maturity at delivery

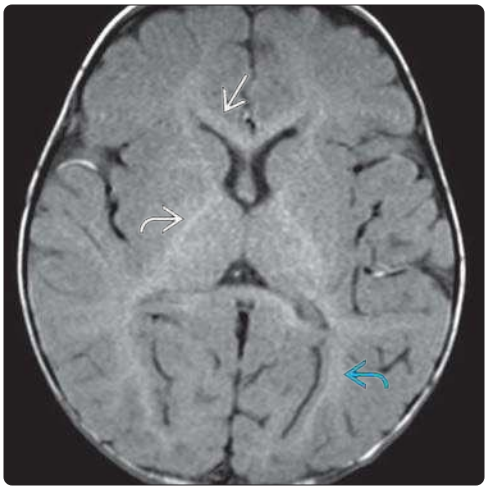


Image Interpretation Pearls

- Use IR for T1 < 10 months
- Use conventional double spin-echo sequences for T2

(Left) *Axial T1 MR in a term newborn shows faint bright signal in the posterior limbs of the internal capsules, indicating the presence of mature oligodendrocytes that are producing myelin in these regions. This process begins in the 2nd trimester of gestation.* **(Right)** *Axial T1 MR in a normal 6-month-old shows faint bright signal in the internal capsules, corpus callosum, & optic radiations well before any hypointense signal will be obvious in these structures on T2.*

(Left) *Axial T1 MR in a 9-month-old shows bright signal throughout the white matter. Myelination is far from complete at this stage, but the T1 confirms the presence of mature oligodendrocytes throughout the brain.* **(Right)** *Axial T2 MR in another 9-month-old shows hypointensity in the internal capsules, corpus callosum, & optic radiations, areas that appear fully mature on T1. The displacement of interstitial water by the thickening myelin sheath lags far behind the signal changes on T1.*

(Left) *Axial T2 MR at 18 months of age shows some residual bright signal in the periventricular white matter of the parietal lobes. Displacement of interstitial water may lag in these regions due to the large volume of parenchyma contributing to centripetal CSF flow.* **(Right)** *Axial T2 MR in a 2-year-old shows an adult pattern of myelination. Progressive myelination beyond this stage is not detectable by standard MR techniques.*

Enlarged Subarachnoid Spaces

KEY FACTS

TERMINOLOGY

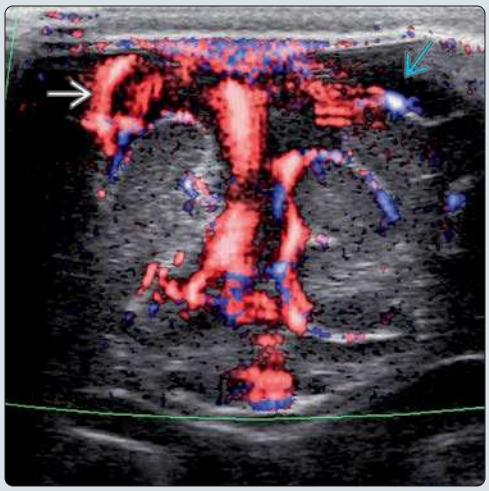
- Idiopathic enlargement of subarachnoid spaces (SAS) during infancy

IMAGING

- Primary imaging modality: US
  - CT/MR is used if fontanelle is closing or to further investigate atypical clinical/US findings
- Best clue: Enlarged SAS & ↑ head circumference (> 95th percentile)
  - Ventricles may be mildly enlarged
- Symmetric bifrontal & bitemporal SAS
- All modalities show veins coursing through SAS
- SAS follow CSF appearance on all modalities
- No compression of veins or gyri
- No inward displacement of arachnoid membrane by subdural fluid
  - Small, nonhemorrhagic subdural collections are seen in ~ 4% of patients with enlarged SAS

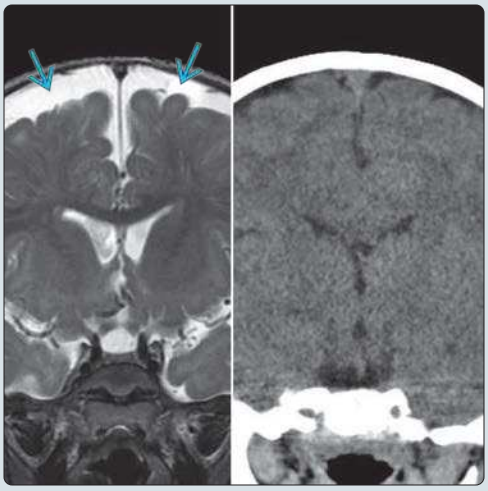
TOP DIFFERENTIAL DIAGNOSES

- Brain volume loss
- Nonaccidental trauma (NAT)
- Communicating hydrocephalus

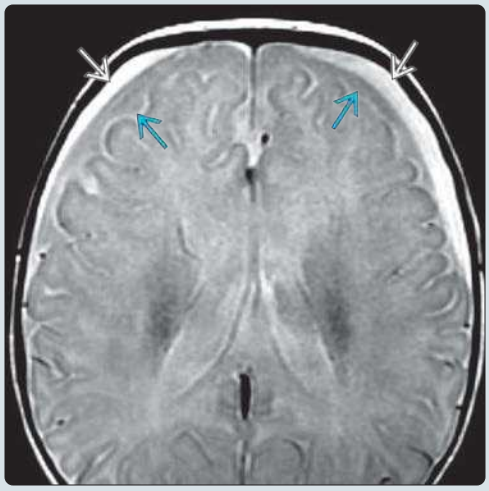


PATHOLOGY

- Immature CSF drainage pathways are likely cause
- Family history of macrocephaly in > 80%



CLINICAL ISSUES



- Mild developmental delay alone should not prompt further imaging or subspecialty evaluation
  - Further evaluation is required only in setting of focal neurologic signs &/or developmental regression
- Consider NAT if enlarged extraaxial spaces are atypical
  - Moderate/large/complex subdural collection → NAT work-up
- SAS enlargement & developmental delay typically resolve without therapy by 2 years of age

(Left) *Coronal US in a 7-month-old boy with macrocrania shows enlarged subarachnoid spaces (SAS) & normal ventricular size. Note the normal size of the sulci. This is a typical clinical history & imaging appearance for benign enlargement of the SAS (BESS). US is the initial exam of choice for infants with macrocrania.* **(Right)** *Coronal color Doppler US in a 4-month-old girl shows vessels traversing the enlarged SAS. Doppler US is often helpful to exclude subdural collections by demonstrating normal veins in the SAS.*

(Left) *Coronal T2 MR at 13 months (left) & NECT at 5 years (right) of age show expected resolution of the enlarged SAS over a 4-year period. Enlarged SAS typically resolve by 24 months of age.* **(Right)** *Axial PD MR in a 4-month-old girl with macrocrania shows enlarged SAS, which are isointense to the brain. Also note the small, bilateral, hyperintense subdural fluid collections. GRE/SWI (not shown) showed no hemorrhage. Small, nonhemorrhagic subdural collections can be seen in ~ 4% of patients with enlarged SAS.*

TERMINOLOGY

Abbreviations

- Subarachnoid spaces (SAS)

Definitions

- Enlarged SAS in patient < 1 year of age with macrocrania [head circumference (HC) > 95%]

IMAGING

General Features

- Enlarged SAS in infant with macrocrania
  - Symmetric at bifrontal & bitemporal SAS
  - Normal SAS values differ significantly between studies
    - Interhemispheric width: 95th percentile ~ 8 mm
    - Craniocortical width: 95th percentile ~ 10 mm
    - Sinocortical width: 95th percentile ~ 7 mm
- Ultrasound: Primary modality used whenever possible
  - Numerous cortical veins traverse singular fluid space on grayscale & Doppler
    - No mass effect displacing veins against pia
    - No inward displacement of arachnoid membrane by subdural fluid (which lack traversing veins)
  - ± mild ventricular enlargement
- CT/MR: Used for screening when no acoustic window is available for US (due to fontanelle closure) or if other neurologic signs/symptoms are present
  - NECT: Enlarged, homogeneous SAS (isodense to ventricular CSF) with normal sulci; no hemorrhage
    - Enlarged cisterns (especially suprasellar/chiasmatic)
  - CECT: Easily demonstrates veins traversing SAS
    - No abnormal meningeal enhancement
  - MR: Normal brain parenchyma without edema
    - SAS fluid follows CSF signal on all sequences
    - Small, nonhemorrhagic subdural collections in ~ 4%

Imaging Recommendations

- Protocol advice
  - After diagnosis, best follow-up: Clinical monitoring of HC & development of any neurologic findings
  - Follow-up with MR/CT is typically not necessary, unless
    - Focal neurologic signs/symptoms develop
    - Subdural collection is suspected on US

DIFFERENTIAL DIAGNOSIS

Brain Volume Loss

- Small HC; sulcal prominence is out of proportion

Nonaccidental Trauma

- Moderate/large or hemorrhagic subdural collections or unusual clinical findings should raise concern

Incidental Bilateral Subdural Fluid Collections

- Subdural fluid is not normally visualized
  - Small, nonhemorrhagic subdural collections are seen in 4% of benign macrocrania patients
  - Characterized by crescentic fluid collection separating dura from arachnoid
    - No cortical veins traverse subdural space
    - Discrete arachnoid membrane is displaced toward cortex & may be compressing SAS veins
    - May have different signal intensity on MR vs. CSF
  - Discuss need for further work-up with referring clinician
    - Close clinical follow-up at minimum; work-up for nonaccidental trauma (NAT) at discretion of clinician

Glutaric Aciduria Type 1

- Enlarged sylvian fissures with delayed myelination
- Subdural collections may be present
- T2-hyperintense basal ganglia

Elevated Venous Pressures

- Causes: Cardiac disease, internal jugular vein sacrifice for ECMO, arteriovenous fistula, or sinus venous thrombosis

Communicating Hydrocephalus

- Often posthemorrhagic/postinflammatory/neoplastic

PATHOLOGY

General Features

- Etiology
  - Immature CSF drainage pathways: Most accepted theory
  - Family history of macrocephaly > 80%
- Associated abnormalities
  - Predisposition to bleed with minor trauma: Controversial
    - Possibility of ↑ risk for bridging vein injury & subdural collection/hematoma in absence of major trauma

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Macrocrania: HC > 95th percentile
  - Danger signs: Persistent or rapid deviation of HC from normal curve; developmental regression, focal neurologic signs, vomiting, bruising
- Other signs/symptoms
  - Mild developmental delay is common (20-50%) & usually resolves over time

Natural History & Prognosis

- Self-limited; resolves without therapy by 12-24 months

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Crucial to know HC
- Further evaluation with brain MR or CT if US is atypical
  - Moderate/large/complex subdural collection → NAT work-up
  - Even small/simple subdural collections should be discussed with referring clinician to identify any concerns for NAT that merit further work-up

Cavum Septum Pellucidum

KEY FACTS

TERMINOLOGY

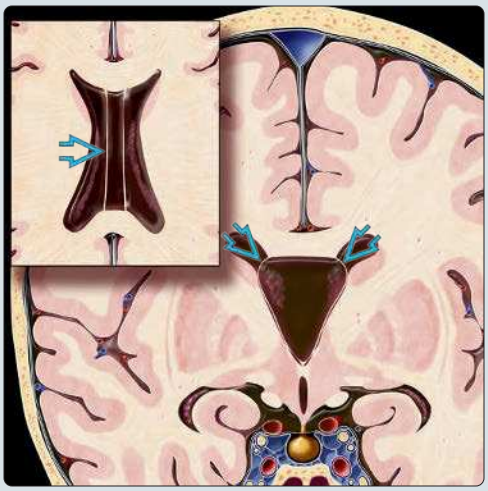
- Cavum septi pellucidi (CSP)
  - ± cavum vergae (CV)

IMAGING

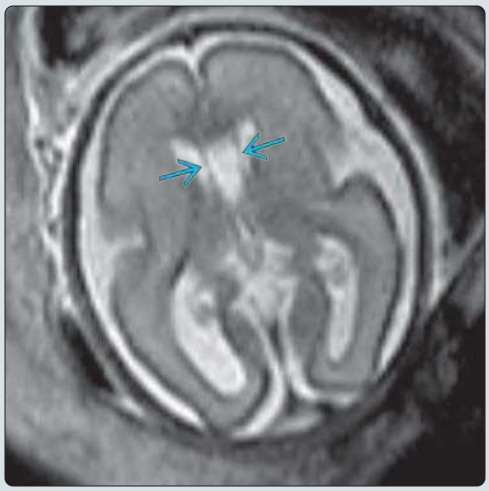
- Visible CSF space between leaves of CSP
- Normally ≤ 1 cm in width
- ± CV = posterior continuation of CSP
  - CSP & CV are divided by arbitrary vertical plane formed by forniceal columns
  - CV is usually seen with CSP but can be seen in isolation
- CSP is normal structure in fetal life & should be present on 2nd-trimester screening US
- Usually begins to close from back to front at 6 months gestation, forming septum pellucidum
  - CSP is present in 100% of premature & 85% of term infants
  - CSP is seen in up to 15-20% of adults

TOP DIFFERENTIAL DIAGNOSES

- Cyst of CSP
- Interhemispheric cyst
- Acquired intracranial cyst
- Dermoid/epidermoid cyst
- Pilocytic astrocytoma



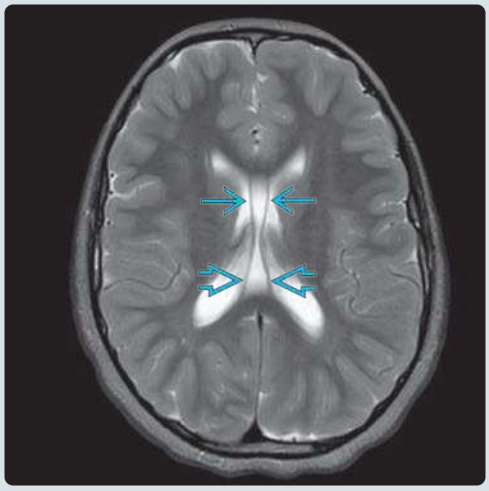
CLINICAL ISSUES



- Almost always incidental finding
- Link to various pathologic conditions is unclear given how commonly this is seen in normal patients
- Rare reports of CSP cyst requiring surgical drainage
  - Look for outward bowing of CSP leaves; likely still incidental unless causing hydrocephalus

DIAGNOSTIC CHECKLIST

- CSP > 10 mm is considered enlarged, particularly in fetus; usually still incidental



(Left) *Coronal graphic with axial insert shows a classic cavum septi pellucidi (CSP) with cavum vergae (CV). Note the CSF space between the leaves of the CSP that is bordered by the medial walls of the lateral ventricles.* **(Right)** *Axial T2 SSFSE MR of a 26-weeks-gestation fetus imaged for an umbilical cord cyst shows a normal brain with a normal CSP, which should be visible in a 2nd-trimester fetus.*

(Left) *Coronal ultrasound in a 22-day-old term infant with cholestasis of unknown etiology shows a normal brain & a normal appearance of the CSP.* **(Right)** *Axial T2 MR in a 7-year-old boy with generalized tonic clonic seizures shows an incidental CSP with cavum vergae. No abnormalities were identified in the brain. Note the normal ventricular size & lack of periventricular edema.*

Cavum Veli Interpositi

KEY FACTS

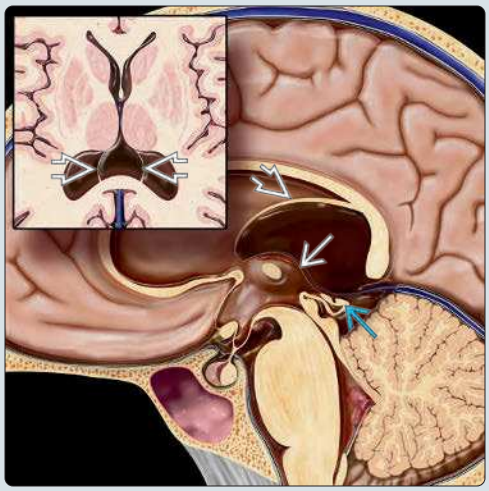
TERMINOLOGY

- Cavum veli interpositi (CVI); cyst of velum interpositum

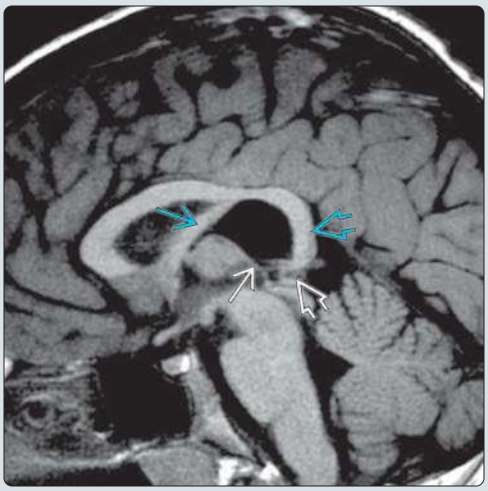
IMAGING

- Triangular CSF space
  - Between lateral ventricles & posterior thalami
  - Apex points toward foramina of Monro
  - Elevates & laterally displaces forniceal body & columns
  - Displaces internal cerebral veins inferolaterally
  - Anterior to splenium of corpus callosum, above pineal gland
- Size varies from slit-like/linear to triangular to round/ovoid CSF collection (CVI cyst)
- Isodense/isointense with CSF; on MR
  - Suppresses completely on FLAIR
  - Does not restrict on DWI
  - Does not enhance
- Infant head US can be diagnostic: Typical morphology & location with lack of internal echoes or Doppler signal

TOP DIFFERENTIAL DIAGNOSES



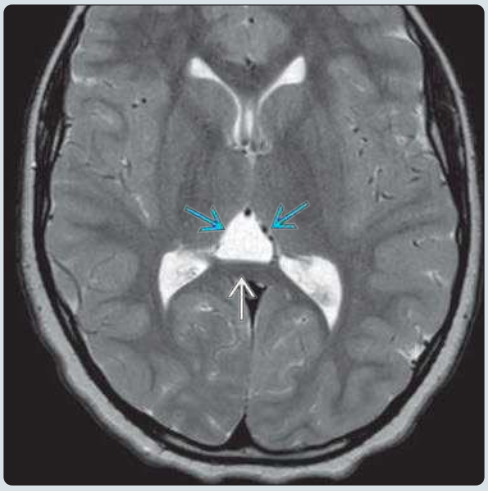
- Pineal cyst
- Arachnoid cyst
- Epidermoid cyst



CLINICAL ISSUES

- Can be found at any age
  - Common in infants, less common in adults
- Symptoms
  - Usually asymptomatic, found incidentally
  - Headache (but relationship to cyst is unclear)
  - CVI cyst can obstruct normal CSF flow though rare → may require neurosurgical drainage

DIAGNOSTIC CHECKLIST



- Considered normal variant but can be associated with cyst
  - Look for signs of ventricular obstruction (rare)

(Left) *Sagittal graphic with axial insert shows a cavum veli interpositi (CVI) with elevation & lateral displacement of the fornices. Also note the inferior displacement of the internal cerebral veins & pineal gland.* **(Right)** *Sagittal T1 MR of a 7-year-old patient with precocious puberty shows an incidentally noted CVI posterior to the forniceal body/columns, anterior to the corpus callosum splenium, & superior to the tela choroidea of the 3rd ventricular roof. The pineal gland is displaced inferiorly.*

(Left) *Coronal T2 MR in the same patient demonstrates mild mass effect on the forniceal columns & internal cerebral veins, suggesting a cyst of the CVI, (which is usually incidental).* **(Right)** *Axial T2 MR in the same patient shows a characteristic triangular morphology of the CVI between the posterior thalami & anterior to the corpus callosum splenium. There is no associated ventriculomegaly.*

Dandy-Walker Continuum

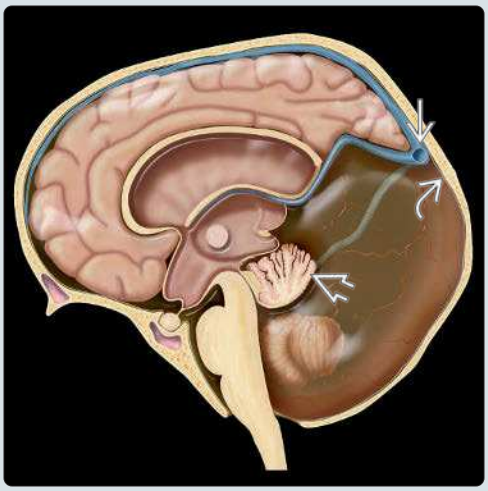
KEY FACTS

TERMINOLOGY

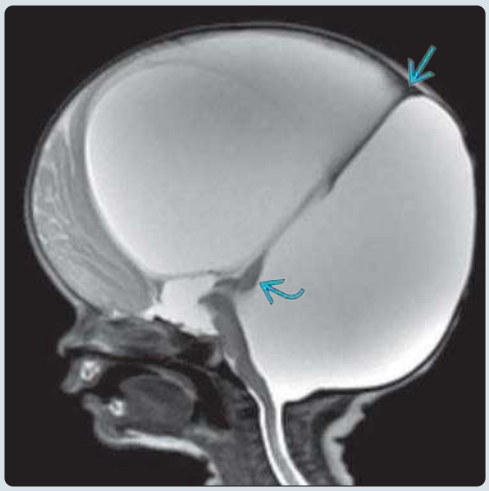
- Dandy-Walker continuum is clinically & radiologically heterogeneous group of posterior fossa (PF) malformations
  - Classic Dandy-Walker malformation (DWM)
  - Vermian hypoplasia (VH)
  - Blake pouch (BP) remnant/cyst
  - Mega cisterna magna (MCM)

IMAGING

- Most severe to mildest: Classic DWM → VH → BP → MCM
- Classic DWM
  - Triad of vermian agenesis/hypogenesis, 4th ventricle cystic dilation, & enlarged PF with elevation of torcular Herophili (torcular-lambdoid inversion)
  - ± hydrocephalus
- VH
  - Variable VH ± superior rotation/elevation of vermis
  - No upward sloping of tentorium or torcular-lambdoid inversion
- BP remnant
  - Elevated tegmentovermian angle
  - Normal size & morphology of vermis
- MCM
  - Enlarged retrocerebellar CSF cistern (≥ 10 mm)

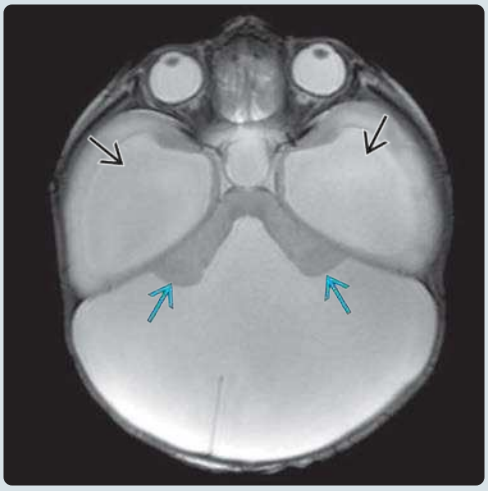


TOP DIFFERENTIAL DIAGNOSES

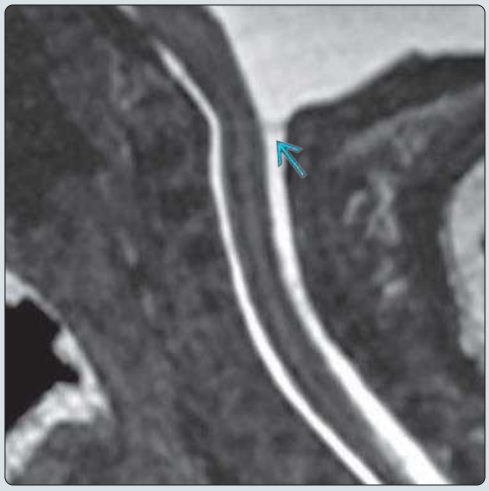


- PF arachnoid cyst
- Joubert syndrome & related disorders
- Dystroglycanopathies
- Cerebellar hypoplasia

CLINICAL ISSUES



- Conflicting terminology, not universally agreed upon
- Wide range of clinical severity
- Classic DWM & VH may be difficult to distinguish; anatomic descriptions may be most useful clinically



(Left) *Graphic of the classic Dandy-Walker malformation (DWM) shows an enlarged posterior fossa, elevated torcular Herophili (above the lambdoid suture), superior rotation of a hypoplastic cerebellar vermis, & posterior cystic expansion of the 4th ventricle.* **(Right)** *Sagittal T2 MR of a 2-day-old girl with prenatally diagnosed classic DWM shows the hypoplastic rotated vermis, upward slanting tentorium with elevated torcular Herophili, & obstructive hydrocephalus.*

(Left) *Axial T2 MR in the same patient with classic DWM shows lateral displacement of the cerebellar hemispheres & obstructive hydrocephalus with dilated lateral ventricular temporal horns. The presence of hydrocephalus & other associated brain malformations are critical in helping to establish prognosis.* **(Right)** *Sagittal 3D FIESTA MR of the craniocervical junction in the same patient demonstrates the Blake pouch remnant obstructing the 4th ventricular outflow tracts.*

TERMINOLOGY

Abbreviations

- Classic Dandy-Walker malformation (DWM)

Synonyms

- Terms DW spectrum, DW variant, & DW complex have complicated clinical & imaging implications in literature

Definitions

- DW continuum represents clinically & radiologically heterogeneous group of posterior fossa (PF) malformations
- Referred to as continuum by some based on belief that DWM, vermian hypoplasia (VH), Blake pouch (BP) remnant/cyst, & mega cisterna magna (MCM) are spectrum of developmental anomalies of rhombencephalic vesicle roof
  - Terminology is controversial & not uniformly accepted
  - Clinical severity ranges widely in this group

IMAGING

General Features

- Best diagnostic clue
  - Classic DWM triad: Vermian agenesis/hypogenesis, 4th ventricle cystic dilation, & enlarged PF with elevation of torcular Herophili (torcular-lambdoid inversion)
  - VH: Vermis is small & usually rotated, may be dysplastic; no torcular-lambdoid inversion
  - BP: Vermis is normal in size & morphology with rotation marked by elevated tegmentovermian angle (≥ 18°)
  - MCM: Enlarged retrocerebellar CSF space (≥ 10 mm) with normal size & orientation of vermis (normal tegmentovermian angle)
- Morphology
  - DW continuum (from most to least severe)
    - DWM classic triad
      - Complete or partial agenesis of vermis
      - Cystic dilation of 4th ventricle → rotation of hypoplastic vermis
      - Enlarged PF with upward displacement of tentorium & torcular Herophili (torcular-lambdoid inversion)
      - Obstructive hydrocephalus: 70-90%, callosal anomalies: 20%, polymicrogyria or gray matter heterotopia: 5-10%
    - VH
      - Variable degree of VH ± rotation
      - ± abnormal vermian foliation/dysplasia
      - No upward slanting tentorium, no torcular-lambdoid inversion
      - May be difficult to distinguish from DWM
    - BP remnant (a.k.a. BP "cyst")
      - Elevated tegmentovermian angle (a.k.a. "open" 4th ventricle)
      - Normal size & morphology of vermis
    - MCM
      - Enlarged retrocerebellar cistern (≥ 10 mm) without mass effect on hindbrain
      - Normal vermis, 4th ventricle, & tegmentovermian angle
      - In isolation, incidental finding

CT Findings

- NECT
  - DWM: Large PF
    - Torcular-lambdoid inversion (torcular above lambdoid sutures)
  - Scalloped occipital bone, remodeled in all types of DW continuum

MR Findings

- T1, T2, FLAIR
  - DWM
    - Vermian agenesis/hypogenesis, hypoplastic vermis with superior rotation/elevation
    - Variable cerebellar hemisphere & brainstem hypoplasia &/or compression
    - Enlarged 4th ventricle communicating with retrocerebellar cystic space
    - Elevated torcular Herophili with upward-slanting tentorium
    - Hydrocephalus is common, though not originally described as part of DWM
  - VH
    - Varying degrees of vermian tissue are present
    - Vertical height of vermis does not reach level of obex
    - ± rotation of vermis
      - Normal tegmentovermian angle is usually close to 0°; however, < 18° has been reported as normal
      - Angle as large as 30° may be normal before 20-weeks gestation on fetal MR
    - ± abnormal foliation/dysplasia
    - May be difficult to distinguish from DWM, particularly in fetus in which there are no reliable landmarks to identify lambdoid sutures
  - BP remnant
    - Rotated but normal-appearing vermis
    - 4th ventricle communicates inferiorly with retrocerebellar CSF cystic space
    - Cyst wall is variably present, often imperceptible on MR
    - Choroid plexus may be seen along inferior surface of vermis (superior margin of cyst wall)
  - MCM
    - Enlarged retrocerebellar CSF space
    - Normal vermis (not rotated, dysplastic, or hypoplastic)
  - ± callosal anomalies, polymicrogyria, gray matter heterotopia, occipital cephalocele, myelination delay

Imaging Recommendations

- Protocol advice
  - Routine MR with thin-section sagittal 3D true FISP/FIESTA to look for cyst wall

DIFFERENTIAL DIAGNOSIS

Posterior Fossa Arachnoid Cyst

- True cyst that does not communicate with 4th ventricle
- ± mass effect on adjacent structures
- May be impossible to distinguish from MCM without CT cisternography

- Distinguishing small AC from MCM is not typically clinically significant

Joubert Syndrome & Related Disorders

- Hypoplastic/dysplastic vermis, "bat wing" 4th ventricle on axial images, thickened & horizontal superior cerebellar peduncles with midbrain cleft → molar tooth appearance on axial images

Dystroglycanopathies

- VH with cobblestone cortex & Z-shaped brainstem (Walker-Warburg phenotype)

Cerebellar Hypoplasia

- ± brainstem hypoplasia (pontocerebellar hypoplasia)

PATHOLOGY

General Features

- Etiology
  - DW continuum is result of abnormal development of posterior fossa mesenchyme
  - Rhombencephalic vesicle roof divides into cranial [anterior membranous area (AMA)] & caudal [posterior membranous area (PMA)] segments
    - AMA invaded by neural cells → cerebellum
    - PMA expands then disappears to form outlet foramina of 4th ventricle
  - Hindbrain development arrest
    - Defective AMA & PMA → DWM & VH
    - Defective PMA only → BP (incomplete/nonperforation of foramen of Magendie) & MCM (delayed perforation)
- Genetics
  - Multiple causative genes identified
    - *FOXC1* (chromosome 6p25.3)
    - Deletion of 3q24 (includes *ZIC1* & *ZIC4* genes)
    - *FGF17*, *LAMC1*, *NID1*
  - DWM can be in isolation or in well-defined syndrome
    - Ritscher-Schinzel syndrome
    - Cranio-cerebello-cardiac syndrome
- Associated abnormalities
  - 2/3 of DWM & related disorders have associated CNS &/or extracranial anomalies
    - Midline anomalies, neurocutaneous melanosis, PHACE(S) syndrome
    - Craniofacial, cardiac, urinary tract, & orthopedic anomalies
    - Trisomy 18 > other trisomies
- Embryology
  - Common association of DWM/VH with facial & cardiovascular anomalies suggests onset between formation & migration of neural crest cells

Gross Pathologic & Surgical Features

- DWM: Large PF with cystic dilation of 4th ventricle
  - Roof of 4th ventricle is in continuity with cyst wall that attaches to hypoplastic vermis anteriorly, cerebellar hemispheres laterally, & medulla caudally
- BP can have variable degrees of perforation & is not true cyst; rather, remnant of PMA

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - DWM: Macrocephaly, bulging fontanel (obstructive hydrocephalus)
  - MCM: Incidental finding
- Clinical profile
  - Motor developmental delay, spastic paraplegia, seizures, variable intellectual disability
    - Marked heterogeneity in clinical findings, even in families with same genetic mutations

Demographics

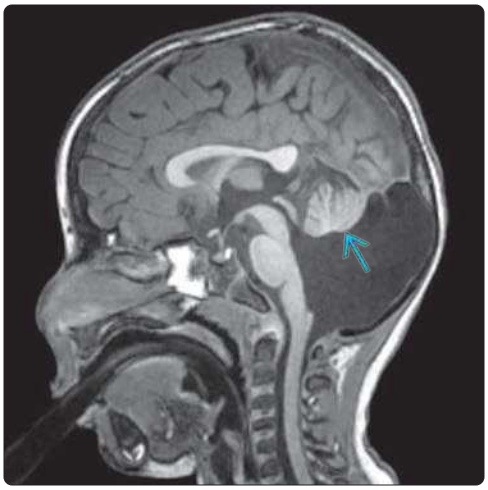
- Age
  - DWM: 80% diagnosed by 1 year of age
    - Age of diagnosis depends on degree of hydrocephalus, supratentorial anomalies, & cerebellar dysfunction
- Epidemiology
  - 1:25,000-30,000 births

Natural History & Prognosis

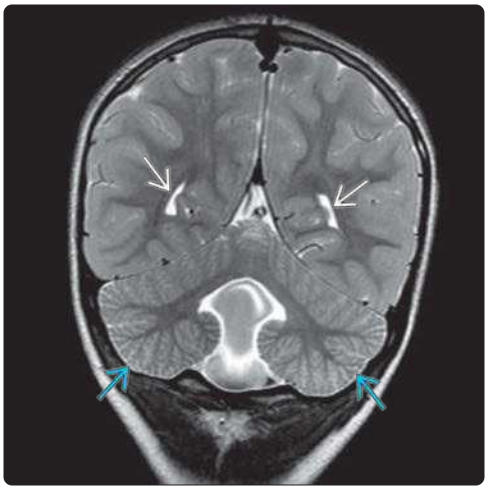
- Cognitive outcome depends on associated syndromes, supratentorial anomalies, & hydrocephalus
- Classic DWM: Poor prognosis overall
  - Though developmental delay was previously reported in 40-60%, recent literature suggests much higher incidence in true DWM
  - 70-90% with hydrocephalus
  - Seizures, hearing &/or visual difficulties, systemic abnormalities
- VH: Highly variable
  - Cognitive abnormalities in 40-50%, though normal neurodevelopment has been reported in isolated VH
- BP: Favorable outcome in isolation; however, significant proportion are associated with other anomalies
- MCM: Normal neurodevelopmental outcome in isolation

Treatment

- CSF diversion for hydrocephalus: Ventriculoperitoneal shunt ± cyst shunt or marsupialization



DIAGNOSTIC CHECKLIST



Reporting Tips

- Terms, such as DW spectrum, variant, & continuum, can be confusing
  - Use clear description & best categorization of abnormal PF findings when possible (may not always be clear cut)
  - Note hydrocephalus & supratentorial anomalies

(Left) *Sagittal T1 MR in a 4-year-old with vermian hypoplasia shows a small & rotated vermis with no significant torcular-lambdoid inversion (though the lambdoid suture is difficult to see on this image).* **(Right)** *Coronal T2 MR in the same patient demonstrates mild separation of the cerebellar hemispheres. The supratentorial ventricles are normal in size, & there is no evidence of ventricular obstruction.*

(Left) *Sagittal 3D FIESTA MR of a 9-month-old with a Blake pouch remnant shows ventricular obstruction with upward stretching of the corpus callosum & anterior bowing of the lamina terminalis. The vermis is normal in size.* **(Right)** *Axial T2 MR in the same patient demonstrates ventriculomegaly of the lateral & 3rd ventricles. However, there is evidence of chronic compensation, as there is no periventricular edema or sulcal effacement.*

(Left) *Sagittal T2 SSFSE fetal MR at 33-weeks gestation shows a mega cisterna magna. In this patient, the cisterna magna is enlarged, measuring 15 mm in AP dimension. The vermis is normal in size, morphology, & orientation.* **(Right)** *Postnatal sagittal T2 MR of the same patient at 6 weeks of age shows that the cisterna magna remains enlarged with a normal vermis. Note the lack of mass effect on the cerebellum & brainstem. In isolation, this is an incidental finding.*

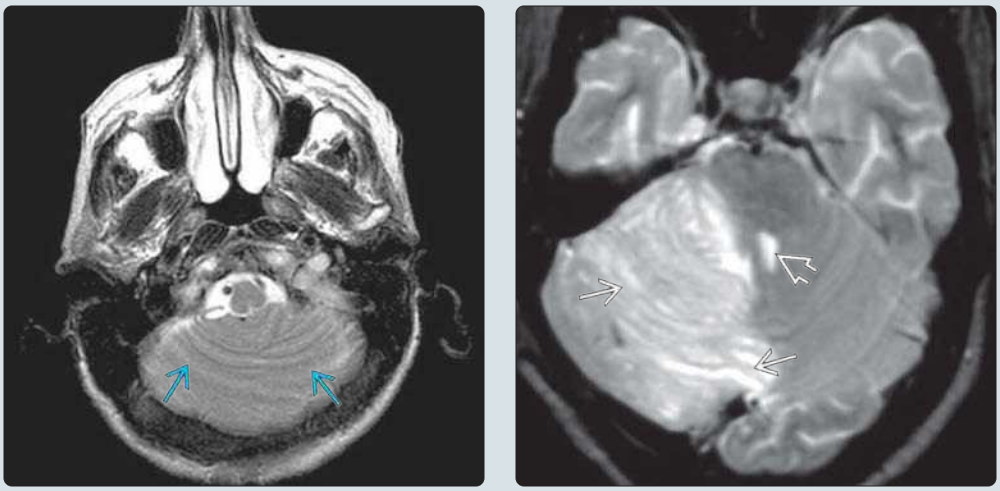
KEY FACTS

TERMINOLOGY

- Rhombencephalosynapsis (RS)
- Lhermitte-Duclos disease (LDD) (dysplastic cerebellar gangliocytoma, Cowden syndrome)
- Joubert syndrome & related disorders (JSRD) (molar tooth malformation)

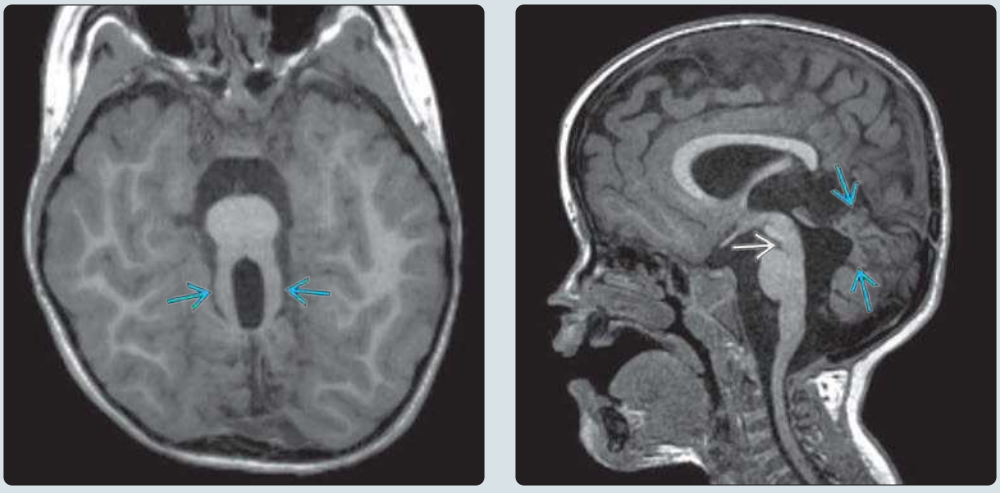
IMAGING

- RS: Incomplete separation of cerebellar hemispheres
  - Partial or complete absence of cerebellar vermis with folia continuous across midline
  - ~ 65% have coexisting aqueductal stenosis & hydrocephalus
- LDD: Well-circumscribed ↑ T2, ↓ T1 expansile lesion with enlarged & dysplastic cerebellar folia
  - Characteristic tiger stripe or corduroy striated pattern
- JSRD: Molar tooth configuration of brainstem is marked by absent decussation of superior cerebellar peduncles
  - Thickened & horizontally oriented superior cerebellar peduncles, deep & broad interpeduncular fossa, deformed 4th ventricle, hypoplastic vermis



TOP DIFFERENTIAL DIAGNOSES

- Hypoplastic cerebellum: Dandy-Walker continuum, congenital muscular dystrophy, isolated cerebellar hypoplasia, pontocerebellar hypoplasia
- Expanded cerebellar hemisphere: Infarct, cerebellitis, tumor



CLINICAL ISSUES

- RS: Widely varied depending on degree of associated anomalies
- LDD: Diagnosis of exclusion; continued imaging follow-up is warranted
- JSRD: Clinically heterogeneous; molar tooth sign must be correlated with clinical presentation & genetic testing (ciliopathy)

(Left) *Axial T2 MR in a patient with rhombencephalosynapsis (RS) shows lack of separation of the cerebellar hemispheres with transversely oriented folia that are continuous across the midline. No discrete vermis is seen. Look carefully for associated aqueductal stenosis in the setting of RS (& vice versa).* **(Right)** *Axial T2 MR shows an expanded, striated, hyperintense right cerebellar hemisphere characteristic of Lhermitte-Duclos disease (LDD). Note the 4th ventricular compression.*

(Left) *Axial T1 MR in a 4-year-old patient shows a classic molar tooth configuration of the midbrain, consistent with Joubert syndrome & related disorders (JSRD). There is characteristic thickening & elongation of the superior cerebellar peduncles.* **(Right)** *Sagittal T1 MR in the same patient with JSRD demonstrates marked cerebellar vermian hypoplasia & flattening of the dysplastic fastigial recess. There is also narrowing of the midbrain at the pontomesencephalic junction.*

TERMINOLOGY

Abbreviations

- Rhombencephalosynapsis (RS)
- Lhermitte-Duclos disease (LDD)
- Joubert syndrome & related disorders (JSRD)

Synonyms

- LDD: Cowden syndrome, dysplastic cerebellar gangliocytoma, diffuse hypertrophy of cerebellar cortex
- JSRD: Molar tooth malformation

Definitions

- RS: Incomplete separation of cerebellar hemispheres with complete or partial absence of vermis
- LDD: Focal enlargement of cerebellar cortex
  - Low-grade tumor vs. dysplasia: Molecular subtype (usually *PTEN* mutation) & location are distinct from gangliocytomas (WHO grade 1) in other locations
- JSRD: Absence of decussation of superior cerebellar peduncles leading to molar tooth sign
  - Ciliopathy: Caused by mutation of genes encoding ciliary proteins

IMAGING

General Features

- Best diagnostic clue
  - RS: Midline continuation of cerebellar hemispheres (a.k.a. fusion) with at least partial absence of vermis
  - LDD: Sharply marginated region of enlarged & dysplastic cerebellar cortex with characteristic striated (a.k.a. tiger stripe) folial pattern on MR
  - JSRD: Molar tooth sign of midbrain with absence of decussation of superior cerebellar peduncles on DTI + small, malformed vermis

MR Findings

- RS
  - Incomplete separation of cerebellar hemispheres: Diamond-shaped 4th ventricle on axial images, flattened fastigial recess, transversely oriented continuous folia, flat-based cerebellum
  - ± aqueductal stenosis with ventriculomegaly (~ 65%)
  - ± supratentorial anomalies of midline development: Deficiency/absence of septum pellucidum, corpus callosum hypogenesis/dysgenesis, absent anterior commissure, united fornices, incompletely separated thalami, holoprosencephaly, pituitary abnormalities
- LDD
  - Well-circumscribed, nonenhancing ↓ T1, ↑ T2 expansile cerebellar mass
  - Enlargement of dysplastic cerebellar folia creating striated pattern
  - Mass effect can cause obstructive hydrocephalus
  - DWI: Intermediate diffusion (similar to cerebellar cortex)
- JSRD
  - Molar tooth sign: Deep & broad posterior interpeduncular fossa + thick, elongated superior cerebellar peduncles
  - Hypoplastic & dysplastic cerebellar vermis, high position of fastigium, superior midline vermian cleft on coronal images, enlarged posterior fossa
  - Deformed 4th ventricle: Triangular-shaped in midportion & batwing-shaped in superior portion on axial images
  - Hypoplasia of middle cerebellar peduncles, hypoplastic brainstem at pontomesencephalic junction, hypoplastic/dysplastic cerebellar hemispheres
  - ± supratentorial anomalies: Ventriculomegaly, ↓ cerebral volume, hypomyelination, corpus callosum dysgenesis

DIFFERENTIAL DIAGNOSIS

Dandy-Walker Continuum

- Absence or hypoplasia of vermis, communication of 4th ventricle with posterior cyst, enlargement of posterior fossa

Congenital Muscular Dystrophy

- Cerebellar hypoplasia, Z-shaped brainstem
- Extensive cortical abnormalities, eye anomalies

Isolated Cerebellar Hypoplasia

- TORCH infections, trisomy 21, many other causes

Pontocerebellar Hypoplasia

- Numerous syndromic forms

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - RS: Widely varied depending on degree of associated anomalies; isolated cases may have subclinical symptomatology
  - LDD: Longstanding history of poorly localized neurological symptoms
  - JSRD: Clinically heterogeneous, including neonatal hyperpnea intermixed with central apnea, oculomotor apraxia, developmental delay, hypotonia/ataxia

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- RS: Can be partial or complete; isolated partial can be difficult to diagnose → midline sagittal image is necessary to identify all parts of vermis
- LDD: Classic striated pattern, but LDD is diagnosis of exclusion → continued imaging follow-up is warranted to exclude other etiologies (infarct, cerebellitis, tumor)
- JSRD: Molar tooth sign is classic, though must be correlated with clinical presentation & genetic work-up (ciliopathy)

Cephalocele

KEY FACTS

TERMINOLOGY

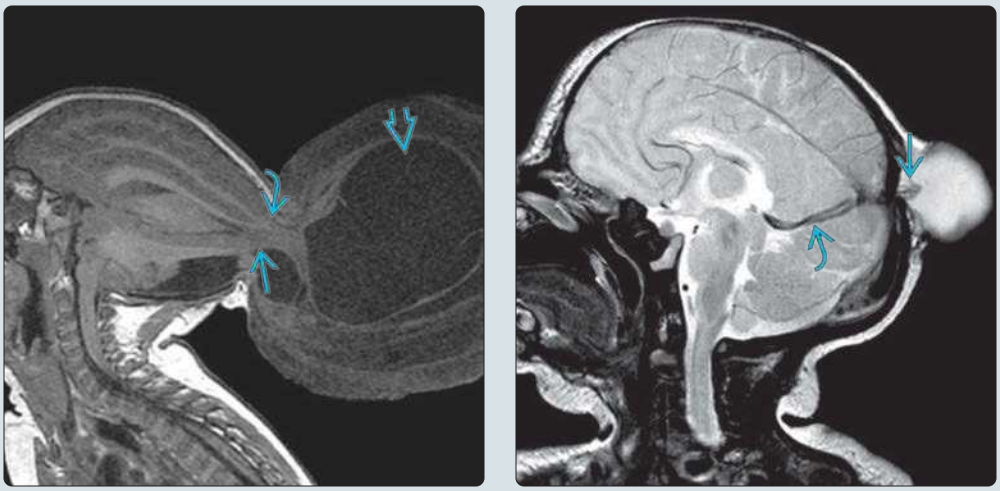
- Extracranial extension of intracranial contents through defect in skull
  - Contents
    - Meningocele: Meninges & CSF
    - Encephalocele: Brain tissue, meninges, CSF
  - Locations
    - Occipital (most common)
    - Frontoethmoidal/sincipital
    - Parietal (usually atretic)
    - Basal/nasopharyngeal
    - Remaining cranial vault, including calvarium, mastoid & petrous temporal bones, cavum trigeminale

IMAGING

- Meninges & CSF ± brain tissue protrude through defect
  - Herniated brain tissue is often dysplastic
- MR + MRV to assess cephalocele contents & abnormal venous sinuses; CT to assess bone defect

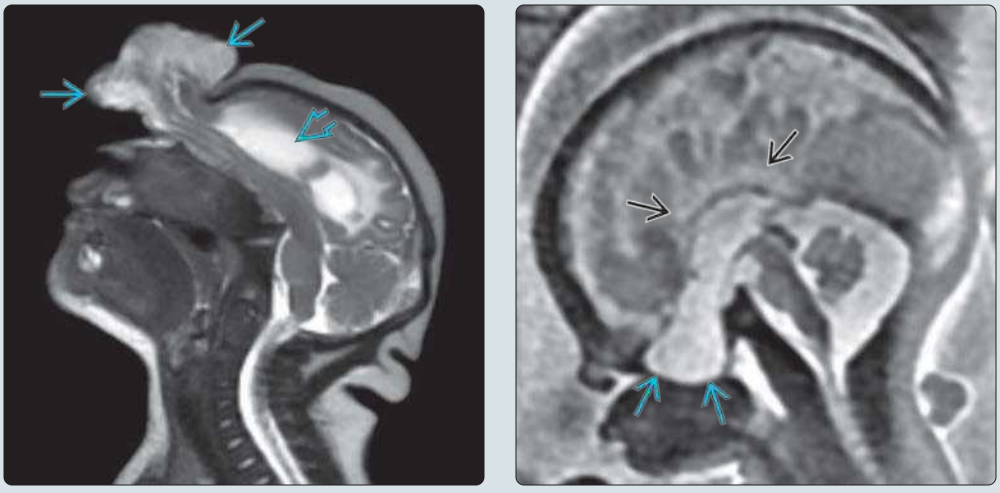
TOP DIFFERENTIAL DIAGNOSES

- Dermoid/epidermoid cyst
- Nasal glial heterotopia ("nasal glioma")
- Sinus pericranii
- Assorted vascular anomalies (neoplasms & malformations)
- Cutis aplasia congenita
- Giant parietal foramina



CLINICAL ISSUES

- Congenital is more common than acquired
- Most cephaloceles (occipital) are clinically obvious at birth
- Basal/nasopharyngeal cephaloceles may not manifest until end of 1st decade
- Prognosis & surgical options depend on cephalocele size, location, contents, & associated anomalies



DIAGNOSTIC CHECKLIST

- Normal cartilaginous nasofrontal region in infants can mimic defect on CT; correlate with MR

(Left) *Sagittal T1 MR of a 2-year-old patient shows a giant occipital encephalocele containing a portion of the cerebrum, cerebellum, & dilated lateral ventricle. There is no associated cervical spinal dysraphism (which would suggest a Chiari 3 malformation).* **(Right)** *Sagittal T2 MR of a 5-day-old patient shows a parietal cephalocele containing CSF & fibrous tissue. Note the persistent falcine sinus. Special attention to vascular involvement is critical in cephalocele evaluation.*

(Left) *Sagittal T2 MR of a 1-month-old patient shows a frontonasal encephalocele. There is associated microcephaly & lateral ventriculomegaly.* **(Right)** *Sagittal T2 SSFSE MR of a 32-week fetus demonstrates a large basal cephalocele due to Sakoda complex. Agenesis of the corpus callosum is present, & there is an associated midline cleft lip/palate. This patient required an EXIT-to-airway procedure at delivery.*

TERMINOLOGY

Definitions

- Extracranial extension of intracranial contents through defect in skull; categorized by contents & location
  - Congenital is more common than acquired
- Contents
  - Cephalocele: Broad term for any focal extracranial extension of intracranial contents
  - Meningocele: Meninges & CSF only
  - Encephalocele: Brain, meninges, CSF
    - a.k.a. meningoencephalocele
  - Meningoencephalocystocele: Ventricle, brain, meninges, CSF
  - Atretic cephalocele: Meningeal & neuroglial elements retain fibrous connection to intracranial compartment, often without significant protrusion through defect
- Locations
  - Occipital: Most common location, up to 80% of cases
    - Supra- &/or infratentorial structures in cephalocele, including tentorium cerebelli & dural venous sinuses
    - Occipitocervical form (Chiari 3): Very rare
  - Frontoethmoidal/sincipital/anterior: 15% (↑ in Southeast Asia)
  - Parietal: 10% (↑ in Japan at 38%)
    - Atretic parietal cephalocele is most common
      - Majority have benign clinical course
  - Basal/nasopharyngeal: Up to 10% of cases
  - Remaining calvarium: Rare
  - Mastoid &/or petrous temporal bone: Rare
  - Cavum trigeminale: Rare

IMAGING

General Features

- Best diagnostic clue
  - Meninges & CSF ± brain tissue protruding through skull defect

CT Findings

- Best for delineation of osseous defect

MR Findings

- T1, T2, FLAIR
  - Heterogeneous signal intensity of cephalocele contents reflecting brain parenchyma & CSF
    - Neural tissue may be dysplastic/gliotic
- MRV
  - Helps to characterize venous relationships to cephaloceles, particularly occipital
  - Venous anomalies occur in most atretic parietal cephaloceles
    - Persistent falcine sinus (± absent vein of Galen, straight sinus)
    - Superior sagittal sinus fenestration/duplication

Ultrasonographic Findings

- Prenatal: Cephaloceles (mainly occipital) can be detected in utero
- Postnatal: Small superficial bumps over calvarium may receive ultrasound request first (particularly for small nasofrontal or atretic parietal cephaloceles)
  - May visualize calvarial defect, altered venous anatomy

DIFFERENTIAL DIAGNOSIS

Dermoid/Epidermoid Cyst

- ± T1-hyperintense fat, diffusion restriction
- Commonly seen near suture lines (scalp, orbit)
- ± nasal pit in association with nasal dermal sinus

Nasal Glial Heterotopia

- Dysplastic neural tissue (a.k.a. "nasal glioma" but not true glioma)
- No communication with subarachnoid space

Sinus Pericranii

- Anomalous connection of intracranial & extracranial veins
- Compressible; engorge with Valsalva/crying

Vascular Anomaly

- Variety of solid & cystic lesions found in neonatal period
- Other than sinus pericranii, rarely have communication through calvarium

Cutis Aplasia Congenita

- Skin defect ± calvarial defect, typically off midline

Giant Parietal Foramina

- Symmetric round/ovoid calvarial defects of paramidline parietal bones
- Can be single midline defect early

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Majority (occipital) are clinically obvious
  - Smaller lesions: Soft & bluish mass if skin covered (majority) or moist & red if lacking skin covering (rare)
- Other signs/symptoms
  - Occipital: Microcephaly, hydrocephalus
  - Basal/nasopharyngeal: Occult mass in oro-/nasopharynx → changes in size with Valsalva + upper airway obstruction, nasal stuffiness/mouth breathing
  - Frontoethmoidal: Hypertelorism, broad nasal bridge, CSF rhinorrhea → meningitis

Treatment

- Depends on cephalocele location, contents, size, & associated anomalies
- Goals of surgery: Prevent CSF leak & meningitis, improve functional & cosmetic deformities

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Always consider cephalocele when encountering cystic skull base lesion

SELECTED REFERENCES

1. Khodarahmi I et al: Imaging spectrum of calvarial abnormalities. Radiographics. 41(4):1144-63, 2021
2. Nagaraj UD et al: Prenatal evaluation of the Sakoda complex. Pediatr Radiol. 49(13):1843-7, 2019

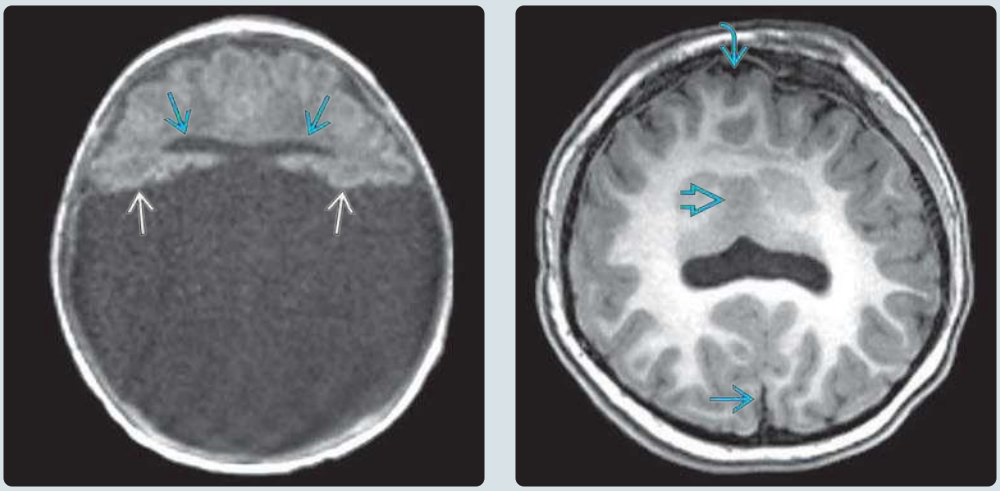
Holoprosencephalies

KEY FACTS

TERMINOLOGY

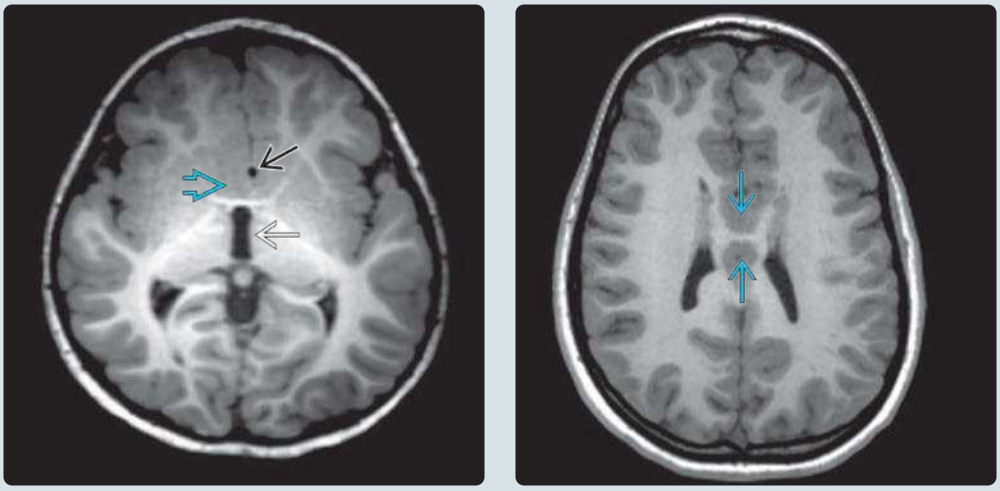
- Holoprosencephaly (HPE): Spectrum of congenital forebrain malformations characterized by failure of differentiation & midline cleavage of prosencephalon
- Traditionally divided (from most to least severe) into alobar, semilobar, & lobar subtypes
- Middle interhemispheric variant (MIH) or syntelencephaly is generally accepted as subtype of HPE

IMAGING



- Abnormal midline communications of gray & white matter
- Categories represent continuum of forebrain malformations without clear distinction between subtypes
- Alobar HPE: Complete absence of cleavage with "pancake" of anterior cerebral tissue, crescent-shaped anterior monoventricle communicating with large dorsal cyst, fused thalami
- Semilobar HPE: Interhemispheric fissure & falx cerebri are formed posteriorly with absence of frontal lobe separation & varying degrees of failed diencephalon cleavage
- Lobar HPE: 3rd ventricle is fully formed (diencephalon separation), interhemispheric fissure & falx are mostly formed with absent cleavage in inferior frontal lobes
- MIH: Lack of posterior frontal & parietal midline separation with cleavage of anterior frontal & occipital lobes

TOP DIFFERENTIAL DIAGNOSES



- Aqueductal stenosis
- Hydranencephaly
- Callosal agenesis with interhemispheric cyst
- Open-lip schizencephaly
- Hypoplastic optic nerve syndrome (a.k.a. septooptic dysplasia)

CLINICAL ISSUES

- Presentation varies widely depending on severity of malformation

(Left) *Axial T1 MR of a 4-day-old with alobar holoprosencephaly shows a monoventricle & a dorsal cyst that displaces the brain anteriorly in a pancake configuration. Note the normal lack of myelination of the cerebral white matter at this age.* **(Right)** *Axial T1 MR in a 6-year-old with semilobar holoprosencephaly shows nonseparation of the frontal lobes & anterior caudate nuclei. However, there is separation of the parietal & occipital lobes with the falx cerebri identified posteriorly.*

(Left) *Axial T1 MR in a 2-year-old with lobar holoprosencephaly shows failed separation of the anterior inferior frontal lobes with a small amount of gray matter crossing the midline. Note the characteristic azygous anterior cerebral artery. The 3rd ventricle is not hypoplastic.* **(Right)** *Axial T1 MR in a 13-year-old with seizures shows the middle interhemispheric variant of holoprosencephaly marked by focal incomplete separation of the posterior frontal & anterior parietal regions.*

TERMINOLOGY

Abbreviations

- Holoprosencephaly (HPE)

Definitions

- Spectrum of congenital forebrain malformations characterized by failure of differentiation & midline cleavage of prosencephalon
- Traditionally, classic HPE is divided into alobar, semilobar, & lobar subtypes
- Middle interhemispheric variant (MIH) (a.k.a. syntelencephaly) is generally accepted as subtype of HPE
- Subtypes represent continuum of forebrain malformations without clear distinction between different subtypes

IMAGING

General Features

- Best diagnostic clue
  - Alobar HPE: Complete absence of cleavage with "pancake" of anterior cerebral tissue, crescent-shaped anterior monoventricle communicating with large dorsal cyst, fused thalami
  - Semilobar HPE: Absent frontal lobe cleavage with parietooccipital lobe separation
  - Lobar HPE: Interhemispheric fissure & falx are mostly formed with partial nonseparation of frontal lobes
  - MIH: Hemispheres are not separated in posterior frontal & anterior parietal regions

MR Findings

- T1, T2, FLAIR
  - Alobar: Anterior monoventricle ± communication with dorsal cyst
    - Cerebral tissue is flattened anteriorly like pancake
    - Absent corpus callosum, falx, interhemispheric fissure
  - Semilobar: Frontal lobes are largely continuous across midline
    - Varying degrees of diencephalon separation (absent/small 3rd ventricle)
    - Posterior corpus callosum (splenium) is present
  - Lobar: Interhemispheric fissure is present along nearly entire midline
    - Rudimentary frontal horns are typical, inferior portions of frontal lobes are uncleaved
    - 3rd ventricle is fully formed
    - Absence of genu & rostrum of corpus callosum
  - MIH: Lack of midline separation in posterior frontal & anterior parietal regions with normal cleavage of polar areas of cerebrum
    - Genu & splenium are present with absent body of corpus callosum
    - Normal basal ganglia
  - Absent septum pellucidum is typical though it can be seen in milder subtypes
  - No precise distinction between lobar & semilobar HPE
- Variable findings
  - Brainstem & cerebellar anomalies, such as rhombencephalosynapsis
  - Gray matter heterotopia: MIH > classic HPE
  - Azygous anterior cerebral artery

DIFFERENTIAL DIAGNOSIS

Aqueductal Stenosis

- Macrocephalic with moderate to severe enlargement of ventricles; small rind of cerebral tissue in maximal cases
- Falx may be disrupted

Hydranencephaly

- Absence of anterior circulation cerebrum with fluid-filled cranial vault
- Preservation of falx

Hypoplastic Optic Nerve Syndrome (a.k.a. Septooptic Dysplasia)

- Optic nerve hypoplasia ± absent/deficient septum pellucidum, hypothalamic-pituitary axis abnormalities, schizencephaly

PATHOLOGY

General Features

- Etiology
  - Teratogen exposure
    - Ethanol, diabetes, cigarette smoking, retinoic acid
  - Many genetic/syndromic etiologies
    - Smith-Lemli-Opitz, Stromme, Steinfeld, Hartsfield, Kallman syndrome 2
- Genetics
  - Standard karyotyping is abnormal in 40-60% of HPE
    - Classically trisomy 13 (Patau syndrome)
      - Arrhinencephaly is seen in ~70%
  - 18-25% have pathogenic variant in single gene
    - > 20 known HPE-associated genes
- Associated abnormalities
  - Facial anomalies → hypotelorism/cyclopia, ethmocephaly (proboscis), cebocephaly (single naris), arrhinia, central incisor, midline or bilateral cleft lip/palate

Staging, Grading, & Classification

- Alobar, semilobar, lobar classification of DeMyer
- MIH described as HPE variant by Barkovich in 1993
- Milder subtypes may be often observed in clinical practice, such as preseptooptic subtype

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- HPE represents continuum of forebrain malformations
  - No clear distinction amongst different categories → provide clear anatomic descriptions in reports
  - Less severe lack of separation is described at many different locations in telencephalon & considered as midline anomalies vs. forme fruste of HPE

Callosal Anomalies

KEY FACTS

TERMINOLOGY

- Agenesis (absence) of corpus callosum (ACC)
- Dysgenesis of CC
  - Hypogenesis of CC (partial agenesis)
  - Hypoplasia of CC

IMAGING

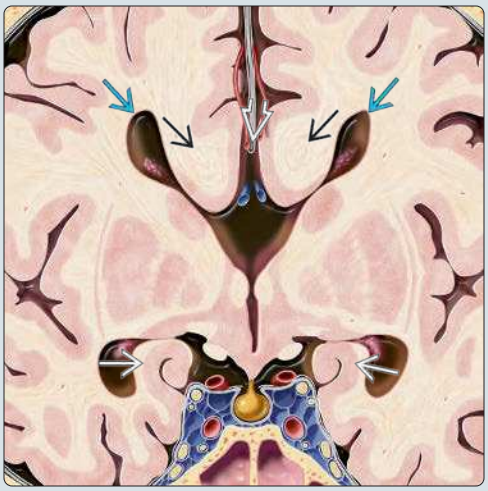
- Axial: Parallel configuration of lateral ventricles with colpocephaly (dilation of trigones/posterior horns of lateral ventricles)
  - Probst bundles: Densely packed heterotopic white matter (WM) tracts parallel to interhemispheric fissure
- Sagittal: Absent or abnormal CC
  - Absent cingulate sulcus
  - Interhemispheric sulci radiate to 3rd ventricular margin
- Coronal images: No band of WM bridging cerebral hemispheres over 3rd ventricle
  - Upturned anterior horns of lateral ventricles & high-riding 3rd ventricle
- ± interhemispheric cyst or lipoma

TOP DIFFERENTIAL DIAGNOSES

- Destruction, attenuation, or immaturity of CC
- Failure of forebrain cleavage (holoprosencephaly spectrum)

PATHOLOGY

- Associated with hundreds of described genetic abnormalities & nongenetic syndromes
- Can be seen in isolation in minority of cases

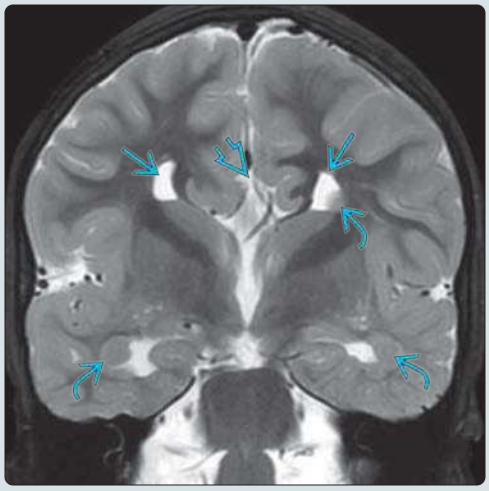


CLINICAL ISSUES

- Typical manifestations include seizures, developmental delay, anomalies of hypothalamic-pituitary axis

DIAGNOSTIC CHECKLIST

- When CC is absent, evaluate presence & morphology of other forebrain commissures
- Description of other brain anomalies is important in prognosis



(Left) *Coronal graphic shows agenesis of the corpus callosum (ACC) with bundles of Probst & everted cingulate gyri. The 3rd ventricle is high riding with upturned lateral ventricles in a trident configuration. The hippocampi are underrotated with vertical orientation.* **(Right)** *Sagittal SSFP MR in a 31-weeks-gestational age female fetus with ACC shows that the cingulate sulcus is absent, & the interhemispheric sulci reach the 3rd ventricle margin. The anterior commissure is present.*

(Left) *Axial T2 SSFSE MR in the same fetus shows a parallel configuration of the lateral ventricles with colpocephaly characterized by selective dilation of the atria & occipital horns of lateral ventricles.* **(Right)** *Coronal T2 MR in a 4-year-old patient shows ACC with upturned lateral ventricular frontal horns in a trident configuration. Note the foci of associated subependymal gray matter heterotopia. MR is the most sensitive examination for the detection of associated anomalies in ACC.*

TERMINOLOGY

Definitions

- Heterogeneous condition of congenital hypoplasia/dysplasia or absence of corpus callosum
- Complete agenesis of corpus callosum (ACC)
  - Agenesis of CC & hippocampal commissure with presence of anterior commissure: Most common
  - ACC with presence of anterior & hippocampal commissures
  - Tricommissural agenesis: Complete absence of CC, anterior commissure, & hippocampal commissure
- Dysgenesis of corpus callosum
  - Hypogenesis of corpus callosum (partial agenesis of corpus callosum)
    - All 5 parts of CC are not present → shortening of CC in AP dimension
  - Hypoplasia of corpus callosum
    - Diffusely thin CC with normal AP length & all parts present

IMAGING

General Features

- Best diagnostic clue
  - Axial: Parallel configuration of lateral ventricles with colpocephaly
  - Sagittal: Absent cingulate sulcus with interhemispheric sulci radiating to margin of 3rd ventricle
  - Coronal: High-riding 3rd ventricle with upturned lateral ventricles in trident morphology
  - Absent septum pellucidi
  - Associated interhemispheric lipoma or cyst
    - Interhemispheric cyst of ACC may be communicating (type I) or noncommunicating (type II) with ventricle
  - Anterior cerebral arteries & branches do not conform to expected normal CC shape

Imaging Recommendations

- Best imaging tool
  - MR is most sensitive examination for detection of associated anomalies

DIFFERENTIAL DIAGNOSIS

Destruction of Corpus Callosum

- Surgery (callosotomy), trauma
- WM injury of prematurity
- Cerebral infarcts → focal thinning of CC

Attenuation of Corpus Callosum

- Hydrocephalus stretches/deforms CC, flattens fiber tracts
- CC often looks "dysplastic" in severe hydrocephalus s/p shunting

Immaturity of Corpus Callosum

- CC is relatively thin & unmyelinated in normal neonates

Failure of Forebrain Cleavage

- Varying degrees of CC absence depending on type of holoprosencephaly

PATHOLOGY

General Features

- Associated abnormalities
  - Additional CNS malformations may be present
  - Associated with hundreds of described genetic abnormalities & nongenetic syndromes
    - Aicardi: ACC in female patient with polymicrogyria, interhemispheric cyst, & gray matter heterotopias
    - Genetic Syndromes: Rubinstein-Taybi, Apert, Smith-Lemli-Opitz syndrome
    - Ciliopathies: Joubert, acrocallosal, Meckel syndrome
- Embryology
  - Cells destined for CC begin forming at 6-weeks gestation
  - Glial sling connecting anterior & hippocampal commissure begins to form at 12 weeks
  - Developing anterior & posterior parts fuse to form single structure with all parts of CC present by 15 weeks

Staging, Grading, & Classification

- Complete ACC
  - Classification of ACC based on evaluation of 3 main forebrain commissures: Corpus callosum, anterior commissure, & hippocampal commissure
  - Only anterior commissure is present (most common)
    - Anterior commissure may be small or thickened
  - Both anterior & hippocampal commissures are present
    - Hippocampal commissure can be difficult to differentiate from hypogenetic CC
    - Hippocampal commissure connects forniceal crura while CC connects cerebral hemispheres
  - Tricommissural agenesis: Complete absence of all 3 commissures (least common)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizures, developmental delay
  - Anomalies of hypothalamic-pituitary axis
- Other signs/symptoms
  - Widely variable depending on type of CC anomaly, associated CNS malformations, genetic syndromes
  - In isolated ACC, patients may be asymptomatic

DIAGNOSTIC CHECKLIST

Consider

- Anterior commissure is usually present in complete ACC & should be described

Image Interpretation Pearls

- Look for additional CNS malformations

Hemimegalencephaly

KEY FACTS

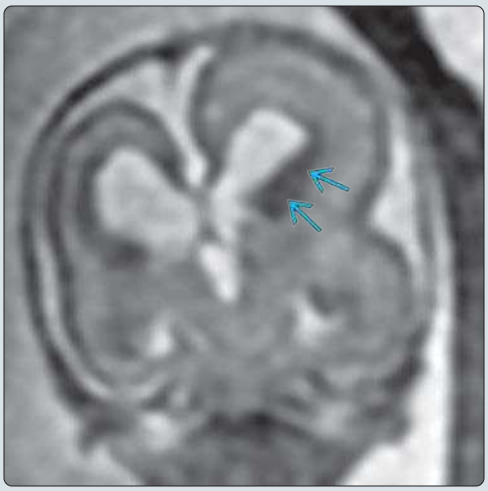
TERMINOLOGY

- Hemimegalencephaly (HMEG): Overgrowth & malformation of part vs. entire hemisphere
- Due to defects in neuronal proliferation, migration, & organization

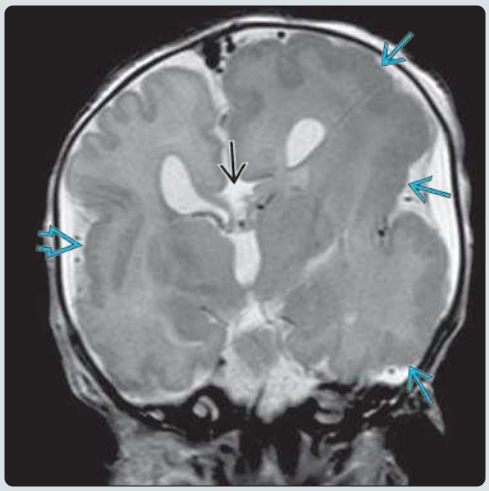
IMAGING

- Large cerebral hemisphere & hemicranium
  - Displaced posterior falx & occipital pole extending to contralateral side
  - Enlarged ipsilateral ventricle with abnormally shaped frontal horn (often pointed)
- Associated cortical malformations include pachygyria, polymicrogyria, & heterotopias
- White matter (WM) abnormalities
  - ↑ volume, abnormal T2 signal intensity
    - Often dark prior to typical myelination timeframe
- Size & signal intensity of HMEG can change over time
  - May atrophy with chronic seizure activity

PATHOLOGY

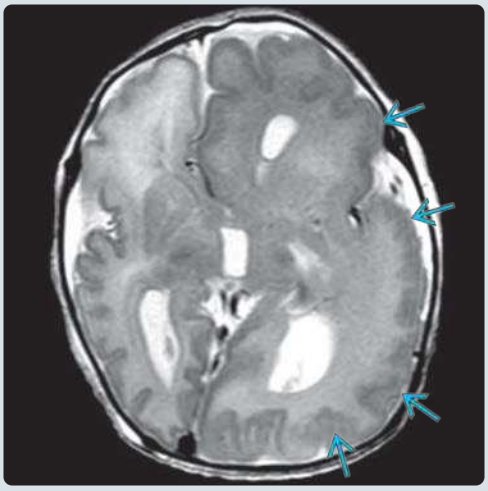


- Classified as cortical dysgenesis with abnormal cell proliferation but without neoplasia
- Same pathologic & genetic spectrum as focal cortical dysplasia type II & tuberous sclerosis complex



CLINICAL ISSUES

- Most common presentations: Seizures, hemiparesis, developmental delay
  - 50% have associated skin lesions, truncal/extremity overgrowth, &/or vascular malformations
    - Seen in *PIK3CA*-related overgrowth spectrum (PROS)
- Functional hemispherectomy is used for seizure control (as anticonvulsants are usually ineffective)



DIAGNOSTIC CHECKLIST

- Must exclude contralateral abnormalities for successful epilepsy surgery

(Left) *Coronal SSFSE T2 fetal MR at 20-weeks gestational age shows left hemimegalencephaly (HMEG). The left germinal matrix ⇨ is asymmetrically larger than the right, compatible with ↑ neuronal proliferation.* **(Right)** *Coronal T2 MR in the same patient after delivery shows extensive associated left polymicrogyria ⇨, consistent with abnormal neuronal organization. There is also callosal hypogenesis ⇨ & right perisylvian polymicrogyria ⇨, making this patient a poor surgical candidate.*

(Left) *Axial T2 MR in the same newborn with left HMEG shows asymmetric relative T2 hypointensity of the white matter in the left cerebral hemisphere, compatible with abnormal neuronal migration. Extensive left polymicrogyria ⇨ is again seen.* **(Right)** *Axial T1 MR in the same patient with HMEG shows characteristic asymmetric enlargement of the lateral ventricle on the affected side ⇨ with the occipital lobe crossing midline posteriorly ⇨. Note the abnormal gray matter-white matter differentiation on the left.*

TERMINOLOGY

Definitions

- Hemimegalencephaly (HMEG): Nonneoplastic overgrowth of part or entire hemisphere
  - Classic HMEG (or unilateral megalencephaly): Holohemispheric involvement
  - Partial HMEG (or focal megalencephaly): Portion of hemisphere involved
- Dysplastic megalencephaly (DMEG): Macrocephaly with significant portions of both hemispheres involved
- Same pathologic & genetic spectrum as focal cortical dysplasia type II & tuberous sclerosis complex (TSC)

IMAGING

General Features

- Best diagnostic clue
  - Enlarged dysplastic cerebral hemisphere (or portion of hemisphere) with enlarged ipsilateral lateral ventricle
    - Abnormal gray matter (GM) & white matter (WM)
  - Displaced posterior falx with enlarged occipital lobe crossing midline

MR Findings

- T1, T2, FLAIR
  - Abnormal GM: Pachygyria, polymicrogyria, heterotopia
  - Abnormal WM: ↑ volume, ↓ T2 signal intensity prior to expected myelination timeframe, variable T2 signal intensity after myelination is complete
  - Blurring of GM-WM junction
  - Enlarged ipsilateral ventricle, pointed frontal horn
  - ± cerebellar, brainstem ipsilateral overgrowth
  - Size & signal intensity of HMEG can change over time
- T2* GRE
  - Signal loss from dystrophic Ca^{2+}
- Fetal MR, 2nd trimester
  - Disruption of normal cerebral mantle lamination (described on SSFSE T2) secondary to abnormal neuronal migration & proliferation
  - Mass-like low T2 signal proliferation of germinal matrix/ventricular zone mimics hemorrhage

DIFFERENTIAL DIAGNOSIS

Rasmussen Encephalitis

- Unilateral encephalitis with progressive atrophy

Gliomatosis Cerebri

- Diffusely infiltrating glioma effaces ipsilateral ventricle (rather than enlarging it)

Unilateral Cerebral Edema

- May be seen with trauma, infarction, or infection
- Effaces ipsilateral ventricle

PATHOLOGY

General Features

- Etiology
  - Defect in neuronal proliferation, migration, & organization
- Genetics
  - Classified as cortical dysgenesis with abnormal cell proliferation but without neoplasia
    - 3 subtypes: Isolated, associated with TSC, & associated with other neurocutaneous syndromes
      - TSC is given its own subcategory based on differences in etiology & treatment (i.e., mTOR inhibitors)
    - Abnormal cellular proliferation, migration, & differentiation
  - Currently believed to be result of gene mutations coding PI3K-AKT-mTOR pathway proteins → *PIK3CA*-related overgrowth spectrum (PROS)

Microscopic Features

- Dyslamination, dysplastic neurons, immature neurons, astrogliosis
- ± hypercellularity, balloon cells, dystrophic Ca^{2+}

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Macrocephaly
  - Seizures, hemiparesis, developmental delay
- Other signs/symptoms
  - 50% of patients have associated abnormalities
    - Cutaneous lesions, hemihypertrophy

Demographics

- Usually diagnosed during 1st year of life

Natural History & Prognosis

- Intractable seizures with progressive hemiparesis
- Best seizure control is offered by functional hemispherectomy, though motor deficits/hemiparesis frequently persist
- Some infants develop obstructive hydrocephalus requiring CSF diversion

Treatment

- Anticonvulsants are usually ineffective
- Functional hemispherectomy or hemispherotomy
  - Earlier surgical intervention yields better outcomes
  - Must first confirm normal contralateral hemisphere

DIAGNOSTIC CHECKLIST

Reporting Tips

- Define extent of HMEG + contralateral abnormalities

Lissencephaly

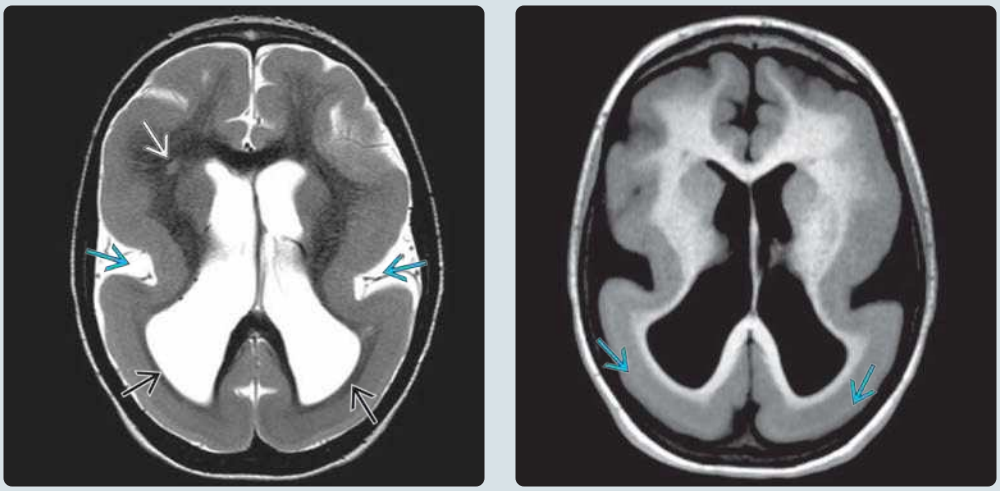
KEY FACTS

TERMINOLOGY

- Extensive cortical malformation caused by ↓ transmantle neuronal migration
  - Results in thick cortex & ↓ sulcation
- Spectrum of agyria, pachygyria, & band heterotopia

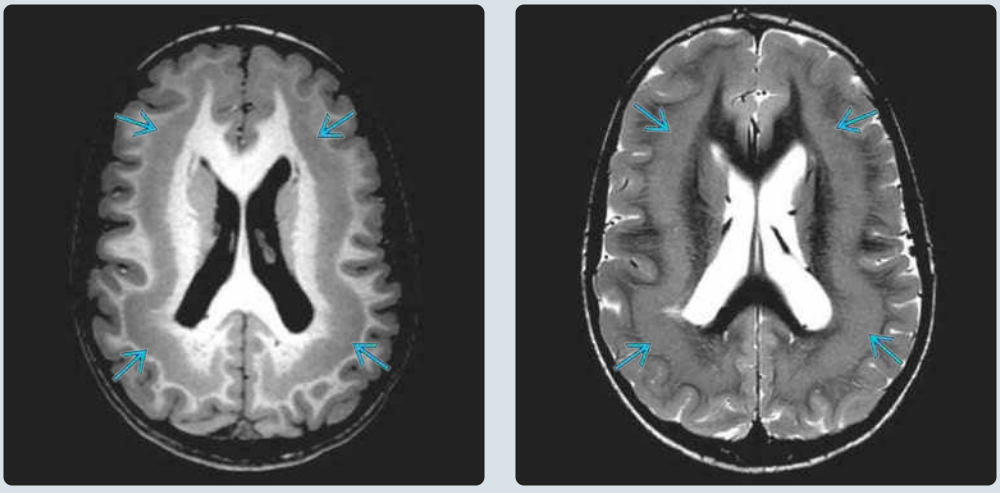
IMAGING

- Classic lissencephaly: Most common, considered subtype of tubulinopathies
  - Spectrum of ↓ number & depth of sulci + broad gyri
    - Graded based on anteroposterior predominance ± band heterotopia
  - Hourglass or figure 8 cerebral hemispheres in agyria
  - Few other major brain abnormalities; no severe congenital microcephaly
- Variant lissencephaly
  - Thick cortex, though not as thick as classic lissencephaly; no cell-sparse zone
  - Additional anomalies: Marked callosal dysgenesis, dysmorphic basal ganglia, cerebellar hypoplasia
- Microcephaly & additional anomalies with tubulinopathies from TUBA & TUBB mutations
- Deep white matter: Volume loss, ↓ arborization
- Ventriculomegaly



TOP DIFFERENTIAL DIAGNOSES

- Microcephaly with simplified gyral pattern
- Congenital muscular dystrophies: Dystroglycanopathies
- Expected immature sulcation pattern of prematurity
- Polymicrogyria



PATHOLOGY

- Many genetic mutations → spectrum of phenotypes
- Genetically based classification divides into tubulinopathies & variant lissencephalies
- Classic lissencephaly is most common, subtype of tubulinopathies

(Left) *Axial T2 MR in a 10-year-old girl with a LIS1 gene mutation shows posterior predominant agyria & bifrontal pachygyria. There is diffuse cortical thickening & vertically oriented sylvian fissures, consistent with classic lissencephaly. Posterior predominant ventriculomegaly is seen as well as right frontal gray matter heterotopia.* **(Right)** *Axial T1 MR in the same patient shows similar findings. The T1-hyperintense cell-sparse zone can be faintly seen posteriorly.*

(Left) *Axial T1 MR in an 8-year-old girl with a DCX mutation & generalized seizures shows diffuse subcortical band heterotopia, which is in the classic lissencephaly spectrum.* **(Right)** *Axial T2 MR in the same patient shows bilateral hemispheric band heterotopia. The overlying gyral-sulcal pattern is normal with normal cortical thickness. Band heterotopia can be diffuse (as in this case), but in some cases may only involve the frontal or parietooccipital regions.*

TERMINOLOGY

Definitions

- Spectrum of cortical malformation caused by arrested or ↓ transmantle neuronal migration
  - Agyria, pachygyria, & subcortical band heterotopia
- Most updated classification is based on combination of involved stage of neuronal migration & genetic information
- Abnormalities of neuronal proliferation (microlissencephaly, microcephaly with simplified gyral pattern, megalencephalies) & dystroglycanopathies (cobblestone malformations, previously type II lissencephaly) are described in separate categories
  - However, there is phenotypic & genetic overlap with congenital microcephaly & tubulinopathies

IMAGING

General Features

- Best diagnostic clue
  - Thick cortex with absence (agyria) or ↓ (pachygyria) number of sulci
  - Hourglass or figure 8 shape of cerebral hemispheres on axial images
- Location
  - Gradients of anterior to posterior cerebral hemispheric involvement are described in classic lissencephalies

MR Findings

- Smooth cortical surface
  - Spectrum of ↓ number & depth of sulci with large, broad gyri
- Thick, abnormal cortex
  - Classic lissencephaly: Thick cortex
    - 4-layer pattern described with cell-sparse zone deep to thin outer cortical layer & superficial to thick deeper cortical layer
      - Not always seen on MR; can be difficult to distinguish from band heterotopia in certain cases
  - Variant lissencephaly: Thick cortex, not as thick as classic lissencephaly (5-7 mm)
    - No cell-sparse zone
- Deep white matter abnormalities
  - ↓ volume with ↓ arborization
- Enlarged lateral ventricles
- Common associated findings
  - Callosal dysgenesis/agenesis
  - Pontocerebellar hypoplasia
  - Hippocampal anomalies

DIFFERENTIAL DIAGNOSIS

Microcephaly With Simplified Gyral Pattern

- Head circumference > 3 standard deviations below normal
- Broad gyri, ↓ number of sulci without cortical thickening

Congenital Muscular Dystrophies: Dystroglycanopathies

- Cobblestone cortex (formerly type II lissencephaly)
- Z-shaped hypoplastic brainstem on sagittal images
- Walker-Warburg, Fukuyama, muscle-eye-brain disease

Delayed Gyral-Sulcal Pattern

- Seen in preterm infants, infants with prenatal/neonatal systemic stressors, or genetic abnormalities/syndromes

Polymicrogyria

- Irregular pial surface ("lumpy-bumpy") & gray matter-white matter junction, shallow sulci + abnormal gyri

PATHOLOGY

General Features

- Genetics
  - Many identified mutations → spectrum of phenotypes
    - Tubulinopathies
      - Microtubules are essential in neuronal proliferation, migration, & axonal pathfinding
      - Mutations of genes encoding microtubule-associated proteins (MAPs: *LIS1*, *DCX*, *KIF5C*, *KIF2A*, & *DYNC1H1)*, α-tubulin (TUBA genes, mainly *TUBA1A*), & β-tubulin (TUBB genes, mainly *TUBB2B* & *TUBB3*)
      - Classic lissencephalies fall under this category, most caused by MAP mutations (50% *LIS1*, 10% *DCX*), but up to 7% are from tubulin mutations
      - *DCX* mutations: Classic lissencephaly in male patients, band heterotopia in female patients
    - Variant lissencephalies
      - Primarily consists of *ARX* mutations & mutations of Reelin signaling pathway

CLINICAL ISSUES

Presentation

- Clinical profile depends on severity of malformation & associated anomalies
  - Complete agyric lissencephaly: Neonatal hypotonia, gradual spasticity, severe epilepsy
  - Isolated band heterotopia (BH): Intellectual disability, seizures

DIAGNOSTIC CHECKLIST

Consider

- Patterns of gyral abnormalities may provide insight into underlying genetic defect

Image Interpretation Pearls

- If lissencephaly is suspected in fetus or neonate, verify gestational age

Reporting Tips

- Describe regions & types of involvement ± associated abnormalities to help in classification

Heterotopic Gray Matter

KEY FACTS

TERMINOLOGY

- Heterotopia (HTP): Abnormally located gray matter (GM) due to foreshortened or prolonged neuronal migration
  - Anywhere from periventricular germinal zone to pia

IMAGING

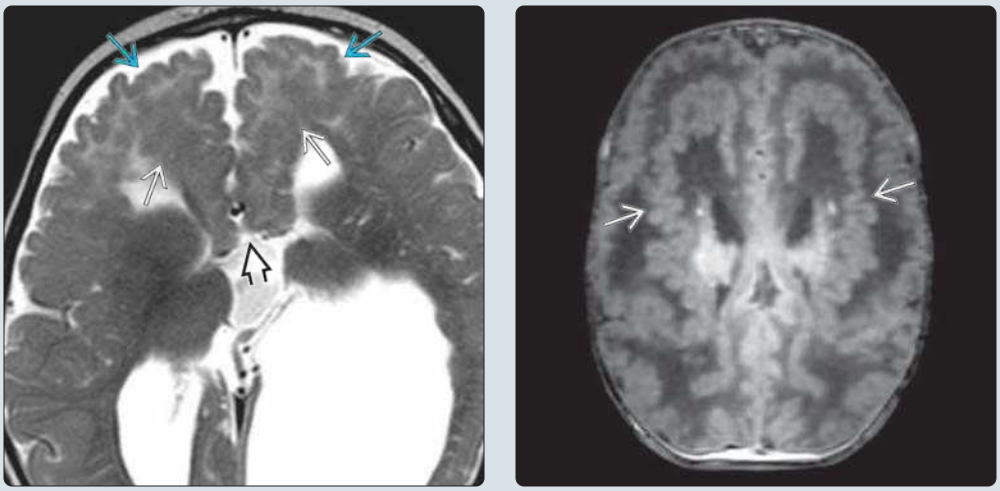
- Ectopic nodular or ribbon-like foci following GM signal intensity on every MR sequence
- Locations: Periventricular, subcortical, pial
  - Periventricular nodular HTP (most common)
  - Band HTP ≈ laminar HTP, double cortex
  - Subcortical nodular HTP (focal or multinodular)
  - Pial: Cobblestone cortex
- Best MR sequences (with multiplanar reformats)
  - Myelinated brain: 3D T1-spoiled GRE (e.g., SPGR)
  - Unmyelinated brain: 3D T2 FSE (e.g., Cube/VISTA/SPACE)

TOP DIFFERENTIAL DIAGNOSES

- Tuberous sclerosis
- Closed-lip schizencephaly
- Ependymal spread of tumor
- Congenital cytomegalovirus

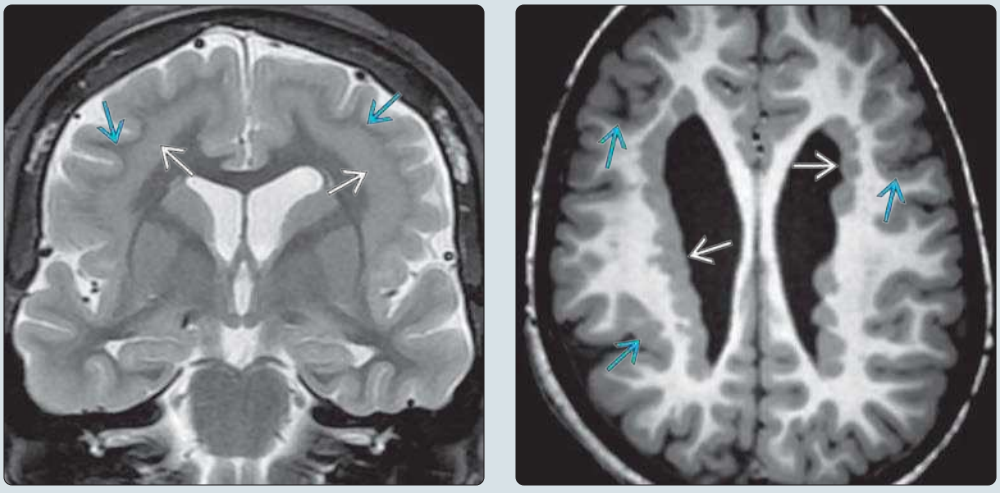
PATHOLOGY

- Genetic & acquired etiologies cause disturbed neuronal migration resulting in ectopic rests of GM
  - At germinal zone → periventricular HTP
  - Before reaching cortex → subcortical & band HTP
  - At pia → cobblestone brain



CLINICAL ISSUES

- Symptoms: Developmental delay, motor dysfunction, seizures (40% of intractable epilepsy cases)
- Palliative surgery is reserved for intractable seizures



DIAGNOSTIC CHECKLIST

- Look closely for associated anomalies of adjacent cortex

(Left) *Axial T2 MR in an 18-month-old girl with Aicardi syndrome & seizures shows extensive bifrontal periventricular & subcortical gray matter heterotopia. Note the thin, irregular cortex overlying the foci of heterotopia. The corpus callosum is absent.* **(Right)** *Axial T1 MR in a 2-month-old with seizures shows extensive, symmetric heterotopic gray matter with a brain-in-brain appearance. The more superficial cortex is thinner than usual with poor sulcation.*

(Left) *Coronal T2 MR in a 15-year-old girl with seizures demonstrates a band of gray matter of variable thickness within the deep & subcortical white matter, consistent with band heterotopia. Note the thin layer of intervening white matter between the band of heterotopic gray matter & cortex.* **(Right)** *Axial T1 MR in a 9-year-old boy with epilepsy shows the diffuse form of periventricular nodular heterotopia. Note the abnormal overlying cortex in multiple areas.*

TERMINOLOGY

Synonyms

- Gray matter (GM) heterotopia (HTP)
- Double cortex ≈ band HTP

Definitions

- Abnormally located GM due to foreshortened or prolonged migration of neuronal groups
  - Occurs anywhere from periventricular germinal zone (GZ) to pia

IMAGING

General Features

- Best diagnostic clue
  - Nodules or ribbons of ectopic tissue that follow GM on all MR sequences
- Location
  - Periventricular, subcortical/transcerebral, pial

CT Findings

- NECT**:** Isodense with GM; rare dysplastic Ca^{2+}

MR Findings

- T1: Isointense to GM; well marginated
- T2: Isointense to GM
- FLAIR: Isointense to minimally hyperintense to GM
- DWI: Isointense to GM
- T1 C+: No enhancement
- Fetal MR: Nodular, irregular ventricular lining ± abnormal sulcation

Ultrasonographic Findings

- Nodular periventricular HTP may be evident as irregular/lobulated ventricular margin

Imaging Recommendations

- Protocol advice
  - Multiplanar reconstructions of
    - Volumetric 3D T1 spoiled GRE MR (e.g., SPGR) in myelinated brain
    - Volumetric 3D T2 FSE MR (e.g., Cube/VISTA/SPACE) in unmyelinated brain

DIFFERENTIAL DIAGNOSIS

Tuberous Sclerosis

- Subependymal nodules in regions of fetal germinal matrix
- Often calcify; may enhance
- Associated with cortical/subcortical tubers

Closed-Lip Schizencephaly

- Polymicrogyric GM lines apposed walls of pial-ependymal cleft with funnel-shaped outpouching (dimple) of ventricular wall

Ependymal Spread of Tumor

- Nodular or crescentic foci along ventricular lining
- Usually enhance, may restrict diffusion

Congenital Cytomegalovirus

- Periventricular Ca^{2+} without protrusion into ventricle
- ± white matter injury, polymicrogyria, schizencephaly, cerebellar hypoplasia, microcephaly

PATHOLOGY

General Features

- Etiology
  - Genetic: Mutations alter molecular interactions at multiple migration points → migration arrest → HTP
  - Acquired: Fetal insult (ischemia, infection, etc.) → disturbed neuronal migration/cortical positioning
- Genetics
  - Diffuse periventricular nodular HTP is often genetic
    - *FLNA* (Xq28), *ARFGEF2* (20q13.13), 5p15
  - Band HTP: Mild form of classic lissencephaly (agyria/pachygyria/double cortex)
    - *LIS1* (17p13.3), *DCX* (Xq22.3-q23), tubulin genes
- Associated abnormalities
  - Focal periventricular nodular HTP in 30% of Chiari 2
- Embryology
  - Landing zones with abnormal neuronal migration
    - At GZ → periventricular HTP
    - Before reaching cortex → subcortical & band HTP
    - At pia → cobblestone brain

Microscopic Features

- Multiple types of immature/dysplastic cells
  - Excitatory exceed inhibitory

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Developmental delay, seizures, motor dysfunction
  - Age of onset & severity of symptoms depend on location & extent of abnormalities

Demographics

- Epidemiology
  - Found in up to 40% of patients with intractable epilepsy

Natural History & Prognosis

- Prognosis depends on location & extent of HTP, associated malformations, & seizure severity
- Focal HTP can be incidental on imaging/autopsy

Treatment

- Palliative surgery is reserved for intractable seizures

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- HTP is commonly associated with other anomalies
  - Look closely for overlying cortical abnormalities

Schizencephaly

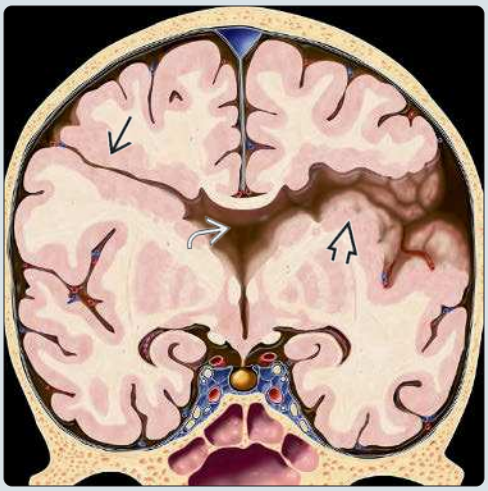
KEY FACTS

IMAGING

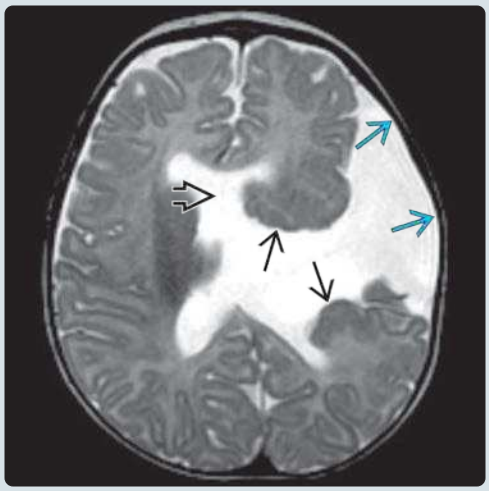
- Transmantle cleft lined by gray matter (GM) extending from cortical surface to ventricle
  - Closed-lip defect: Cleft walls are closely apposed
    - Dimple along ependymal surface of lateral ventricle
    - CSF cleft should be present but may be subtle
  - Open-lip defect: Cleft walls are clearly separated by CSF; widths & shapes of clefts are variable
- GM lining cleft is inherently abnormal
  - Polymicrogyria, heterotopia
- May occur anywhere but most often perisylvian
- Bilateral in up to 1/2 of patients
  - Unilateral often shows contralateral polymicrogyria
- ± hemosiderin staining of cleft, ventricles
- Associated with absence of cavum septum pellucidum ± optic nerve hypoplasia (a.k.a. septo-optic dysplasia)
  - Anomalies of hypothalamic-pituitary axis
  - Callosal hypogenesis other midline anomalies

TOP DIFFERENTIAL DIAGNOSES

- Encephaloclastic porencephaly
- Transmantle heterotopia
- Ventricular rupture
- Hydranencephaly

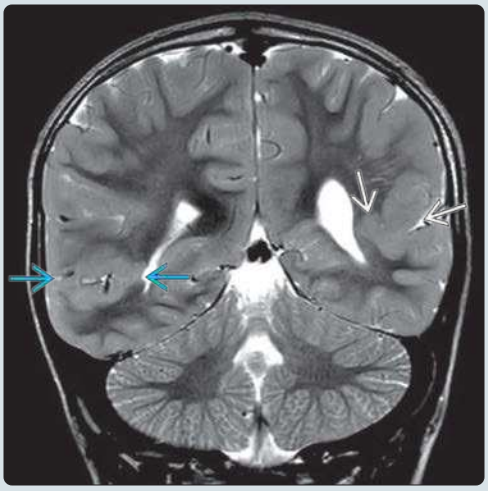


PATHOLOGY

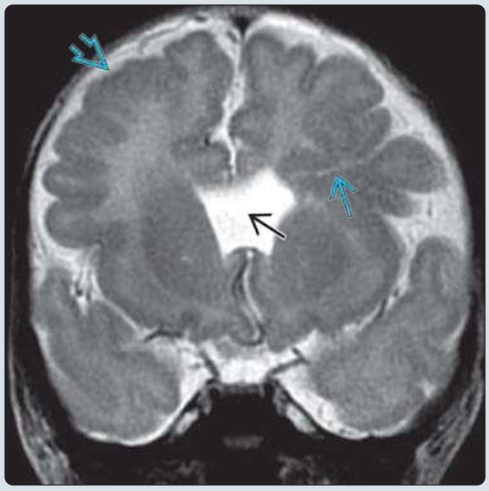


- In utero insult affecting neuronal organization
- Considered to be extreme spectrum of polymicrogyria
- Etiologies include: Vascular insult, infection (CMV, HSV), maternal trauma, toxins; rare genetic etiologies

CLINICAL ISSUES



- Seizures, motor abnormalities, developmental delay
- Type & severity of clinical impairment is determined by
  - Number, size, & location of clefts
    - Worse prognosis for bilateral open clefts vs. unilateral closed defect
  - Presence of associated malformations



(Left) *Coronal graphic shows bilateral schizencephalic clefts, closed lip on the right ⇨ & open lip on the left ⇨. Both clefts are lined by dysplastic gray matter. Note the absence of the septum pellucidum ⇨.* **(Right)** *Axial T2 MR of a 4-month-old girl with a left open-lip schizencephaly shows mild overlying calvarial thinning/expansion ⇨ secondary to CSF pulsation. There is polymicrogyria ⇨ of gray matter lining the cleft. The septum pellucidum is absent ⇨.*

(Left) *Coronal T2 MR in a 13-year-old boy with a right closed-lip schizencephaly shows buckling of the inner ependymal margin on the right ⇨. There is also left polymicrogyria with transmantle heterotopia ⇨.* **(Right)** *Coronal T2 MR in an 11-month-old with septo-optic dysplasia (SOD) shows left closed-lip schizencephaly ⇨, absence of the septum pellucidum ⇨, & contralateral right polymicrogyria ⇨. Schizencephaly & polymicrogyria are commonly associated with SOD.*

TERMINOLOGY

Definitions

- Transmantle cleft in brain parenchyma extending from cortical surface to ventricle (i.e., pia to ependyma)
  - Lined by dysplastic gray matter (GM)

IMAGING

General Features

- Best diagnostic clue
  - Full-thickness transmantle, GM-lined cleft extending from pial to ependymal surfaces
    - Closed lip (type I): Walls of cleft are in direct contact
    - Open lip (type II): CSF throughout cleft
      - Variable cleft widths
  - Up to 50% are bilateral

CT Findings

- NECT
  - Cerebral cleft of CSF density (in open-lip type)
  - Thinned, expanded calvarium with large open-lip clefts
    - Calvarial remodeling from CSF pulsations through cleft or expansion of diverticulum associated with cleft (roofing membrane)

MR Findings

- T1, T2, FLAIR
  - Closed type may appear as irregular tract of GM from cortical surface to ventricle (fused cleft)
    - Look for dimple in wall of lateral ventricle
  - Open type can be wide & wedge-shaped or have nearly parallel walls
  - Abnormal GM lining cleft: Polymicrogyria or heterotopia
  - ± thin overlying membrane of pia or ependyma (a.k.a. roofing membrane)
- T2* GRE
  - ± hemosiderin staining of ventricles &/or cleft from prenatal insult

Imaging Recommendations

- Protocol advice
  - Multiplanar sequences (± volumetric acquisition) are particularly important for closed-lip type

DIFFERENTIAL DIAGNOSIS

Encephaloclastic Porencephaly

- Parenchymal cavity due to insult after cortical organization is complete
- Lined by gliotic white matter, not dysplastic GM

Transmantle Heterotopia

- No cleft; can be difficult to differentiate from closed-lip schizencephaly (lies along same pathologic spectrum)

Ventricular Rupture

- Due to severe congenital hydrocephalus (e.g., aqueductal stenosis), most often in medial parietal region

Hydranencephaly

- Destruction of middle & anterior cerebral artery territories
- May mimic severe bilateral open-lip schizencephaly

PATHOLOGY

General Features

- Etiology
  - In utero injury to developing brain prior to completion of neuronal organization
    - Often considered to be extreme spectrum of polymicrogyria
  - Etiologies may be hypoxic-ischemic, vascular, teratogenic (alcohol, warfarin, & cocaine), infectious (CMV, HSV)
- Genetics
  - Genetic cause is uncommon
  - Single gene mutations
    - Mutations of *COL4A1*, *EMX2*
- Associated abnormalities
  - GM heterotopia is often seen adjacent to cleft
  - Contralateral polymicrogyria is common
  - Septum pellucidum is absent in large percentage of schizencephaly cases, especially bilateral clefts
  - Hypoplastic optic nerve syndrome [a.k.a. septo-optic dysplasia (SOD)]
    - Optic nerve hypoplasia: Key to diagnosis (& best determined by ophthalmologic exam) ± other commonly associated findings
      - Absence of septum pellucidum
      - Abnormalities of hypothalamic-pituitary axis
      - Corpus callosum dysgenesis
    - Schizencephaly in 30-50% of SOD patients

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizures, hemiparesis, developmental delay
  - Bilateral clefts: Tetraparesis, blindness, more severe cognitive impairment

Demographics

- Epidemiology
  - Incidence: 1.5/100,000 births
  - 1 in 3 children have non-CNS abnormalities
    - > 50% likely due to vascular disruption
      - Gastroschisis, bowel atresias, & amniotic band disruption sequence
  - Associated with ↓ maternal age, lack of prenatal care, ethanol abuse
  - Other risk factors: Prenatal infection, thrombophilia, disorders of blood vessel wall integrity

Treatment

- Surgery for medically intractable epilepsy
- CSF diversion/shunting in cases of ↑ intracranial pressure
  - Abnormal CSF dynamics associated with cleft

Polymicrogyria

KEY FACTS

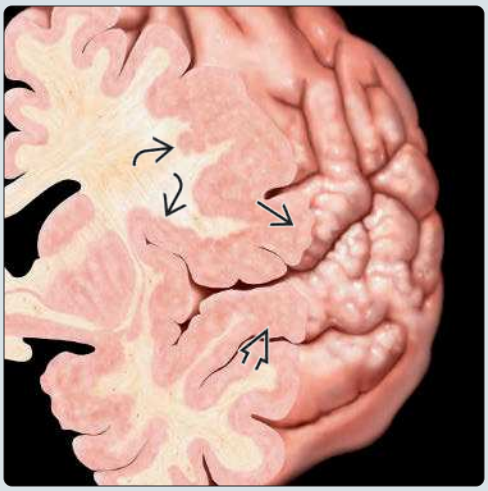
TERMINOLOGY

- Polymicrogyria (PMG)
- Traditionally considered malformation of late neuronal migration & cortical organization resulting in abnormal distribution of neurons; disputed by some literature

IMAGING

- Excessively small & disorganized gyral convolutions with shallow sulci, creating appearance of nodular cortex
- Commonly perisylvian; may be unilateral or bilateral
- Imaging findings depend on patient age
  - Fetal: Premature appearance of sulci
  - 1-2 years: Abnormal sulcation pattern
  - > 2 years: Abnormally thick, irregular cortex
- Optimal MR sequence depends on brain maturation
  - Incomplete myelination (< 1 year): Thin-section T2 MR
  - Complete myelination (> 1-2 years): 3D SPGR T1 MR
- Look for additional findings to suggest underlying CMV or metabolic/syndromic diagnosis
  - NECT or SWI/GRE MR may detect Ca^{2+} in CMV

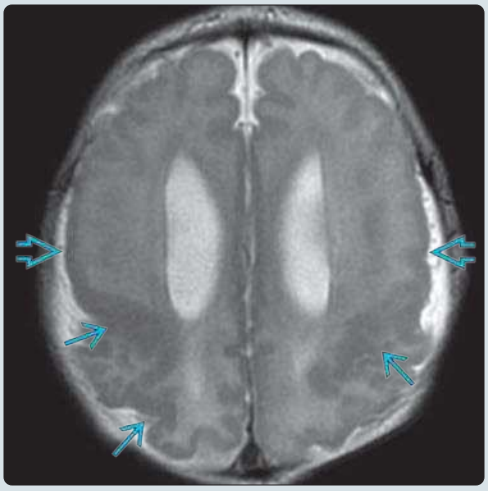
TOP DIFFERENTIAL DIAGNOSES



- Microcephaly with simplified gyral pattern
- Hemimegalencephaly
- Pachygyria
- Cobblestone malformations

PATHOLOGY

- Causes: Fetal infection, ischemia, or genetic/syndromic
- Associated syndromes: Aicardi, Zellweger, DiGeorge, Warburg microsyndromes
- PMG lines clefts of schizencephaly



CLINICAL ISSUES

- Most common presentation: Seizures, developmental delay, spasticity; varies with extent/location of PMG
  - Neonatal (in severe) vs. adolescence (in mild, focal)

(Left) *Coronal oblique graphic shows thickened "pebbly" or nodular gyri of polymicrogyria (PMG) involving the frontal & temporal opercula. Note the abnormal sulcation & irregular gray matter-white matter (GM-WM) junctions in the affected regions.* **(Right)** *Sagittal T1 MR in a 17-year-old with extensive PMG shows diffuse nodularity along the surface of the cortex & at the GM-WM junction. Note the continuation of the sylvian fissure into the superior parietal lobule, a characteristic appearance for PMG.*

(Left) *Axial T2 MR in a 3-month-old with congenital CMV shows a nearly symmetric appearance of abnormally thick & irregular/nodular cortex in a perisylvian distribution, consistent with PMG. A paucity of gyri & sulci is seen more anteriorly.* **(Right)** *Coronal SSFSE T2 MR in a 25-weeks-gestation fetus shows bilateral foci of irregular cortex, consistent with extensive PMG. The cortex in these regions should appear smooth at this time in gestation.*

TERMINOLOGY

Abbreviations

- Polymicrogyria (PMG)

Definitions

- Traditionally considered malformation of late neuronal migration & cortical organization resulting in abnormal distribution of neurons; disputed by some literature
  - Regardless, macroscopic result is nodular cortex with disorganized small, undulating gyri & shallow sulci

IMAGING

General Features

- Best diagnostic clue
  - Excessively small & numerous gyri
- Location
  - Can be unilateral, bilateral, multifocal
  - Most common in perisylvian regions (60-70%)
- Size
  - Ranges from single gyrus to entire cerebrum
- Morphology
  - Small, irregular gyri
  - Thick nodular cortex with irregular gray matter-white matter (GM-WM) junctions
  - May appear as deep infolding of thick cortex
  - Schizencephalic clefts are lined by PMG
  - Sylvian fissure may extend into parietal lobe

CT Findings

- Look for altered sulcation pattern (suggests PMG)
- Periventricular Ca^{2+} in CMV

MR Findings

- **T1**: Irregular cortical surface; thick-appearing cortex; deep infolding of irregular cortex
- **T2**: 2 imaging patterns depending on patient age
  - < 12 months: Undulating cortex of normal thickness
  - > 18 months: Thick, bumpy cortex (6-8 mm)

Nuclear Medicine Findings

- **PET**: Ictal hypermetabolism & interictal hypometabolism

Imaging Recommendations

- Protocol advice
  - Volumetric 3D SPGR (T1) MR in mature brain
  - Thin-section T2 MR if unmyelinated

DIFFERENTIAL DIAGNOSIS

Microcephaly With Simplified Gyral Pattern

- Normal cortex with primary & secondary sulci but absent tertiary sulci

Hemimegalencephaly

- ↑ size of involved hemisphere (vs. ↓ in PMG)

Pachygyria

- Thick cortex (8-10 mm), smooth GM-WM junction

Cobblestone Malformations

- Hypomyelination, cerebellar dysgenesis, pontine hypoplasia
- Often associated with congenital muscular dystrophy

PATHOLOGY

General Features

- Etiology
  - Intrauterine infection, ischemia, or gene mutations
- Genetics
  - Most common: 1p36.3 & 22q11.2 microdeletions
- Associated abnormalities
  - Aicardi, Zellweger, Warburg microsyndromes
  - Congenital bilateral perisylvian syndrome (Foix-Chavany-Marie)
  - Corpus callosum dysgenesis, periventricular nodular heterotopia, & subcortical heterotopia
  - Microcephaly (~ 50%); more common in generalized forms of PMG

Gross Pathologic & Surgical Features

- Multiple small gyri lie in haphazard orientation

Microscopic Features

- Derangements of normal 6-layered cortex
  - Reduced numbers of neurons
  - Areas of 2-, 4-, & 6-layered cortex are described, even in different regions of same brain
    - Normal vs. abnormal laminar arrangement is disputed

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizures, developmental delay, spasticity

Demographics

- Age
  - Symptom onset varies with extent/location of malformation
    - Neonatal manifestations in severely affected vs. 2nd decade of life for focal unilateral PMG
- Epidemiology
  - Malformations of cortical development are found in ~ 40% of children with intractable epilepsy

Treatment

- Surgical options with medically refractory seizures
  - Focal PMG may be resected
  - Corpus callosotomy if bilateral or unresectable lesions

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Look for PMG in congenital hemiplegia with epilepsy
  - Schizencephaly is always lined by PMG
  - Open sylvian fissures with thick cortex suggest PMG
- Look for secondary findings of CMV or syndrome

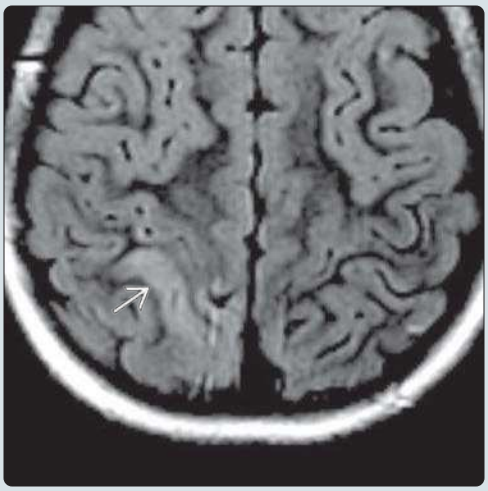
Focal Cortical Dysplasia

KEY FACTS

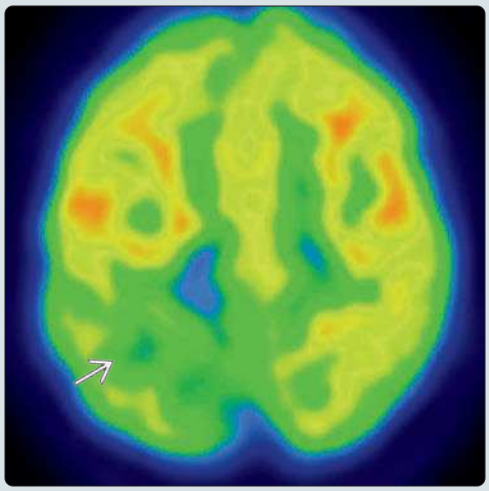
TERMINOLOGY

- Cortical disorganization & abnormal laminar architecture

IMAGING

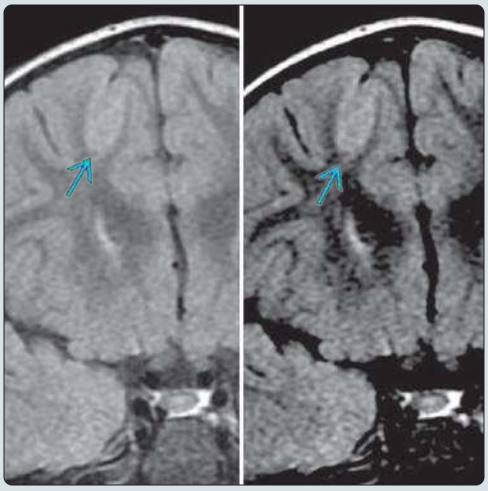


- Focal cortical dysplasia (FCD) type 1
  - MR imaging findings are present in 22-64%, may be lower in children
    - White matter (WM) volume loss
    - Ill-defined WM ↑ signal
    - Blurring of gray matter-WM junction
    - Cortical signal change
    - Abnormal sulcal & gyral pattern
- FCD type 2
  - MR imaging findings are more commonly present (60-100%)
    - Focal signal abnormality in subcortical WM
    - Blurring of gray matter-WM junction
    - Cortical thickening & signal change
    - Abnormal sulcal & gyral pattern

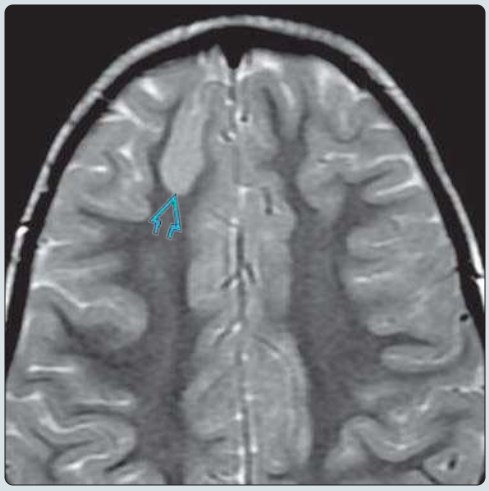


PATHOLOGY

- FCD type 1
  - Abnormal lamination of cortex without dysmorphic neurons
- FCD type 2
  - Abnormal lamination of cortex with dysmorphic neurons, ± balloon cells
- FCD type 3
  - FCD associated with other structural lesions



CLINICAL ISSUES



- FCD is most common pathology seen in pediatric patients with surgically treated epilepsy
  - Type 1 dysplasias are more commonly seen in adults
- Epilepsy surgery effectiveness is dependent on type of underlying pathology
  - Type 1 FCD: 13-21% seizure free
  - Type 2 FCD: 52-91% seizure free

(Left) *Axial FLAIR MR in an 8-year-old girl shows hyperintense signal in the right parietal cortex, a common finding in focal cortical dysplasia (FCD). Pathology demonstrated FCD type 2B, which is usually visible on imaging.* **(Right)** *Axial color-coded FDG PET in the same patient shows focally ↓ metabolism in the area of MR signal abnormality. FDG PET is particularly helpful in identifying FCD lesions that are not visible or very subtle on conventional MR imaging.*

(Left) *Coronal FLAIR MR images in a 3-year-old with FCD type 2B with varying contrast windowing are shown. Note how FCD is much more conspicuous in the image on the right with windowing emphasizing greater contrast. Windowing is an important means to increasing detection of subtle FCD lesions.* **(Right)** *Axial T2 MR in the same patient shows an abnormally deep sulcus with cortex that is both thickened & slightly ↑ in signal intensity compared to adjacent normal cortex, typical findings in FCD.*

TERMINOLOGY

Definitions

- Focal cortical dysplasia (FCD)
  - Cortical disorganization & abnormal laminar architecture

IMAGING

General Features

- FCD type 1
  - Only 22-64% have imaging findings, may be lower in children (12%)
  - When present, MR findings are often subtle
    - White matter (WM) volume loss
    - Ill-defined WM ↑ signal
    - Blurring of gray matter-WM junction
    - Cortical signal change
    - Abnormal gyral & sulcal pattern
- FCD type 2
  - 60-100% have identifiable abnormalities on MR
    - Focal signal abnormality in subcortical WM
    - Blurring of gray-WM junction
    - ↑ cortical thickness
    - Cortical signal change
    - Abnormal gyral & sulcal pattern
  - MR findings highly suggestive of type 2
    - Transmantle sign: WM signal tapering from subcortical region to ventricular margin
    - Depth of sulcus morphology: ↑ signal at depth of abnormal sulcus ± transmantle sign

Nuclear Medicine Findings

- PET
  - ↓ interictal vs. ↑ ictal metabolic activity
- Perfusion SPECT
  - Comparative ictal & interictal scans with Tc-99m HMPAO or Tc-99m ECD
    - ↑ ictal vs. ↓ interictal perfusion

Imaging Recommendations

- Protocol advice
  - Higher field strength (3T) is preferred
  - 3D isotropic MR techniques (T1 & FLAIR) allow multiplanar reconstruction, PET/SPECT/MEG fusion, & intraoperative guidance

DIFFERENTIAL DIAGNOSIS

Tuberous Sclerosis

- Radial migration lines & cortical tubers share many imaging features with FCD, especially FCD type 2B
- Tubers & FCD type 2B share similar histopathology

Cortical Neoplasm

- Especially DNET, ganglioglioma, or other low-grade glioma
- Abnormal enhancement excludes FCD

Incomplete or Delayed Myelination

- Focal incomplete myelination may mimic FCD
- Follow-up imaging after myelin maturation is helpful

PATHOLOGY

General Features

- Etiology
  - FCD type 1: Disturbance of cortical organization
  - FCD type 2: Disturbance of cellular proliferation

Staging, Grading, & Classification

- FCD type 1
  - Isolated alterations in cortical organization & lamination
    - 1A: Abnormal radial cortical lamination
    - 1B: Abnormal tangential cortical lamination
    - 1C: Abnormal radial & tangential cortical lamination
- FCD type 2
  - Isolated alterations in cortical organization & lamination with dysmorphic neurons
    - 2A: Presence of dysmorphic neurons
    - 2B: Dysmorphic neurons & balloon cells
- FCD type 3
  - FCD associated with another principal (non-FCD) lesion
    - 3A: FCD associated with hippocampal sclerosis
    - 3B: FCD associated with glial or glioneuronal tumor
    - 3C: FCD associated with vascular malformation
    - 3D: FCD associated with early-acquired encephaloclastic lesion

CLINICAL ISSUES

Presentation

- 10% of all epilepsy patients
- 50% of children undergoing surgery for intractable epilepsy

Natural History & Prognosis

- Seizure-free outcome following surgery is much better in FCD type 2 (52-91%) compared to FCD type 1 (21%)

Treatment

- Focal resection ± preceding subdural EEG grid localization

DIAGNOSTIC CHECKLIST

Consider

- Review localizing EEG findings during image interpretation if available

Image Interpretation Pearls

- Consideration of seizure semiology, localizing EEG findings, & NM imaging to help localize MR abnormalities
- ~ 1/3 of cases are initially missed because findings are subtle
- Proper MR imaging technique improves lesion detection
- Windowing to ↑ contrast on T2 & FLAIR imaging is helpful to improve subtle FCD detection.

Chiari 1

KEY FACTS

TERMINOLOGY

- Chiari 1 malformation (CM1); synonyms: Chiari type 1, Chiari 1 deformity, cerebellar tonsillar ectopia

IMAGING

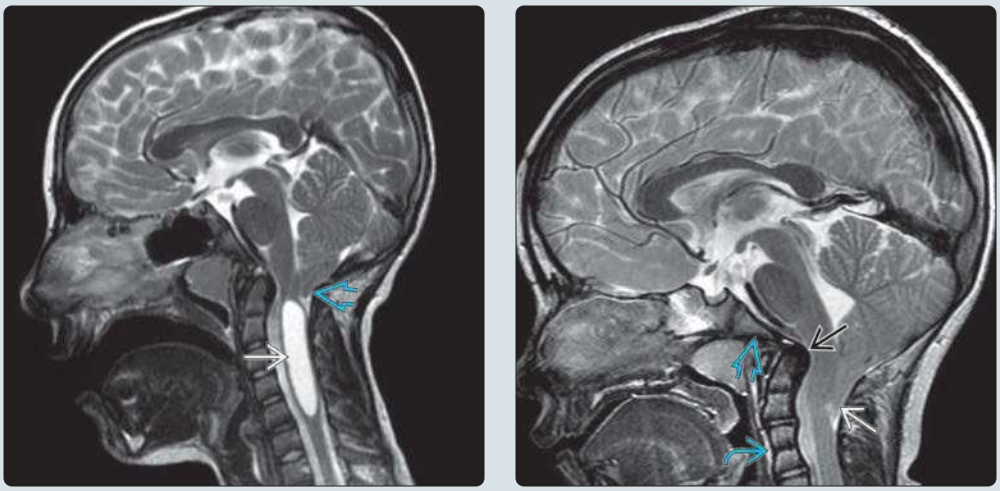
- Pointed cerebellar tonsils extending ≥ 5 mm below foramen magnum (basion-opisthion/McRae line) with effacement of CSF spaces
- ± retroflexed odontoid, horizontal shortened clivus, basilar invagination, atlantooccipital assimilation
- ± caudal descent of brainstem, brainstem compression, medullary bump
- ± syringohydromyelia, scoliosis

TOP DIFFERENTIAL DIAGNOSES

- Normal low-lying cerebellar tonsils
- Chiari 2 malformation
- Tonsillar herniation due to ↑ intracranial pressure
- Intracranial hypotension

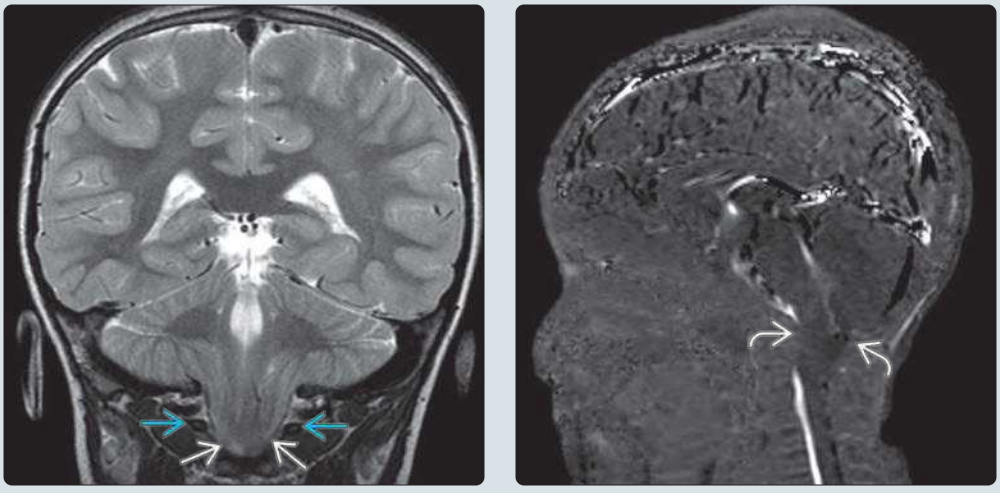
PATHOLOGY

- Most common cause is believed to be small/underdeveloped posterior fossa; no association with open spinal dysraphism
- Can result from premature closure of sutures
  - Causes include shunted infantile hydrocephalus, bone dysplasias, genetic syndromes



CLINICAL ISSUES

- Most common presenting symptom: Occipital headache
  - Up to 30% of patients are asymptomatic
- Goal of surgery in symptomatic patients: Restore normal CSF flow at foramen magnum
  - Suboccipital decompression, resection of C1 posterior arch ± duraplasty, cerebellar tonsil cautery



DIAGNOSTIC CHECKLIST

- Look for presence of syrinx → usually requires surgical treatment of Chiari 1

(Left) *Sagittal T2 MR shows the low-lying, pointed cerebellar tonsils typical of a Chiari 1 malformation. Note the expansion of the cervical spinal cord by a large syrinx.* **(Right)** *Sagittal T2 MR in a 5-year-old with occipital headaches demonstrates pointed, low-lying cerebellar tonsils with associated effacement of CSF spaces. Note the short horizontal clivus, retroverted dens, impression upon the medulla, & segmentation anomaly at the C3-C4 levels, consistent with a complex Chiari 1 malformation.*

(Left) *Coronal T2 MR in the same patient demonstrates pointed, low-lying cerebellar tonsils extending below the C1 ring, typical of a Chiari 1 malformation.* **(Right)** *Sagittal image from a phase-contrast cine MR (with hyperintense signal at sites of active CSF or venous flow) in the same patient shows absence of CSF flow at the craniocervical junction due to the Chiari 1 malformation.*

TERMINOLOGY

Definitions

- Compressed & pointed cerebellar tonsils extending below foramen magnum with effacement of CSF spaces

IMAGING

General Features

- Best diagnostic clue
  - Pointed cerebellar tonsils (unilateral or bilateral) extending ≥ 5 mm below foramen magnum (basion-opisthion line)
    - No consensus statement on exact definition

CT Findings

- Crowding of foramen magnum on axial CT images
  - Sagittal reconstructed images are very helpful
  - Beware that streak artifact from skull base can falsely simulate Chiari 1 malformation
- Superior aspect of syrinx may be imaged on head CT
- Associated osseous anomalies may include small posterior fossa, short horizontal clivus, retroverted dens, basilar invagination, platybasia, hypoplastic occipital condyles, segmentation anomalies (such as atlantooccipital assimilation), scoliosis

MR Findings

- T1, T2, FLAIR
  - Pointed (not rounded) cerebellar tonsils extending ≥ 5 mm below foramen magnum
  - Crowded foramen magnum with small/effaced cisterns ± brainstem compression
  - ± small posterior fossa, elongated 4th ventricle
  - ± syringohydromyelia/syrinx, scoliosis
  - ± dorsal cervicomedullary "bump"
  - Other descriptions are usually considered subtypes
    - Chiari 1.5: Brainstem herniation
    - Complex Chiari: Retroflexed odontoid causes medullary bump, abnormally acute clival-cervical angle; ± atlantooccipital assimilation, ± basilar invagination, ± platybasia
- MR cine
  - Restricted CSF flow through foramen magnum ± ↑ brainstem/cerebellar tonsil motion (pistoning)

DIFFERENTIAL DIAGNOSIS

Normal Variation of Cerebellar Tonsil Position

- Tonsils may normally lie below foramen magnum
  - May be accentuated by certain head positions
- Rounded tonsils but no crowding at foramen magnum

Chiari 2 Malformation

- Very small posterior fossa with hindbrain herniation in setting of open spinal dysraphism at birth
- ± hydrocephalus, tectal beaking, & other findings

Tonsillar Herniation Due to ↑ Intracranial Pressure

- Neoplasm, hemorrhage, hydrocephalus, infarct

Intracranial Hypotension

- Sagging brain with dural thickening/enhancement, distended dural sinuses

PATHOLOGY

General Features

- Etiology
  - Primary congenital malformation vs. secondarily acquired morphologic changes
  - Primary: Posterior fossa underdevelopment theory is most common
  - Secondary: Premature closure of cranial sutures &/or generalized abnormal bone formation
    - Shunted infantile hydrocephalus
    - Calvarial thickening of bone dysplasias or thalassemia
    - Genetic syndromes
  - Seen in 2-10% of patients with idiopathic intracranial hypertension (a.k.a. pseudotumor cerebri)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Occipital headache
    - Exacerbated by cough, Valsalva, neck extension, or physical exertion
  - Less common: Cerebellar, brainstem, bulbar, cord motor/sensory symptoms

Demographics

- True prevalence is unknown given how frequently Chiari 1 is picked up incidentally

Treatment

- Posterior fossa decompression (PFD): Suboccipital craniectomy with C1 laminectomy ± duraplasty, arachnoid opening/dissection, cerebellar tonsillar reduction/cautery
- Complex Chiari 1 may also require odontoid resection &/or craniocervical junction fusion
- Operative complications depend upon surgery
  - PFD: ~ 2% have CSF-related complications with ↑ reoperation rate
  - PFD + duraplasty: ~ 18% have CSF-related complications but ↓ reoperation rate
  - Most common: CSF leak, pseudomeningocele, infection
- Conservative management for asymptomatic or minimally symptomatic children without syrinx

DIAGNOSTIC CHECKLIST

Consider

- Degree of tonsillar descent does not always correlate with symptoms: Chiari 1 is frequently picked up incidentally

SELECTED REFERENCES

1. Alford EN et al: Imaging characteristics associated with surgery in Chiari malformation type I. J Neurosurg Pediatr. 1-9, 2021
2. Hiremath SB et al: The perplexity surrounding Chiari malformations - are we any wiser now? AJNR Am J Neuroradiol. 41(11):1975-81, 2020

Chiari 2

KEY FACTS

TERMINOLOGY

- Constellation of intracranial findings, mainly hindbrain herniation, due to open spinal dysraphism [either myelomeningocele (MMC) or myelocele]

IMAGING

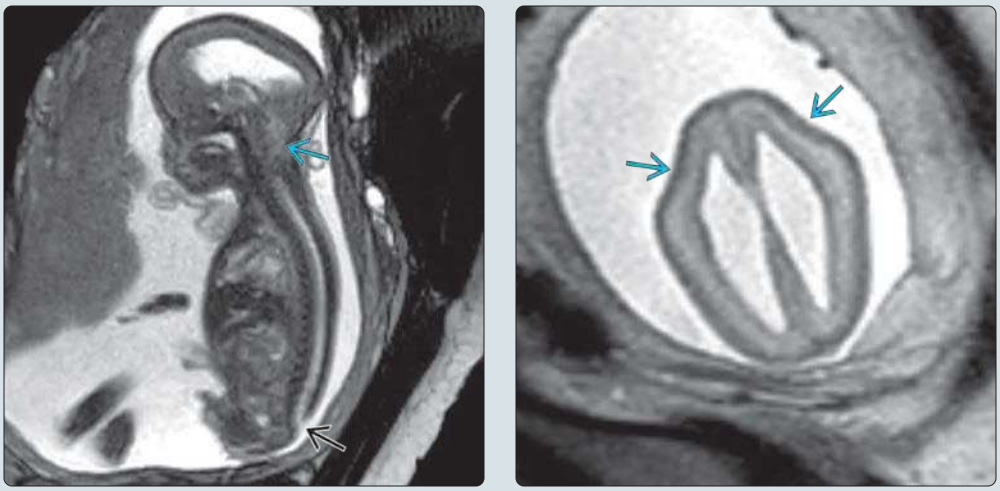
- Small posterior fossa: Cerebellum herniates downward through foramen magnum & upward through incisura
- Caudal brainstem herniation with cervicomedullary kink, tectal beaking
- ± ventriculomegaly
- Falx insufficiency, thickened massa intermedia, callosal dysgenesis, ↓ white matter volume
- ± subependymal gray matter heterotopias
- Lacunar skull (lückenschädel)

TOP DIFFERENTIAL DIAGNOSES

- Chiari 1 malformation
- Chiari 3 malformation
- Intracranial hypotension
- Severe, chronic shunted hydrocephalus

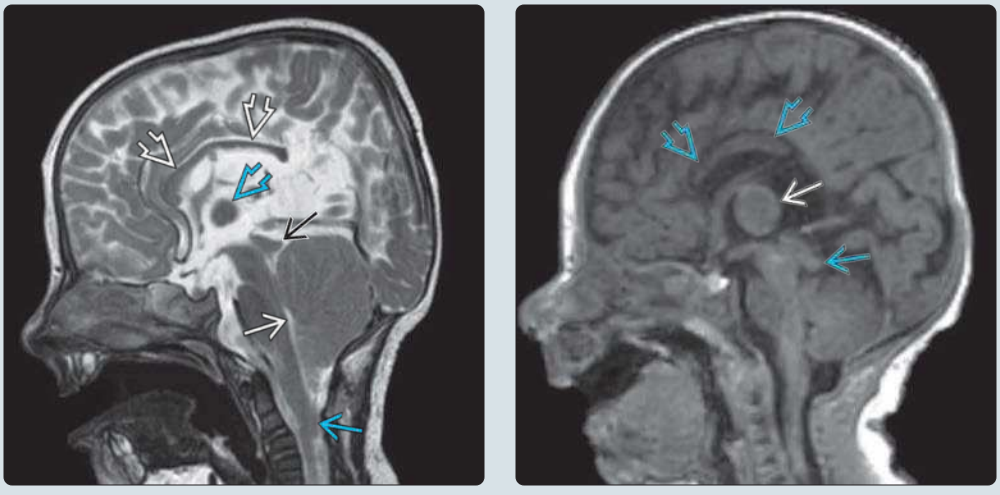
PATHOLOGY

- Secondary to sequelae of chronic in utero CSF leakage through open spinal dysraphism (4th fetal week)



CLINICAL ISSUES

- Lower extremity paresis/spasticity, bowel/bladder dysfunction, symptoms of brainstem compression (swallowing difficulties, stridor, apnea), epilepsy
- In utero repair of MMC ↓ need for postnatal CSF diversion (shunting) & may improve neurologic outcomes in some patients



DIAGNOSTIC CHECKLIST

- Confirm history of open spinal dysraphism before assigning Chiari 2 malformation
- Fetal surgery results in milder Chiari 2 phenotype with less hindbrain herniation

(Left) *Sagittal SSFP FIESTA MR of a 23-weeks-gestation fetus shows hindbrain herniation in the setting of an open sacral spinal dysraphism, consistent with Chiari 2 malformation. Effacement of the 4th ventricle & cisterna magna is consistent with grade 3 Chiari 2 malformation based on fetal grading system.* **(Right)** *Axial SSFSE T2 MR in the same fetus demonstrates classic bifrontal concavity of the calvarium (a.k.a. lemon sign) & associated lateral ventriculomegaly. Note the effacement of subarachnoid CSF spaces.*

(Left) *Sagittal T2 MR in a 1-year-old after postnatal repair of a myelomeningocele (MMC) shows typical findings of Chiari 2 malformation, including cerebellar herniation, elongated & effaced 4th ventricle, tectal beaking, enlarged massa intermedia, & callosal hypogenesis.* **(Right)** *Sagittal T1 MR in a 1-month-old status post prenatal repair of a MMC shows no hindbrain herniation. Other findings of Chiari 2 are present, including callosal hypogenesis, large massa intermedia, & tectal beaking.*

TERMINOLOGY

Definitions

- Constellation of intracranial anomalies, mainly hindbrain herniation, due to open spinal dysraphism [either myelomeningocele (MMC) or myelocele]

IMAGING

General Features

- Best diagnostic clue
  - Small posterior fossa (PF) with inferior cerebellar & brainstem herniation in presence of open spinal dysraphism

Radiographic Findings

- Radiography
  - Lacunar skull (lückenschädel) → numerous undulations of inner calvarium with focal thinning

MR Findings

- Infratentorial
  - Small PF with downward sloping tentorium, low torcular Herophili
  - Hindbrain herniation (postnatal repair)
    - Caudal descent of pointed cerebellar tonsils/vermis
    - Towering appearance of cerebellum with upward herniation through widened incisura
    - Elongated, effaced, inferiorly displaced 4th ventricle with flattened fastigium
    - Cerebellar hemispheres wrap around brainstem on axial images
  - Significant hindbrain herniation is unusual after prenatal repair
  - Tectal beaking, brainstem caudal displacement ± cervicomedullary kink
- Supratentorial
  - ± ventriculomegaly
  - Midline anomalies: Large massa intermedia, callosal hypogenesis/dysgenesis, absent septum pellucidum
  - ± neuronal migrational anomalies: Subependymal gray matter (GM) heterotopia (~ 25%), polymicrogyria (rare)
  - Falx insufficiency with interdigitation of hemispheric gyri
  - Stenogyria (elongated, compact gyri) after shunting (differs from polymicrogyria)

Ultrasonographic Findings

- Grayscale ultrasound
  - Prenatal US is key for early diagnosis
    - Lemon sign: Bifrontal concavity of calvarium
    - Banana sign: Cerebellum wraps around brainstem with effacement of cisterna magna

DIFFERENTIAL DIAGNOSIS

Chiari 1 Malformation

- Low pointed cerebellar tonsils effacing CSF at foramen magnum
- Absence of associated open spinal dysraphism
- None of associated supratentorial findings seen in Chiari 2

Chiari 3 Malformation

- PF contents herniate through suboccipital encephalocele + high cervical spinal dysraphism

Intracranial Hypotension

- Dural enhancement, venous sinus engorgement, ± subdural collections
- Typically in setting of CSF leak with postural headaches

Severe Chronically Shunted Hydrocephalus

- May cause collapsed & dysmorphic brain with upward cerebellar herniation

PATHOLOGY

General Features

- Etiology
  - Folate deficiency during pregnancy is leading preventable risk factor

Staging, Grading, & Classification

- Grading system for Chari 2 malformation on fetal MR is based on PF morphology
  - Grade 1: 4th ventricle & cisterna magna are patent
  - Grade 2: 4th ventricle is effaced, cisterna magna is patent
  - Grade 3: 4th ventricle & cisterna magna are effaced

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 80-90% develop hydrocephalus requiring shunting, though incidence is lower in those who undergo prenatal repair of open spinal dysraphism
  - Varying degrees of lower extremity paresis/spasticity, clubfoot, bowel/bladder dysfunction
  - ± epilepsy, symptoms from brainstem compression (swallowing difficulties, stridor, apnea)

Treatment

- Surgical management
  - MMC is classically repaired in first 48 hours after delivery
  - CSF diversion/shunting is classically required in 80-90%
  - PF decompression in those who do not improve with shunting
  - Fetal MMC repair in select patients
    - Must have hindbrain herniation & upper level of spinal defect T1-S1
    - Reduces need for shunting; may improve neurologic outcomes in some patients
    - Improved neurologic outcomes must be balanced with potential surgical risks (e.g., premature birth)

Aqueductal Stenosis

KEY FACTS

TERMINOLOGY

- Aqueductal stenosis (AS)

IMAGING

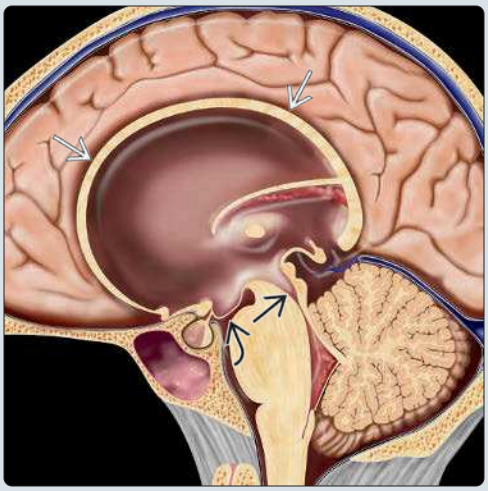
- Lateral & 3rd ventriculomegaly with normal 4th ventricle
- Obstruction of cerebral aqueduct ± tectal thickening
- Funnel-shaped enlargement of proximal cerebral aqueduct or diffuse ↓ caliber of entire aqueduct
- Absent CSF flow void in cerebral aqueduct in most cases
- Macrocephaly in fetus & infant
- Best imaging tool: MR with sagittal 3D SSFP/FISP/BTFE sequence to evaluate aqueduct

TOP DIFFERENTIAL DIAGNOSES

- Posthemorrhagic hydrocephalus
- Secondary obstructive hydrocephalus
- Supratentorial volume loss
- Communicating hydrocephalus

PATHOLOGY

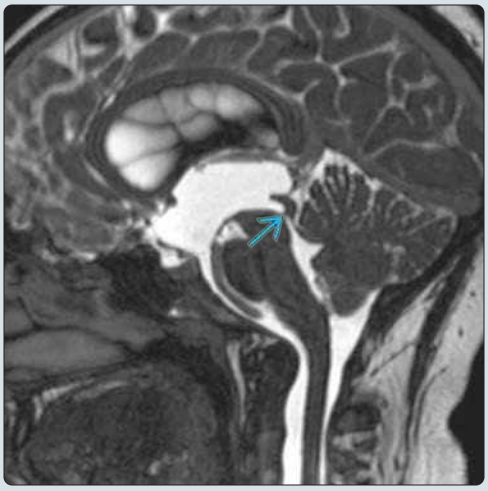
- Congenital AS is common cause of fetal hydrocephalus
- Can be isolated or associated with genetic disorder
- Subsets include stenosis from tectal thickening, obstructing web/gliotic tissue, or forking



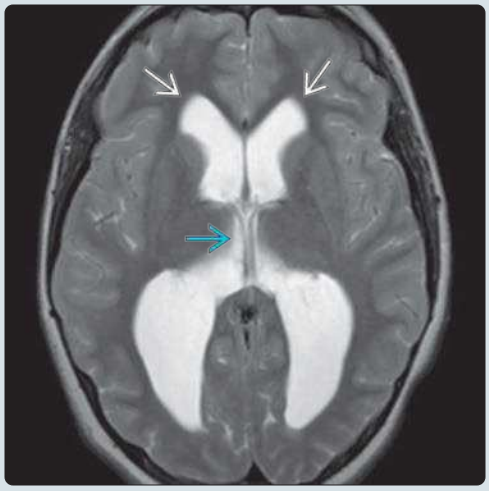
CLINICAL ISSUES

- May present at any time from birth to adulthood; bimodal distribution: 1st year of life vs. adolescence
- Fetus/infant: Macrocephaly, bulging fontanelle
- Older children: Headache, papilledema, 6th nerve palsy
- C-section may be required for prenatally diagnosed cases due to macrocephaly
- Preferred treatment → endoscopic 3rd ventriculostomy

DIAGNOSTIC CHECKLIST



- Identify associated brain anomalies, such as rhombencephalosynapsis
  - Important for prognosis



(Left) *Sagittal graphic shows obstructive hydrocephalus with a stretched (thinned) corpus callosum ➡ & a funnel-shaped cerebral aqueduct ⇨ related to obstruction at its inferior aspect. This site of obstruction allows for a normal 4th ventricle but a depressed floor of the enlarged 3rd ventricle ⇨.* **(Right)** *Sagittal SSFSE T2 MR of a fetus at 25-weeks gestation shows macrocephaly from aqueductal stenosis causing lateral & 3rd ventriculomegaly. There is no CSF in the cerebral aqueduct ⇨.*

(Left) *Sagittal 3D SSFP MR in a 15-year-old girl with a several-year history of headaches & new generalized seizures shows aqueductal stenosis with an obstructing web ⇨ at the inferior margin of the aqueduct.* **(Right)** *Axial T2 MR in the same patient shows ventriculomegaly of the lateral ➡ & 3rd ⇨ ventricles. There is no periventricular edema as late-presentation cases are often offset by alternative microscopic pathways of CSF drainage.*

TERMINOLOGY

Definitions

- Aqueductal stenosis (AS): Lateral & 3rd ventriculomegaly due to complete or partial obstruction of CSF flow through cerebral aqueduct

IMAGING

General Features

- Best diagnostic clue
  - Lateral & 3rd ventriculomegaly with normal 4th ventricle

MR Findings

- T1WI
  - Enlargement of lateral & 3rd ventricles
    - Corpus callosum (CC) is thinned & stretched upward
    - ± lateral ventricular diverticulum (a.k.a. ventricular rupture or dehiscence)
    - Extraaxial CSF effacement
      - Limits ability to evaluate gyral-sulcal pattern
- T2WI
  - Funnel-shaped enlargement of proximal cerebral aqueduct or diffuse ↓ caliber of entire aqueduct
  - Typical CSF flow void in cerebral aqueduct is usually absent
  - ± tectal plate thickening
  - Septum pellucidum is often absent due to perforation
- MR cine
  - Phase-contrast imaging may demonstrate absent or diminished CSF flow in aqueduct
  - Useful in posttreatment setting to confirm patency of endoscopic 3rd ventriculostomy
- 3D SSFP/FISP/BTFE: Sagittal plane may demonstrate membrane/web or narrowed aqueduct

Ultrasonographic Findings

- Grayscale ultrasound
  - Lateral & 3rd ventriculomegaly in newborn with macrocephaly
  - Obstetrical ultrasound may permit prenatal diagnosis
    - Usually severe lateral ventriculomegaly (> 15 mm)

Imaging Recommendations

- Best imaging tool
  - Multiplanar MR with sagittal 3D SSFP/FISP/BTFE (i.e., FIESTA, CISS, etc.) to evaluate aqueduct

DIFFERENTIAL DIAGNOSIS

Posthemorrhagic Hydrocephalus

- Most common cause of acquired hydrocephalus in infancy
- Look for blood products in ventricles & cerebral aqueduct

Secondary Obstructive Hydrocephalus

- Cause of obstruction extrinsic to aqueduct: Tumor, vascular lesion, etc.

Supratentorial Volume Loss

- Normal or ↓ head circumference
- Extraaxial CSF spaces should not be effaced

Communicating Hydrocephalus

- Secondary to impaired absorption of CSF in subarachnoid spaces rather than anatomic obstruction
- Causes include meningitis, leptomeningeal metastatic disease, venous hypertension

PATHOLOGY

General Features

- Etiology
  - AS pathologically obstructs CSF flow into 4th ventricle
    - CSF production in choroid plexus continues → ↑ CSF pressure → lateral & 3rd ventriculomegaly
- Genetics
  - X-linked hydrocephalus
    - One of most common inherited causes of AS
- Associated abnormalities
  - Rhombencephalosynapsis
    - Up to 65% have coexisting AS

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Symptoms depend on patient age at time of diagnosis
  - Onset can be insidious in older patients
- Other signs/symptoms
  - Fetus/infants: Macrocrania
  - Older patients: Headache, papilledema, 6th nerve palsy

Demographics

- Age
  - 2 peaks: 1st year of life (more common) vs. adolescence
- Epidemiology
  - AS is responsible for ~ 20% of congenital hydrocephalus

Natural History & Prognosis

- Hydrocephalus is usually progressive unless treated
  - May stabilize as compensated hydrocephalus
- Isolated congenital AS has much better prognosis than AS with genetic disorder or other brain anomalies

Treatment

- Endoscopic 3rd ventriculostomy (preferred) vs. CSF diversion by shunt
- Fetal cases may require C-section due to macrocephaly

DIAGNOSTIC CHECKLIST

Consider

- Look for coexisting brain anomalies that affect prognosis

Neurofibromatosis Type 1

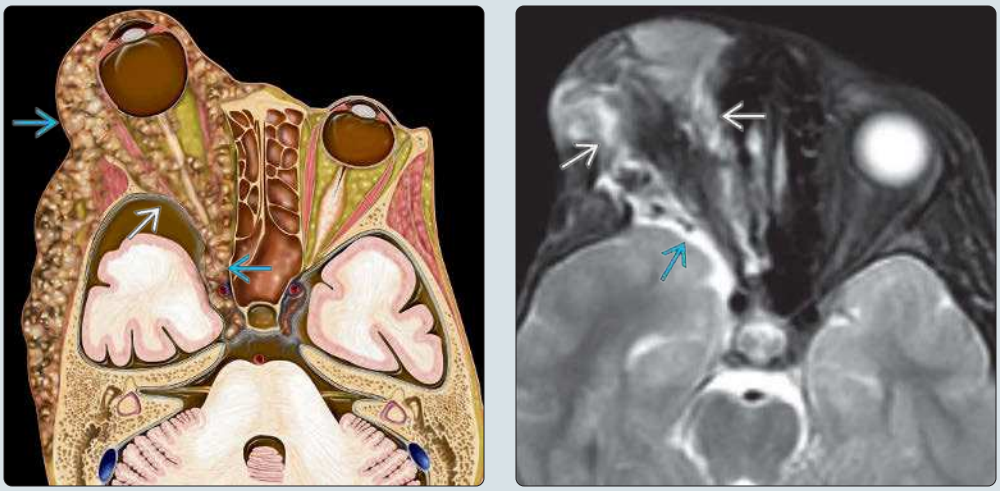
KEY FACTS

IMAGING

- Nonenhancing T2/FLAIR MR hyperintense lesions
  - 60-85% of children with neurofibromatosis type 1 (NF1)
  - Characteristic sites: Globus pallidus, cerebellar WM
  - Little/no mass effect, no enhancement
  - Higher lesion burden may ↓ cognitive functioning
  - ↓ with puberty, resolved by adulthood
- Optic pathway glioma (OPG)
  - 15-20% of children with NF1
  - Anywhere from optic nerve (ON) through optic radiations
  - Fusiform to lobular in shape, ± ON tortuosity
  - ± contrast enhancement
- Plexiform neurofibromas (PNF)
  - Lobular infiltrating soft tissue masses
  - Target appearance in cross section on T2 MR
  - Orbital PNFs are associated with sphenoid wing defects
- Vascular dysplasia (moyamoya arteriopathy)
  - 3-7% of children with NF1
  - Vessel narrowing (especially distal ICA) with collaterals

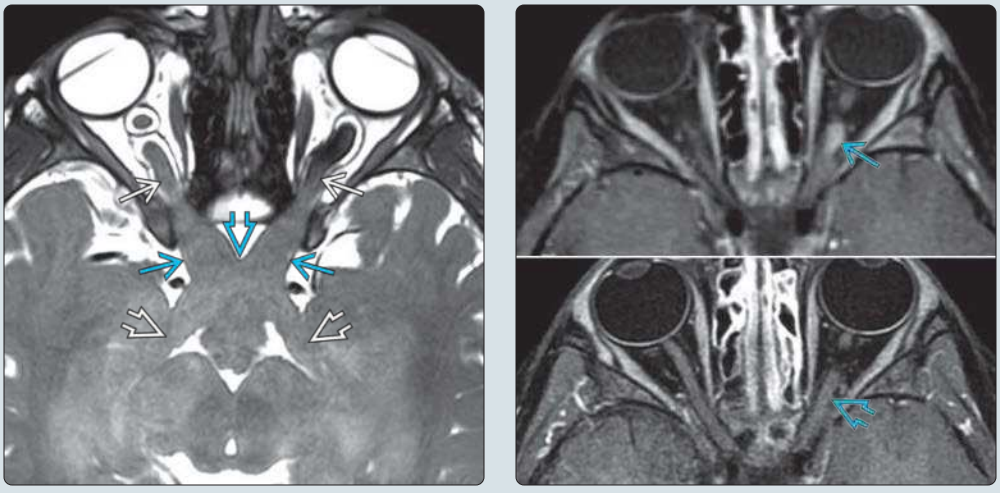
PATHOLOGY

- *NF1* gene locus on long arm of chromosome 17
- Autosomal dominant; 50% are new mutations
- Variable expression, virtually 100% penetrance



CLINICAL ISSUES

- 1:3,000-5,000 people have NF1
- NF1-related learning disability in 30-60%
- OPG & brainstem gliomas have more indolent behavior in NF1 compared to non-NF1 patients
  - OPG is typically not progressive; treatment in ~ 15%
- Phenotype is quite variable: Can be dominated by peripheral, paraspinal, or intracranial lesions



DIAGNOSTIC CHECKLIST

- Include dedicated imaging of orbits with all brain MR scans
- Look closely for vascular dysplasia

(Left) *Axial graphic of the orbits shows an infiltrating plexiform neurofibroma (PNF) ⇨ extending from the cavernous sinus through the orbit with associated "dysplasia" of the sphenoid wing ➡. (Right) Axial T2 FS MR in a 12-year-old girl with NF1 shows a large infiltrating hyperintense lesion ➡ in the right orbit, consistent with a PFN. Note the absence of the greater sphenoid wing ⇨, consistent with sphenoid wing dysplasia. Such osseous changes in the sphenoid occur almost exclusively in the setting of a PFN.*

(Left) *Axial MIP of a 3D CISS MR in a 3-year-old with NF1 shows enlargement & tortuosity of the orbital ➡ & prechiasmatic ⇨ optic nerves, optic chiasm ⇨, & optic tracts ➡, consistent with an OPG. (Right) Axial T1 C+ FS MRs show a patient with NF1 at 3 years (top) & 6 years (bottom) of age. The initial image shows mild enlargement & marked enhancement of the left orbital optic nerve ⇨, consistent with an OPG. Without any therapy, the lesion has resolved spontaneously over a 3-year period ⇨.*

TERMINOLOGY

Abbreviations

- Neurofibromatosis type 1 (NF1)

Synonyms

- von Recklinghausen disease

Definitions

- Neurocutaneous disorder (phakomatosis) characterized by
  - Nonenhancing T2/FLAIR MR signal abnormalities at characteristic brain locations
    - Unidentified bright objects (UBOs) or focal abnormal signal intensities (FASI)
  - Plexiform neurofibromas (PNF) of soft tissues
    - Differ from diffuse & localized neurofibromas (NF)
  - Astrocytomas, primarily optic pathway glioma (OPG)
  - Vascular dysplasias (moyamoya arteriopathy)
  - Skeletal dysplastic lesions
  - Café au lait spots of skin

IMAGING

General Features

- **Nonenhancing T2/FLAIR MR hyperintense lesions**
  - 60-85% of children with NF1
  - Commonly found in deep gray matter (especially globus pallidus & thalamus), hippocampus, brainstem, cerebellar white matter (WM)
  - Hyperintense on T2/FLAIR, little/no mass effect
  - Often inapparent on T1 & CT
  - No enhancement
  - Characteristic time course
    - Not present in first 1-2 years of life
    - ↑ in number/size in younger children
    - ↓ in teenage years; usually resolved by adulthood
- **Increased WM volume**
  - Macrocephaly &/or thickened corpus callosum
- **OPG**
  - Occur in ~ 15-20% of children with NF1
  - Anywhere from optic nerves through optic radiations
  - Fusiform enlargement ± enhancement
    - Tortuosity in orbit: Dotted i sign on axial images
- **Plexiform neurofibroma**
  - Infiltrating soft tissue lobules along peripheral nerves
  - Hyperintense on T2/STIR MR
    - Target sign in cross section (central hypointensity)
  - Variable enhancement, classically central
- **Sphenoid wing dysplasia**
  - Almost always associated with orbital PNF
  - Distortion/absence of lateral orbital wall with anterior expansion of middle cranial fossa
- **Lambdoid defect**
  - Absence of bone along lambdoid suture
- **Vascular dysplasia (moyamoya arteriopathy)**
  - Occurs in 3-7% of children with NF1
  - Vessel narrowing (especially distal internal carotid artery) with collateral formation

CT Findings

- NECT
  - Bone defects of sphenoid wing & lambdoid suture
  - Enlargement of ON, chiasm, superior orbital fissure
- CECT
  - ± enhancement in OPG
  - PNFs typically have little enhancement
- CTA
  - May be best test to determine degree of stenosis in moyamoya arteriopathy

MR Findings

- T1WI
  - Thick corpus callosum on sagittal images
  - OPG: Enlargement of optic nerve & chiasm
  - PNF: Isointense to brain/cord
  - May see hyperintense globus pallidus & dentate nuclei in older patients who have had multiple gadolinium administrations from prior screening MRs
    - Pathologically proven to represent gadolinium deposition
- T2WI
  - Poorly defined, round, or ovoid hyperintense WM lesions in characteristic locations
- T2WI FS
  - OPG may have hyperintense signal
- STIR
  - Helpful to identify soft tissue PNFs
- FLAIR
  - Best sequence to identify nonenhancing parenchymal signal abnormalities
- DWI
  - ↑ ADC values in nonenhancing signal abnormalities
- T1WI C+
  - PNF & OPG have variable enhancement patterns that often change over time
  - Parenchymal signal abnormalities should not enhance (which would suggest gliomatous degeneration)
- MRA
  - Major cerebral artery narrowing (especially carotid terminus) in moyamoya arteriopathy
- MRS
  - Can help distinguish nonenhancing signal abnormalities from glioma
    - Nonenhancing signal abnormalities → ↑ myoinositol (mI), preserved NAA
    - Glioma → ↑ choline, ↓ NAA

Angiographic Findings

- Typically reserved for cases of moyamoya arteriopathy where revascularization is contemplated

Imaging Recommendations

- Best imaging tool
  - Brain/orbits MR C+
- Protocol advice
  - Dedicated orbital protocol to include T1 C+ FS MR for optimal detection of OPG & orbital PNF
  - Thin-section T2 or MRA for vascular dysplasia
  - 3D volumetric analysis is helpful for treatment surveillance

DIFFERENTIAL DIAGNOSIS

Neurocutaneous Syndromes: Phakomatoses

- **Tuberous sclerosis complex (TSC)**
  - Dysplasias (a.k.a. tubers) + subependymal nodules
- **Sturge-Weber syndrome (SWS)**
  - Retinal & pial angiomatosis with focal/lobar cerebral atrophy due to abnormal cerebral venous drainage
- **Neurofibromatosis type 2 (NF2)**
  - Multiple schwannomas, meningiomas, & ependymomas
- **PHACE(S)**
  - **P**osterior fossa malformations, infantile **h**emangiomas, **a**rterial anomalies, **c**ardiac anomalies, **e**ye anomalies, & **s**ternal clefting
- **von Hippel-Lindau disease (VHL)**
  - Hemangioblastomas, retinal angiomas, renal cysts & carcinomas, pancreatic cysts & tumors
- **Other phakomatoses**
  - Multiple others, including ataxia-telangiectasia, neurocutaneous melanosis, incontinentia pigmenti, basal cell nevus syndrome

PATHOLOGY

General Features

- Genetics
  - *NF1* gene locus lies on long arm of chromosome 17
    - Neurofibromin, inactivated in NF1 → allows cellular proliferation & tumor development
      - Neurofibromin: RAS GTPase-activating protein responsible for tumor suppression
    - Oligodendrocyte myelin glycoprotein lies within *NF1* gene
      - May cause myelin dysplasia UBOs & FASIs
  - Autosomal dominant; 50% are new mutations
  - Variable expression; virtually 100% penetrance
- Associated abnormalities
  - Pheochromocytomas, malignant peripheral nerve sheath tumors (MPNST)

Staging, Grading, & Classification

- NF1 if ≥ 2 of following
  - ≥ 6 skin café au lait spots, > 5 mm
  - ≥ 2 NF or 1 PNF
  - Axillary/inguinal freckling
  - Optic nerve glioma
  - Distinctive bone lesion
  - Primary relative with NF1

Gross Pathologic & Surgical Features

- Visual pathway glioma is usually low grade
  - Can extend to geniculate bodies & optic radiations
  - Perichiasmatic infiltration → more likely to be aggressive, ↑ frequency of precocious puberty
- Lisch nodules (iris hamartomas) in 85% > 10 years old
- Buphthalmos (globe)

Microscopic Features

- Nonenhancing T2/FLAIR MR hyperintense lesions: Foci of "myelin vacuolization"; no inflammation/demyelination
- PNF: Schwann cells, perineural fibroblasts, growth along nerve fascicles

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - > 95% have skin lesions
  - > 95% have Lisch nodules (adults)
  - ~ 50% have macrocephaly → ↑ WM volume
  - > 30% have learning disabilities
  - ~ 15% have scoliosis
  - ~ 15% have OPG
- Phenotype is quite variable: Can be dominated by peripheral, paraspinal, or intracranial lesions

Demographics

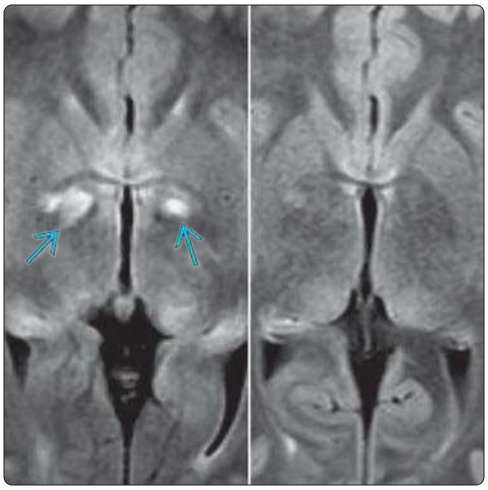
- Age
  - Café au lait spots appear in 1st year of life
  - OPG usually occurs in 1st few years
    - Median age at diagnosis: 3 years
    - If no OPG is identified before 15 months, patient is unlikely to develop symptomatic OPG
- Epidemiology
  - Most common autosomal dominant disorder
  - 1:3,000-5,000 people have NF1

Natural History & Prognosis

- NF1-related learning disability in 30-60%
  - May be associated with ↑ number of characteristic T2/FLAIR MR parenchymal lesions
- 1-3% risk of other CNS glial tumors
  - Typically low grade in children, higher grade in adults
- 8-13% lifetime risk of MPNST
- Vascular dysplasia: If progressive, may cause ischemic injury
- OPG typically has indolent course with observation being sufficient in most cases
  - Chiasmatic & postchiasmatic are more likely to progress than prechiasmatic
  - Small percentage resolve spontaneously

Treatment

- Observation/surveillance is sufficient unless symptoms arise
- PNF: Debulking surgery if symptomatic, though not preferable, as tumor cannot be separated from nerves
  - MEK inhibitors (e.g., selumetinib) for inoperable lesions
- OPG: ~ 15% require chemotherapy for progression
  - Decision to treat is based on combination of clinical & radiologic findings
- Moyamoya arteriopathy: Surgical revascularization



DIAGNOSTIC CHECKLIST

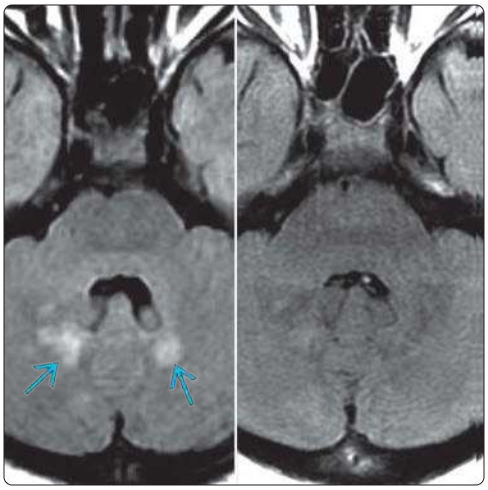


Image Interpretation Pearls

- Remember to look for vascular lesions
- Signal abnormalities with mass effect, enhancement, or atypical location should be viewed with suspicion

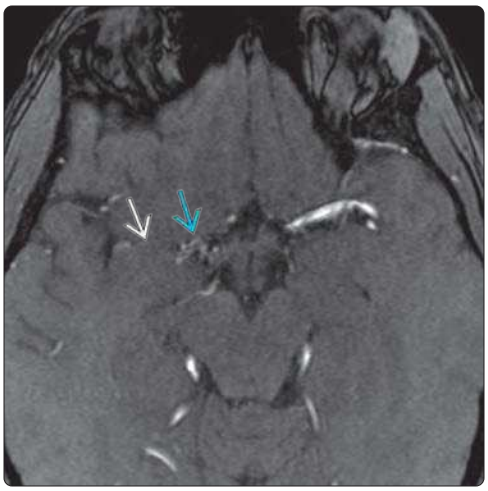
2. de Blank PMK et al: Optic pathway gliomas in neurofibromatosis type 1: an update: surveillance, treatment indications, and biomarkers of vision. J Neuroophthalmol. 37 Suppl 1:S23-32, 2017



(Left) *Axial FLAIR MRs in a patient with NF1 at 10 (L) & 15 (R) years of age show interval near-complete resolution of the characteristic nonenhancing signal abnormalities ⇨ within the globus pallidus nuclei.* **(Right)** *Axial FLAIR MRs in a patient with NF1 at 10 (L) & 15 (R) years of age show interval near-complete resolution of the nonenhancing signal abnormalities ⇨ within the cerebellar white matter & dentate nuclei. These signal abnormalities typically resolve in the late teenage years.*

(Left) *Axial FLAIR MR in an 8-year-old with NF1 shows nearly symmetric ↑ signal intensity within the centrum semiovale ⇨ without volume loss. This degree of delayed/abnormal myelination is uncommon, though mildly delayed myelination is frequently seen in younger NF1 patients.* **(Right)** *Axial T2 MRs in a patient with NF1 at 6 (L) & 9 (R) years of age show minimal change in the lesion size over time. Brainstem masses in NF1 typically have a more indolent behavior than brainstem masses seen in otherwise healthy individuals.*

(Left) *Sagittal T1 MR in a 15-year-old with NF1 shows a diffusely thickened corpus callosum with normal signal. On average, NF1 patients have higher corpus callosum volumes compared to normal subjects.* **(Right)** *Axial 3D TOF MRA in a 14-year-old with NF1 shows a complete lack of flow-related signal in the right middle cerebral artery ➡ with multiple small collateral vessels ⇨ in the expected region of the M1 segment, consistent with moyamoya arteriopathy. Moyamoya arteriopathy is seen in 3-7% of patients with NF1.*

Tuberous Sclerosis

KEY FACTS

TERMINOLOGY

- Tuberous sclerosis complex (TSC): Hamartomas of multiple organs → CNS, skin, kidney, bone

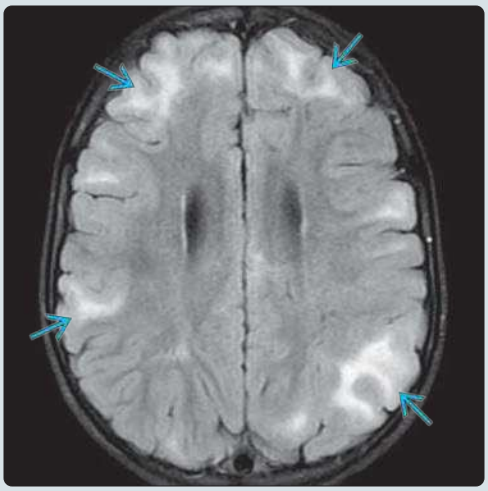
IMAGING

- Cerebral tubers
  - Cortical/subcortical lesion expanding overlying gyrus
  - T2/FLAIR hyperintense, T1 hypointense after myelination
    - T1 hyperintense prior to myelination
- Cerebellar tubers
  - Wedge-shaped foci of volume loss
  - More likely to enhance & calcify
- Subependymal nodules (SENs)
  - Elongated nodules in locations of fetal germinal matrix
  - ↑ Ca^{2+} over time
  - 30-80% enhance
- Subependymal giant cell astrocytoma (SEGA)
  - Growing nodule at caudothalamic groove
  - WHO grade 1 neoplasm

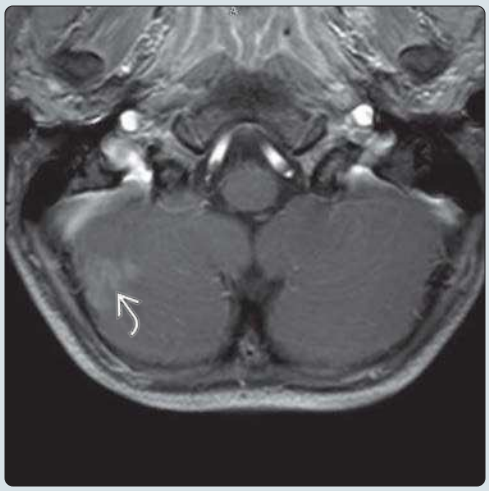
TOP DIFFERENTIAL DIAGNOSES

- Focal cortical dysplasia
- Dysembryoplastic neuroepithelial tumor
- Ganglioglioma
- TORCH infections that cause periventricular Ca^{2+}
- X-linked subependymal heterotopia

PATHOLOGY

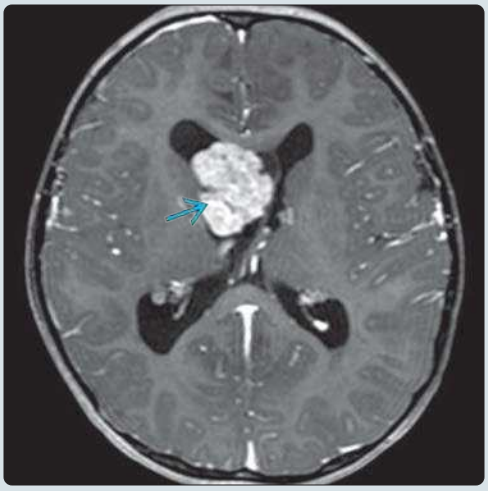


- 2 distinct gene loci
  - *TSC1* (9q34) encodes hamartin
  - *TSC2* (16p13) encodes tuberin → more severe



CLINICAL ISSUES

- Medical antiseizure therapy, resection of seizure focus
- mTOR inhibitors are now 1st-line therapy for SEGA



DIAGNOSTIC CHECKLIST

- Tubers + SEN → pathognomonic for TSC
- Surveillance imaging is performed to detect SEGA

(Left) *Axial FLAIR MR of a 6-year-old girl with tuberous sclerosis complex (TSC) shows a moderate to severe burden of cerebral tubers. Tubers are dysplastic lesions that are present in nearly all patients with TSC. After the brain is myelinated, FLAIR is the most sensitive sequence for tuber detection.* **(Right)** *Axial T1 C+ MR in the same patient shows a wedge-shaped, enhancing right cerebellar tuber. Cerebellar tubers differ from cerebral tubers in that volume loss, Ca^{2+}, & enhancement are very common.*

(Left) *Axial T1 C+ MR in a 4-year-old boy with TSC shows a lobular, homogeneously enhancing mass in the right caudothalamic groove, consistent with a subependymal giant cell astrocytoma (SEGA).* **(Right)** *Axial NECT in the same patient 1 year after resection of the SEGA (note the surgical tract) shows multiple calcified subependymal nodules. The location of the subependymal nodules adheres to the anatomic distribution of fetal germinal matrix with a preponderance in the caudothalamic grooves.*

TERMINOLOGY

Synonyms

- Tuberous sclerosis complex (TSC), Bourneville syndrome, Pringle disease

Definitions

- Neurocutaneous syndrome: Hamartomatosis
  - Hamartomas of multiple organs → CNS, skin, kidney, bone

IMAGING

General Features

- Best diagnostic clue
  - Cerebral & cerebellar "tubers"
  - Subependymal nodules (SENs)
  - Subependymal giant cell astrocytoma (SEGA)

Tubers

- Cerebral
  - Cortical/subcortical tubers expand overlying gyri
  - Hyperintense on T2/FLAIR, hypointense on T1 MR
    - T1 hyperintense prior to myelination
  - Typically hypoattenuating on CT
  - Subcortical cystic degeneration in tubers → "empty gyrus"
  - Often associated with radial migration lines extending toward lateral ventricles
  - 3-4% enhance; 50% calcify (by age 10)
- Cerebellar
  - Typically wedge-shaped with volume loss & folia distortion
  - Many show enhancement (33-92%)
  - Many calcify (29%)

SEN

- Located in areas of fetal germinal matrix with preponderance in caudothalamic grooves
- Caudothalamic groove > body/atrium > temporal horn
- ↑ Ca^{2+} over time; 30-80% enhance

SEGA

- Growing nodule at caudothalamic groove
  - NAA ↓, choline ↑ compared to SEN
  - WHO grade 1 neoplasm
- Irregular & diffuse enhancement
- Can cause obstructive hydrocephalus

Other Lesions

- Cerebral aneurysms (0.78%) & dolichoectasia
- Retinal hamartoma
- Renal angiomyolipoma (AML)
- Lymphangioleiomyomatosis (LAM)
- Cardiac rhabdomyoma

Imaging Recommendations

- Best imaging tool
  - Traditionally: MR with contrast
    - Recent studies suggest contrast is likely not necessary for detection of SEGAs

DIFFERENTIAL DIAGNOSIS

Infection

- TORCH infections that cause periventricular Ca^{2+}
  - Cytomegalovirus (CMV), toxoplasmosis
  - Periventricular, not subependymal

Neoplasms

- Superficial tumors that can resemble tubers
- Intraventricular tumors

Cortical Dysplasia

- Focal cortical dysplasia, especially type II

X-Linked Subependymal Heterotopia

- Gray matter heterotopia along lateral ventricle margins
- No Ca^{2+} or enhancement

PATHOLOGY

General Features

- Etiology
  - Tuberin & hamartin combine to form complex in vivo
    - Act together to regulate mTOR pathway
      - **M**ammalian **t**arget **o**f **r**apamycin
    - Regulate cell growth & proliferation
  - Mutations prevent them from downregulating mTOR
  - Affects germinal matrix → disordered neuronal migration & growth
- Genetics
  - 2 distinct gene loci
    - *TSC1* (9q34) encodes hamartin
    - *TSC2* (16p13) encodes tuberin
    - *TSC2* is most common with severe phenotype
      - More likely to have complex partial seizures, infantile spasms, SEGAs, & intellectual disability

Staging, Grading, & Classification

- Diagnostic criteria: 2 major (definite) or 1 major + 1 minor (probable)
  - Major: Tuber, SEN, SEGA, cardiac rhabdomyoma, renal AML, LAM, adenoma sebaceum, sub-/periungual fibroma, hypomelanotic macules, shagreen patch, retinal hamartoma
  - Minor: WM lesions, dental pits, gingival fibromas, rectal polyps, bone cysts, nonrenal hamartoma, retinal achromic patch, confetti skin lesions, multiple renal cysts

CLINICAL ISSUES

Treatment

- Medical antiseizure therapy, resection of seizure focus
- mTOR inhibitors are now 1st-line therapy for SEGA

SELECTED REFERENCES

1. Gaillard AL et al: Magnetic resonance imaging diagnosis of subependymal giant cell astrocytomas in follow-up of children with tuberous sclerosis complex: should we always use contrast enhancement? Pediatr Radiol. 50(10):1397-408, 2020

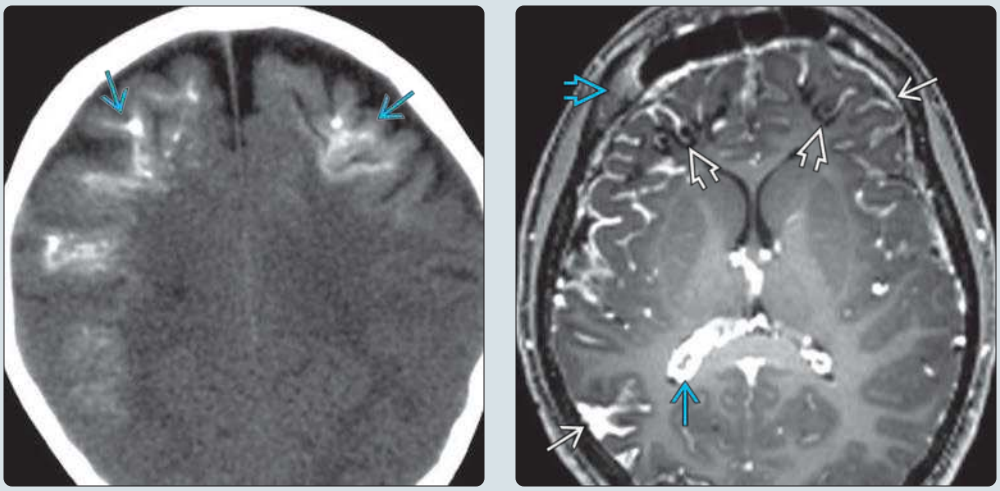
Sturge-Weber Syndrome

KEY FACTS

TERMINOLOGY

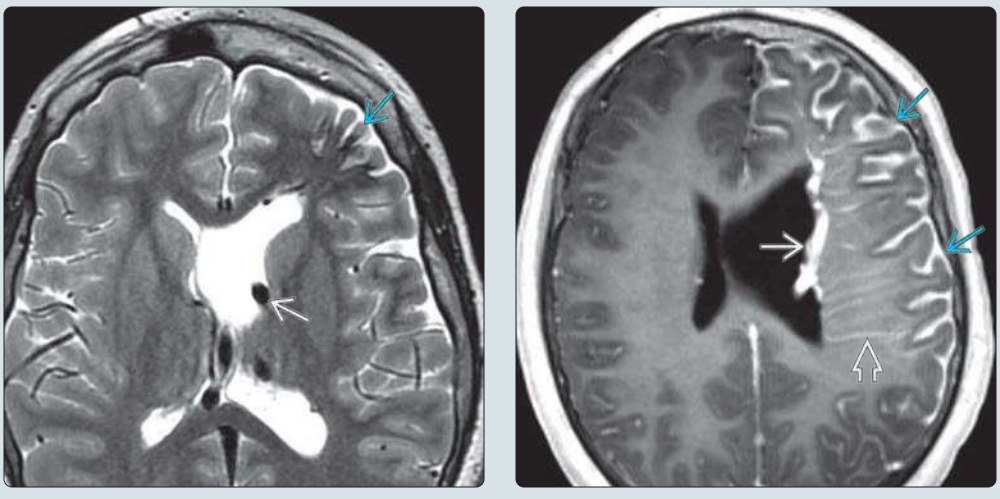
- Syndrome of abnormal cortical venous development
- Imaging features result from progressive venous occlusion, recruitment of alternate drainage pathways, & chronic venous ischemia

IMAGING



- **CT**: Gyral/subcortical Ca^{2+} → tram-track appearance
  - ± calvarial thickening & sinus hyperpneumatization
- **MR**: Regions of atrophy ± abnormal myelination
  - **T2**: Flow voids in enlarged deep/transcerebral veins
  - **FLAIR**: Atrophied lobe(s) ± bright sulcal signal of leptomeningeal angiomatosis
  - **SWI/T2* GRE**: ↓ cortical/subcortical signal from Ca^{2+}
  - **T1 C+**: Enhancing leptomeningeal angiomatosis
    - Abundant medullary & deep draining veins
    - Choroidal globe enhancement of angioma
  - **MRV**: Absent normal cortical veins in affected region
  - **PWI**: ↑ perfusion early, ↓ perfusion late
- **FDG PET**: Progressive ↓ metabolism in affected brain

TOP DIFFERENTIAL DIAGNOSES



- Acquired meningeal processes
- PHACE(S) syndrome
- Blue rubber bleb nevus syndrome
- Meningioangiomatosis

CLINICAL ISSUES

- Seizures (75-90%), hemiparesis (30-66%)
  - Holohemispheric/bilateral angiomatosis (10-20%) → worse than focal involvement
- Forehead cutaneous capillary malformation (port-wine stain) in ~ 95%
- Choroidal angioma in 70% → glaucoma
- Treatment: Aggressive seizure control, resection/hemispherectomy for intractable epilepsy
- MR in early infancy may be normal: Recommend follow-up if patient is at risk for Sturge-Weber syndrome clinically

(Left) *Axial NECT in an 11-year-old girl with intractable epilepsy shows bilateral (right > left) subcortical Ca^{2+}, characteristic of Sturge-Weber syndrome.* **(Right)** *Axial T1 C+ FS MR in the same patient shows bilateral leptomeningeal enhancement & enlargement of the right choroid plexus. Note the low signal within the subcortical white matter at the depth of sulci, consistent with Ca^{2+}. There is mildly ↑ right calvarial thickness secondary to underlying brain parenchymal volume loss.*

(Left) *Axial T2 MR in a 10-year-old boy with right-sided hemiplegia & seizures shows marked parenchymal volume loss & low signal corresponding to an area of cortical/subcortical Ca^{2+} seen on CT. Also note the ipsilateral enlarged deep draining vein.* **(Right)** *Axial T1 C+ MR in the same patient shows extensive left cerebral leptomeningeal enhancement with multiple prominent medullary veins & a large subependymal draining vein. The enlargement of the left lateral ventricle is due to left cerebral volume loss.*

TERMINOLOGY

Abbreviations

- Sturge-Weber syndrome (SWS)

Definitions

- Congenital (but not inherited) syndrome in which cortical veins fail to develop normally, leading to numerous long-term intracranial manifestations of chronic ischemia & expanded alternate routes of venous drainage

IMAGING

General Features

- Best diagnostic clue
  - Cerebral lobar atrophy with cortical/subcortical Ca^{2+}, leptomeningeal enhancement, & enlarged ipsilateral choroid plexus in patient with V1 port-wine stain
- Location
  - Leptomeningeal angiomatosis is unilateral in 80-90%, bilateral in 10-20%

CT Findings

- NECT
  - Gyral/subcortical Ca^{2+} (may have tram-track appearance)
    - Progressive process, usually not present in very young
  - Calvarial thickening & hyperpneumatization of sinuses

MR Findings

- **T1**: Altered ("accelerated") white matter (WM) myelination in young patients
- **T2**: Hypointense subcortical signal of Ca^{2+} at depth of sulci; ↓ WM signal of accelerated myelination &/or low oxygen tension; enlarged deep vein flow voids
- **FLAIR**: Gliosis is often seen late in affected regions
- **SWI/T2* GRE**: ↓ cortical/subcortical signal (Ca^{2+})
  - SWI: Most sensitive to transcerebral medullary collaterals
- **T1 C+**: Leptomeningeal enhancement (angiomatosis)
  - Late stage: ↓ leptomeningeal enhancement, atrophy
  - Choroidal globe enhancement (choroidal angioma)
- **MRA**: Normal early but ↓ artery size in affected areas later
- **MRV**: Absent cortical veins in affected region
  - ↑ size of medullary & deep draining veins
- **Perfusion imaging (arterial spin labeling & contrast perfusion)**
  - Early: ↑ perfusion in affected regions
  - Late: ↓ perfusion in affected regions
    - ↓ perfusion associated with frequent seizures, ↑ duration of epilepsy, & brain atrophy

Nuclear Medicine Findings

- **FDG PET**: Progressive hypometabolism in affected regions
- **SPECT**: Hyperperfusion (early), hypoperfusion (late) on interictal scans
- Note that ictal scans (which may be intentional on SPECT or unintentional on FDG PET) will show ↑ activity

Imaging Recommendations

- Protocol advice
  - MR C+: May be normal at early age; consider follow-up
    - FLAIR C+ improves detection of leptomeningeal angiomatosis
    - Perfusion may predict progression

DIFFERENTIAL DIAGNOSIS

Acquired Meningeal Processes

- Meningitis, tumor spread, hemorrhage, high inspired oxygen content of CSF (usually with anesthesia)

PHACE(S) Syndrome

- **P**osterior fossa malformations, infantile **h**emangiomas, **a**rterial anomalies, **c**oarctation of aorta, **c**ardiac, **e**ye, & **e**ternal anomalies
- Segmental hemangioma of face is not fully present at birth

Blue Rubber Bleb Nevus Syndrome

- Multiple small soft tissue venous malformations + intracranial developmental venous anomalies

Klippel-Trenaunay Syndrome

- Extremity overgrowth with extensive capillary-venous-lymphatic malformations & abnormal deep venous system

Meningioangiomatosis

- Rare meningovascular hamartomatous plaque-like mass ± Ca^{2+} & cyst formation

PATHOLOGY

General Features

- Sporadic: Mosaic somatic mutation in gene *GNAQ* (9q21)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Seizures (75-90%), hemiparesis (30-66%)
  - Stroke-like episodes, neurological deficit, headaches, & intellectual disability
  - Facial capillary malformation (port-wine stain) in ~ 95%
    - V1 distribution is classic
  - Choroidal angioma (70%), especially with eyelid stain
    - ↑ intraocular pressure/congenital glaucoma → buphthalmos in young

Demographics

- Rare: 1:20,000-50,000
- Seizures typically develop in 1st year of life

Natural History & Prognosis

- Seizures exacerbate vascular compromise to affected brain → progressive brain injury
- Holohemispheric &/or bilateral involvement is worse compared with focal involvement

Treatment

- Presymptomatic: Some recommend low-dose aspirin ± anticonvulsant
- Symptomatic: Aggressive medical management of seizures
- Symptomatic & medically refractory: Consider surgical resection/hemispherectomy

SELECTED REFERENCES

1. Sabeti S et al: Consensus statement for the management and treatment of sturge-weber syndrome: neurology, neuroimaging, and ophthalmology recommendations. Pediatr Neurol. 121:59-66, 2021

PHACE Syndrome

KEY FACTS

TERMINOLOGY

- **PHACE(S)**: Association of segmental craniofacial infantile hemangioma (IH) & 1 or more other features listed in acronym
  - **P**osterior fossa malformations
  - **H**emangioma
  - **A**rterial lesions
  - **C**ardiac abnormalities/aortic coarctation
  - **E**ye abnormalities
  - **S**ternal defects or supraumbilical raphe
    - Deemphasized in recent literature

IMAGING

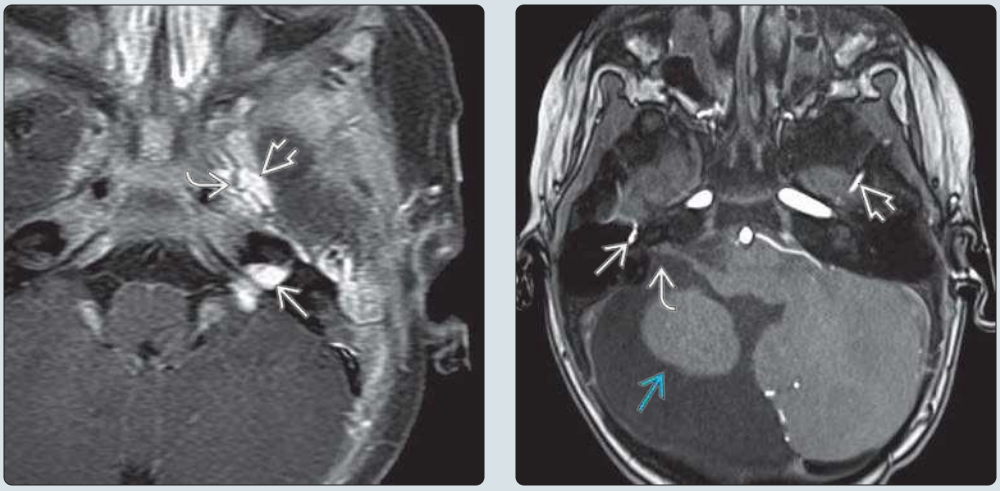
- Proliferating regional or midline cervicofacial IH: Lobulated or plaque-like, prominent vascularity
- Unilateral cerebellar hypoplasia & prominent retrocerebellar CSF space
- Widened internal auditory canal ± IH ± persistent stapedial artery
- Hypoplasia, aplasia, aberrancy, ectasia, tortuosity, &/or stenoocclusive changes of major craniocervical arteries
- ± reduced perfusion (or infarction) in affected arterial territory

TOP DIFFERENTIAL DIAGNOSES

- Sturge-Weber syndrome
- Vestibular schwannoma
- Loeys-Dietz syndrome

CLINICAL ISSUES

- Cutaneous: Large regional or midline craniofacial IH → 20% have PHACE
  - IH appears in early neonatal period
- Sex: 80-90% female



DIAGNOSTIC CHECKLIST

- Look for ipsilateral cerebellar hemisphere anomaly of PHACE in patient clinically mistaken for Sturge-Weber syndrome with port-wine stain

(Left) *Axial T1 C+ FS MR in an 8-month-old with PHACE syndrome shows R > L parotid/periparotid infantile hemangiomas (IHs) with typical intense enhancement, well-defined margins, & intralesional flow voids. Also note the absence of a normal flow void in the expected location of the right internal carotid artery (ICA).* **(Right)** *Anterior 3D time-of-flight (TOF) MRA in the same child shows marked hypoplasia of the right ICA. The patient also had IHs in a bearded distribution as well as in the floor of mouth & airway.*

(Left) *Axial T1 C+ FS MR in a 3-week-old boy with left facial palsy shows avidly enhancing masses within the left internal auditory canal (IAC) & cavernous sinus with a prominent flow void in the left cavernous sinus mass. The IAC mass mimics a schwannoma. These IHs involuted after the 1st year of life.* **(Right)** *Axial 3D TOF MRA of an infant girl with PHACE & right cerebellar hypoplasia shows a right persistent stapedial artery. Note the normal left middle meningeal artery. The right IAC is widened.*

KEY FACTS

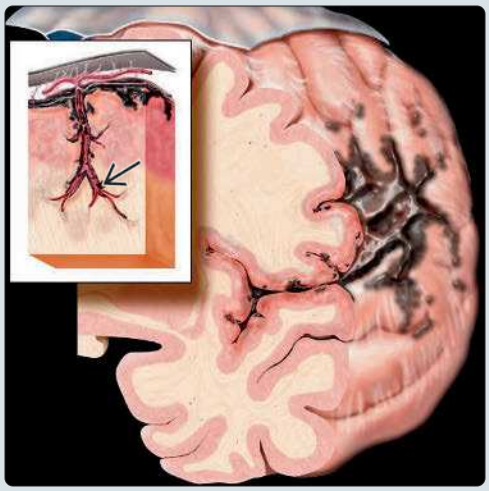
TERMINOLOGY

- Congenital phakomatosis characterized by giant or multiple cutaneous melanocytic nevi (CMN) + benign & malignant melanotic lesions of CNS
  - Parenchymal melanosis (Ms): Nonmalignant intraparenchymal foci
  - Leptomeningeal melanosis (LMs): Excess of benign melanotic cells in leptomeninges
  - Leptomeningeal melanoma (LM): Malignant melanoma of leptomeninges
  - Primary CNS malignant melanoma (MM): Focal malignant melanoma of CNS

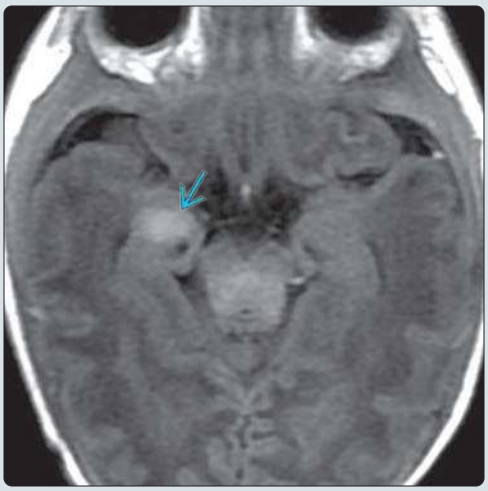
IMAGING

- Parenchymal melanosis: CMN + foci of intraaxial T1 MR hyperintensity (hyperdense on CT, echogenic on US)
  - Medial temporal lobe, cerebellum, pons, thalami, base of frontal lobes
- LMs & LM: CMN + diffuse leptomeningeal enhancement
  - Typically develop communicating hydrocephalus
- MM: Focal intraparenchymal enhancing mass

PATHOLOGY



- Focal or diffuse proliferation of melanin-producing cells in both skin & leptomeninges
- Associated cerebellar hypoplasia ~ 10%



CLINICAL ISSUES

- Only ~ 10-15% of CMN patients have NCM
  - ~ 80-90% of have parenchymal Ms
  - ~ 10% have LMs or LM
  - ~ 1-5% have MM
- Screening is recommended for CMN patients < 6 months
- Poor prognosis with LMs, LM, or MM

DIAGNOSTIC CHECKLIST

- Normal MR does not exclude diagnosis of NCM
- LMs cannot be distinguished from LM by imaging

(Left) *Graphic shows localized dark (melanotic) pigmentation of the leptomeninges. Inset demonstrates extension of melanosis into the brain substance along the Virchow-Robin spaces.* **(Right)** *Axial T1 MR in a 4-day-old patient with a giant congenital melanocytic nevus on the buttock shows a hyperintense lesion in the medial right temporal lobe. A solitary focus of T1 hyperintensity in the medial temporal lobe is the most common appearance of neurocutaneous melanosis (NCM).*

(Left) *Clinical photograph of the back of a young child with NCM shows numerous cutaneous melanocytic nevi, many of which are several centimeters in size, qualifying for the distinction of "giant" nevi.* **(Right)** *Axial T1 C+ MR in a 6-year-old patient shows diffuse leptomeningeal NCM. The pial melanosis involves virtually the entire surface of the brain, enhancing strongly & uniformly. There is moderate ventriculomegaly from associated communicating hydrocephalus.*

Colloid Cyst

KEY FACTS

TERMINOLOGY

- Benign epithelial-lined cyst of anterior 3rd ventricle

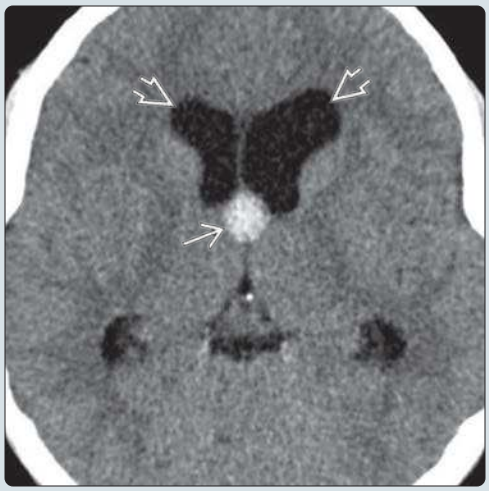
IMAGING

- Best clue: Round, homogeneous midline mass at foramen of Monro with lateral ventricular enlargement
- Mean size: Asymptomatic = 0.8 cm, symptomatic = 1.4 cm
- CT: Hyperdense (70-80%); iso-/hypodense (20-30%)
- MR: Variable signal characteristics
  - T1 hyperintense (40-60%)
  - T2 hypointense (50-60%)
  - No FLAIR suppression
  - No restricted diffusion
  - No enhancement; rarely, thin rim enhancement
- Pillars of fornix straddle anterior aspect of cyst

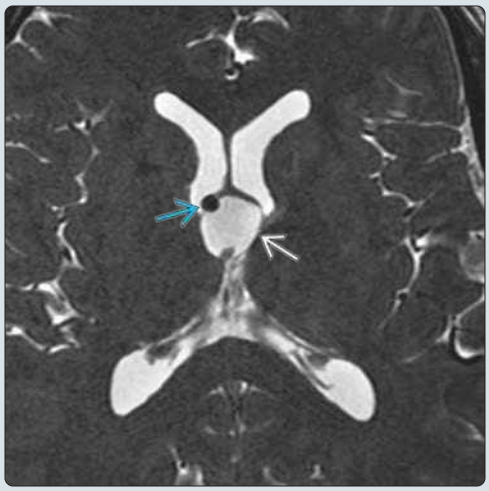
TOP DIFFERENTIAL DIAGNOSES

- CSF flow artifact (MR pseudocyst)
- Subependymal giant cell astrocytoma (SEGA)
- Arachnoid cyst
- Neurocysticercosis

PATHOLOGY

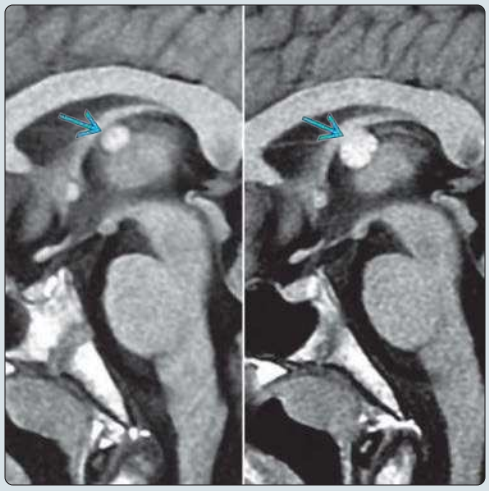


- Derived from embryonic endoderm
  - Outer wall: Thin fibrous capsule
  - Inner lining: Columnar epithelium
  - Cyst contents: Proteinaceous material, exfoliated cells

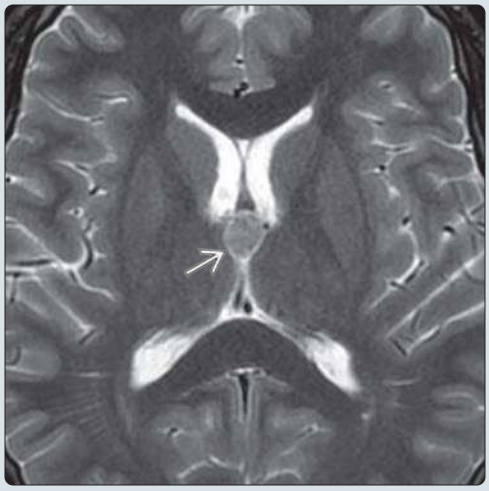


CLINICAL ISSUES

- 40-50% are asymptomatic & discovered incidentally
- ~ 90% stable over time
- Most common treatment: Complete surgical resection
  - Recurrence rare if resection is complete
- Asymptomatic patients may be treated conservatively with clinical & imaging follow-up



DIAGNOSTIC CHECKLIST



- NECT & T1 MR are often more sensitive than T2, FLAIR, or DWI MR

(Left) *Axial NECT in a 14-year-old boy with headaches shows a hyperattenuating lesion at the foramen of Monro, which is causing mild enlargement of the lateral ventricles. The finding of ventricular enlargement suggests that the cyst is likely symptomatic. The lesion was endoscopically resected, & pathology confirmed a colloid cyst.* **(Right)** *Follow-up axial 3D SSFP MR in the same patient shows recurrence of the colloid cyst, an uncommon occurrence. Note the small focus of hemosiderin from the prior resection.*

(Left) *Sagittal T1 MR images in an asymptomatic boy at 10 (left) & 15 (right) years of age show an interval ↑ in the size of the colloid cyst in the anterior superior 3rd ventricle. Most colloid cysts are stable over years but some will ↑.* **(Right)** *Axial T2 MR in the same patient shows a foramen of Monro mass with contents that are isointense to gray matter. The majority of colloid cysts are hypo- or isointense to gray matter on T2 MR, as ↓ T2 signal correlates with ↑ cholesterol content & viscosity.*

TERMINOLOGY

Definitions

- Benign epithelial-lined, mucin-containing cyst; almost exclusively located in anterior superior 3rd ventricle

IMAGING

General Features

- Best diagnostic clue
  - Hyperdense midline foramen of Monro mass on NECT
- Location
  - 99% in anterior superior 3rd ventricle
    - Anterior to interthalamic adhesion
    - Posterior to fornices
    - Posteromedial but bulging into foramen of Monro
- Size
  - Few millimeters to 3 cm
    - Symptomatic mean size: 1.4 cm
    - Asymptomatic mean size: 0.8 cm
- Morphology
  - Usually spherical or ovoid

CT Findings

- NECT
  - Usually hyperdense (70-80%)
    - ↑ density correlates with ↑ T1 & ↓ T2 signal on MR
  - Minority are iso-/hypodense (20-30%)
  - ± hydrocephalus

MR Findings

- **T1**: Hyper- (40-60%), isointense (~ 20%); hypointense (~ 20%)
- **T2**: Hypointense (50-60%); iso-/hyperintense (~ 40%)
- **FLAIR**: Does not suppress like CSF; usually iso-/hyperintense
- **DWI**: No diffusion restriction
- **T1 C+**: Nonenhancing or rare peripheral (rim) enhancement

DIFFERENTIAL DIAGNOSIS

CSF Flow Artifact (MR Pseudocyst)

- Most pronounced on FLAIR MR
- Multiple different sequences & planes confirm artifact

Subependymal Giant Cell Astrocytoma

- Off-midline solid, lobulated, enhancing mass at foramen of Monro in child with tuberous sclerosis

Arachnoid Cyst

- Rare in ventricle; usually arises from suprasellar cistern
- Follows CSF signal intensity on all sequences

Craniopharyngioma

- Suprasellar location is much more common than 3rd ventricle
- Often multilobulated with Ca^{2+} & rim/nodular enhancement

Metastases

- Dissemination of tumor in CSF, most commonly of primary CNS origin in children

Neurocysticercosis

- Single or multiple lesions within parenchyma & cisterns
  - Look for scolex along margin of cyst
- Ca^{2+} is frequent

PATHOLOGY

General Features

- Outer wall: Thin fibrous capsule
- Inner lining
  - Pseudostratified epithelium with ciliated & goblet cells
  - Individual cells are positive for cytokeratin & EMA
- Cyst contents
  - Amorphous proteinaceous ("colloid") material
  - Scattered exfoliated cells

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Headache (~ 75%), nausea & vomiting, visual symptoms
  - 40-50% are asymptomatic & discovered incidentally
    - 3-, 5-, 10-year incidence of developing cyst-related symptoms: 0%, 0%, 8%, respectively
- Other signs/symptoms
  - Acute foramen of Monro obstruction may rarely lead to acute hydrocephalus, herniation, death (usually with cysts > 1 cm)

Demographics

- Age
  - Mean: 30-40 years; 8% < 15 years at diagnosis

Natural History & Prognosis

- Factors associated with symptomatic cysts
  - Younger age
  - Ventricular dilation
  - Larger cyst size
  - ↑ signal intensity on T2/FLAIR MR
  - Location immediately adjacent to foramen of Monro
- Rare cases of sudden death are reported in literature

Treatment

- Symptomatic patients
  - Complete resection: Endoscopic vs. microsurgical
  - Recurrence is rare, especially with complete resection
- Asymptomatic (incidental) patients
  - Conservative management: Clinical & imaging follow-up
  - However, with relatively low morbidity, surgery is also considered for asymptomatic patients

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- NECT & T1 MR are often more obvious than pathology-weighted sequences (T2, FLAIR, or DWI)

SELECTED REFERENCES

Arachnoid Cyst

KEY FACTS

TERMINOLOGY

- Focal extraaxial CSF collection lined by arachnoid

IMAGING

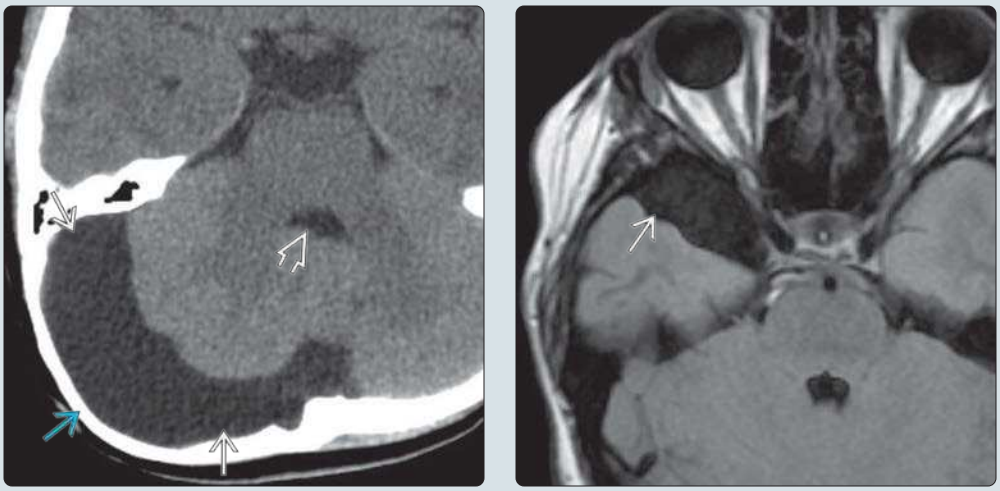
- Location
  - Middle cranial fossa: 50-70%
  - Retrocerebellar: 15-20%
  - Less common: Basilar cisterns, interhemispheric fissure, cerebral convexities
  - Rare: Intraventricular
- Displaces adjacent vessels & nerves
- Typically shows less mass effect than expected
  - Adjacent brain accommodates cyst
- Calvarial remodeling: Thinning/scalloping ± bulging
- **US**: Anechoic; no internal vascularity
- **NECT**: Isodense to CSF, unless hemorrhage occurs (rare)
- **MR**: Follows CSF signal intensity on all sequences
  - Fluid signal suppression on FLAIR
  - DWI/ADC signal equal to CSF

TOP DIFFERENTIAL DIAGNOSES

- Epidermoid cyst
- Chronic subdural hematoma
- Subdural hygroma
- Mega cisterna magna

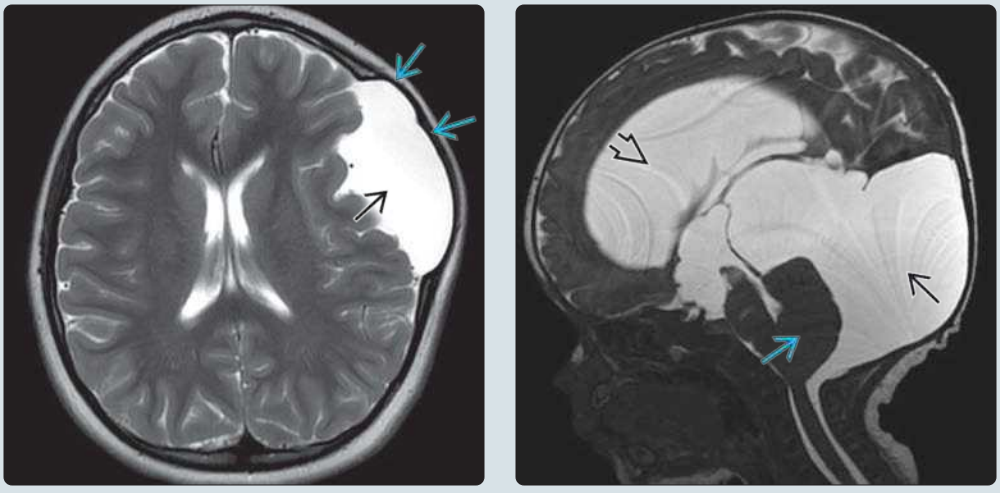
PATHOLOGY

- Wall consists of flattened but normal arachnoid cells



CLINICAL ISSUES

- Asymptomatic in vast majority (typically found incidentally)
- More likely to grow in younger patients (< 4 years of age)
- In young children: 80% stable, 10% enlarge, 10% ↓
- Surgery is only indicated if symptoms are directly attributable to arachnoid cyst



DIAGNOSTIC CHECKLIST

- FLAIR & DWI are best MR sequences for distinguishing cystic-appearing intracranial masses

(Left) *Axial NECT in a 6-year-old boy shows a right retrocerebellar cystic collection. Note the characteristic imaging features of an arachnoid cyst (AC): Isoattenuating to CSF, bulging & thinning of the overlying calvarium, & relatively mild mass effect on the 4th ventricle.* **(Right)** *Axial FLAIR MR in a 14-year-old girl with headaches shows fluid signal suppression within the right middle cranial fossa arachnoid cyst.*

(Left) *Axial T2 MR in a 10-year-old with a head deformity shows a moderate left frontal AC. Note the expansion & remodeling of the overlying calvarium & minimal mass effect on the brain relative to the size of the cyst.* **(Right)** *Sagittal 3D FIESTA MR in an infant with macrocephaly shows a large posterior fossa AC. Note the mass effect on the cerebellum & associated ventriculomegaly. While most ACs are incidental, larger cysts in the posterior fossa & basilar cisterns may cause significant mass effect & symptoms.*

TERMINOLOGY

Abbreviations

- Arachnoid cyst (AC)

Definitions

- Focal extraaxial CSF collection lined by arachnoid; generally lacks free communication with ventricles or subarachnoid space

IMAGING

General Features

- Location
  - Middle cranial fossa (MCF): 50-70%
  - Retrocerebellar: 15-20%
  - Less common locations: Cerebral convexities or interhemispheric fissure (5-10%), cerebellopontine angle (5-10%), quadrigeminal plate (1-5%), suprasellar (1-5%)
- Size
  - Mean diameter: 3 cm; ~ 20% > 5 cm
- Morphology
  - Sharply marginated extraaxial fluid collection
    - Lentiform, crescentic, ovoid, or lobular
    - Thin, nearly imperceptible wall
  - Less than expected mass effect
    - Adjacent brain accommodates cyst; parenchyma may be mildly hypoplastic
  - Thinning/scalloping ± bulging of overlying calvarium

CT Findings

- **NECT**: Isodense to CSF
- **CECT**: Nonenhancing cystic mass displaces vessels
- **CT cisternogram**: AC shows absent or delayed opacification relative to subarachnoid spaces

MR Findings

- **T1**: Isointense to CSF
- **T2**: Isointense to CSF
  - Displaces vascular flow voids; mild deformation of adjacent cortex
- **DWI**: Follows CSF signal
- **FLAIR**: Suppresses completely, similar to CSF
  - No edema in adjacent brain parenchyma
- **T1 C+**: No cyst enhancement
- **Phase-contrast cine**: Reduced/absent CSF flow compared to subarachnoid spaces (e.g., mega cisterna magna)

Ultrasonographic Findings

- Only useful in young infants with open fontanelle
- **Grayscale**: Anechoic with ↑ posterior acoustic shadowing
- **Color Doppler**: No internal vascularity

DIFFERENTIAL DIAGNOSIS

Epidermoid Cyst

- Does not follow CSF on all modalities/sequences
  - Markedly restricted diffusion on MR
- Engulfs (rather than displaces) vessels & nerves

Chronic Subdural Hematoma

- Crescentic collection differing from CSF appearance
  - Hyperdense on CT & hyperintense on FLAIR, PD, & T1 MR relative to CSF (difference may only be mild)

Subdural Hygroma

- CSF leak from subarachnoid space into subdural space
  - 2-7 days after trauma

Mega Cisterna Magna

- Communicates freely with subarachnoid space

Porencephalic Cyst

- Result of remote trauma or ischemic injury
- Surrounded by injured, chronically abnormal brain

Neuroepithelial Cyst

- Periventricular, intraventricular, or choroidal fissure cyst

Epidural Abscess

- Collection with enhancing wall & restricted diffusion
- Typically with relevant causative findings (e.g., sinusitis, penetrating injury)

PATHOLOGY

Microscopic Features

- Wall consists of flattened but normal arachnoid cells
- No inflammation or neoplastic changes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Vast majority are asymptomatic & found incidentally
  - Associated symptoms vary with size & location of cyst

Demographics

- Age: Most symptomatic ACs are diagnosed in infants & young children; cysts in older children & adults are usually incidental

Natural History & Prognosis

- More likely to enlarge in younger patients (< 4 years old)
  - In young children: 80% stable, 10% ↑, 10% ↓

Treatment

- Typically none
- Treatment only if symptoms are directly attributable to AC & potential benefits of surgery outweigh risks
- Surgical options
  - Long-term outcomes are similar among different options
    - Endoscopic cyst fenestration; open microsurgical cyst resection/fenestration; cystoperitoneal shunt

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- FLAIR & DWI are best MR sequences for distinguishing cystic-appearing intracranial masses

Dermoid and Epidermoid Cysts

KEY FACTS

TERMINOLOGY

- Intracranial inclusion cysts containing ectodermal tissue
  - Dermoids contain squamous epithelium & associated dermal appendages
  - Epidermoids consist of squamous epithelium

IMAGING

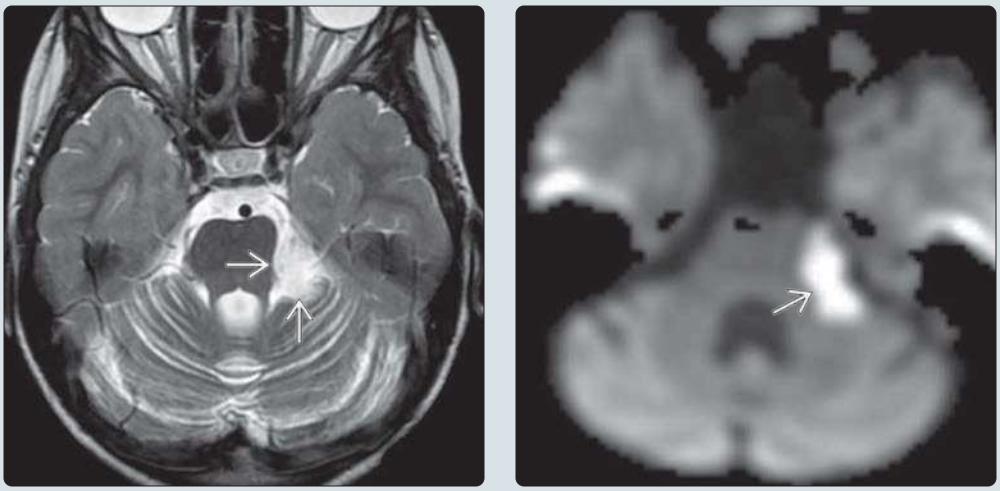
- Dermoid: Fatty mass with layered septations
  - NECT: Fat density may mimic gas; Ca^{2+} in 20%
  - MR: Striated/layered appearance, nonenhancing
    - T1: Iso-/hyperintense to brain
      - Incomplete fat suppression
    - T2: Heterogeneous signal
- Epidermoid: Nonenhancing, T2-hyperintense (~ CSF) mass
  - NECT: Iso- to slightly hyperdense to CSF
  - MR: Well-defined mass, lobulations on 3D SSFP images
    - T1: Iso-/hyperintense to CSF on T1
    - T2: Isointense to CSF but no FLAIR suppression
    - DWI: Marked diffusion restriction

TOP DIFFERENTIAL DIAGNOSES

- Craniopharyngioma
- Arachnoid cyst
- Lipoma
- Teratoma

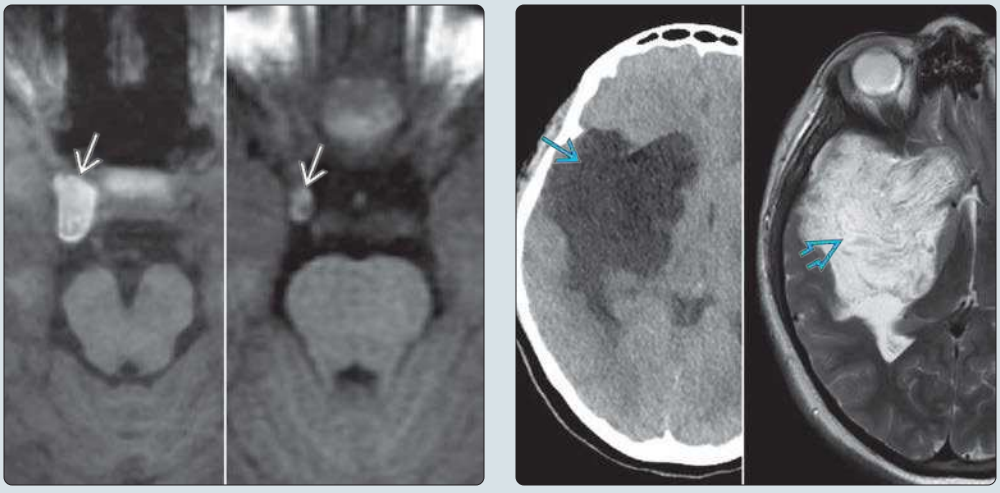
PATHOLOGY

- Dermoids: Mixture of greasy lipid, cholesterol debris
- Epidermoids: Lobular mass with shiny (pearl-like) surface



CLINICAL ISSUES

- Dermoid rupture → acute severe headache, collapse
- Dermoids are rare: < 0.5% of primary intracranial tumors
- Epidermoids 5-10x more common



DIAGNOSTIC CHECKLIST

- Fat suppression of dermoid is much less "clean" than lipoma
- IV contrast helps distinguish dermoid from craniopharyngioma

(Left) *Axial T2 MR in a 7-year-old child shows an epidermoid cyst ➡ in the left cerebellopontine angle. The T2 signal is essentially isointense to CSF. Without the associated mass effect on the brainstem & cerebellum, this lesion would not be visible on this sequence.* **(Right)** *Axial DWI MR in the same patient shows "light bulb" hyperintense signal within the mass ➡, consistent with diffusion restriction. This is a characteristic feature of an epidermoid cyst, which was confirmed at surgery.*

(Left) *Axial T1 MR images in a patient at 1 year (right) & 15 years (left) show a hyperintense parasellar mass ➡ that has ↑ in size. It can be difficult to distinguish a lipoma from a dermoid cyst, but growth over time favors the latter.* **(Right)** *Axial NECT (left) in a 14-year-old shows a very low-density mass ➡ in the right sylvian fissure. Axial T2 MR (right) shows the mass to be CSF isointense ➡ with many dark striations. DWI (not shown) demonstrated diffusion restriction. Pathology confirmed an epidermoid cyst.*

TERMINOLOGY

Definitions

- Intracranial inclusions of ectodermal tissue
- Dermoids contain squamous epithelium & associated dermal appendages
  - Sebaceous glands, dental enamel, hair follicles
- Epidermoids consist of squamous epithelium

IMAGING

General Features

- Best diagnostic clue
  - Dermoids: Fatty, nonenhancing mass with layered septations
  - Epidermoids: T2-hyperintense (~ CSF intensity), nonenhancing, diffusion-restricting mass
- Location
  - Dermoids: Usually midline, common in parasellar & frontonasal regions
  - Epidermoids: Most commonly in cerebellopontine angle & near 4th ventricle
    - Peripheral epidermoids are typically located adjacent to cranial sutures

CT Findings

- NECT
  - Dermoids: Often have fat density; Ca^{2+} in 20%
    - Rupture → fat droplets within cisterns & sulci, fat/fluid levels in ventricles
  - Epidermoids: Usually iso- to hyperdense to CSF

MR Findings

- Dermoids: Striated or layered internal appearance
  - **T1:** Iso- to hyperintense to brain
    - Not as uniformly bright as lipomas
    - Suppress with fat saturation but not as uniformly as lipoma
  - **T2:** Heterogeneous signal
  - **DWI:** Variable but diffusion restriction is typically < epidermoids
  - **T1 C+:** No internal contrast enhancement
    - Rupture → chemical ventriculitis & ependymal enhancement
- Epidermoids: Small septations or lobules may be visible, especially on 3D SSFP imaging
  - **T1:** Iso- to slightly hyperintense to CSF
  - **T2:** Isointense to CSF (may mimic arachnoid cyst)
  - **FLAIR:** Does not suppress like CSF
  - **DWI:** Marked diffusion restriction ("light bulb bright")
  - **T1 C+:** No internal contrast enhancement
  - "Atypical" epidermoids (< 5%)
    - T1 hyperintense & T2 hypointense
    - Atypical signal corresponds to hemorrhage

Imaging Recommendations

- Best imaging tool
  - MR with contrast
- Protocol advice
  - Use fat suppression, DWI, & FLAIR
  - Use MRA to assess vascular narrowing/encasement
  - Look for chemical shift artifact, especially with rupture

DIFFERENTIAL DIAGNOSIS

Craniopharyngioma

- T1-hyperintense foci do not change with fat suppression
- Enhancement in > 90%

Arachnoid Cyst

- Similar to epidermoids on NECT & T2 MR
- Suppresses on FLAIR MR; does not restrict diffusion

Lipoma

- Fatty signal/attenuation is more homogeneous

Teratoma

- Germ cell tumor that contains ≥ 2 embryologic layers
- Usually has enhancing components

PATHOLOGY

General Features

- Etiology
  - Congenital: Inclusion of cutaneous ectoderm during neural tube closure
  - Acquired: Displacement of epithelium into CNS during lumbar puncture, trauma, surgery

Gross Pathologic & Surgical Features

- Dermoids: Mixture of greasy lipid, cholesterol debris
  - Often contain hair, may contain enamel
- Epidermoids: Lobular mass with shiny (pearl-like) surface
  - Cyst contents: Soft, waxy, flaky material

CLINICAL ISSUES

Demographics

- Epidemiology
  - Dermoids are rare: < 0.5% of primary intracranial tumors
  - Epidermoids are 5-10x more common

Natural History & Prognosis

- Slowly growing, often asymptomatic
- Dermoid rupture can cause significant morbidity/mortality

Treatment

- Complete microsurgical excision
  - Residual capsule may lead to recurrence
  - Subarachnoid dissemination of contents may occur

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Use contrast to distinguish suprasellar dermoid from craniopharyngioma
- Fat suppression of dermoid is less "clean" than lipoma
- Epidermoids are easily distinguished from arachnoid cysts with appropriate MR sequences; FLAIR, DWI, & 3D SSFP (FIESTA, CISS, etc.)

SELECTED REFERENCES

Pineal Cyst

KEY FACTS

TERMINOLOGY

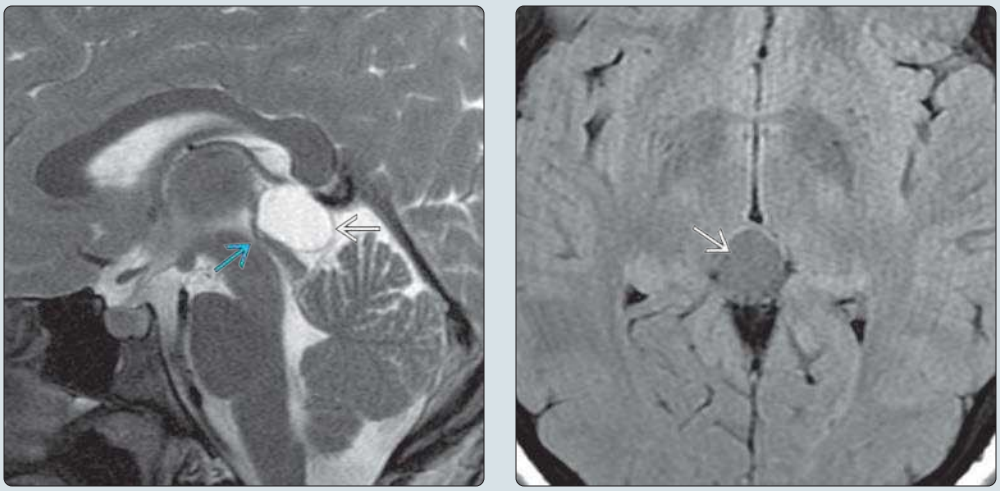
- Nonneoplastic, intrapineal, glial-lined cyst

IMAGING

- Most common appearance: Single, round/ovoid cyst < 1 cm
- Lobulations & internal septations are common
- CT
  - Low-attenuation focus in pineal region
    - May be difficult to identify thin walls on CT
  - 25% show Ca^{2+} in cyst wall; more common with ↑ age
- MR
  - Cyst contents are typically similar to CSF on T1, T2
  - Cyst contents do not suppress on FLAIR
  - Cyst contents do not restrict diffusion
  - ~ 90% show wall enhancement
    - Most common pattern: Thin rim (≤ 2 mm)

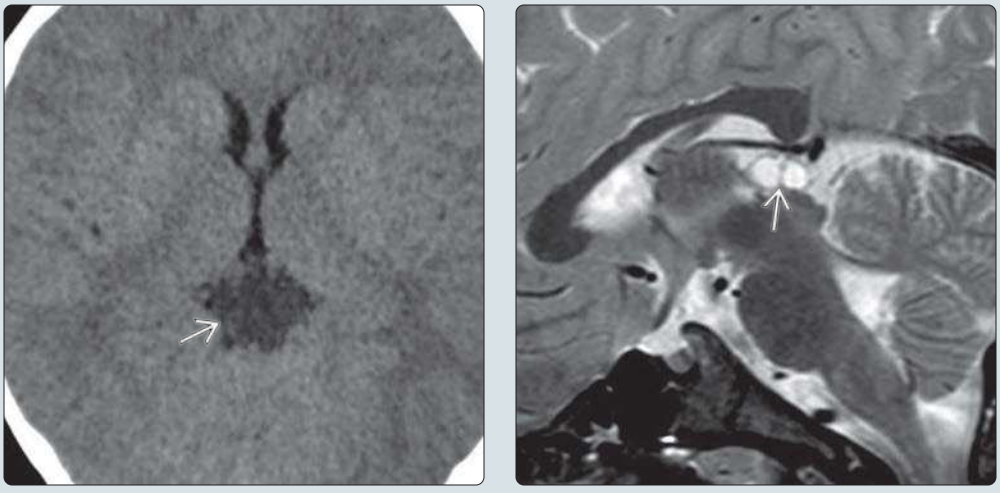
TOP DIFFERENTIAL DIAGNOSES

- Arachnoid cyst
- Epidermoid cyst
- Velum interpositum cyst
- Pineocytoma



CLINICAL ISSUES

- Very common: > 50% prevalence with high-resolution MR
- Occur at all ages but prevalence ↓ in older adults
- Most commonly incidental
- Large cysts (> 1 cm) may become symptomatic
  - Headache (aqueduct compression → hydrocephalus)
  - Parinaud syndrome (due to tectal plate compression)
  - In absence of hydrocephalus & visual changes, symptoms are unlikely to be related to cyst



DIAGNOSTIC CHECKLIST

- Development of pineal gland cyst is considered normal
- Imaging follow-up is typically not necessary in children
  - Unless size or degree of enhancement are unusual
- Pineocytoma appearance overlaps (but rare in children)

(Left) *Sagittal T2 MR in a 17-year-old girl with headaches shows a simple pineal cyst. The lesion is well defined, isointense to CSF, & contains no septations. There is mild mass effect on the tectum & cerebral aqueduct. Given the lack of associated hydrocephalus, this finding is likely incidental.* **(Right)** *Axial FLAIR MR in the same patient shows that the cyst does not suppress like CSF, typical of pineal cysts.*

(Left) *Axial NECT in a 9-year-old with headaches shows a hypodense (but slightly hyperdense to CSF) lesion in the pineal region. It is difficult to clearly delineate the borders of the cyst on CT. Note the lack of ventriculomegaly.* **(Right)** *Sagittal T2 MR in a 6-year-old with seizures shows a pineal cyst, either containing a septation or representing 2 adjacent cysts. Septations are a common finding, seen in ≥ 25% of pineal cysts, & are especially evident when using high spatial resolution MR imaging.*

KEY FACTS

TERMINOLOGY

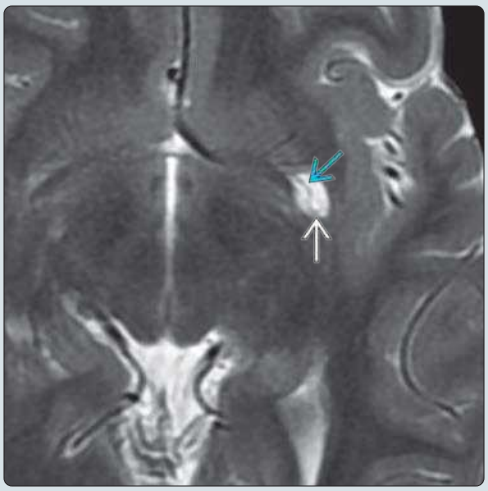
- Fluid-filled channels in subpial space that accompany penetrating arteries into brain

IMAGING

- Round/oval in basal ganglia; tubular in white matter
- Found in virtually all locations; conspicuity ↑ at 3T MR
  - Inferior basal ganglia > cerebral white matter
- **NECT**: Well-defined low-attenuation lesion (~ CSF)
- **MR**: PVS contents follow CSF signal on all sequences
  - May see penetrating vessels within PVS
  - No significant adjacent parenchymal signal abnormality
- ↑ size & number with ↑ age
- "Giant" or "tumefactive" clusters of PVSs are most often located in midbrain; may have associated mass effect

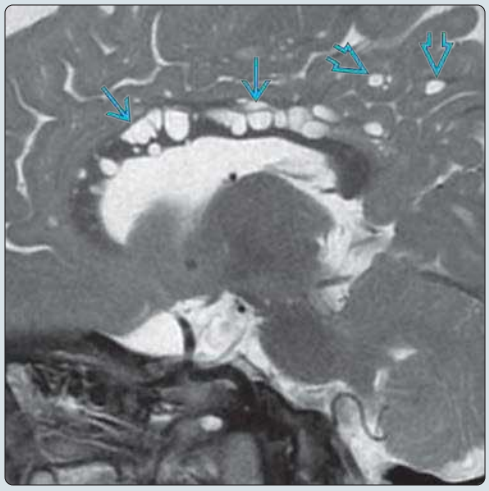
TOP DIFFERENTIAL DIAGNOSES

- Mucopolysaccharidoses
- Cystic neoplasms (e.g., DNET)
- Multiple sclerosis
- Cystic encephalomalacia
- Neurocysticercosis & other cyst-forming parasites
- Lacunar infarcts (typically in older patients)



PATHOLOGY

- Actually contain interstitial fluid, not CSF
- Single or double layer of invaginated pia



CLINICAL ISSUES

- Most common history: Incidentally identified focus of low attenuation on CT
- "Leave alone" lesion; MR ± contrast can typically distinguish from more serious considerations
  - PVSs are usually stable in otherwise normal patients
- "Giant" or "tumefactive" PVSs are very uncommon in children, consider mucopolysaccharidosis
- Recent studies in adults have shown PVSs to be imaging markers of cerebral small vessel disease

(Left) *Axial NECT in a 15-year-old girl with headache shows a focus of low attenuation in the left basal ganglia. While statistically this most likely represents an enlarged perivascular space (PVS), the finding is nonspecific on CT & warrants MR.* **(Right)** *Axial T2 MR in the same patient further characterizes the lesion seen on CT as an ovoid focus isointense to CSF & centered around a vessel, consistent with an incidental PVS. The inferior basal ganglia are the most common locations for PVSs.*

(Left) *Sagittal T2 MR in a 17-month-old patient with Hurler syndrome shows extensive cystic spaces within the corpus callosum & more peripheral subcortical white matter.* **(Right)** *Axial FLAIR MR in the same patient shows signal suppression of the cysts. This extent of PVSs in a child is rare & should prompt consideration of an underlying mucopolysaccharidosis (MPS). Solitary, small PVSs are common in children, but extensive PVSs are extremely rare outside of MPS & a few other rare syndromes.*

Pilocytic Astrocytoma

KEY FACTS

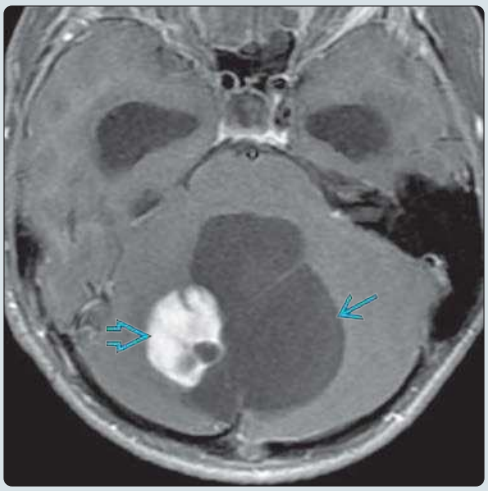
TERMINOLOGY

- Pilocytic astrocytoma (PA)
  - WHO grade 1 astrocytic tumor
  - Most common primary brain tumor of children

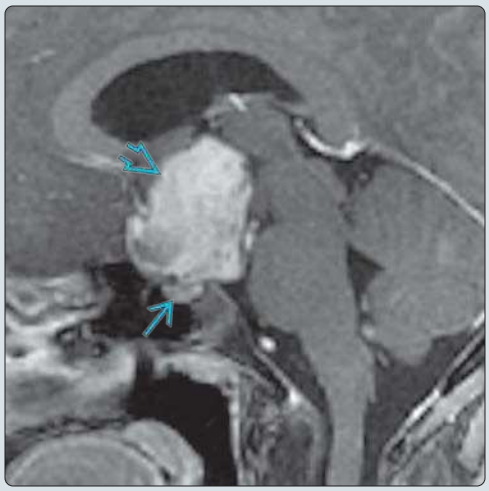
IMAGING

- Location
  - Without neurofibromatosis type 1 (NF1): Cerebellum (midline or off midline) > hypothalamus, brainstem, cerebral hemispheres > optic pathway (OP)
  - With NF1: OP is most common
- Size: Cerebellar & cerebral lesions are often > 5 cm
- > 95% enhance (patterns vary)
  - Nonenhancing cyst with enhancing mural nodule: 50%
  - Heterogeneous enhancement with smaller cysts: 40%
  - Solid, (typically) avid enhancement: 10%
- Ca^{2+} in 20%; hemorrhage is uncommon
- May show little surrounding vasogenic edema
- Often causes obstructive hydrocephalus
- ↑ diffusivity is typical (unlike highly cellular tumors)
- Paradoxical aggressive-appearing MR spectroscopy
  - High choline, low NAA, ± lactate

TOP DIFFERENTIAL DIAGNOSES

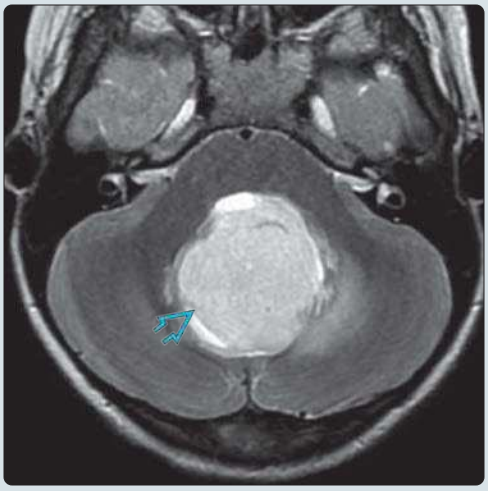


- Posterior fossa: Medulloblastoma, ependymoma
- Hypothalamus/OP: Pilomyxoid astrocytoma, optic neuritis

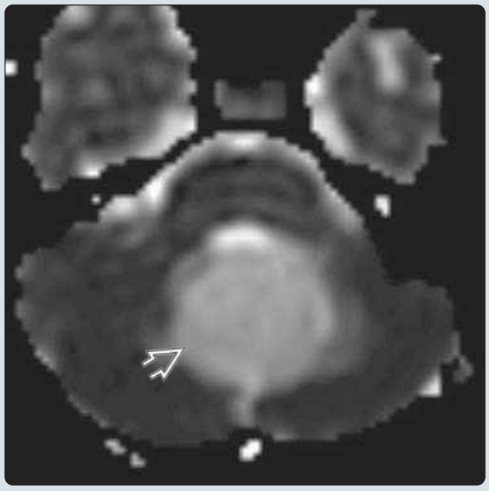


PATHOLOGY

- Sporadic > syndromic
  - 15% of NF1 patients develop PAs: OP > brainstem
    - 50-60% of patients with OP PAs have NF1



CLINICAL ISSUES



- Location determines presentation, treatment, prognosis
  - Headaches, nausea/vomiting, cerebellar signs, visual loss
  - Cerebellar & cerebral lesions: Cured with total resection
  - OP lesions (especially NF1) may be observed for growth or visual loss prior to chemotherapy or radiation
- 10-year survival > 90%

(Left) *Axial T1 C+ MR in a 13-year-old with a pilocytic astrocytoma (PA) shows a large, cystic mass with an enhancing mural nodule centered in the midline cerebellum. This is the classic appearance for a PA.* **(Right)** *Sagittal T1 C+ MR in a 10-year-old with PA shows an avidly enhancing mass centered in the hypothalamus. Note the normal pituitary, which excludes a pituitary tumor. The hypothalamus/optic chiasm is a common location for PA.*

(Left) *Axial T2 MR in a 9-year-old girl with headaches shows a solid-appearing midline mass with ↑ signal intensity that is slightly lower than CSF, typical for PA.* **(Right)** *Axial ADC map MR in the same patient shows signal intensity in the mass that is much > the adjacent brain parenchyma. This ↑ diffusivity is typical of a PA. Diffusion characteristics can be helpful in distinguishing PA from medulloblastoma, especially with midline tumors extending into the 4th ventricle.*

TERMINOLOGY

Abbreviations

- Pilocytic astrocytoma (PA)

IMAGING

General Features

- Location
  - In patients without neurofibromatosis type 1 (NF1): Cerebellum > hypothalamus, brainstem, cerebral hemispheres > optic pathway (OP)
  - With NF1: OP is most common

CT Findings

- Mixed cystic/solid mass
  - Solid component: Iso- or hypoattenuating to white matter (WM)
  - Cystic component: Similar attenuation to CSF
- Ca^{2+} in 20%; hemorrhage is rare
- Frequently cause obstructive hydrocephalus

MR Findings

- T1WI
  - Cyst contents: Iso- to slightly hyperintense to CSF
- T2WI
  - Solid portions: Hyperintense to gray matter (GM)
- FLAIR
  - Solid portions are hyperintense to GM
  - Cyst contents are iso- to hyperintense to nulled CSF
    - Can help determine relationship to 4th ventricle
  - May cause only mild surrounding vasogenic edema
- DWI
  - Variable, but classically bright on ADC (not DWI)
    - ↑ diffusivity is typical in PA
- T1WI C+
  - > 95% enhance (with exception of OP glioma)
    - 50% with large cyst & enhancing mural nodule
      - ± cyst wall enhancement
    - 40% with heterogeneous enhancement
    - 10% with solid homogeneous enhancement
  - Leptomeningeal spread of tumor is very uncommon
- MRS
  - Paradoxical aggressive-appearing pattern
    - High Cho, low NAA ± lactate

DIFFERENTIAL DIAGNOSIS

Medulloblastoma

- Midline posterior fossa mass with hyperattenuation (CT) & diffusion restriction (MR)
- Younger patient age (median: 6 years)

Ependymoma

- "Plastic" tumor: Extends out 4th ventricular foramina
- Ca^{2+}, cysts, & hemorrhage are common

Pilomyxoid Astrocytoma

- More aggressive, less common tumor; usually suprasellar
- Hemorrhage & ↑ arterial spin labeling perfusion are suggestive

PATHOLOGY

General Features

- WHO grade 1, localized astrocytic neoplasm
  - Progression to higher grades is uncommon
- Genetics
  - Sporadic (majority): *BRAF* gene (at chromosome 7q34) mutations are most common → activation of RAS/ERK/MAPK pathways
  - Syndromic: Loss of neurofibromin protein (*NF1* gene at 17q11.2) activates RAS pathway
    - 15-21% of NF1 patients develop PAs, usually of OP
      - 50-60% of OP PAs occur in NF1

Microscopic Features

- Typically biphasic histologic pattern
  - Dense fibrillar piloid with Rosenthal fibers
  - Hypofibrillar spongy tissue

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - ↑ intracranial pressure: Headaches, nausea, vomiting
  - Cerebellar lesions: Ataxia, dysdiadochokinesia
  - OP lesions: Visual loss
- Clinical profile
  - Most common primary CNS tumor in children
  - Most common posterior fossa tumor in ages 5-19 years

Natural History & Prognosis

- > 90% survival at 10 years
- Poorer prognosis: Solid lesions, brainstem extension, hypothalamic location, leptomeningeal spread, anaplasia
  - Pathology still demonstrates WHO grade 1 tumor

Treatment

- Cerebellar or cerebral locations: Surgical
  - Prognosis is related to success of total resection
    - Complete resection is curative
  - Adjuvant chemotherapy or radiation only with residual progressive unresectable tumor
  - Recent major advances in targeted molecular therapy for unresectable low-grade tumors
    - Biopsy & molecular characterization is critical
- OP: Often none, especially in NF1
  - Decision to treat is driven by vision loss & tumor growth
  - Radiation or chemotherapy for progressive disease

Medulloblastoma

KEY FACTS

TERMINOLOGY

- Malignant (WHO grade 4), invasive, highly cellular embryonal tumor

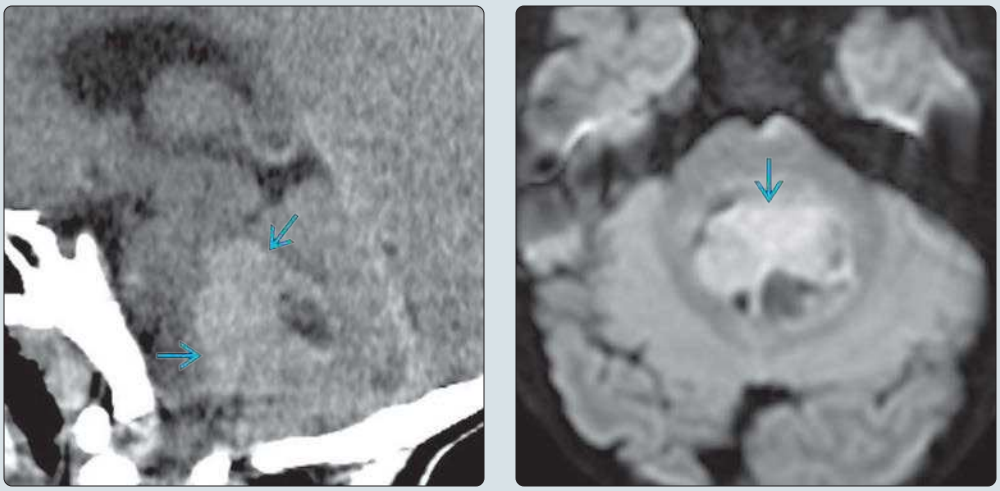
IMAGING

- Round midline 4th ventricular mass
  - If hemispheric → SHH subtype
- Obstructive hydrocephalus in 95%
- CT: 90% hyperattenuating (due to ↑ cellularity)
- CT: Ca^{2+} in up to 20%; hemorrhage is rare
- MR: Restricted diffusion reflects ↑ cellularity
- Complete neuraxis C+ MR to detect CSF spread
- 33% have subarachnoid metastatic disease at diagnosis
- 5% develop bone metastases, usually sclerotic

TOP DIFFERENTIAL DIAGNOSES

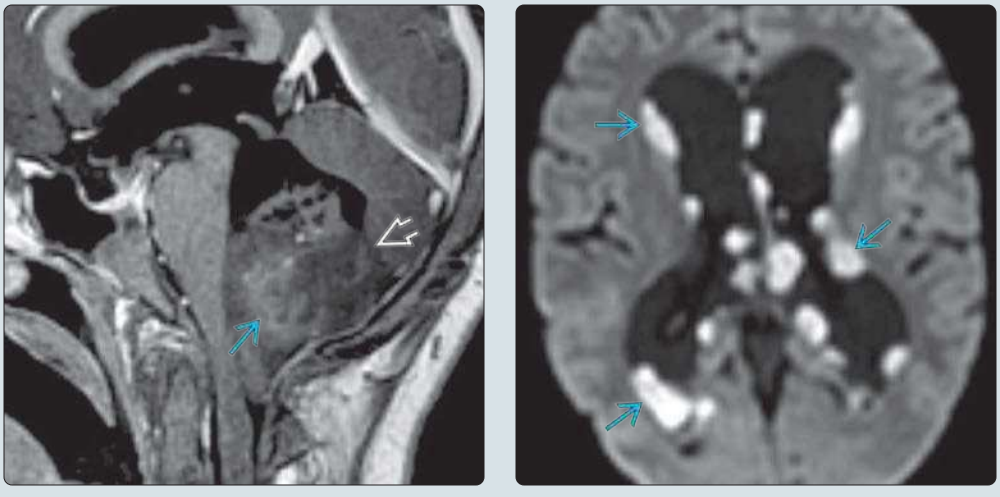
- Atypical teratoid/rhabdoid tumor (AT/RT)
- Ependymoma
- Pilocytic astrocytoma

PATHOLOGY



- 4 major molecular subgroups
  - Wnt-wingless (favorable prognosis)
  - SHH-Sonic hedgehog (intermediate prognosis)
  - Group 3 (poor prognosis)
  - Group 4 (intermediate prognosis)
- Histology is still important in treatment decisions
  - Classic, desmoplastic/nodular, & large cell/anaplastic

CLINICAL ISSUES



- Most common posterior fossa tumor in ages 0-4 years
  - 15-20% of all pediatric brain tumors
- Prognosis depends on residual tumor status post resection & presence of metastatic disease

DIAGNOSTIC CHECKLIST

- 4th ventricular tumor arising from roof: Medulloblastoma
- 4th ventricular tumor arising from floor: Ependymoma
- Consider AT/RT in patients < 3 years of age

(Left) *Sagittal NECT in a 3-year-old boy with intractable vomiting shows a predominantly solid hyperdense mass ⇨ centered in the midline posterior fossa. The ↑ attenuation is consistent with high cellularity & should suggest medulloblastoma (MB).* **(Right)** *Axial DWI MR in the same patient shows diffusion restriction throughout most of the midline mass ⇨, consistent with a highly cellular tumor.*

(Left) *Sagittal T1 C+ MR in a 14-year-old patient with Rubenstein-Taybi syndrome shows mild patchy enhancement of a midline posterior fossa mass ⇨. Note the indistinct interface with the posterior 4th ventricle (roof) ⇨, typical of MB.* **(Right)** *Axial DWI MR in a 13-year-old with MB status post gross total resection 3 years ago shows CSF dissemination of recurrent multifocal tumor ⇨ along ventricular margins. DWI is helpful in surveillance imaging & is often the most sensitive sequence for detecting recurrent disease.*

TERMINOLOGY

Abbreviations

- Medulloblastoma (MB)

Definitions

- Malignant (WHO grade 4), invasive, highly cellular embryonal tumor

IMAGING

General Features

- Best diagnostic clue
  - Midline 4th ventricular mass in 1st decade of life
  - Hyperattenuating (CT), diffusion restricting (MR)
- Location
  - 75-90% occur in midline
    - 4th ventricular mass arising from roof (dorsal 4th ventricle)
    - Cerebellar hemisphere is more frequent location in older children & adults
  - ~ 33% have subarachnoid metastatic disease at diagnosis
  - Bony metastases may occur in ~ 5%; usually sclerotic

CT Findings

- Hyperattenuation (90%) reflects high cellularity
- Ca^{2+} in up to 20%; hemorrhage is rare
- Obstructive hydrocephalus in up to 95%

MR Findings

- **T1**: Hypointense to gray matter (GM)
- **T2**: Iso- to hyperintense to GM
- **FLAIR**: Hyperintense to brain
- **DWI**: Hyperintense on DWI; hypointense on ADC
  - Reflects high cellularity
  - Excellent detection of recurrent nonenhancing MB
- **MRS**: Taurine peak may be detected at 3.4 ppm
- **T1 C+**: Variable enhancement of primary tumor
  - Contrast improves detection of CSF dissemination

Imaging Recommendations

- Best imaging tool
  - MR with DWI & postcontrast sequences
- Protocol advice
  - Sagittal images pre- & postcontrast often show site of origin (roof vs. floor of 4th ventricle)
  - Appropriate staging requires total spine imaging

DIFFERENTIAL DIAGNOSIS

Atypical Teratoid/Rhabdoid Tumor

- No differentiating imaging features; often more heterogeneous than MB
- Younger children (usually < 3 years of age)

Ependymoma

- Punctate Ca^{2} & hemorrhage are more common than MB
- Extension through 4th ventricle foramina: "Plastic" tumor

Pilocytic Astrocytoma

- Cerebellar hemispheric lesion; often cystic
- Solid portion: ↑ ADC signal (↑ diffusivity, not ↓)

Choroid Plexus Papilloma

- 4th ventricle location is less common
- Vigorous enhancement is typical
- No diffusion restriction unless higher grade (carcinoma)

PATHOLOGY

General Features

- Most common posterior fossa tumor in ages 0-4 years
- Associated with many familial cancer syndromes

Staging, Grading, & Classification

- Molecular subgroups are increasingly important
  - Wnt-wingless (least common): Favorable prognosis
    - Often located in cerebellopontine angle
  - SHH-Sonic hedgehog: Intermediate prognosis, except infants → good prognosis
    - 50% located in cerebellar hemisphere
  - Group 3: Poor prognosis
    - *MYC* amplification is common
    - Located in midline/4th ventricle
  - Group 4 (most common): Intermediate prognosis
    - i17q mutation is common
    - Located in midline/4th ventricle

Microscopic Features

- Densely packed hyperchromatic cells with scant cytoplasm
- Histologic subtypes (still important in treatment decisions)
  - Classic (~ 70%)
  - Nodular/desmoplastic (~ 20%)
  - Anaplastic/large cell (~ 10%)

CLINICAL ISSUES

Presentation

- Ataxia, signs of ↑ intracranial pressure

Demographics

- M > F = 2-4:1
- 75% < 10 years of age

Treatment

- Surgical excision, adjuvant chemotherapy
- Craniospinal irradiation if > 3 years of age
- 5-year survival rate
  - No metastases or gross residual tumor status post resection: 60-100%
  - Presence of gross residual tumor after surgery or metastatic disease: 20%

Atypical Teratoid/Rhabdoid Tumor

KEY FACTS

TERMINOLOGY

- Highly malignant (WHO grade 4) embryonal neoplasm

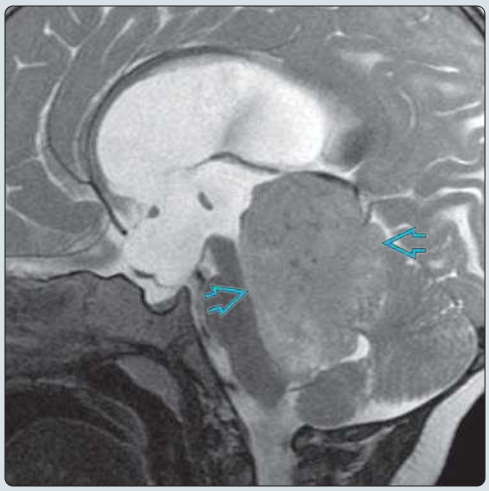
IMAGING

- Heterogeneous intracranial mass in infant/young child
  - Commonly contains cysts or hemorrhage
  - Solid components show ↑ attenuation on CT & restricted diffusion on MR due to high cellularity
- 47% infratentorial, 41% supratentorial, 12% both
- Often causes obstructive hydrocephalus
- Leptomeningeal spread is common (15-20%)

TOP DIFFERENTIAL DIAGNOSES

- Medulloblastoma
- Supratentorial CNS embryonal tumor (formerly PNET)
- Ependymoma
- Desmoplastic infantile tumor
- Teratoma
- Choroid plexus tumor

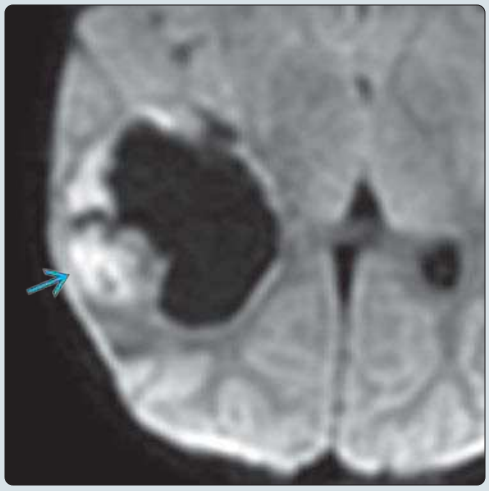
PATHOLOGY



- Morphologic & immunophenotypic heterogeneity
- Divergent differentiation accounts for teratoid label
  - Sheets of primitive cells separated by fibrovascular septa
  - Large rhabdoid cells with eosinophilic cytoplasm
- Most rhabdoid tumors show lack of INI1 immunostain due to *SMARCB1* (hSNF5/INI1) mutation (22q11.2)
- Histology is similar to renal & soft tissue rhabdoid tumors
  - May be concurrent with CNS AT/RT

CLINICAL ISSUES

- Child < 3 years old with increasing head size, vomiting
- Median survival: 12-18 months; overall survival rate: 23-37%



DIAGNOSTIC CHECKLIST

- Always consider AT/RT in young child (< 3 years old) with
  - Large, heterogeneous CNS tumor
  - MB or PNET being considered
  - Infant with new cranial nerve palsy + cisternal mass

(Left) *Sagittal T2 MR in a 15-month-old with developmental regression & macrocephaly shows a large mass ⇨ in the anterior superior cerebellum. The mass fills the 4th ventricle & aqueduct of Sylvius, causing hydrocephalus, & extends through the tentorial incisura.* **(Right)** *Axial DWI MR in the same patient shows diffusion restriction ⇨ throughout the mass, consistent with a high cellularity tumor. Atypical teratoid/rhabdoid tumor (AT/RT) should be considered for any highly cellular tumor in a young child.*

(Left) *Axial DWI MR in a 2-year-old shows a mixed solid & cystic tumor with diffusion restriction (with ↓ ADC not shown) in the solid portion ⇨ of the tumor. DWI is very important in evaluating the cellularity of tumors & is predictive of high- vs. low-grade tumors.* **(Right)** *Axial T1 C+ MR in a 2-year-old with right ptosis shows a lobular, enhancing mass of the right cerebral peduncle ⇨ & proximal right 3rd cranial nerve ⇨. Restricted diffusion was seen in the lesion (not shown). AT/RT was confirmed at subtotal resection.*

TERMINOLOGY

Definitions

- Atypical teratoid/rhabdoid tumor (AT/RT): Malignant embryonal tumor of CNS in early childhood
  - Closely related to renal & soft tissue rhabdoid tumors

IMAGING

General Features

- Best diagnostic clue
  - Large, solid & cystic tumor (± hemorrhage) with diffusion restriction in infant/young child
- Location
  - Infratentorial (47%)
    - Often off midline
      - Cerebellopontine angle
      - Cerebellum &/or brainstem
      - Individual cranial nerves
  - Supratentorial (41%)
    - Hemispheric or intraventricular
  - Both infra- & supratentorial (12%)
  - 15-20% have disseminated tumor at initial diagnosis

CT Findings

- NECT
  - Hyperattenuating mass
  - Commonly contains cysts &/or hemorrhage
  - May contain Ca^{2+}
  - Obstructive hydrocephalus is common

MR Findings

- **T1**: Heterogeneous ± hyperintense hemorrhage
- **T2**: Heterogeneous signal ± hyperintense cystic foci
- **FLAIR**: Hyperintense cysts ± peritumoral edema
- **T2* GRE/SWI**: Hemorrhagic foci causing exaggerated signal loss (blooming)
- **DWI**: ↑ DWI & ↓ ADC signal due to high cellularity
- **T1 C+**: Heterogeneous enhancement is most common; no enhancement is less common
  - Key for detecting local recurrence & CSF metastases

DIFFERENTIAL DIAGNOSIS

Medulloblastoma

- AT/RT is more likely to have cysts

CNS Embryonal Tumor (Formerly PNET)

- Cellular supratentorial tumor with diffusion restriction

Ependymoma

- Infratentorial tumor often extends through 4th ventricular foramina
- Supratentorial form is often large & cystic

Desmoplastic Infantile Ganglioglioma/Astrocytoma

- Very young children (peak age: 3-6 months)
- Very large cystic components

Teratoma

- More often pineal or parasellar in location
- Heterogeneous due to Ca^{2+}, ± fat

Choroid Plexus Tumors

- Centered in ventricle
- Vigorous, homogeneous enhancement
- Lobulated, frond-like margins
- Diffusion restriction is much less common than AT/RT

PATHOLOGY

General Features

- Genetics
  - Loss of tumor suppressor gene *SMARCB1* (hSNF5/INI1) in most rhabdoid tumors, including CNS, renal, extrarenal
    - Gene located at chromosome 22q11.2
    - Mutation at 19p13.2 is less common (*SMARCA4*)

Staging, Grading, & Classification

- WHO grade 4
- Molecular subgroups
  - MYC-TYR-SHH molecular classification (Johann PD et al)
    - MYC: Supratentorial; + edema; + enhancement
    - TYR: Infratentorial; peripheral cysts; + enhancement
    - SHH: Any location; + hemorrhage, - enhancement
  - ASCL1 subgroups (Torchia J et al)
    - ASCL1 positive: Better prognosis; usually supratentorial
    - ASCL1 negative: Worse prognosis; usually infratentorial

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Signs of ↑ intracranial pressure
    - Lethargy, vomiting, ↑ head circumference
- Clinical profile
  - Child < 3 years (70-80%); median age: 1 year

Natural History & Prognosis

- Aggressive tumor with poor prognosis
  - Age < 3 years → worse prognosis (~ 30% 5-year survival)
  - Metastases → < 20% 5-year survival
  - ASCL 1-negative tumors → < 20% 5-year survival

Treatment

- Intensive trimodal therapy has ↑ survival
  - Localized disease + trimodal therapy → ~ 50% 5-year survival

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Hemorrhagic, cystic, highly cellular tumor in young child → think AT/RT

SELECTED REFERENCES

Posterior Fossa Ependymoma

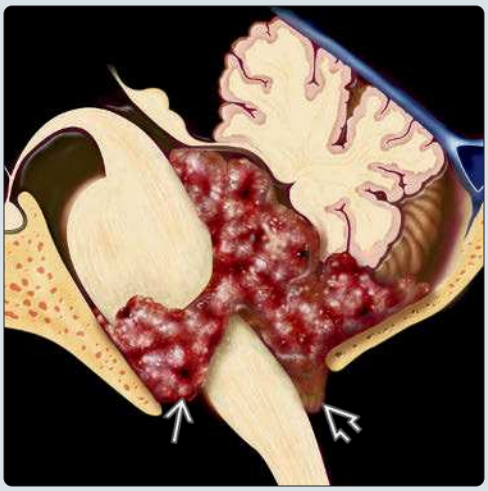
KEY FACTS

TERMINOLOGY

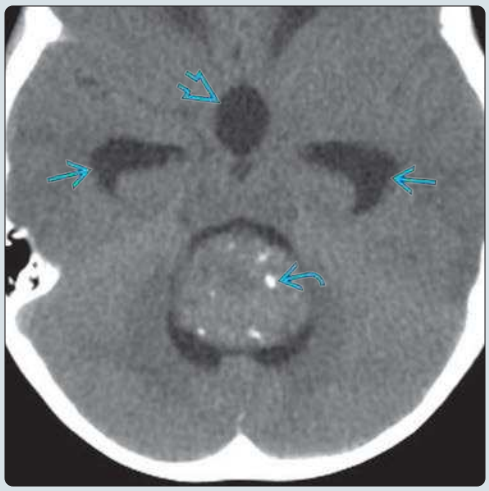
- Posterior fossa ependymoma (PF-EPN)

IMAGING

- Posterior fossa (2/3 of all CNS ependymomas)
  - Lobulated mass in body/inferior 4th ventricle
    - Soft or "plastic" tumor
      - Accommodates to shape of ventricle
      - Squeezes through foramen of Magendie into cisterna magna
      - ± extension through foramina of Luschka into CPA cisterns
- NECT
  - Fine, stippled Ca^{2+} is common (50%)
  - ± cysts, hemorrhage
  - Obstructive hydrocephalus is common
- MR
  - Variable enhancement
  - Iso- to hyperintense on ADC compared to brain

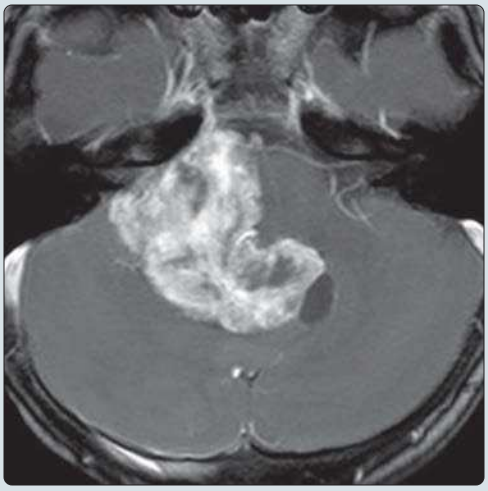


TOP DIFFERENTIAL DIAGNOSES

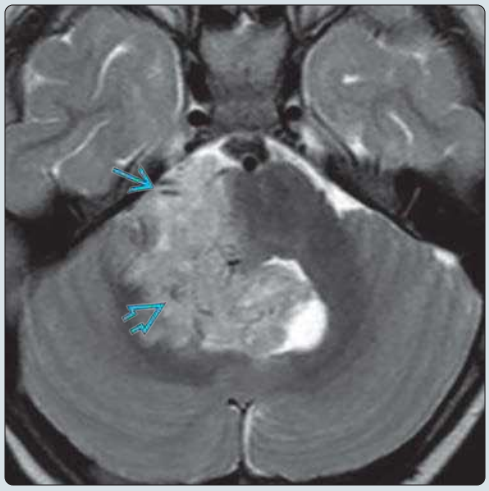


- Medulloblastoma (MB)
- Pilocytic astrocytoma (PA)
- Choroid plexus papilloma
- Atypical teratoid/rhabdoid tumor

PATHOLOGY



- PF-EPN subtype A (PF-EPN-A)
  - Most common (~ 80% of PF-EPNs)
  - Predominately infants & young children
  - Poor prognosis
- PF-EPN subtype B (PF-EPN-B)
  - Less common (~ 10-20% of PF-EPNs)
  - Predominantly older children & adults
  - Better prognosis
- 3-17% have CSF dissemination



(Left) *Sagittal graphic shows a posterior fossa ependymoma (PF-EPN) extending through the 4th ventricular outlets into the cisterna magna & cerebellopontine angle (CPA) cistern. This plastic pattern of growth is typical of EPN.* **(Right)** *Axial NECT in a 2-year-old girl shows a mass centered in the 4th ventricle containing scattered fine, stippled Ca^{2+}, which are seen in ~ 50% of PF-EPNs. Note the enlargement of the temporal horns & 3rd ventricle, consistent with obstructive hydrocephalus.*

(Left) *Axial T1 C+ MR in a 2-year-old girl shows a heterogeneously enhancing mass centered in the right foramen of Luschka with extension to the 4th ventricle & CPA.* **(Right)** *Axial T2 MR in the same patient shows a heterogeneously hyperintense tumor. This tumor likely corresponds to the PF-EPN molecular subtype A given the lateral location & patient age. Note flow voids encased by tumor. Involvement of the CPA & cranial nerves & vessels that course through it often makes complete resection difficult.*

TERMINOLOGY

Definitions

- Posterior fossa ependymoma (PF-EPN)
  - Slow-growing tumor of ependymal cells

IMAGING

General Features

- Best diagnostic clue
  - Soft "plastic" tumor squeezes out through 4th ventricle foramina into cisterns
- Location
  - Posterior fossa (typically in 4th ventricle)
    - Usually arises from inferior 1/2 of 4th ventricle
      - Much less commonly arises from cerebellopontine angle (CPA)
    - Anterolateral extension through foramina of Luschka into CPA cistern
    - Posteroinferior extension through foramen of Magendie into cisterna magna

CT Findings

- NECT
  - Fine, stippled Ca^{2+} is common (50%); ± cysts, hemorrhage

MR Findings

- T1: Heterogeneous; hyperintense Ca^{2+} & hemorrhage
- T2: Hyperintense cystic foci; hypointense Ca^{2+}
- FLAIR: Tumor cysts are hyperintense to CSF
- DWI: ADC usually iso- to hyperintense to gray matter
  - Diffusion restriction depends on tumor grade
- GRE/SWI: Hypointense blooming of Ca^{2+} & blood products
- T1 C+: Variable, heterogeneous enhancement
- MRS: ↓ NAA; ↑ Cho, lipid/lactate peaks

Imaging Recommendations

- Best imaging tool
  - MR of brain & spine with contrast
    - Spine imaging is necessary for complete staging
- Protocol advice
  - Sagittal imaging may distinguish point of origin as floor vs. roof of 4th ventricle
  - High-resolution 3D SSFP MR can visualize cranial nerve involvement by tumor extending into cisterns
  - MR angiography can delineate involvement of posterior fossa vessels by tumor extending into cisterns

DIFFERENTIAL DIAGNOSIS

Medulloblastoma

- Hyperdense on NECT; diffusion restriction (↑ DWI, ↓ ADC)
- Arises from roof of 4th ventricle with 90% in midline

Cerebellar Pilocytic Astrocytoma

- Arises from cerebellar parenchyma
- 90% are off midline
- Most have cystic component
- Enhancing portion enhances vigorously in > 90%

Choroid Plexus Papilloma

- Vigorously enhancing, intraventricular tumor
- 4th ventricle location is more common in adults
- Look for lobulated, frond-like border

Atypical Teratoid/Rhabdoid Tumor

- Cellular mass with diffusion restriction (↑ DWI, ↓ ADC)
- More likely to be off midline compared to medulloblastoma (MB)
- More likely to have cysts & hemorrhage compared to MB
- Most common in very young children

PATHOLOGY

General Features

- Genetics
  - Supratentorial, posterior fossa, & spinal ependymomas are genetically distinct
  - 3 PF-EPN subgroups
    - Subependymoma (PF-SE)
    - PF-EPN subtype A (PF-EPN-A)
      - ~ 80% of posterior fossa EPN
      - Location: Foramen of Luschka & CPA are common
      - More common in younger children; M:F = 2:1
      - Worse prognosis
    - PF-EPN subtype B (PF-EPN-B)
      - ~ 10-20% of all cases
      - Location: Midline 4th ventricle
      - Older children, adults; M:F = 1:1
      - Better prognosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - ↑ intracranial pressure: Headache, nausea, vomiting
- Less common: Ataxia, hemiparesis, visual disturbances, neck pain, torticollis, dizziness

Demographics

- Epidemiology
  - 3-5% of all intracranial tumors
  - 15% of posterior fossa tumors in children

Natural History & Prognosis

- Prognosis is highly variable
  - PF-EPN-A: 50-60% 5-year survival
  - PF-EPN-B: 90-95% 5-year survival
- 3-17% have CSF dissemination
- 15% 5-year survival after recurrence

Treatment

- Maximal safe surgical resection, then XRT
- Chemotherapy has limited role, if any

Supratentorial Ependymoma

KEY FACTS

TERMINOLOGY

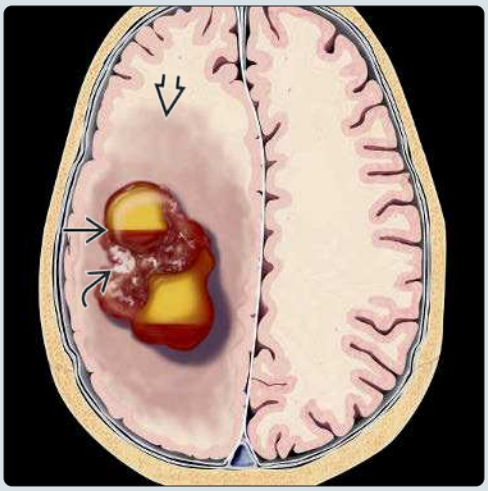
- Genetically & molecularly distinct entity from posterior fossa & spinal cord ependymomas

IMAGING

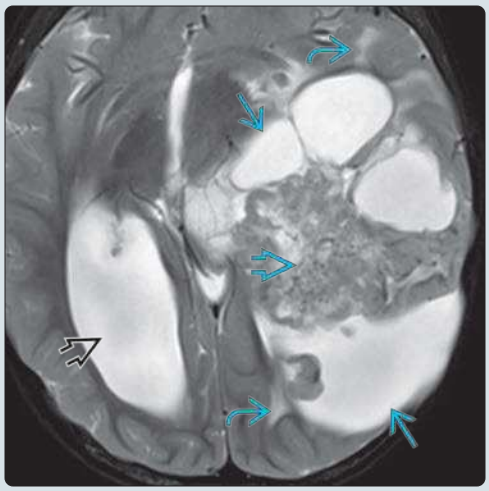
- Imaging features
  - Large, complex-appearing, mixed solid/cystic mass ± Ca^{2+} & hemorrhage
  - Common locations of supratentorial ependymoma (ST-EPN): Cerebral hemisphere > 3rd ventricle > lateral ventricle
  - CT: Heterogeneous, cystic & solid mass ± Ca^{2+}
  - MR: Complex, mixed solid & cystic mass
    - SWI/GRE: Foci of ↓ signal → hemorrhage or Ca^{2+}
    - DWI: Often shows ↑ DWI, ↓ ADC in solid portions
    - Variable enhancement, usually moderately heterogeneous
    - Surrounding vasogenic edema is typical

TOP DIFFERENTIAL DIAGNOSES

- Glioblastoma
- Embryonal tumor with multilayered rosettes
- Atypical teratoid/rhabdoid tumor
- Ganglioglioma
- Astrocytoma (other)

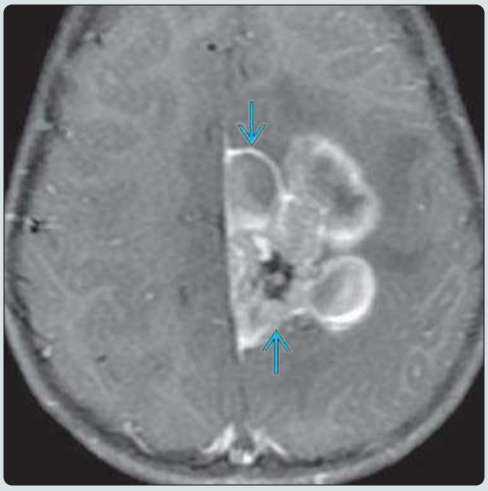


PATHOLOGY



- Most ST-EPNs are WHO grade 3 tumors (anaplastic ependymoma)
- *RELA* fusion is present in ~ 70% of ST-EPNs
  - Associated with worse prognosis

CLINICAL ISSUES



- Most important prognostic factor: Location
- Children < 3 years have poor outcome

(Left) *Graphic depicts supratentorial ependymoma (ST-EPN) as a large, hemorrhagic, hemispheric mass with multiple cysts, fluid-fluid levels, Ca^{2+}, mass effect, & peritumoral edema.* **(Right)** *Axial T2 MR in a 2-year-old patient demonstrates a large, mixed cystic & solid mass with peritumoral edema. The large size, heterogeneous solid component, & cysts are typical of a ST-EPN. When large, entrapment of the contralateral lateral ventricle is common.*

(Left) *Axial T1 C+ FS MR in a 5-year-old with ataxia & double vision shows a lobulated, multicystic mass in the periphery of the left frontoparietal region.* **(Right)** *Axial T2 MR in the same patient shows the mixed solid & cystic nature of the lesion. Note the focal ↓ signal, consistent with Ca^{2+}, a common finding in ST-EPN. Also note the peritumoral edema. Any time a large, heterogeneous supratentorial lesion is encountered, ST-EPN should be considered.*

KEY FACTS

TERMINOLOGY

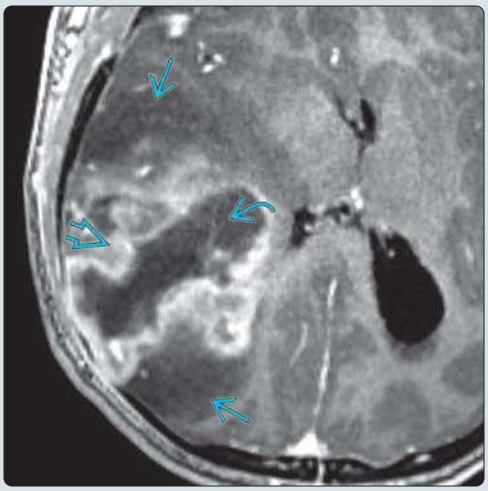
- Rapidly enlarging, malignant WHO grade 4 astrocytic tumor characterized by necrosis & neovascularity

IMAGING

- Best imaging clue: Thick, irregularly enhancing rind of neoplastic tissue surrounding necrotic core
- Heterogeneous, hyperintense mass with adjacent tumor infiltration/vasogenic edema
- Necrosis, cysts, hemorrhage, fluid/debris levels, & flow voids (neovascularity) may be seen
- Supratentorial white matter is most common location
  - Cerebral hemispheres > brainstem > cerebellum
- Viable tumor often extends far beyond signal changes

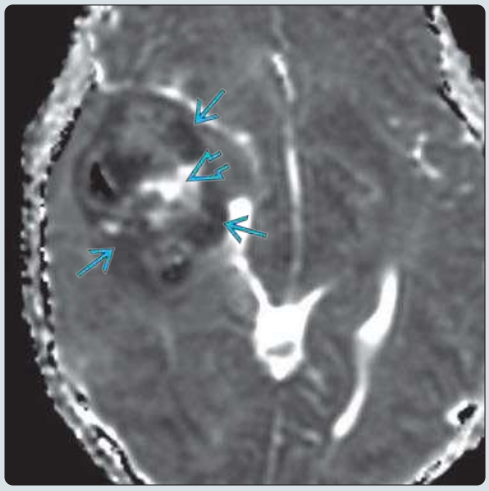
TOP DIFFERENTIAL DIAGNOSES

- Abscess
- Anaplastic astrocytoma
- Supratentorial ependymoma
- Atypical teratoid/rhabdoid tumor
- Ganglioglioma
- Embryonal tumor with multilayered rosettes
- Tumefactive demyelination
- Subacute ischemia

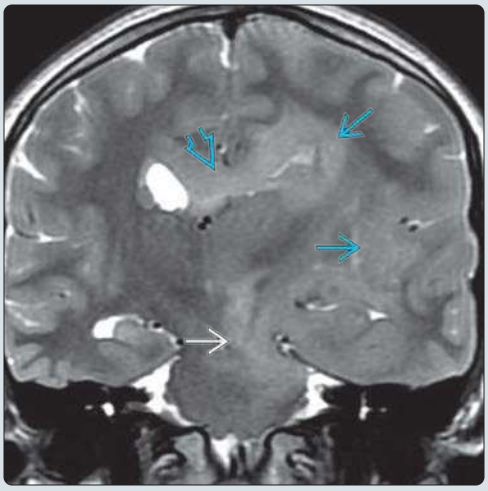


PATHOLOGY

- 2 types: Primary (de novo) & secondary (degeneration from lower grade astrocytoma)
- Necrosis & microvascular proliferation are hallmarks



CLINICAL ISSUES



- Symptoms vary with location: Seizures & focal neurologic deficits are common
- Much less common in children (~ 5% of pediatric CNS neoplasms)
- Prognosis is poor but better in children than adults

(Left) *Axial PD MR in a neonate shows a large mass of the posterior left cerebral hemisphere with numerous low signal intensity foci due to hemorrhage. Glioblastomas in neonates & infants are often large & hemorrhagic at presentation.* **(Right)** *Axial T1 C+ MR in a 17-year-old with Lynch syndrome shows a heterogeneously enhancing glioblastoma with central necrosis, a typical finding in glioblastoma. Also note the extensive peritumoral signal changes.*

(Left) *Axial ADC map in an 8-year-old with right temporal glioblastoma shows markedly ↓ signal in the solid periphery of the lesion, consistent with high cellularity. The area of central hyperintensity corresponds to necrosis.* **(Right)** *Coronal T2 MR in a 10-year-old with glioblastoma shows extensive infiltrative signal throughout the left cerebral white matter, crossing the corpus callosum & involving the brainstem.*

Brainstem Tumors

KEY FACTS

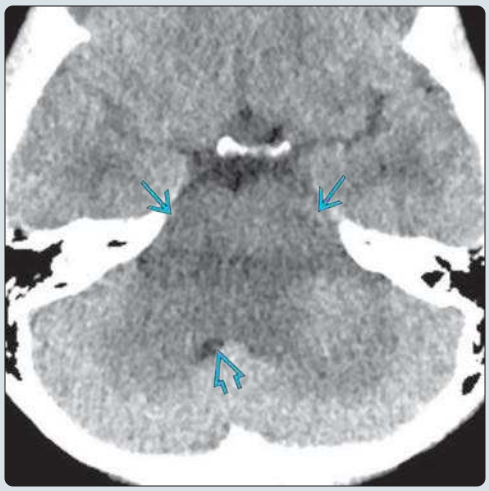
TERMINOLOGY

- Brainstem tumors (BSTs) are distinguished by location, imaging appearance, & histology
  - Medullary, pontine, mesencephalic, or tectal
  - Diffuse or focal

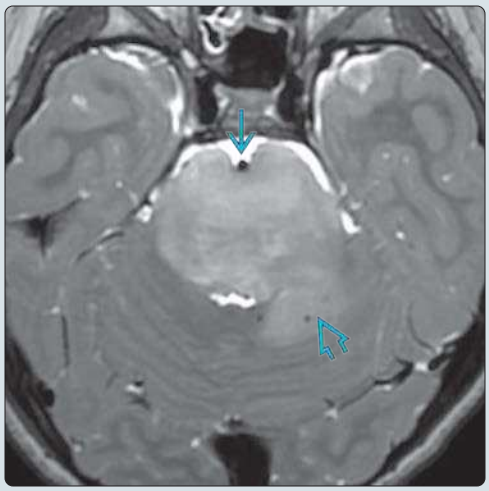
IMAGING

- Diffuse intrinsic pontine glioma (DIPG): Expansile diffuse midline glioma (DMG) in pons with poorly defined margins, effacing CSF cisterns & 4th ventricle; often encases basilar artery
  - Fibrillary tumors: Little or no enhancement
  - High grade: Focal enhancement with central necrosis
  - Foci of diffusion restriction in up to 63%, though, classically, DIPG does not restrict
- PA: Exophytic, enhancing tumor anywhere in brainstem
- Tectal plate glioma: Nonenhancing mass in tectum
- Midbrain tumors: Heterogeneous group

TOP DIFFERENTIAL DIAGNOSES

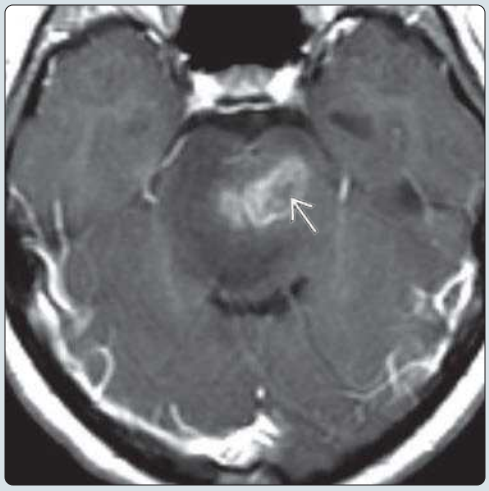


- Acute disseminated encephalomyelitis, brainstem abscess, neurofibromatosis type 1, osmotic demyelination syndrome, cavernous malformation

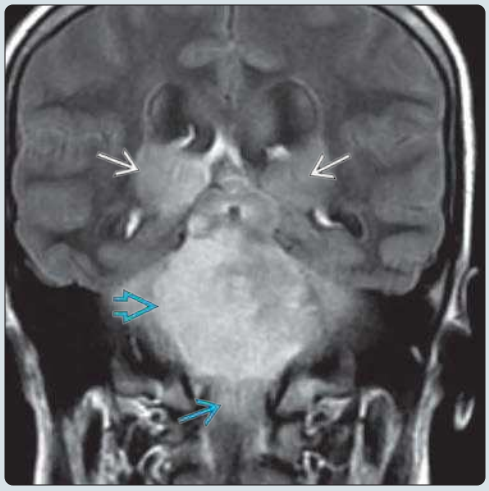


PATHOLOGY

- BSTs: 10-15% of pediatric brain tumors
  - Astrocytomas (WHO grades 1-4) > > embryonal tumor, ganglioglioma, atypical teratoid rhabdoid tumor
    - 80% of BSTs are pontine DMG (DIPG)



CLINICAL ISSUES



- Presentation: Cranial nerve palsies, hemiparesis, gait disturbance, ataxia, headache, nausea, vomiting
- Prognosis depends on location & histology
  - Pons: Poor prognosis (unresectable)
    - DIPG/DMG: Median survival ~ 1 year
  - Medulla or midbrain: Variable prognosis
  - Tectum: Good prognosis (only requires CSF diversion)

(Left) *Axial NECT in an 8-year-old patient with a diffuse intrinsic pontine glioma (DIPG)/pontine diffuse midline glioma (DMG), H3 K27M mutant, shows enlargement of the pons with effacement of the cisterns & near-complete effacement of the 4th ventricle. Mass effect on the cisterns & 4th ventricle may be the only clue to DIPG on CT.* **(Right)** *Axial T2 MR in the same patient shows the pontine mass extending into the left cerebellum with indistinct margins. Note partial encasement of basilar artery, typical of DIPG.*

(Left) *Axial T1 C+ MR in a 9-year-old patient with a DIPG/DMG shows focal areas of enhancement with central nonenhancement, suggesting necrosis. Enhancement has been shown to be associated with shorter survival time in midline glioma.* **(Right)** *Coronal FLAIR MR in the same patient with DIPG/DMG shows extension of abnormal signal into the bilateral thalami & medulla. Such distant extension of signal abnormality typically suggests an infiltrative, higher grade tumor.*

TERMINOLOGY

Abbreviations

- Brainstem tumors (BSTs)
- Diffuse intrinsic pontine glioma (DIPG): Diffuse midline glioma (DMG) in pons
  - Most common form of DMG in children

Synonyms

- Pontine glioma, midbrain glioma, medullary glioma, dorsally exophytic medullary glioma

Definitions

- BSTs are distinguished by location & imaging/histologic characteristics of tumor
  - DMG in pons (classically referred to as DIPG)
    - Glial tumor centered in pons (WHO grades 2-4)
    - 80% of pediatric BSTs
    - Expansile, often poorly marginated, often lacks enhancement
    - 70-80% harbor H3 K27M mutation → poor prognosis
  - Focal pontine tumors: Embryonal tumor with multilayered rosettes (ETMR), ganglioglioma
    - Much less common than DIPG/DMG
  - Tectal gliomas
    - Present with hydrocephalus in 6- to 10-year-olds
    - Rarely progressive
    - CSF diversion is often only treatment required
  - Midbrain or mesencephalic tumors
    - All histologies occur (including embryonal tumors & atypical teratoid/rhabdoid tumors)
  - Medullary tumors
    - Pilocytic astrocytoma (PA) is most likely histology
    - Usually dorsally exophytic & solidly enhancing
  - BSTs associated with neurofibromatosis type 1 (NF1)
    - Typically PA
    - Rarely enlarge, often asymptomatic

IMAGING

General Features

- Best diagnostic clue
  - DIPG/DMG: Expansile lesion in pons
  - PA: Exophytic enhancing lesion anywhere in brainstem
  - Tectal plate glioma: Nonenhancing lesion in tectum
- Location
  - Cervicomedullary junction to cerebral peduncles
    - Medullary, pontine, midbrain, tectal
  - DIPG/DMG: Typically centered in pons
    - Extends out of pons in 86%
      - Extension into cerebellar peduncles, midbrain, or medulla → higher grade
    - CSF dissemination in 3-7%
- Size
  - Varies greatly, partly related to location
    - DIPG is often large at presentation
    - Tectal plate gliomas are often small
- Morphology
  - Depends on histology; focal vs. large/infiltrative
    - Sometimes exophytic

CT Findings

- NECT
  - Brainstem enlargement with ↓ attenuation & effacement of adjacent CSF cisterns
    - Streak artifact from skull base can mimic tumor
  - Pontine tumors → flattening of anterior 4th ventricle
- CECT
  - Variable enhancement
    - PA in any region of brainstem usually enhances

MR Findings

- T1WI
  - Mild to moderate hypointensity
  - Central areas of preserved signal may represent relatively preserved white matter (WM) tracts
- T2WI
  - Hyperintense mass (homogeneous to heterogeneous) & margins (edema vs. infiltrating tumor)
    - Treatment often results in ↑ heterogeneity
  - Basilar artery flow void is often engulfed by DIPG
- FLAIR
  - Hyperintense mass, ± better definition than on T2
- T2* GRE
  - Areas of signal loss usually represent intratumoral hemorrhage
    - Mineralization is uncommon in BST
- DWI
  - DIPG/DMG shows foci of restricted diffusion in up to 63%, though lack of restricted diffusion is classic
    - ↓ ADC values are associated with shorter survival time & higher grade tumor
  - ETMR shows marked diffusion restriction
  - Diffusion tractography (DTI) can show displacement of WM tracts by tumor
    - WM tracts are typically infiltrated or displaced by DIPG (but not interrupted)
- T1WI C+
  - Fibrillary tumors: Variable enhancement, usually minimal
  - High-grade DIPG: Foci of enhancement in 70% ± central necrosis/rim enhancement
    - Changes from treatment are of unclear etiology
      - May reflect steroid effect on blood-brain barrier, not necessarily change in tumor
  - PA: Solid portion enhances
    - ± solid, cystic with nodule, or rim enhancing; most often located dorsally with exophytic component
  - Metastatic disease is more common than initially reported
    - Especially late in disease or post bevacizumab therapy
- MRS
  - ↑ Cho:NAA ratio is associated with shorter survival
  - Lactate implies necrosis & poor prognosis in some studies

Nuclear Medicine Findings

- PET/CT: FDG uptake in ≥ 50% of tumor → shorter survival
  - Hypermetabolic tumors are likely to be higher grade

Imaging Recommendations

- Best imaging tool
  - MR with contrast

- Protocol advice
  - DTI, PWI, & MRS may have prognostic significance in DIPG & can help distinguish high- vs. low-grade tumors

DIFFERENTIAL DIAGNOSIS

Acute Disseminated Encephalomyelitis/Other Autoimmune Inflammation

- Supratentorial & spinal sites are often affected as well
- Delayed onset after viral prodrome or vaccination

Brainstem Abscess

- *Listeria monocytogenes* is often implicated
  - Viral agents: West Nile virus, adenovirus, EBV, HSV
- More acute clinical course; often febrile

Neurofibromatosis Type 1

- Asymptomatic, poorly defined, T2-hyperintense foci in brainstem, cerebellum, globus pallidus
  - Develop in early childhood, diminish with age
- Cerebellar WM involvement is more common than pons
  - Look for additional findings of NF1

Osmotic Demyelination Syndrome

- Central pontine T2 hyperintensity with sparing of periphery
- Classic clinical setting: Rapid correction of hyponatremia

Cavernous Malformation

- Low-flow vascular malformation with locules containing fluid-fluid levels
- SWI/T2* GRE hypointensity is classic
- Often associated with DVA

PATHOLOGY

General Features

- Genetics
  - DIPG/DMG: H3 K27M mutants carry worse prognosis, regardless of histologic grade
- Associated abnormalities
  - Better prognosis of BST if associated with NF1
    - Medulla is most common site in NF1

Staging, Grading, & Classification

- DMG: Astrocytomas of varying grade (WHO grades 2-4)
  - Biopsy of presumed DIPG is becoming more common
    - Molecular subtyping allows improved prognostication & potential targeted therapy
- PA, ganglioglioma, embryonal tumors
  - If suspected based on imaging, recommend biopsy

Gross Pathologic & Surgical Features

- Pontine swelling in DIPG/DMG
  - Diffuse tumor infiltration; craniocaudal extension along fiber tracts

Microscopic Features

- Variable cellularity & mitoses with pleomorphism & nuclear atypia, necrosis, & endothelial proliferation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Cranial nerve palsies with long tract signs
  - Hemiparesis, ataxia, gait disturbance
  - Headache, nausea, vomiting

Demographics

- Age
  - Peak incidence ~ 3-10 years of age
- Epidemiology
  - ~ 10-15% of pediatric brain tumors
  - 20-30% of pediatric posterior fossa tumors

Natural History & Prognosis

- DIPG/DMG: Very poor prognosis
  - CSF dissemination in 50% prior to death
  - Median survival ~ 1 year
  - 20% survival at 2 years
  - Worse prognosis: Enhancement, necrosis, low ADC, dissemination
- PA (dorsally exophytic): Fair to good prognosis, especially in setting of NF1
- Tectal plate gliomas: Good prognosis

Treatment

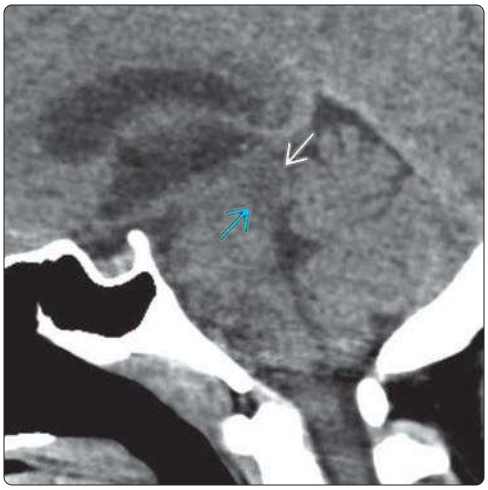
- DIPG/DMG: Radiation therapy if > 3 years old
  - Chemotherapy, though not particularly effective
- PA: Consider surgical resection based upon location
- Tectal plate glioma: Often only requires 3rd ventriculostomy followed by observation

DIAGNOSTIC CHECKLIST

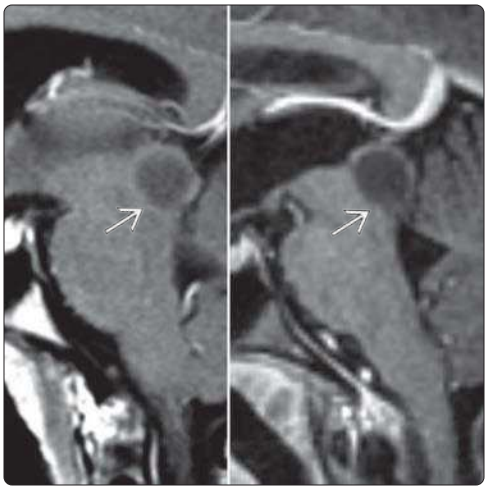
Consider

- Rapid onset of symptoms: Abscess
- Blood products: Cavernous malformation (look for associated DVA)
- Lesions in other locations: Infection or demyelination
- Atypical appearance → consider biopsy

Image Interpretation Pearls



- Sagittal T2/FLAIR is helpful to show extent of lesion
- Hydrocephalus is usually late finding



Reporting Tips

- Pontine tumor signal extending to cerebellum, midbrain, or medulla suggests higher grade
- Solid exophytic enhancement is most common in PA; may suggest better prognosis

(Left) *Midline sagittal NECT in a 16-year-old girl involved in a motor vehicle accident shows a low-attenuation, expansile mass centered in the tectum with obliteration of the cerebral aqueduct.* **(Right)** *Midline sagittal T1 C+ MR in the same patient at diagnosis (left) & 16 months later (right) shows a nonenhancing, expansile mass centered in the tectum. The lack of enhancement & lack of interval growth (or very slow growth over time) is typical for a tectal plate glioma.*

(Left) *Axial T2 MR in an 11-year-old patient with a heterogeneously hyperintense mass at the inferior 4th ventricle shows an indistinct border of the mass with the medulla, but a distinct border with the cerebellum, suggesting an exophytic origin from the dorsal medulla.* **(Right)** *Sagittal T1 C+ MR in the same patient shows homogeneous enhancement of the mass arising from the dorsal medulla, a typical pattern of enhancement for a pilocytic astrocytoma (confirmed histologically).*

(Left) *Sagittal T1 MR in a 3-year-old patient with poor tracking shows a well-defined, hypointense mass centered in the pons. Note the sharp margins of the mass, atypical for DIPG/DMG.* **(Right)** *Axial DWI MR in the same patient shows diffusely ↑ signal (↓ ADC not shown), consistent with a highly cellular tumor. Pathology showed an embryonal tumor with multilayered rosettes (ETMR). While uncommon in the brainstem, embryonal tumors should be considered in any highly cellular focal brainstem tumor.*

DNET

KEY FACTS

TERMINOLOGY

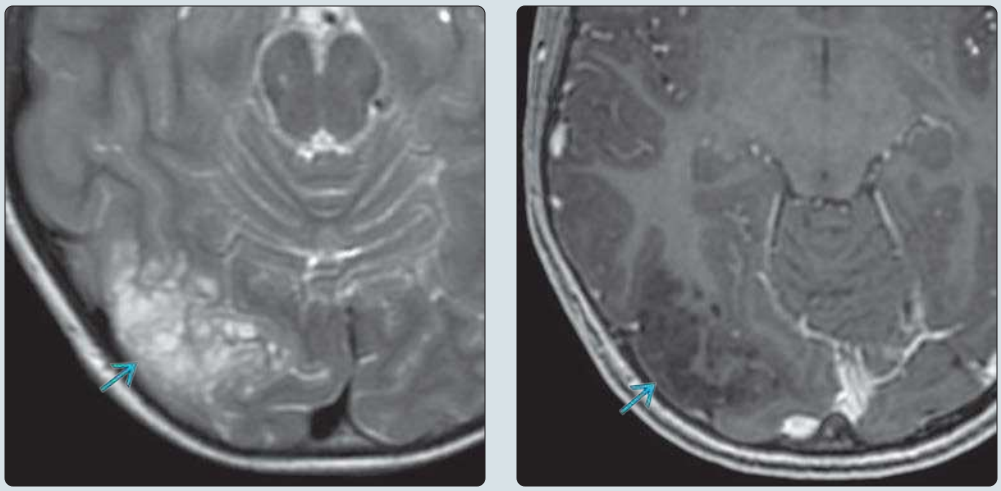
- Dysembryoplastic neuroepithelial tumor (DNET)
  - Benign mixed glial-neuronal neoplasm
  - Adjacent cortical dysplasia is frequently present

IMAGING

- May occur in any region of supratentorial cortex
  - Medial temporal lobe is most common
- Typically sharply demarcated, often wedge-shaped
  - Often cystic ("bubbly")
  - Minimal or no mass effect
  - No peritumoral edema
- Some DNETs have less distinct margins
  - Associated cortical dysplasia is more likely in these cases
- Faint focal punctate or ring enhancement in 20-30%
- Ca^{2+} in 6-36%
- Slow or no growth over years
- Remodel overlying bone in 20-44%

TOP DIFFERENTIAL DIAGNOSES

- Ganglioglioma
- Focal cortical dysplasia
- Neuroepithelial cyst
- Pleomorphic xanthoastrocytoma
- Angiocentric glioma



PATHOLOGY

- WHO grade 1
- Pathologic hallmark: Specific glioneuronal element
- Histologic subtypes: Simple, complex, & nonspecific
  - Complex: Associated cortical dysplasia is present

CLINICAL ISSUES

- Typical history: Child or young adult with seizures
- Gross total resection (including adjacent dysplasia) is usually curative & is most important factor for seizure freedom
- Histology usually remains benign even with enhancing tumor recurrence

(Left) *Axial T2 MR in a 12-year-old patient with seizure shows a bubbly, microcystic lesion in right occipital lobe with no significant mass effect. This bubbly replacement of normal brain parenchyma is the most specific appearance for dysembryoplastic neuroepithelial tumor (DNET).* **(Right)** *Axial T1 C+ MR in the same patient shows hypointensity & no associated enhancement within the lesion. The vast majority of DNETs do not enhance, particularly those with the microcystic bubbly appearance.*

(Left) *Axial FLAIR MR in a 10-year-old patient with seizures shows a unilocular lesion with central hypointensity & a hyperintense rim, recently described as the T2-FLAIR mismatch sign. Even in multicystic lesions, the central portions often suppress on FLAIR, while the margins are typically hyperintense.* **(Right)** *Axial T2 MR in a 14-year-old patient with epilepsy shows the less common solid-appearing cortical DNET with homogenous hyperintensity. T1 C+ MR (not shown) demonstrated no enhancement.*

Ganglioglioma

KEY FACTS

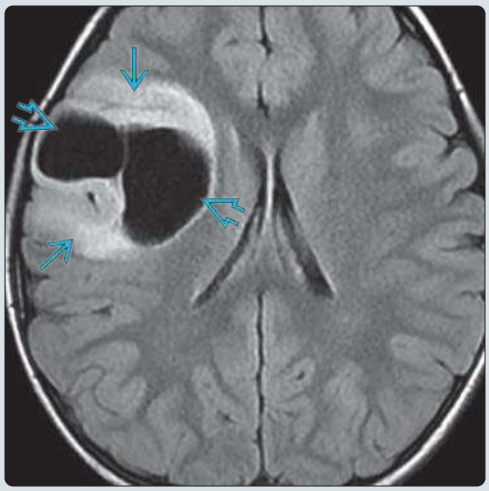
TERMINOLOGY

- Well-differentiated, slowly growing neuroepithelial tumor composed of neoplastic ganglion & glial cells

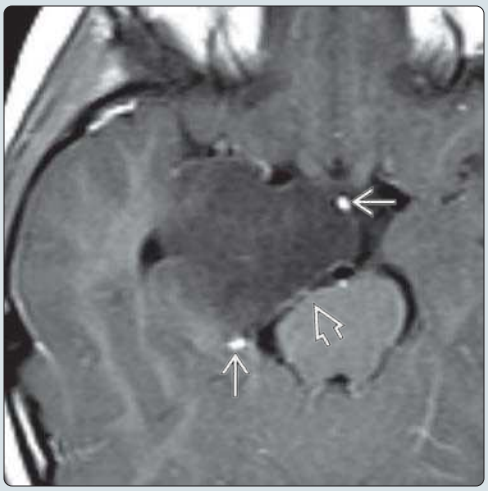
IMAGING

- Best imaging clue: Partially cystic, partially enhancing, cortically based mass in child/young adult with temporal lobe epilepsy
- Supratentorial: 85-90%; infratentorial: 10-15%
- Most commonly involves cerebral cortex, especially temporal lobe (~ 50%)
- Ca^{2+} in up to 50%
- Enhancement in ~ 50%
- Superficial lesions may remodel overlying calvarium
- Ill-defined, adjacent, cortical signal abnormality suggests associated focal cortical dysplasia (FCD)

TOP DIFFERENTIAL DIAGNOSES



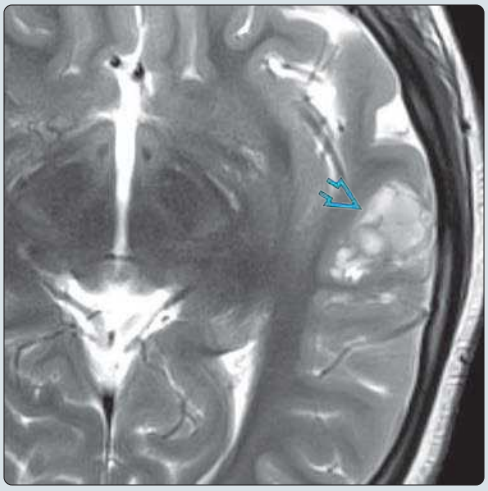
- Dysembryoplastic neuroepithelial tumor (DNET)
- FCD
- Pleomorphic xanthoastrocytoma
- Pilocytic astrocytoma
- Diffuse astrocytoma (grade 2)
- Oligodendroglioma



PATHOLOGY

- WHO grade 1 (80%) or 2
- Uncommon: Anaplastic ganglioglioma (WHO grade 3)
- Rare: Malignant with glioblastoma multiforme-like glial component (WHO grade 4)

CLINICAL ISSUES



- Occurs at all ages; peak: 10-20 years
- 1-4% of all pediatric CNS neoplasms
- Most common glioneuronal tumor
- Most common neoplastic cause of temporal lobe epilepsy
- Excellent prognosis with complete resection
- Seizure freedom is improved by early surgical intervention

(Left) *Axial FLAIR MR in a 6-year-old with a ganglioglioma (GG) shows a mixed solid & cystic lesion involving the frontal cortex with extension to the underlying white matter. Approximately 25-50% of GGs will have a cystic component.* **(Right)** *Axial T1 C+ MR in a 5-year-old boy with episodes of eyelid fluttering & left arm dystonia shows a nonenhancing expansile mass in the right mesial temporal lobe. There is mass effect upon the adjacent vessels & brainstem. Approximately 50% of GGs will demonstrate no enhancement.*

(Left) *Axial NECT in a 14-year-old patient with seizures shows a partially calcified GG in the left temporal lobe. Ca^{2+} is common in GG, seen in ~ 50% of tumors.* **(Right)** *Axial T2 MR in the same patient with a GG shows a cortically based, hyperintense lesion in the left temporal lobe, which is the most common location for GG. The lesion shows relatively little mass effect, another common finding. The associated Ca^{2+} & enhancement (not shown) in this lesion are strongly suggestive of GG.*

Desmoplastic Infantile Tumors

KEY FACTS

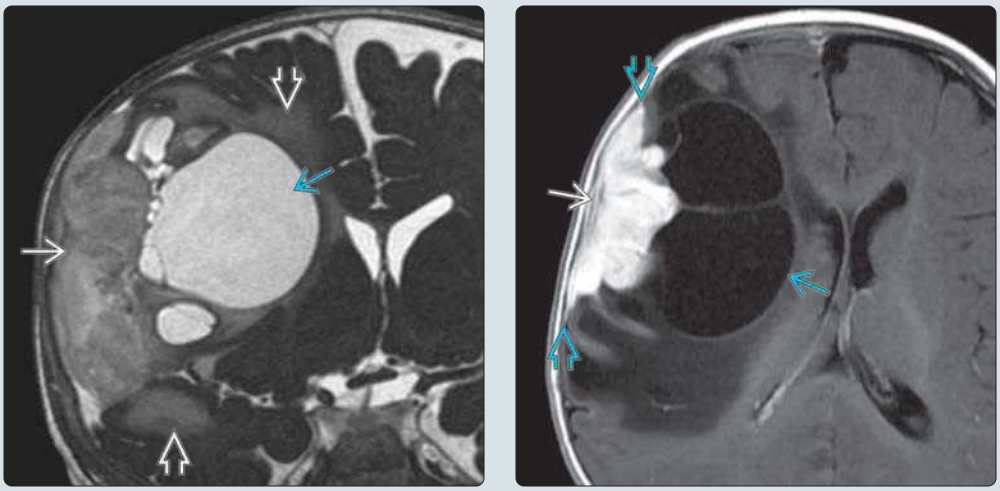
TERMINOLOGY

- Large, cystic tumors of infants involving superficial cerebral cortex & leptomeninges
- Desmoplastic infantile ganglioglioma (DIG)
  - Prominent desmoplastic stroma + neoplastic astrocytes & variable neuronal component
- Desmoplastic infantile astrocytoma (DIA)
  - Desmoplastic stroma + neoplastic astrocytes

IMAGING

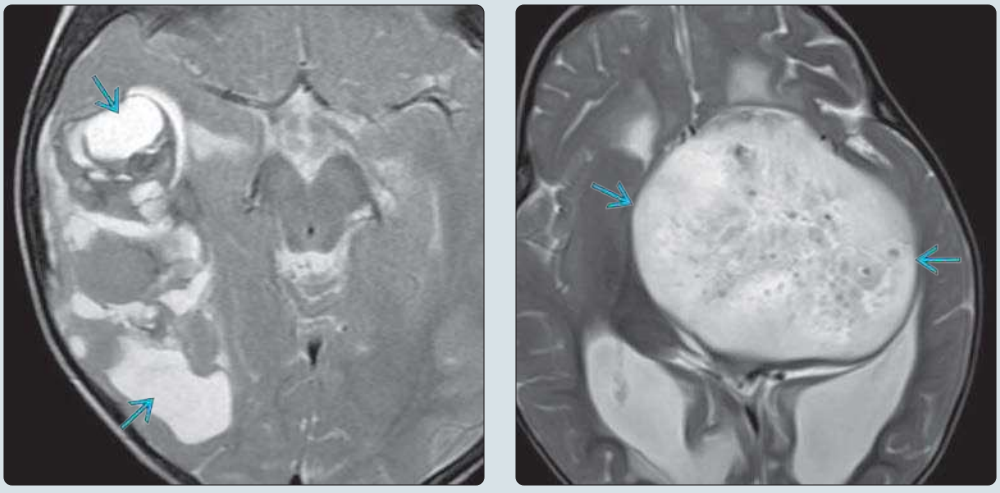
- Peripheral, supratentorial tumor with large cyst(s) & cortically-based, solid nodule/plaque in child < 2 years of age
- Variable T2 signal of solid component, often markedly ↓
  - Peritumoral edema may be vasogenic or interstitial from obstructive hydrocephalus
- May have diffusion restriction despite low histologic grade
- Peripheral, solid component often avidly enhances
- Broad dural base + enhancement of adjacent meninges
- Hemorrhage & Ca^{2+} are uncommon

TOP DIFFERENTIAL DIAGNOSES



- Embryonal tumor with multilayered rosettes (ETMR)
- Infantile glioblastoma
- Atypical teratoid/rhabdoid tumor
- Supratentorial ependymoma
- Pleomorphic xanthoastrocytoma
- Pilocytic astrocytoma

PATHOLOGY



- WHO grade 1; areas of cellular proliferation, mitoses, & necrosis may cause misdiagnosis as higher grade tumor

CLINICAL ISSUES

- Most are found at 1-24 months of age (peak: 3-6 months)
- 16% of intracranial tumors in 1st year of life
- Median survival rate > 75% at 15 years
- Complete surgical resection is typically curative
  - 40% require additional therapy beyond surgery

(Left) *Coronal 3D SSFP MR in a 5-month-old girl with increasing head circumference shows a large mass with a peripheral, hyperintense, solid component & more central cystic component. Note also the peritumoral edema.* **(Right)** *Axial T1 C+ MR in the same patient shows homogeneous enhancement of the peripheral solid component & no significant enhancement along the margins of the central cystic component. Note the broad-based dural attachment of this desmoplastic infantile ganglioglioma (DIG).*

(Left) *Axial T2 MR in a 20-month-old with DIG shows a heterogeneous right temporal lobe mass with multiple cystic components. The 2 most common appearances of DIG/DIA include a single large cyst with a solid, peripheral, enhancing component or a mixed solid & cystic mass with multiple prominent cysts.* **(Right)** *Axial T2 MR in a 1-year-old with a DIG shows a solid mass centered in the left thalamus with associated obstructive hydrocephalus. A solid lesion is the least common appearance of DIG/DIA.*

Embryonal Tumor With Multilayered Rosettes

KEY FACTS

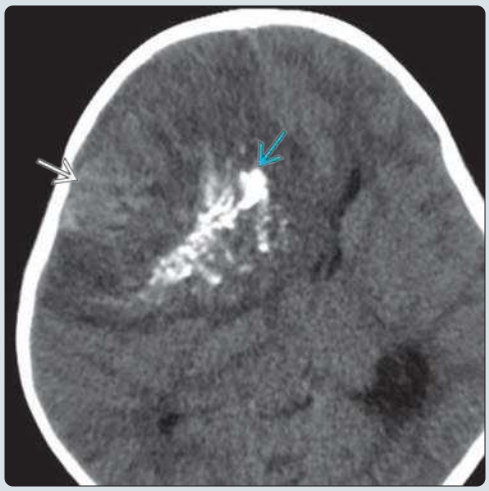
TERMINOLOGY

- Embryonal tumor with multilayered rosettes (ETMR)
- Includes former histologic diagnoses: Ependymal tumor with abundant neuropil & true rosettes (ETANTR) & ependymoblastoma
- Now molecularly & genetically distinct entities considered under embryonal tumors (all WHO grade 4) include
  - ETMR, C19MC altered
  - CNS embryonal tumor, not otherwise specified (NOS)
    - Medulloepithelioma
    - CNS neuroblastoma
  - Medulloblastoma
  - Atypical teratoid/rhabdoid tumor

IMAGING

- Large (mean: 5 cm), complex-appearing, hemispheric mass in infant/young child
- ~ 50% are well defined with minimal peritumoral edema
- Ca^{2+} in 50-70%; hemorrhage is common
- Variable enhancement
- Restricted diffusion of solid highly cellular components
- Subarachnoid spread is common at presentation

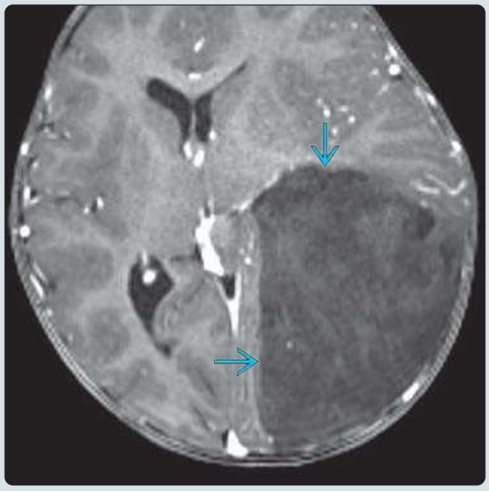
TOP DIFFERENTIAL DIAGNOSES



- Glioblastoma
- Supratentorial ependymoma
- Atypical teratoid/rhabdoid tumor
- Desmoplastic infantile ganglioglioma/astrocytoma
- Choroid plexus carcinoma
- Giant cavernoma

PATHOLOGY

- Defined by genetic alteration at 19q13.42 (*C19MC* amplification), regardless of histology



CLINICAL ISSUES

- Most common in younger children
- Treatment: Aggressive surgical resection, chemotherapy, craniospinal radiation (if of tolerable age)

(Left) *Axial NECT in a 2-year-old child with altered mental status shows a large, heterogeneous, intraaxial mass. Areas of ↑ attenuation ➡ correspond to cellular or hemorrhagic areas foci. Calcification ⇨ is present in ~ 50% of embryonal tumor with multilayered rosettes (ETMR).* **(Right)** *Axial DWI MR in the same patient shows restricted diffusion ⇨ in the solid portions of the mass, consistent with high cellularity. ETMR should be considered in any cellular hemispheric tumor, especially in young children.*

(Left) *Axial T1 C+ FS MR in a 1-year-old shows a well-demarcated tumor ⇨ in the left parietooccipital region with no significant enhancement. The enhancement of ETMR is highly variable, ranging from avid to no enhancement. Note the lack of peritumoral edema, typical of ETMR.* **(Right)** *Axial DWI MR in the same patient shows marked diffusion restriction ⇨ (↓ ADC not shown), consistent with a highly cellular tumor. Pathology revealed an ETMR, C19MC altered.*

Craniopharyngioma

KEY FACTS

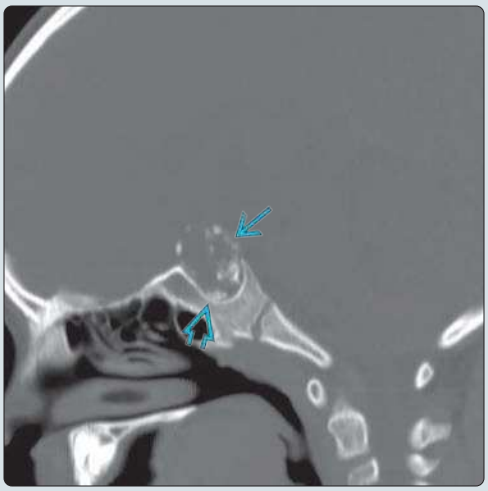
IMAGING

- Best clue: Complex suprasellar cystic mass with Ca^{2+} & wall enhancement
- Location: Suprasellar 75%, suprasellar + intrasellar 21%
  - Larger tumors can extend into multiple cranial fossae
- "90% rule"
  - 90% cystic: MR signal intensity is highly variable
    - Cystic components are frequently T1 hyperintense
  - 90% calcified: SWI/T2* GRE MR are helpful to identify Ca^{2+}
  - 90% enhance (wall & solid portions)
- Often develop obstructive hydrocephalus
- Optic chiasm, hypothalamus, & vessels are often involved
  - Thin sagittal T2 or 3D SSFP MR sequences to assess

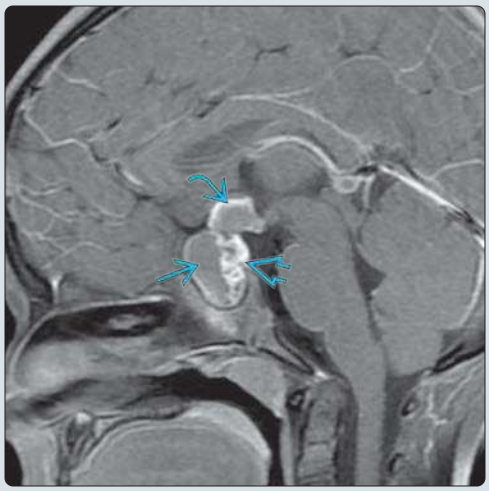
TOP DIFFERENTIAL DIAGNOSES

- Rathke cleft cyst
- Pituitary adenoma
- Germinoma
- Hypothalamic-chiasmatic glioma

PATHOLOGY

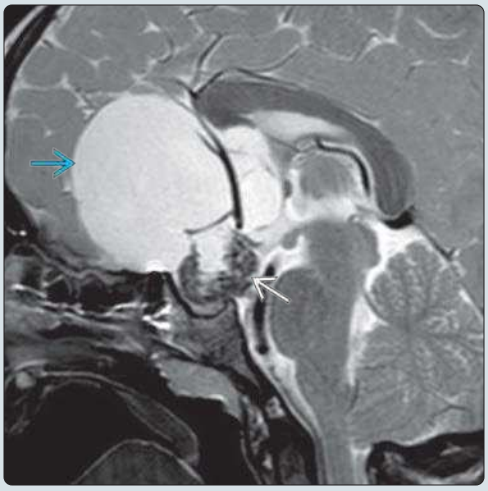


- 2 clinically & pathologically distinct subtypes
  - Adamantinomatous: Cystic & solid, mostly in children
  - Squamous-papillary: Mostly solid tumor found in adults

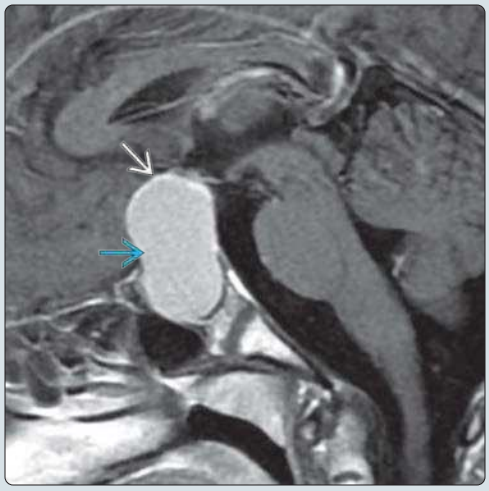


CLINICAL ISSUES

- 6-9% of all pediatric intracranial tumors
- Symptoms: Visual changes, endocrine related, academic decline, headache/vomiting (obstructive hydrocephalus)
  - ~ 1/3 of patients have endocrine symptoms (↓ growth hormone, ↓ thyroid function, diabetes insipidus)
- Benign tumor with high rate of recurrence
- Poor prognostic factors: Hypothalamic involvement, ↑ tumor size



DIAGNOSTIC CHECKLIST



- Must identify relationship of tumor to optic chiasm, hypothalamus, & vessels

(Left) *Sagittal NECT in a 7-year-old patient with diabetes insipidus shows smooth remodeling of the sella turcica ⇨ by a partially calcified mass ⇨, highly suggestive of craniopharyngioma.* **(Right)** *Sagittal T1 C+ MR in the same patient shows a nonenhancing cystic component ⇨ & a nodular enhancing component ⇨. A rim-enhancing lobular component ⇨ protrudes superiorly. This case represents a typical craniopharyngioma with Ca^{2+}, cysts, & solid, enhancing tissue.*

(Left) *Sagittal T2 MR in a 3-year-old patient shows hypointense signal in the posterior components ⇨ of a suprasellar mass, corresponding to Ca^{2+}. Frontal extension of the large cystic components ⇨ is typical of a prechiasmatic location.* **(Right)** *Sagittal T1 C+ MR in a 10-year-old boy with increasing headaches shows a predominantly cystic mass with a very thin rim of enhancement ⇨. The majority of the mass showed intrinsic T1 shortening ⇨ before contrast, a common finding in craniopharyngioma.*

TERMINOLOGY

Definitions

- Craniopharyngioma (CP): Histologically benign epithelial tumor arising from squamous rests along involuted hypophyseal-Rathke duct

IMAGING

General Features

- Best diagnostic clue
  - Cystic suprasellar mass with Ca^{2+} & enhancing wall or mural nodule
- Location
  - Suprasellar: 75%; mixed suprasellar + intrasellar: 21%; intrasellar: 4%
  - Retrochiasmatic vs. prechiasmatic configuration is key determinant for surgical approach
  - Larger tumors can extend into multiple cranial fossae
- Often large at presentation (> 5 cm)
  - Cyst is typically largest component

CT Findings

- "90% rule": 90% cystic, 90% calcified, 90% enhance (wall & solid portions)
- May present with obstructive hydrocephalus from compression on 3rd ventricle & foramen of Monro

MR Findings

- T1: Cysts are often very hyperintense, reflecting protein, cholesterol, &/or blood products in fluid
- T2: Heterogeneous, solid tumor: Hypointense foci of Ca^{2+}, variable signal intensity of cysts
- FLAIR: Cysts typically do not suppress like CSF
- SWI/T2* GRE: Areas of signal loss correspond to Ca^{2+}
- DWI: Variable cystic signal, typically closer to CSF than brain
- T1 C+: Solid portions enhance heterogeneously; cyst wall may show smooth or irregular enhancement

Imaging Recommendations

- Protocol advice
  - Volumetric T1 ± contrast; SWI/GRE for Ca^{2+}
  - Thin 3D sagittal T2 or SSFP sequences help define relationship of tumor to adjacent structures
  - MRA for preoperative identification of arterial involvement

DIFFERENTIAL DIAGNOSIS

Rathke Cleft Cyst

- Ca^{2+} uncommon; no nodular/solid component
- Cyst is more homogeneous, although small, T2-hypointense, intracystic nodules may be present

Germinoma

- Predominantly solid & lobular
- Ca^{2+} is very rare in suprasellar germinoma
- Strong association with diabetes insipidus

Pituitary Adenoma

- Solid tumor arising from adenohypophysis
- Diffuse & homogeneous enhancement

Hypothalamic-Chiasmatic Glioma

- More solid & homogeneous
- Extension into prechiasmatic optic nerves/tracts

Arachnoid Cyst

- Thin/imperceptible nonenhancing wall
- Cyst contents follow CSF

Dermoid & Epidermoid Cysts

- Epidermoids are solid but mimic cysts
- Suprasellar locations rare in children
- Minimal enhancement; marked diffusion restriction

PATHOLOGY

General Features

- 2 clinically & pathologically distinct subtypes
  - Adamantinomatous (~ 90%): Classic calcified cyst with mural nodule, seen in children
  - Papillary (~ 10%): Mostly solid tumor almost exclusively found in adults
  - Adamantinomatous & papillary: WHO grade 1
- Genetics
  - Targetable mutations present in subset of tumors
    - *BRAF* (V600E) in many papillary CPs
    - *CTNNB1* in many adamantinomatous CPs

CLINICAL ISSUES

Presentation

- Headache, vomiting, hydrocephalus, papilledema
- Visual disturbance, decline in school performance
- Endocrine symptoms in at least 1/3 of cases due to mass effect on pituitary/hypothalamus
  - Growth hormone deficiency, hypothyroidism, diabetes insipidus

Demographics

- Epidemiology
  - Most common nonglial pediatric intracranial tumor
    - > 50% of all pediatric suprasellar region tumors

Natural History & Prognosis

- 88% overall survival at 20 years
- Hypothalamic involvement: ↓ overall survival, quality of life
- Factors affecting recurrence
  - Gross total vs. partial resection
  - Radiation therapy (for residual tumor) ↓ recurrence
  - Tumor size (↑ recurrence in larger tumors)

Treatment

- Surgical: Complete resection is ideal but must be weighed against high morbidity associated with extensive resection in suprasellar/hypothalamic region
- Radiation therapy for incomplete resection

Germinoma, Brain

KEY FACTS

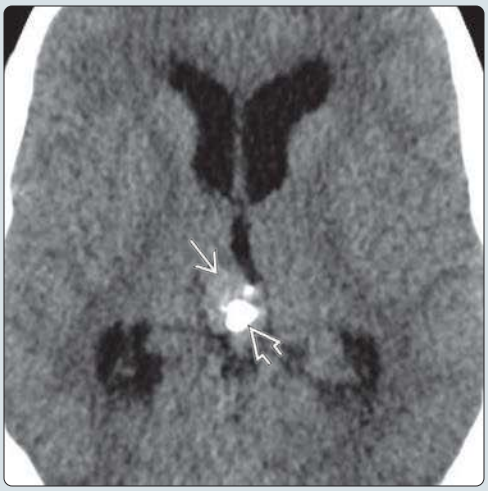
TERMINOLOGY

- Tumor of primordial germ cells, histologically identical to gonadal & nongonadal seminoma or dysgerminoma

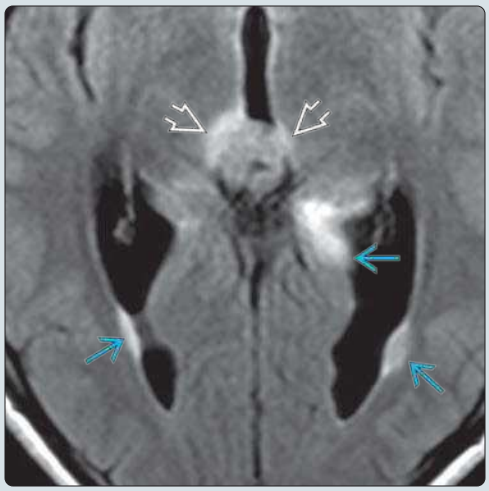
IMAGING

- CT: Hyperattenuating, solid components
  - Pineal region: Localized "engulfed" Ca^{2+}
  - Other sites: Ca^{2+} rare, but hemorrhage may occur
- MR: Mass in suprasellar, pineal, or basal ganglia regions
  - T2: Multiple small cysts are not unusual (~ 25%)
  - DWI: Diffusion restriction in solid components
  - T1 C+: Avid enhancement, often "speckled"
  - Pineal: Bithalamic extension, peritumoral edema
  - Suprasellar: Absent T1 posterior pituitary bright spot
  - Metastatic CSF dissemination is common (25-40%)

TOP DIFFERENTIAL DIAGNOSES

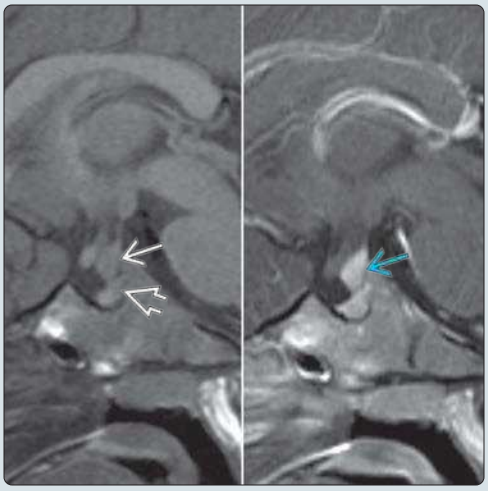


- Pineal region
  - Pineoblastoma
  - Nongerminomatous germ cell tumors (teratoma, etc.)
  - Tectal plate glioma
- Suprasellar
  - Craniopharyngioma
  - Hypothalamic/chiasmatic astrocytoma
  - Langerhans cell histiocytosis

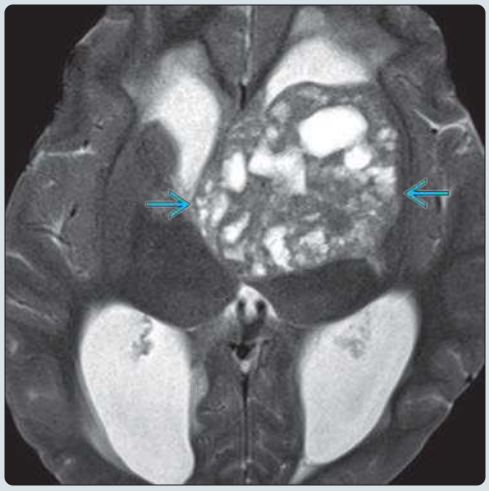


CLINICAL ISSUES

- M > F, especially in pineal region
- Mean age: 10-15 years
- Pineal: Headache, paralysis of upward gaze
- Suprasellar: Diabetes insipidus (DI), vision changes
- ± ↑ serum & CSF human chorionic gonadotropin
- Favorable prognosis (5-year survival > 90%)



DIAGNOSTIC CHECKLIST



- Image entire neuraxis to detect CSF dissemination
- Occult germinoma is possible in child with DI & normal MR
  - Repeat MR in 3-6 months to assess for growing mass

(Left) *Axial NECT in a 14-year-old boy with worsening headaches shows a hyperattenuating mass with localized Ca^{2+}. Calcifications are common in pineal germinoma & are thought to represent pineal Ca^{2+} "engulfed" by tumor.* **(Right)** *Axial FLAIR MR in the same patient shows tumor extension into the right thalamus, parenchymal edema in the thalami (R > L), & CSF spread of tumor. Peritumoral edema & thalamic extension are common findings in pineal germinoma, as is CSF spread of tumor.*

(Left) *Sagittal T1 C+ MR (left) in a 4-year-old boy with central diabetes insipidus (DI) shows an infundibular mass & absence of the posterior pituitary bright spot. After contrast (right), the infundibular mass enhances homogeneously, typical of germinoma.* **(Right)** *Axial T2 MR in a 10-year-old girl with fatigue, headaches, & vomiting shows a large solid, cystic mass centered in the left basal ganglia. The basal ganglia are a less common (~ 15%) location for germinoma (though these tumors are often large).*

TERMINOLOGY

Definitions

- Tumor of primordial germ cells, essentially identical to gonadal or extragonadal seminoma & dysgerminoma

IMAGING

General Features

- Best diagnostic clue
  - Pineal mass with localized Ca^{2+} & bithalamic extension
  - Suprasellar mass with diabetes insipidus (DI)
- Location
  - CNS germinomas typically occur in midline near 3rd ventricle
    - Pineal region (40-50%)
    - Suprasellar (30-40%)
    - Basal ganglia (BG) tumors are less common (5-15%)
  - CSF spread of metastases is common (25-40%)
- Size
  - Typically small (1-3 cm)
  - Tiny or inapparent suprasellar germinoma may cause DI

CT Findings

- Sharply circumscribed, heterogeneously hyperdense mass
- Localized ("engulfed") Ca^{2+} is common in pineal tumors
- Ca^{2+} is rare in suprasellar tumors
- Primary tumors & metastases usually enhance avidly

MR Findings

- T1: Isointense to hypointense
- T2: Hyperintense cystic components
- FLAIR: Sensitive for peritumoral edema
- DWI: Solid components typically show diffusion restriction
- GRE/SWI: Hypointense signal may represent Ca^{2+} (pineal) or hemorrhage (suprasellar & BG)
- T1 C+: Most tumors show marked enhancement
  - Speckled pattern in tumors with small cysts
  - Most sensitive sequence for CSF metastases

DIFFERENTIAL DIAGNOSIS

Pineal Region Masses

- Pineoblastoma
  - Highly cellular pineal mass in young child
  - Scattered ("exploded") Ca^{2+} rather than localized ("engulfed") Ca^{2+} in germinoma
  - Less common than germinoma & typically younger age
- Tectal plate glioma
  - Little or no enhancement
  - High ADC signal (no diffusion restriction)

Sellar/Suprasellar Masses

- Craniopharyngioma
  - Dominant cystic components ± T1 shortening, Ca^{2+}
  - DI is less common until after surgery
- Hypothalamic/chiasmatic astrocytoma
  - No diffusion restriction
  - Rarely associated with DI
- Langerhans cell histiocytosis (LCH)
  - Thickened infundibulum; look for osseus lesions

PATHOLOGY

General Features

- Etiology
  - Germ cell tumors (GCTs) are found in gonads, mediastinum, & intracranial (parasellar & pineal) locations
- Associated abnormalities
  - ± ↑ serum & CSF human chorionic gonadotropin

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Pineal region germinoma
    - Headache secondary to aqueduct obstruction & hydrocephalus
    - Parinaud syndrome (paralysis of upward gaze)
    - Precocious puberty
  - Suprasellar germinoma
    - DI
    - Hypothalamic-pituitary dysfunction (↓ growth, precocious puberty)
    - Visual symptoms

Demographics

- Age
  - Mean age in most studies: 10-15 years
- Sex
  - M > F, especially in pineal region

Natural History & Prognosis

- Pure germinoma has favorable prognosis
- Treatment with radiotherapy ± adjuvant chemotherapy
  - 5-year survival > 90%

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Child or adolescent with DI
  - Expect absence of posterior pituitary bright spot
  - Lobular enhancing suprasellar mass = germinoma
  - Thick, enhancing infundibulum = LCH or germinoma
  - No enhancing lesion = could be occult germinoma
- Adolescent with pineal mass = germinoma or nongerminomatous GCT (NGGCT)
- Child with pineal mass
  - Complex, cystic = also consider NGGCT
  - Homogeneous with restricted diffusion = germinoma vs. pineoblastoma

Choroid Plexus Tumors

KEY FACTS

TERMINOLOGY

- Choroid plexus tumor (CPT)
  - Choroid plexus papilloma (CPP): WHO grade 1
  - Atypical choroid plexus papilloma (aCPP): WHO grade 2
  - Choroid plexus carcinoma (CPCa): WHO grade 3

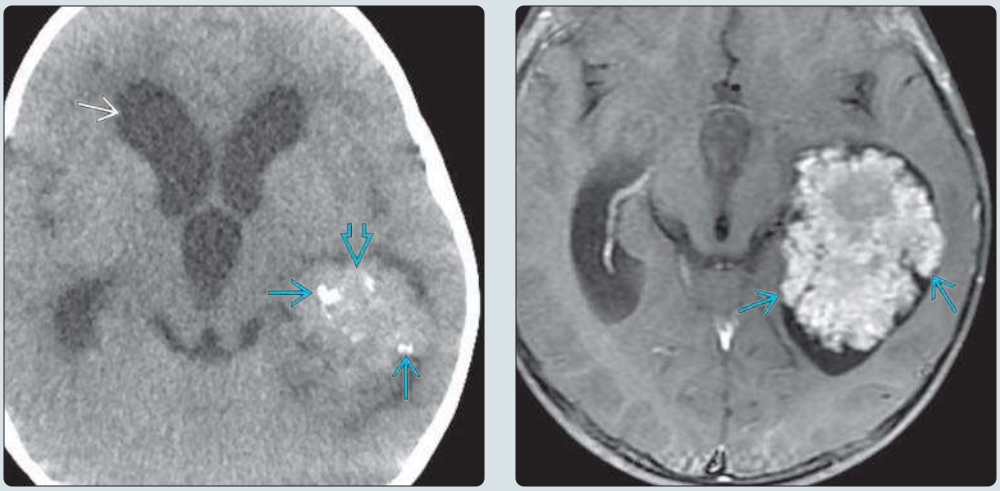
IMAGING

- Strongly enhancing, lobulated intraventricular mass
  - 60-70%: Lateral ventricles (most commonly atrium)
  - 20-30%: 4th ventricle (most common site in adults)
  - < 10%: 3rd ventricle, cerebellomedullary cistern
- Ventriculomegaly from obstruction or ↑ CSF production
- **CT**: Ca^{2+} in 25%
- **MR**: Iso- to hyperintense on T2; internal flow voids
- CPCa are more likely than CPP to show heterogeneous enhancement, necrosis, brain invasion, & CSF spread

TOP DIFFERENTIAL DIAGNOSES

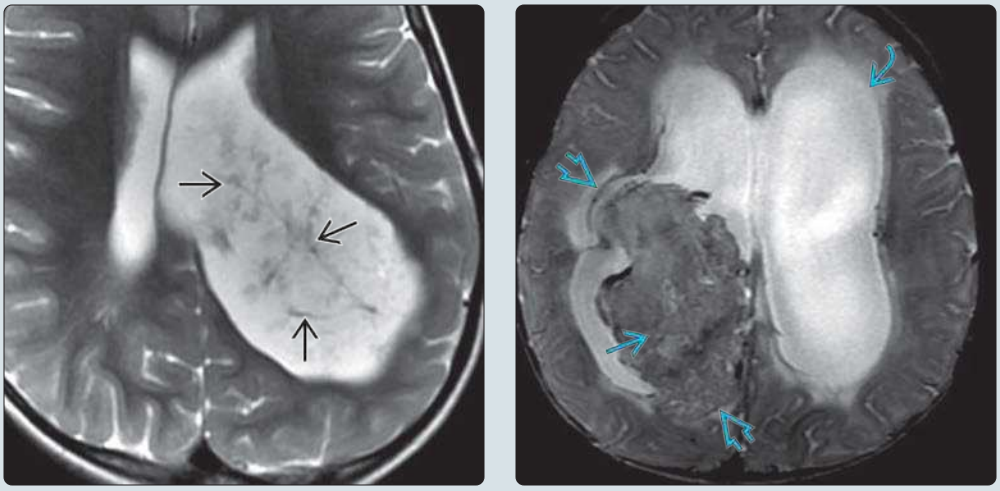
- Intraventricular hemorrhage
- Atypical teratoid/rhabdoid tumor
- Medulloblastoma
- Ependymoma

PATHOLOGY



- ↓ ADC & ↑ tumor volume → ↑ grade & poorer prognosis
- ↑ *TP53* mutations in tumor correlate with poor prognosis
- Molecular subtype may be more prognostic than histology
  - Cluster 1: Pediatric, supratentorial, good prognosis
  - Cluster 2: Adult, infratentorial, good prognosis
  - Cluster 3: Pediatric, supratentorial, poor prognosis
- Associated with Li-Fraumeni & Aicardi syndromes

CLINICAL ISSUES



- ~ 25-33% present < 1 year of age; ~ 49-75% present < 5 years of age

DIAGNOSTIC CHECKLIST

- T1 C+ MR of entire neuraxis before surgery
- Imaging is not reliable for distinguishing CPP from CPCa

(Left) *Axial NECT in a 22-month-old with macrocephaly shows a large mass centered in the atrium of the left lateral ventricle with scattered foci of Ca^{2+}. Note the lateral & 3rd ventricular enlargement without evidence of obstruction, consistent with hydrocephalus due to overproduction of CSF by this choroid plexus papilloma (CPP).* **(Right)** *Axial T1 C+ MR in the same patient shows avid enhancement of the mass & frond-like margins of the tumor. These features are very common in CPP.*

(Left) *Axial T2 MR in a 3-year-old girl shows predominantly hyperintense signal (equal to CSF) throughout a large mass that expands the lateral ventricle. A few branching, hypointense foci within the lesion represent high-flow vessels. CPP was proven upon resection.* **(Right)** *Axial T2 MR in a 9-month-old with macrocephaly shows a heterogeneous choroid plexus carcinoma (CPCa) centered in the right atrium with right frontal & parietal lobe invasion. Also note the hydrocephalus.*

TERMINOLOGY

Abbreviations

- Choroid plexus tumor (CPT)
  - Choroid plexus papilloma (CPP): WHO grade 1
  - Atypical choroid plexus papilloma (aCPP): WHO grade 2
  - Choroid plexus carcinoma (CPCa): WHO grade 3

Definitions

- Intraventricular, papillary neoplasm of CP epithelium

IMAGING

General Features

- Best diagnostic clue
  - Strongly enhancing, lobulated intraventricular mass
  - Associated hydrocephalus may be obstructive or related to overproduction of CSF by tumor
- Location
  - 60-70%: Lateral ventricle (most commonly atrium)
  - 20-30%: 4th ventricle (most common site of origin in adults)
  - < 10%: 3rd ventricle, cerebellomedullary cistern

CT Findings

- Iso- or hyperattenuating in 75%; Ca^{2+} in 25%

MR Findings

- **T1**: Well-delineated, iso- to hypointense mass
- **T2**: Iso- to hyperintense mass
  - Internal dark signal: Ca^{2+} (nodular or irregular) vs. vascular flow voids (linear & branching)
- **FLAIR**: ↑ generalized periventricular signal → transependymal edema due to ventricular obstruction
  - Brain invasion causing focally abnormal signal is more common in CPCa
- **SWI/T2* GRE**: ± foci of low signal → Ca^{2+} or hemorrhage
- **DWI**: Iso- to hyperintense on ADC
  - ↓ ADC correlates with higher grade tumors
- **T1 C+**: Robust enhancement; frond-like margins
  - Heterogeneity with necrosis suggests CPCa
  - CPCa often shows enhancing CSF dissemination
- **Perfusion**: Typically elevated CBF & CBV

Ultrasonographic Findings

- Hyperechoic mass with frond-like projections
- Echogenicity is similar to normal choroid plexus
- ↑ central vascularity on color Doppler

Imaging Recommendations

- Best imaging tool
  - MR with contrast of entire neuraxis prior to surgery
  - US may be obtained 1st in young infant with open fontanelle & macrocephaly

DIFFERENTIAL DIAGNOSIS

Intraventricular Hemorrhage

- Originates from germinal matrix in premature neonate
- Clot adherent to choroid can be echogenic & mass-like but lacks internal vascularity/enhancement

Atypical Teratoid/Rhabdoid Tumor

- May be intraventricular & lobulated
- Shows less enhancement, more diffusion restriction

Medulloblastoma

- Most common 4th ventricular neoplasm in children
- Shows less enhancement, more diffusion restriction

Ependymoma

- Ependymoma is typically intraaxial when supratentorial
- 4th ventricular ependymoma is similar to CPT

PATHOLOGY

General Features

- Genetics
  - 3 molecular subtypes by methylation pattern (which may be more predictive of prognosis than histology)
    - Cluster 1: Pediatric, supratentorial, good prognosis
      - CPP = aCPP histologically
    - Cluster 2: Adult, infratentorial, good prognosis
      - CPP > aCPP histologically
    - Cluster 3: Pediatric, supratentorial, poor prognosis
      - CPCa > aCPP > CPP histologically
  - Associated with Li-Fraumeni & Aicardi syndromes

CLINICAL ISSUES

Presentation

- Young child with signs & symptoms of ↑ intracranial pressure: Macrocrania, bulging fontanelle, vomiting, headache, ataxia, seizure

Demographics

- Age: CPP: 49% < 5 years, 26% < 1 year
  - CPCa: 75% < 5 years, 33% < 1 year

Natural History & Prognosis

- CPP is benign, slowly growing; 5-year survival ~ 100%
- CPCa is usually large & invasive; 5-year survival ~ 60%
- Either may seed CSF pathways

Treatment

- Gross total resection (GTR)

DIAGNOSTIC CHECKLIST

Consider

- Imaging alone is not reliable for distinguishing CPP vs. CPCa
  - ↓ ADC & ↑ tumor volume → higher grade & poorer prognosis
- 4th ventricular CPT is less common than other pediatric posterior fossa tumors

Birth Injury

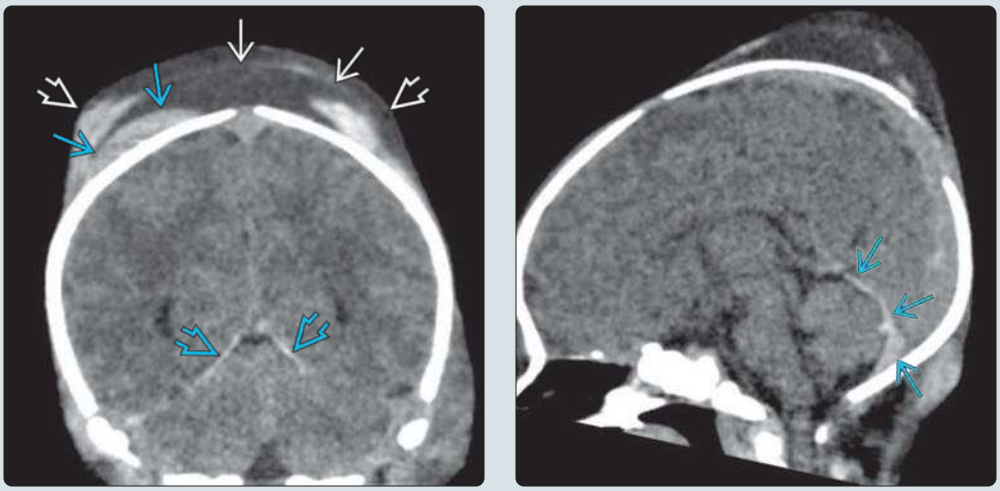
KEY FACTS

IMAGING

- Scalp hematomas
  - Caput succedaneum: In superficial soft tissues; crosses sutures & midline
  - Subgaleal hematoma: Deep to epicranial aponeurosis; crosses sutures & midline
  - Cephalohematoma: Subperiosteal; limited by sutures; ↓ & calcifies over time
- Calvarial fractures
  - Usually nondisplaced
  - Depressed fractures often have smooth margins ("ping pong fracture")
- Intracranial hemorrhages
  - Subdural hematomas are most common: Usually small (< 3-mm thickness) without associated mass effect
  - Epidural hematomas are rare & usually associated with skull fracture
- Hypoxic-ischemic injury: Considered separately

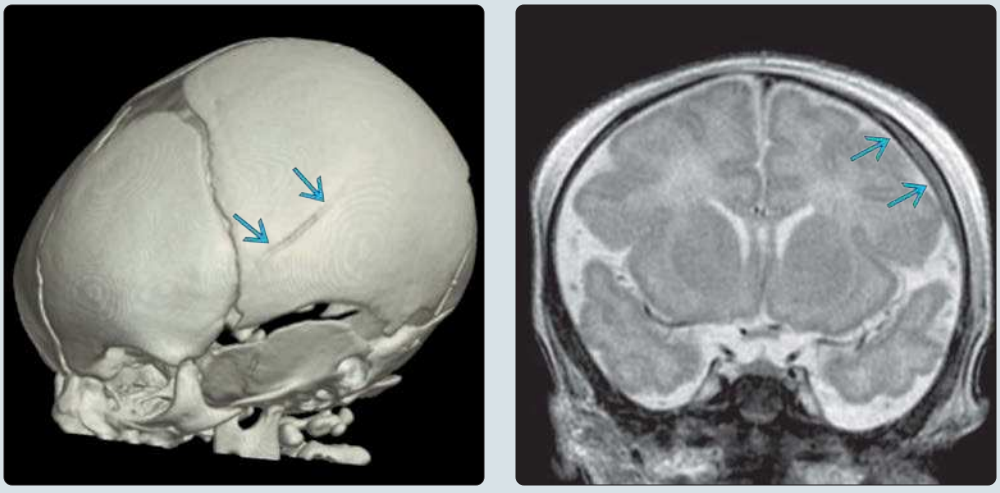
TOP DIFFERENTIAL DIAGNOSES

- Coagulopathy
- Abusive head trauma
- Accidental postnatal head injury
- Venous sinus thrombosis



CLINICAL ISSUES

- Subdural hematomas, typically small, are seen in 26-63% of uncomplicated vaginal deliveries
- Cephalohematomas occur in 1% of all births; ↑ incidence in forceps &/or vacuum assisted deliveries
- Usually of no clinical significance & managed conservatively
  - However, subgaleal hematoma may lead to significant blood loss & shock



DIAGNOSTIC CHECKLIST

- US or CT can exclude need for surgical intervention
- Parenchymal injury not typical; MR study of choice to evaluate for suspected hypoxic-ischemic injury

(Left) *Coronal NECT in a 1-day-old infant status post vaginal delivery with vacuum & forceps assist shows marked scalp swelling. There is subperiosteal cephalohematoma, subgaleal hematoma deep to the epicranial aponeurosis, & diffuse overlying caput succedaneum. Also note the small subdural hemorrhages along the tentorial leaflets.* **(Right)** *Sagittal NECT in the same patient demonstrates subdural hemorrhage along the tentorium & in the posterior fossa.*

(Left) *Left lateral view of a NECT 3D reformat in the same patient demonstrates an obliquely oriented nondisplaced fracture of the left parietal bone.* **(Right)** *Coronal T2 MR in the same patient shows a small, left-sided epidural hematoma in association with the skull fracture. No brain parenchymal abnormality was seen. This was managed conservatively given the small size & lack of mass effect.*

IMAGING

General Features

- Location
  - Scalp injury
    - Caput succedaneum: Hemorrhage & edema in subcutaneous tissues; extends across suture lines, crosses midline, & extends into facial soft tissues
    - Subgaleal hematoma: Deep to aponeurosis of scalp, beneath occipitofrontalis muscle
    - Cephalohematoma: Subperiosteal hematoma; confined by sutures
  - Calvarial fractures
    - Frontal & parietal bones are most common
    - Most are nondisplaced
    - Due to ↑ plasticity of infant skull, depressed fractures tend to be of concave morphology rather than angulated
      - a.k.a. "ping pong fracture"
  - Subdural hematoma
    - Usually posterior in location (dependent)

Imaging Recommendations

- Best imaging tool
  - Ultrasound vs. CT: Initial study to exclude large intracranial hemorrhages requiring surgical intervention
  - MR: Used to exclude hypoxic-ischemic injury (if there is clinical concern)
- Protocol advice
  - MR: SWI most sensitive for intraparenchymal hemorrhage; DWI most sensitive for acute infarct

DIFFERENTIAL DIAGNOSIS

Coagulopathy

- Such as neonatal alloimmune thrombocytopenia

Abusive Head Trauma

- Usually not considered if patient has not yet left hospital
- Look for atypical patterns of fracture & hemorrhage

Accidental Postnatal Head Trauma

- Appropriate history for degree of injury

Venous Sinus Thrombosis

- Common cause of newborn intraparenchymal hemorrhage

PATHOLOGY

General Features

- Subdural hematoma
  - Typically < 3 mm in thickness
  - Supratentorial: Caused by lacerations of falx or subdural veins (near falcotentorial junction) from molding of head
  - Posterior fossa: Caused by tentorial lacerations or occipital osteodiastasis (at posterior occipital or supraoccipital-exoccipital synchondrosis)
- Subarachnoid hemorrhage
  - Germinal matrix origin in preterm neonate; usually associated with subdural hematoma in term neonate
- Epidural hematoma
  - Usually associated with cephalohematoma & fracture
- Intraventricular hemorrhage common in premature neonates but presumed to be germinal matrix in origin
- Intraparenchymal hemorrhage
  - Thought to be related to venous obstruction or injury, though may be contusional
  - Parenchymal brain injury not typical of birth trauma, though small parenchymal hemorrhages can be seen

CLINICAL ISSUES

Demographics

- Epidemiology
  - Subdural hematomas are seen in 26-63% of uncomplicated vaginal deliveries
  - Cephalohematomas occur in 1% of all births; ↑ incidence with forceps &/or vacuum-assisted deliveries
  - Epidural hematomas are rare

Natural History & Prognosis

- Scalp hematomas
  - Caput succedaneum: Steadily ↓ 1-2 days after birth
  - Subgaleal hematoma: ↑ in size after birth; resolves over 2-3 weeks
    - May lead to significant blood loss & shock
  - Cephalohematoma: Eventually calcifies, resolving over weeks to months
- Intracranial hemorrhage
  - Subdural hematoma: Most resolve by 1 month; nearly all resolve by 3 months
  - Subarachnoid hemorrhage: Usually of no clinical significance unless large (possibly leading to communicating hydrocephalus)

Treatment

- Depressed skull fractures can be treated neurosurgically, though vacuum/breastpump reduction & spontaneous resolution have been described

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- On CT, dural venous sinuses are diffusely hyperdense in normal neonates, which can be confused for dural venous sinus thrombosis or subdural hemorrhage

Reporting Tips

- Important to communicate significance of findings
  - Small subdural hematomas & trace amounts of subarachnoid hemorrhage are not unexpected in neonates & are of no clinical significance
  - Scalp hematomas are not unexpected in neonatal period & typically do not need to be imaged

Abusive Head Trauma

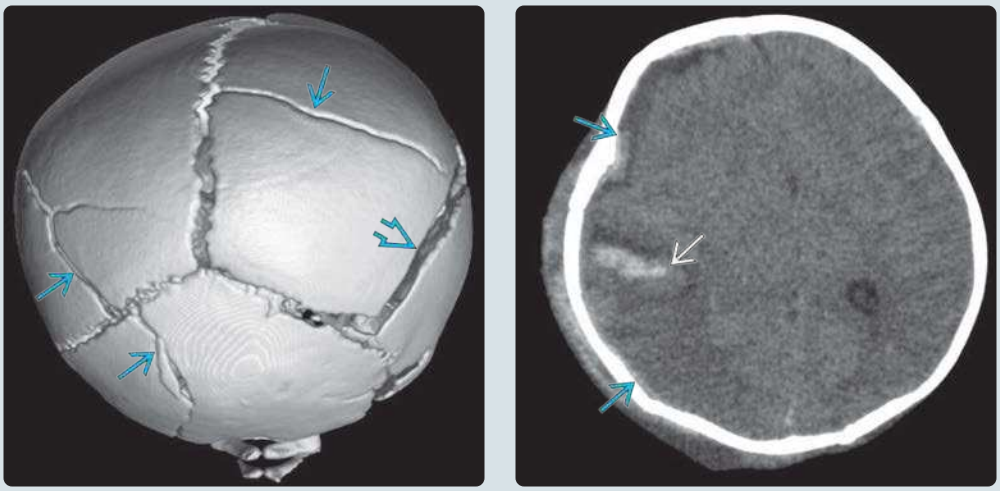
KEY FACTS

TERMINOLOGY

- Nonaccidental trauma (NAT), abusive head trauma (AHT)
- Traumatic injury inflicted on infants & children by adults

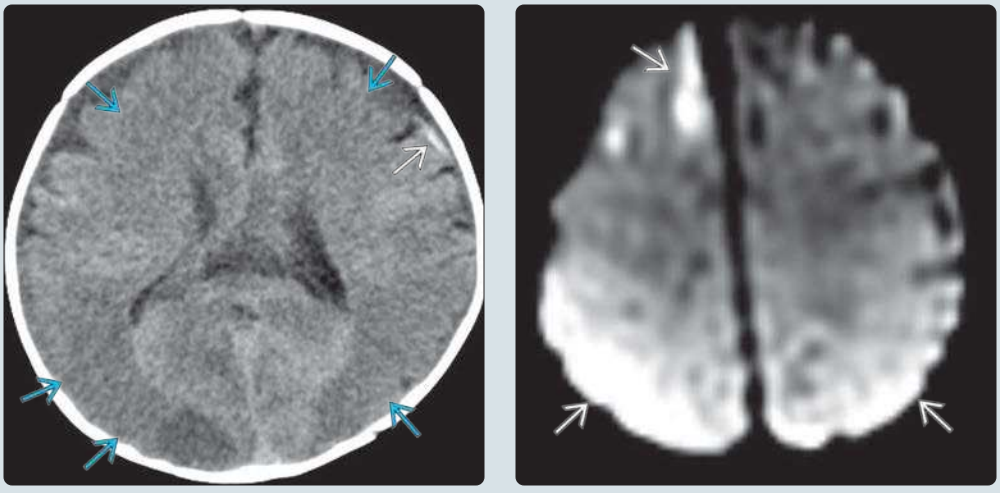
IMAGING

- Direct impact injury: Direct blow to cranium or impact of skull on object
  - Calvarial (often complex) & skull base fractures
  - Focal brain injury deep to impact
- Shaking injury: Result of violent to-&-fro motion of head
  - Subdural hematomas (SDHs) in 90-98%
  - Generalized parenchymal injuries (cytotoxic edema, lacerations, axonal injury)
  - Bridging vein injury & thrombosis are common
- NECT is primary imaging tool in initial evaluation of AHT
  - Multiplanar reconstructions improve detection of
    - Small intracranial hemorrhages (ICHs)
    - Fractures (with bone algorithm & 3D reformats)
- MR is best for determining full extent of injury
  - DWI is paramount for parenchymal injury
  - PD & SWI/T2* GRE for hemorrhage
  - T1 C+ for chronic SDH membranes



TOP DIFFERENTIAL DIAGNOSES

- Accidental trauma
- Benign macrocrania of infancy
- Mitochondrial encephalopathies
- Bleeding disorders



CLINICAL ISSUES

- Discordance between stated history & degree of injury
  - "Killer couch": Injuries blamed on infant rolling off couch
- Retinal hemorrhages in ~ 75%
- Most common cause of brain injury death in children < 2 years of age
  - 17-25:100,000 annual incidence
  - Cause of death in 80% of fatalities is brain swelling

(Left) *Posterior oblique view of a 3D NECT in a 9-week-old who "fell off the couch" shows multiple complex skull fractures, including a displaced right parietal fracture. 3D renderings are helpful in improving the detection & characterization of skull fractures.* **(Right)** *Axial NECT in the same patient shows a right subdural hematoma (SDH) & right opercular parenchymal laceration with significant midline shift & sulcal effacement. Parenchymal lacerations are seen in 10-15% of abusive head trauma (AHT).*

(Left) *Axial NECT in a 4-month-old boy with seizure activity shows multiple bilateral foci of low attenuation with loss of cortical differentiation as well as a left frontal SDH. There was no fracture, making these findings highly concerning for the shaking type of AHT.* **(Right)** *Axial DWI MR in a 2-month-old boy with AHT shows areas of diffusion restriction in the right frontal lobe & bilateral parietal lobes, consistent with parenchymal injury. MR is the most sensitive examination for parenchymal injury.*

TERMINOLOGY

Abbreviations

- Nonaccidental trauma (NAT), abusive head trauma (AHT)

Definitions

- Traumatic injury inflicted on infants & children by adults

IMAGING

General Features

- Multiple brain injuries disproportionately severe relative to offered history
- 2 major groupings of injuries (but can occur together)
  - Direct impact injury: Result of direct blow to cranium or impact of skull on object
  - Shaking injury: Result of violent to-&-fro head motion
- Direct impact injury is typified by skull fractures & injury to immediate subjacent brain
  - Scalp laceration, hematoma, & swelling are strongly associated
  - High association with injuries to other organs
- Shaking injury is typified by subdural hematoma (SDH), generalized parenchymal injury, & absence of fracture(s)
  - Cytotoxic injury not conforming to arterial territories
    - Exact etiology of injury is uncertain but usually permanent
      - Hypoxic-ischemic vs. direct traumatic brain injury
  - May see bridging vein injury ± thrombosis
  - Imaging findings may suggest injuries of differing ages

Radiographic Findings

- Sensitive in detection of linear skull fractures
  - Fracture detection is key component in forensic evaluation of suspected NAT
- Some fractures are considered more suspicious for NAT but evidence does not support this
  - Multiple compound, diastatic fractures, & fractures crossing sutures imply significant trauma but are not specific for NAT
  - Discordance with provided history is best indicator

CT Findings

- NECT: Primary imaging tool for initial evaluation of AHT
- Intracranial hemorrhage (ICH)
  - SDH: 90-98% (dominant feature of shaking injury)
    - Overlie cerebral convexities, extend into interhemispheric fissure, overlie tentorium
    - Normal density of subarachnoid space (SAS) stands out next to ↑ density of SDH
    - Acute SDHs are usually hyperdense but often have associated low-attenuation subdural hygromas (SDHys)
      - Blood density based upon multiple factors: CSF dilution, hematocrit, coagulation status
  - Subarachnoid hemorrhage: > 50%
  - Epidural hemorrhage (EDH) is uncommon but may occur
    - More characteristic of accidental trauma
- SDHy may develop after injury
  - CSF density subdural collection due to arachnoid membrane tear with CSF leakage from SAS
  - Usually develops ~ 12-24 hours after injury
  - Typically resolves without direct treatment
- Bridging vein injury ± thrombosis: 40-50%
  - Areas of ↑ density in paramedian high convexities
    - Pollywog & lollipop signs: Small round focus of clot adjacent to small segment of thrombosed injured vein
      - Fairly specific signs for AHT
- Extensive parenchymal ischemic injury is often seen in shaking injuries
  - Areas of ↓ density (with loss of gray-white differentiation) & sulcal effacement not confined to arterial territories; may be diffuse
  - ↓ density of cerebrum vs. cerebellum: "Bright cerebellum"
- Subcortical laceration or contusional tear: ~ 15%
  - More commonly seen in AHT vs. accidental injury
- Shear injury (axonal injury): ~ 15%
- Retinal hemorrhages are uncommonly visualized on CT
- CECT: Enhancing membranes are best sign of chronic SDHs

MR Findings

- DWI: Key sequence for parenchymal injury
- T1: Bright foci of hemorrhage or evolving cortical injury
- T2: Loss of normal lower signal intensity cortical ribbon & deep nuclei in neonates
- PD/intermediate echo sequences: Very sensitive for detection of small subdural collections
- SWI/T2* GRE: Detects small ICHs ± retinal hemorrhages
  - SWI is ~ 50% sensitive & 100% specific for retinal hemorrhage
- T1 C+: Enhancing membranes are best sign of chronic SDH
- MRA: Proximal vascular correlate (e.g., dissection, spasm) is rarely shown in association with parenchymal injury
- MRS: ↓ NAA, ↑ lactate in regions of parenchymal injury
  - May detect injury in normal-appearing regions

Ultrasonographic Findings

- Not used primarily for suspected AHT
- May be ordered in infant for other indications (e.g., macrocrania, scalp swelling) with incidental detection of NAT findings
  - Subdural collections: Displacement of discrete arachnoid membrane & subjacent vessels toward pial surface
  - Skull fracture: Linear interruption of bone not corresponding to predictable & symmetric suture

Imaging Recommendations

- Best imaging tool
  - NECT (with 3D bone reconstructions): Gold standard exam for acute evaluation of suspected AHT
    - Best for detection & characterization of fractures
    - Very sensitive in detection & characterization of ICH
  - ↑ interest in using limited SSFSE MR as initial screening tool
  - Complete MR after 2-4 days: Most sensitive to define full extent of brain injury
- Protocol advice
  - NECT: Multiplanar reconstructions improve detection of
    - Small ICHs
    - Skull fractures (especially with bone algorithm & 3Ds)
    - Craniocervical junction/upper cervical spine injuries (so cover through C2)

- MR: DWI to assess parenchymal injury; PD/SWI sequence to detect subtle SDH/SDHy
- Perform spine imaging (as spine injury seen in ~ 50%)
  - NAT in spine: SDH > EDH > osseous > cord

DIFFERENTIAL DIAGNOSIS

Accidental Trauma

- Appropriate history for degree of injury

Benign Macrocrania of Infancy

- Self-limited communicating hydrocephalus
- Symmetric enlargement of bifrontal SASs that are isodense to CSF & contain numerous tiny cortical vessels

Mitochondrial Encephalopathies

- May cause atrophy with subdural collections
  - Glutaric acidurias (types I & II), Menkes syndrome
  - Rare diseases with preexisting neurologic symptoms

Overshunting

- "Passive" subdurals can develop from ↓ volume associated with CSF shunting

Subdural Empyema

- Febrile, sinusitis, meningitis

Bleeding Disorders

- von Willebrand, thrombocytopenia
- Intracranial bleeding with minor trauma

PATHOLOGY

General Features

- ↑ vulnerability in infants due to
  - Large head:body ratio + weak neck muscles
  - Developing brain has less structural integrity prior to myelination → greater susceptibility to injury
- 85% of fatal child abuse victims have evidence of impact head injury at postmortem examination
- Retinal hemorrhages in ~ 75% (50-100% in literature)
  - Much less common in accidental head trauma (~ 6%)
- Retroclival collections can be seen in ~ 30% of AHT victims

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Discordance between stated history & degree of injury
    - Attempt by perpetrator to minimize suspicion
    - "Killer couch": Severe injuries are blamed on infant rolling off of couch onto floor
      - Infants are frequently too young to roll over at all
  - Unprovoked seizures & apnea raise suspicion for AHT
- Other signs/symptoms
  - Poor feeding, vomiting, irritability, seizures, lethargy, coma, apnea
  - Retinal hemorrhages (detected on eye exam)
    - Can be missed on cursory evaluation
  - Cause of death in 80% of fatalities is brain swelling
    - Severe hypoxic-ischemic encephalopathy > diffuse axonal injury
- Clinical profile
  - Perpetrators are most often direct caretakers: Parents, babysitters, mother's boyfriend
  - Developmentally delayed & "colicky," premature or low-birth-weight infants at higher risk
  - Psychosocial stressors & poor coping mechanisms are often present in family environment

Demographics

- Most common from 1-6 months of age
- 17-25:100,000 annual incidence
  - Almost certainly underreported
  - Leading cause of brain injury death in children < 2 years of age

Natural History & Prognosis

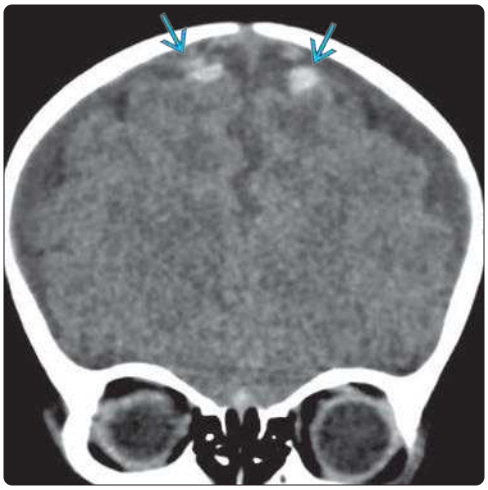
- Mortality rate: 20-25%
- High rates of impairment for survivors
  - Psychomotor delay, epilepsy, visual impairment, cognitive/behavioral disorders

Treatment

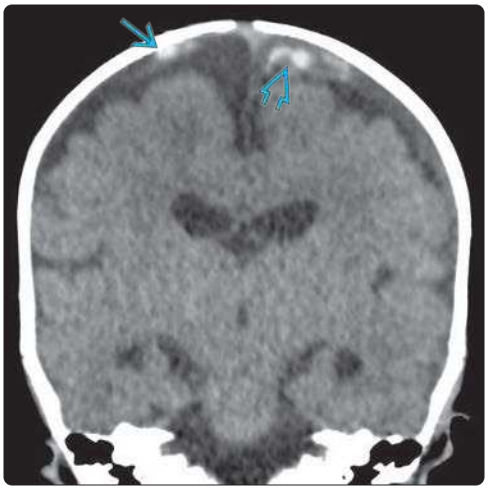
- Multidisciplinary child abuse & neglect team intervention
- Notification of local Child Protection Agency

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls



- Avoid temptation to precisely time ICH
  - Impossible to precisely state age of bleeding in absence of "before & after" imaging
    - Mixed-density hematohygromas are most commonly caused by single acute injury with mixing of blood & CSF
      - **Should not** be mistaken for acute-on-chronic SDHs
  - Reasonable estimates & conclusions are more defensible in court



Reporting Tips

- Carefully proofread, as report may become legal document
- Avoid use of vague, oblique, obscuring language
  - Can hamper care of child & legal investigation
  - May ↑ likelihood of interpretation being challenged in legal proceedings
- Avoid speculation regarding source of injury
  - Report for identification & evaluation of injuries
  - May be appropriate to note discordance between reported mechanism & extent of injury

(Left) *Coronal NECT in a 1-month-old patient with AHT shows bilateral paramedian extraaxial hemorrhages, a characteristic finding in AHT attributed to bridging vein injury & thrombosis. In all, 40-50% of AHT cases show evidence of bridging vein injury.* **(Right)** *Coronal NECT in a 3-month-old patient with AHT shows focal areas of parasagittal hemorrhage. The lesion on the left has a lollipop or pollywog appearance, typical for cortical vein avulsion, a finding that is fairly specific for AHT.*

(Left) *Axial NECT in a 2-month-old patient with AHT shows subdural hemorrhage over the left frontal lobe & along the falx. Note the extensive left cerebral ↓ attenuation with loss of gray-white differentiation & significant left-to-right midline shift.* **(Right)** *Coronal FLAIR MR in the same patient 7 years later shows extensive cystic & noncystic encephalomalacia affecting the left > right cerebral hemispheres. There is associated ex vacuo ventriculomegaly.*

(Left) *Axial SWI MR in a 6-week-old shows subdural & subarachnoid hemorrhages as well as an evolving left frontal lobe laceration containing a hemorrhage level, a constellation of findings very suspicious for AHT.* **(Right)** *Axial SWI MR in a 4-month-old with AHT shows bilateral retinal hemorrhages. Although SWI is the most sensitive imaging sequence for retinal hemorrhages, it is insensitive relative to a funduscopic exam. Note that a normal MR appearance of the globes does not exclude retinal hemorrhages.*

Germinal Matrix Hemorrhage

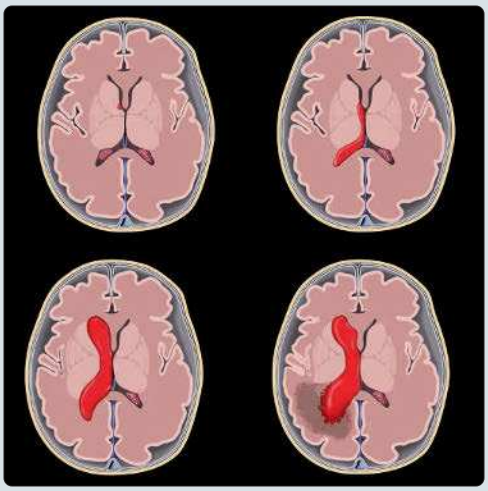
KEY FACTS

TERMINOLOGY

- Hemorrhage that occurs in richly vascular, but fragile, germinal matrix in premature infants

IMAGING

- Can occur anywhere along germinal matrix
  - Most commonly at caudothalamic groove
- Look for intraventricular extension, ventriculomegaly, & secondary intraparenchymal hemorrhage
- US: Globular echogenic focus in caudothalamic groove
  - Acute blood is echogenic; clot later retracts & becomes iso- to hypoechoic
  - May appear as abnormally thick choroid plexus but of slightly different echogenicity & lacking vascularity
  - Fluid-debris levels may be visible in dependent ventricles
  - Coronal & sagittal cine clips sweeping though ventricles help differentiate hemorrhage from normal choroid
- MR: Sensitive for detection of germinal matrix hemorrhage (GMH) & intraventricular hemorrhage (IVH)
  - ↑ T1 signal; ↓ SWI/T2* GRE
  - Best imaging modality for detection of associated parenchymal abnormalities

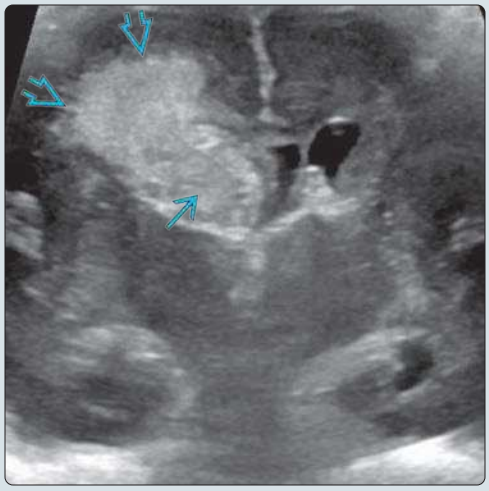


PATHOLOGY

- Germinal matrix is transiently present as region of fragile, thin-walled vessels & migrating neuronal components
  - Involutes by 34 weeks of gestation
- In premature infants, perinatal stresses + poor cerebral autoregulation + germinal matrix → hemorrhage
- GMH-IVH grading system
  - Grade 1: GMH only
  - Grade 2: GMH + IVH, normal ventricle size
  - Grade 3: GMH + IVH + ventricular expansion
  - Grade 4: GMH-IVH + intraparenchymal hemorrhage
    - Venous compression leads to venous infarction

CLINICAL ISSUES

- Most common < 32 weeks of gestation & < 1,500 grams



(Left) *Axial graphic shows germinal matrix hemorrhages (GMHs) grades 1 (top left) to 4 (bottom right) with ventricular dilation seen above grade 2 & parenchymal involvement (from hemorrhagic venous infarction) in grade 4.* **(Right)** *Coronal head US in a former 29-weeks-gestation male fetus 1 day after delivery shows an asymmetric globular echogenic focus in the right caudothalamic groove, consistent with a GMH. The lack of intraventricular hemorrhage (IVH) makes this a grade 1 hemorrhage.*

(Left) *Coronal US in a 1-day-old neonate born at 25-weeks gestation shows a heterogeneously echogenic IVH that expands the left lateral ventricle, consistent with a grade 3 IVH. Note the ↓ parenchymal sulcation, reflective of prematurity.* **(Right)** *Coronal US in a 3-day-old neonate born at 24-weeks gestation shows a large right IVH with a fan-shaped area of hyperechogenicity in the adjacent white matter, consistent with hemorrhagic venous infarction (grade 4 IVH).*

TERMINOLOGY

Abbreviations

- Germinal matrix hemorrhage (GMH), intraventricular hemorrhage (IVH)

Synonyms

- Germinal matrix bleed, preterm caudothalamic hemorrhage, GMH-IVH

Definitions

- Hemorrhage that occurs in very specific, richly vascular, stress-sensitive areas of premature brain
- Germinal matrix has developed more sturdy blood vessels by 34 weeks of gestation

IMAGING

General Features

- Best diagnostic clue
  - Globular echogenic focus in caudothalamic groove
    - Clearly asymmetric from contralateral normal choroid plexus
- Location
  - Within distribution of fetal germinal matrix
    - Most commonly caudothalamic groove
  - May extend into ventricular system
    - Adherent to choroid plexus or layering in occipital horns
- Size
  - Variable
- Morphology
  - Globular & rounded when limited to caudothalamic groove (grade 1)
  - Lobulated or amorphous with posterior intraventricular extension (grade 2)

Ultrasonographic Findings

- Grayscale ultrasound
  - Hyperechoic acute hemorrhage
    - Evolving clot retracts & becomes iso- to hypoechoic
  - IVH is often adherent to choroid plexus
    - Fluid-debris levels may be visible in dependent ventricular occipital horns
    - Chemical ventriculitis in 2-3 days after IVH
      - Ependymal lining becomes thick & echogenic
  - Larger IVH will expand ventricle(s) (grade 3)
    - Posthemorrhagic hydrocephalus often develops
  - Fan-shaped echogenic parenchymal focus due to hemorrhagic venous infarction (grade 4)
  - Examine remainder of brain for
    - Associated white matter injury
    - Lack of congenital anomalies
- Color Doppler
  - Useful to differentiate avascular hemorrhage from vascular choroid plexus

MR Findings

- Variable signal intensity based on age of blood
  - **T1**: ↑ in subacute blood, ↓ in chronic hemosiderin
  - **T2**: ↓ in most phases of hemorrhage evolution
  - **SWI**: Most sensitive for small or remote GMH-IVH
- Helpful to identify brain injury often associated with GMH-IVH
  - White matter injury of prematurity
  - Cerebellar microhemorrhage
- Also useful to detect underlying congenital anomalies

CT Findings

- Not typically used in premature neonate due to availability of US & superior soft tissue contrast of MR
- Excellent for detection of intracranial hemorrhage elsewhere: Parenchymal, subdural, subarachnoid

Imaging Recommendations

- Best imaging tool
  - US is primary imaging modality
    - Portability allows US to go to patient in NICU
    - Available sonographic windows of anterior & mastoid fontanelles
    - Lack of ionizing radiation
    - High sensitivity & specificity for GMH-IVH
  - MR is useful adjunctive imaging modality
    - More sensitive, specific, & reproducible than US but not usually practical in critically ill premature infants
    - MR is rarely performed acutely; usually performed later to evaluate extent of parenchymal injury
- Protocol advice
  - US: Use small-footprint, high-frequency linear transducer with multiple focal zones
    - Coronal & sagittal cine clips are helpful in distinguishing hemorrhage from normal choroid plexus
  - MR: Include SWI or T2* GRE to identify hemorrhage

DIFFERENTIAL DIAGNOSIS

Hypoxic-Ischemic Encephalopathy

- Deep or peripheral patterns of parenchymal injury due to perinatal insult to preterm or term infant
- Abnormal ↑ echogenicity of white matter ± deep gray nuclei
- Usually fairly symmetric

Hemorrhagic Infarction From Venous Thrombosis

- Superficial or deep venous thrombosis may lead to echogenic parenchyma ± discrete hematoma in neonate
  - Can liquefy & mimic abscess
- Isolated or secondary to infection or systemic processes

Choroid Plexus Cysts or Hematoma

- Small cysts &/or hemorrhage may occur in choroid plexus
- Often without consequence

Ventriculitis

- Echogenic ependyma & infectious debris may mimic IVH
- May lead to communicating hydrocephalus

Periventricular Calcifications

- Not typically seen in caudothalamic groove
- Related to TORCH infections most commonly

Periventricular Gray Matter Heterotopia

- Nodular heterotopic foci are less echogenic than blood
- Follow gray matter on all MR sequences

Tuberous Sclerosis

- Echogenic nodular periventricular foci
- Echogenic cortical/subcortical tubers

PATHOLOGY

General Features

- Etiology
  - Germinal matrix is transiently present as vascular-rich area of neuronal precursors
    - Involutes gradually → hemorrhage is less likely with ↑ gestational age
    - Most GMHs occur in 1st week of life
  - Germinal matrix is prone to hemorrhage in prematurity
    - High density of fragile vascularized tissue
    - Poor cerebral autoregulation in premature infants
  - Hemorrhage occurs secondary to perinatal stresses: Labile blood pressure, hypoxia, hypercarbia, etc.

Staging, Grading, & Classification

- Germinal matrix grading system created by Burstein et al in 1979
  - Performed on initial head US within days of delivery
  - Grading is not changed on follow-up exams (even with progression)
- Grade 1: GMH only
- Grade 2: GMH, IVH, normal ventricle size
- Grade 3: GMH, IVH, & ventricular expansion from IVH
  - Secondary hydrocephalus occurring several days after grade 2 IVH should not be mislabeled as grade 3 IVH
- Grade 4: IVH + intraparenchymal hemorrhage
  - Intraparenchymal hemorrhage represents hemorrhagic venous infarction, not direct extension of GMH or IVH
    - Deep draining vein compression → venous congestion → venous infarction → hemorrhagic infarction
    - Debated whether or not ventricular dilation is necessary
      - Is periventricular hemorrhagic infarction of premature infant with grade 1 or 2 GMH actually due to GMH vs. discrete focus of hypoxic-ischemic injury or venous thrombosis
  - Grade 4 may be called posthemorrhagic venous infarction

Gross Pathologic & Surgical Features

- Areas of hemorrhagic necrosis, liquefaction, & gliosis

CLINICAL ISSUES

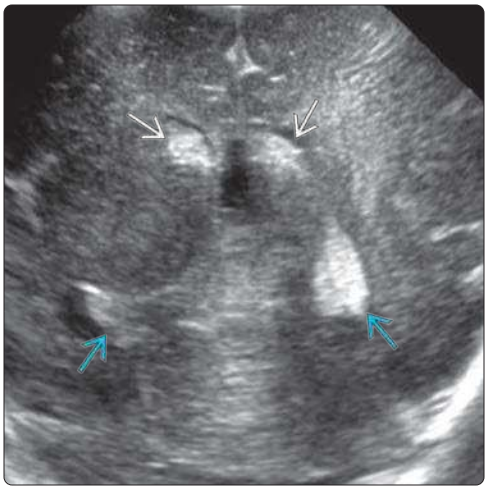
Presentation

- Most common signs/symptoms
  - Variable: Hypotonia, seizures, hyperreflexia, falling hematocrit, irritability, failure to thrive, paresis, acidosis, feeding difficulties
- Other signs/symptoms
  - GMH may occur in utero & follow same pathway of evolution & complications

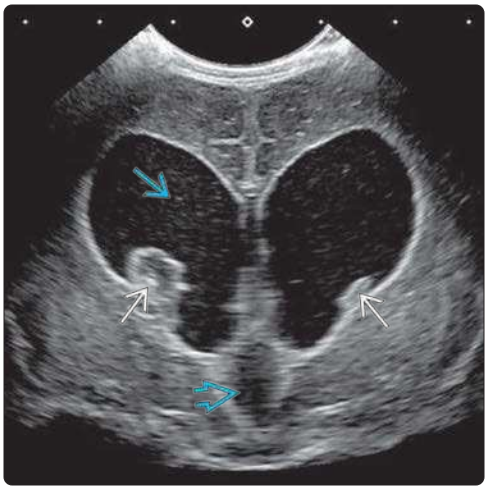
Demographics

- Age
  - Premature infants in 1st week of life
  - 1/3-1/2 of all GMHs occur on 1st day of life
- Sex
  - M:F = 1:1
- Ethnicity
  - No predisposition
- Epidemiology
  - Most common in infants < 32 weeks of gestation & < 1,500 grams
  - Higher risk of GMH in premature infants with congenital heart disease, surgical procedures, severe respiratory distress
  - Incidence of GMH-IVH: 50% from 1975 to 1980 & then ↓ to ~ 15% after 2005
    - Improved modern outcomes attributed to prenatal steroids & surfactant, among other therapies

Natural History & Prognosis



- GMHs may progress or rebleed
- In general, clot retracts, lyses, & becomes hypoechoic, leaving behind cyst or area of porencephaly
- Prognosis
  - Grades 1 & 2 bleeds generally have good prognosis
  - Grades 3 & 4 bleeds have variable long-term deficits
    - Spastic diplegia, seizures, neurocognitive impairment
    - Up to 44% mortality
- Posthemorrhagic hydrocephalus develops in 60% of grade 3-4 IVHs
  - Classically due to blood products, fibrosis, &/or gliosis obstructing ventricular outlets & arachnoid granulations
  - May also impair CSF dynamics at levels of microvasculature & ependyma



Treatment

- Prenatal
  - Prevent preterm delivery
  - Prenatal steroids
- Postnatal
  - Optimize neonatal resuscitation
  - Reduce fluctuations in cerebral blood flow
    - Minimize handling, gentle/synchronized ventilation, prompt treatment of patent ductus arteriosus, maintain normal oxygenation
- Posthemorrhagic hydrocephalus often requires CSF shunting (20-25% of grades 3-4 IVH)

(Left) *Coronal head US in a former 30-weeks-gestation premature infant < 24 hours after delivery shows bilateral GMHs ➡ & IVHs ⇨ without ventriculomegaly, consistent with grade 2 IVH. Cine clips are the easiest way to distinguish GMH/IVH from normal choroid plexus (which is not easily done on this static image).* **(Right)** *Coronal head US in the same patient 3 weeks later shows evolution of the IVHs ➡ with interval enlargement of the lateral ⇨ & 3rd ⇨ ventricles, consistent with posthemorrhagic hydrocephalus.*

(Left) *Coronal head US in a former 24-weeks-gestation premature infant (now 6 days old) shows bilateral GMHs ⇨. There is left intraventricular extension of the hemorrhage ➡ with expansion of the left frontal horn ⇨, consistent with a grade 3 IVH. A grade 2 IVH was seen on the right.* **(Right)** *Axial T1 MR 3 weeks later in the same patient shows foci of T1 shortening from the prior IVHs ⇨. Further ventriculomegaly ➡ has developed, consistent with posthemorrhagic hydrocephalus.*

(Left) *Coronal US in a 28-weeks-gestational age premature infant at 2 days of life shows bilateral germinal matrix hemorrhage (GMH) ⇨ (L > R) & fan-shaped echogenic hemorrhagic infarction ➡ in the left centrum semiovale, consistent with grade 4 IVH.* **(Right)** *Coronal T2 MR in the same infant 6 weeks later shows residua of the left-sided IVH ➡ & intraparenchymal hemorrhage ⇨ with the development of cystic encephalomalacia ⇨, an expected evolution of grade 4 IVH.*

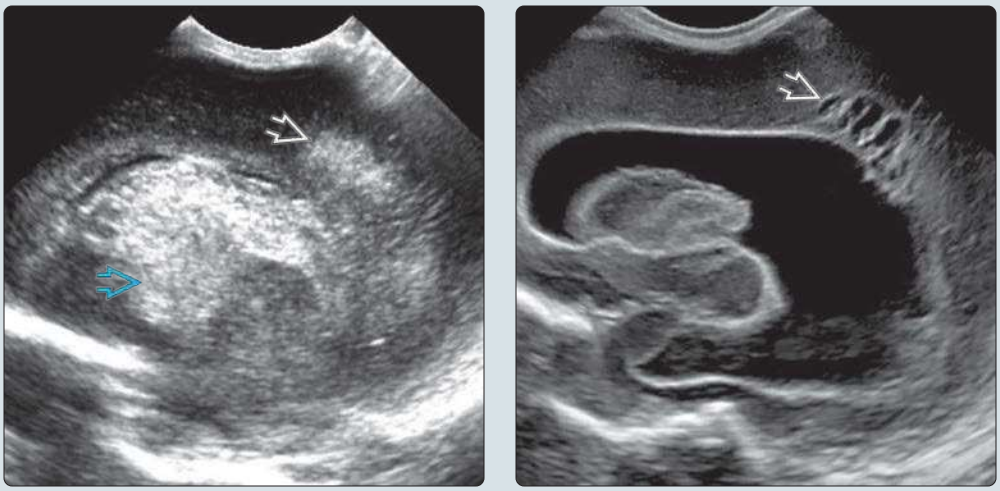
White Matter Injury of Prematurity

KEY FACTS

TERMINOLOGY

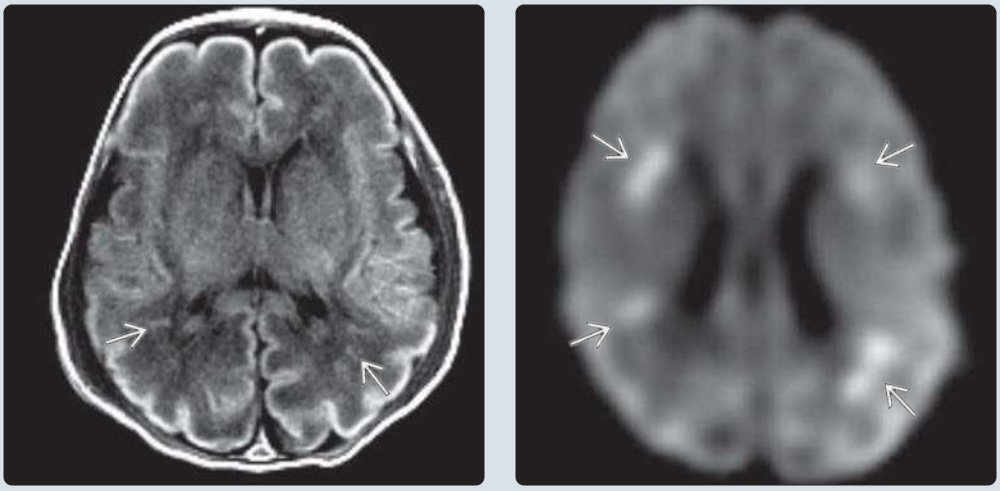
- White matter (WM) injury of prematurity
- Brain injury occurring before 34-weeks gestation, resulting in loss of periventricular WM

IMAGING



- Ultrasound: Reliable for more severe or late disease; less reliable for mild/moderate or early disease
  - Acute findings
    - Patchy, globular foci of ↑ echogenicity in periventricular/deep WM
  - Subacute/chronic findings
    - Clusters of periventricular cysts
- MR: Reliable for entire spectrum of disease
  - Acute findings
    - T1-hyperintense, T2-hypointense foci
    - Hypointense SWI/GRE foci with hemorrhage
    - ↓ ADC (may miss if imaging < 24 hours or > 5 days)
    - MRS: Lactate peak or ↑ excitatory neurotransmitters
  - Subacute findings
    - Periventricular cysts
  - Chronic finding
    - Periventricular/deep WM volume loss
    - Typically minimal associated gliosis

TOP DIFFERENTIAL DIAGNOSES



- Normal periventricular halo on ultrasound
- Infection
- Shunted hydrocephalus

PATHOLOGY

- Preceding inflammation (e.g., chorioamnionitis) + ischemia superimposed on vulnerable premature brain
- Characteristic pattern of injury reflects distribution of immature oligodendrocytes during vulnerable period
  - Selective injury to immature oligodendrocytes dramatically reduces WM volume in affected areas
- Some WM injury is due to deep medullary vein thrombosis

(Left) *Sagittal head ultrasound in a 5-day-old, former 27-weeks-gestational age (GA) infant shows globular ↑ echogenicity in the periventricular white matter (WM), consistent with ischemic injury. Intraventricular hemorrhage & deep gray nuclei insult were also noted.* **(Right)** *Sagittal head ultrasound 1 month later shows that the previously seen focus of ↑ echogenicity has now evolved into cystic encephalomalacia. The new ventriculomegaly is likely due to volume loss & obstruction by blood products.*

(Left) *Axial T1 MR in an 18-day-old, former 33-weeks-GA neonate with tricuspid atresia demonstrates patchy foci of hyperintense signal in the bilateral parietooccipital periventricular WM.* **(Right)** *Axial DWI MR in the same patient shows corresponding foci of restricted diffusion (↓ signal on the ADC map, not shown) in the bilateral periventricular WM, consistent with acute injury. MR is the most sensitive test for WM injury in neonates that can safely tolerate the exam.*

TERMINOLOGY

Synonyms

- White matter (WM) injury of prematurity, perinatal WM damage, punctate WM lesions, periventricular leukomalacia (PVL)

Definitions

- Perinatal WM injury occurring before 34-weeks gestation

IMAGING

Ultrasonographic Findings

- Reliable for more severe or late disease; less reliable for mild/moderate or early injury
- Acute findings
  - Patchy, globular foci of ↑ echogenicity in periventricular/deep WM
  - Loss of normal WM echotexture
- Subacute findings
  - Periventricular cystic foci

CT Findings

- Reliable for more severe or late disease; less reliable for mild/moderate or early injury
  - Due to high water content of normal newborn brain

MR Findings

- T1WI
  - Acute: Areas of T1 hyperintensity
  - Chronic: WM volume loss, callosal thinning
- T2WI
  - Acute: Areas of T2 hypointensity
  - Subacute: Cystic changes in periventricular WM
  - Chronic: WM volume loss, ventriculomegaly
    - Cortical ribbon extending down to ventricular margin
    - Angular ventricles with "squared-off" trigones
- FLAIR
  - Not usually performed in newborn due to high water content & lack of myelination in normal neonatal brain
  - Chronic: Hyperintense signal in periventricular/deep WM
- T2* GRE
  - Hypointense SWI/GRE foci in areas of hemorrhage
- DWI
  - Restricted diffusion often precedes other abnormalities
  - May miss or underestimate WM injury if DWI is performed < 24 hours or > 5 days after injury
    - ADC values may "normalize" after 5 days
  - Always review ADC maps as DWI may be falsely negative due to normally long T2 values in neonatal brain
- MRS
  - Lactate peak, ↓ NAA, ↑ excitatory neurotransmitters; alterations may antedate MR image abnormalities

Imaging Recommendations

- Best imaging tool
  - Ultrasound in perinatal period
    - Convenient & well tolerated by neonates
    - Poor sensitivity/specificity for WM injury, especially for mild, early, or noncavitary lesions
  - MR (including DWI & MRS)
    - Best performed 1-5 days after suspected injury

DIFFERENTIAL DIAGNOSIS

Normal Periventricular Halo

- Specular reflections of normal perpendicular WM tracts
- Most prominent in posterior periventricular WM but less echogenic than choroid plexus
- Usually linear & symmetric, not heterogeneous & globular

Infection

- CMV: Microcephaly, periventricular Ca^{2+}, ± periventricular WM abnormalities, ± polymicrogyria

Shunted Hydrocephalus

- Ventricular distortion ± abnormal WM after shunting

PATHOLOGY

General Features

- Etiology
  - Predisposing factors of premature brain: Unique cellular vulnerability, impaired cerebrovascular autoregulation, periventricular arterial end zones
  - Superimposed insult
    - Chorioamnionitis → vasculitis of chorionic plate → ↑ inflammatory cytokines
    - With pre-/perinatal hypoxia → WM damage via inflammatory response, oxidative stress linked to reoxygenation during perinatal period
  - Subset of WM injury is due to deep medullary vein thrombosis
    - More common in late preterm (> 32-weeks) & term (> 37-weeks) infants

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - May be clinically silent initially ± EEG findings
  - Spastic diplegia, visual & cognitive impairment
- Clinical profile
  - Risk factors for WM injury of prematurity
    - Pregnancy: Low gestational age/weight, previous preterm birth, spontaneous preterm labor
    - Intrapartum: Preeclampsia, premature rupture of membranes, chorioamnionitis, group B *Streptococcus* infection
    - Perinatal: Respiratory distress, patent ductus arteriosus, ↓ PaCO2, sepsis, anemia, apnea, bradycardia, cardiac arrest

Hypoxic-Ischemic Encephalopathy

KEY FACTS

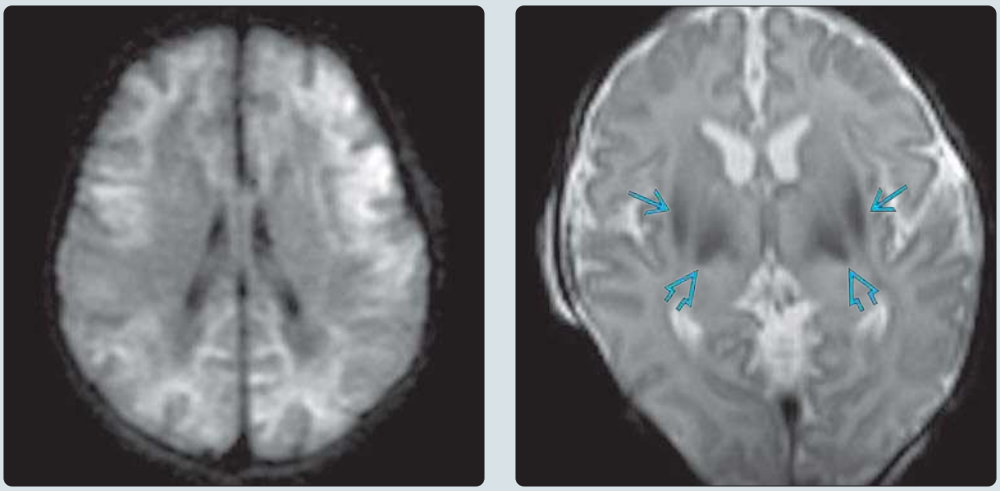
TERMINOLOGY

- Brain injury in neonate caused by hypoxic-ischemic insult

IMAGING

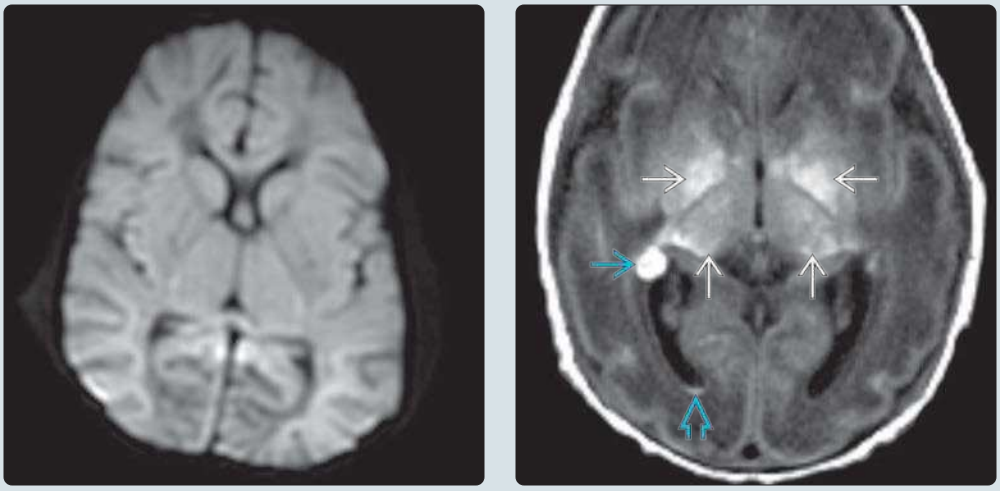
- Deep or central pattern of injury
  - Basal ganglia, thalamus, ± brainstem
- Peripheral pattern of injury
  - Injury to watershed zones of hemispheres
- Mixed (deep gray + cortex) pattern is often encountered
- US may be used for screening, particularly in acute setting or with concern for hemorrhage
  - Less sensitive for early injury or certain patterns
- MR is best imaging test for parenchymal injury
  - T1 & T2: Usually normal in 1st few days
    - T1: ↑ signal in affected regions
    - T2: ↑ or ↓ signal in affected regions
  - DWI: Best sequence to define extent of injury
    - ↑ DWI, ↓ ADC in affected regions from 1-10 days
  - MRS: ↓ NAA & ↑ lactate in affected areas

PATHOLOGY



- Central pattern is due to severe hypoxia of relatively brief (10-25 minutes) duration
  - Injury to regions of greatest metabolic demand
- Peripheral pattern is due to less severe hypoxia over longer period of time
  - Regions of greatest metabolic demand are protected
- Preterm infants are more susceptible to equivalent ischemic injury compared to term infants
- Preterm neonates are more likely to have associated white matter injury & hemorrhage

CLINICAL ISSUES



- Deep pattern is associated with dyskinetic cerebral palsy
- Peripheral pattern is associated with spastic cerebral palsy

DIAGNOSTIC CHECKLIST

- Findings may be inapparent/subtle in first 24 hours
- Image at 3-7 days for best MR evaluation of injury extent

(Left) *Axial DWI MR in a 5-day-old term neonate with HIE from meconium aspiration shows symmetric diffusion restriction in the watershed cortex & white matter. The involvement of cerebral cortex with sparing of the deep gray nuclei is consistent with a partial prolonged pattern of asphyxia.* **(Right)** *Axial T2 MR in a 7-day-old term neonate with HIE from placental abruption shows symmetric T2 signal hypointensity in the posterior putamina & anterolateral thalami, typical of an acute profound pattern of asphyxia.*

(Left) *Axial DWI MR in a 4-day-old term neonate with severe HIE shows a "superscan" with marked diffusion restriction throughout the brain. With the symmetry of severe findings, this is sometimes interpreted as normal. Comparing it to usually normal cerebellum is helpful.* **(Right)** *Axial T1 MR in a 31-week premature infant 11 days following placental abruption shows irregular hyperintense signal in the bilateral thalami & nuclei of the globus pallidus. Also note the GMH & small layering IVH, findings often seen in this setting.*

TERMINOLOGY

Definitions

- Hypoxic-ischemic encephalopathy (HIE): Neonatal brain injury caused by perinatal hypoxic-ischemic insult

IMAGING

General Features

- 2 patterns of injury have been described
  - Deep or central pattern
    - Injury to basal ganglia, thalami, ± perirolandic cortex
    - Profound hypoxic-ischemic injury (e.g., placental abruption)
    - More severe motor/cognitive outcomes
  - Peripheral pattern
    - Injury to watershed zones of cerebral hemispheres
    - Prolonged partial ischemia (e.g., fetal bradycardia)
    - Less severe motor/cognitive outcomes
  - Often have mixed pattern
    - Involving deep gray nuclei & cortex
  - Late findings: Atrophy, gliosis/encephalomalacia

Ultrasonographic Findings

- Insensitive compared to MR, especially early & for certain injury patterns
- Patchy or extensive hyperechoic foci in white matter (WM) & deep gray nuclei
  - May accentuate gray matter (GM)-WM differentiation at cortical/subcortical level
- Slit-like lateral ventricles & sulcal effacement
  - Common normally in newborns due to compression during labor &/or hypovolemia

MR Findings

- T1: Usually normal during 1st few days
  - ↑ signal in affected areas beginning at ~ 2-3 days
  - Loss of normal bright T1 signal in posterior limb of internal capsule
- T2: Usually normal during 1st few days
  - Indistinct deep gray nuclei & loss of cortical ribbon
  - ↑ or ↓ signal in affected areas after ~ 2-3 days
- SWI: Germinal matrix & intraventricular hemorrhages are often seen in preterm, less commonly in term neonates
- DWI: Most important sequence
  - Restricted diffusion is seen ~ 1-10 days after injury
  - Pseudonormalization occurs at ~ 7-10 days
  - Primary injury is apparent early; secondary injury (e.g., corpus callosum) develops days later
- MRS: ↓ NAA & ↑ lactate in affected areas
  - ↑ Lac:NAA ratio correlates with more severe injury
- Perfusion: ↑ ASL in affected deep gray nuclei during 1st week

Imaging Recommendations

- Best imaging tool
  - MR with DWI & MRS
- Protocol advice
  - Findings may be inapparent/subtle in first 24 hours
  - Image at 3-7 days for best MR evaluation of injury extent
    - ADC changes peak at ~ 5 days

DIFFERENTIAL DIAGNOSIS

Urea Cycle Disorders

- Elevated ammonia, present at 24-28 hours
- Diffuse cerebral edema

Maple Syrup Urine Disease

- Edema in myelinated areas
- Brainstem, perirolandic & cerebellar WM

Hypoglycemia

- Characteristic occipital cortex injury

Arterial Ischemic Stroke

- Focal arterial territory injury without hypoxic event

Venous Injury

- Edema, hemorrhage, &/or ischemia in venous distribution

TORCH Infections

- Microcephaly, migration anomalies, Ca^{2+}

PATHOLOGY

General Features

- Etiology
  - Central pattern is associated with severe hypoxia of relatively brief (10-25 minutes) duration
    - Causative (sentinel) event is usually identifiable
    - Injury to regions of greatest metabolic demand
  - Peripheral pattern is associated with less severe hypoxia over longer period
    - Causative event is sometimes cryptic
    - Regions of greatest metabolic demand are protected
    - Watershed regions are susceptible
  - Preterm infants are more susceptible to equivalent ischemic injury as compared to term infants
    - Preterm neonates more likely to have associated WM injury & hemorrhage
- Associated abnormalities
  - Maternal: Infection, preeclampsia, diabetes, cocaine

Staging, Grading, & Classification

- Sarnat stage (based on clinical & EEG findings)
  - I (mild): Hyperalert/irritable, mydriasis, ↑ heart rate, EEG is normal
  - II (moderate): Lethargy, hypotonia, miosis, ↓ heart rate
  - III (severe): Stupor, flaccid, reflexes absent, seizures

CLINICAL ISSUES

Natural History & Prognosis

- Deep pattern is associated with dyskinetic cerebral palsy
- Peripheral pattern is associated with spastic cerebral palsy

Childhood Stroke

KEY FACTS

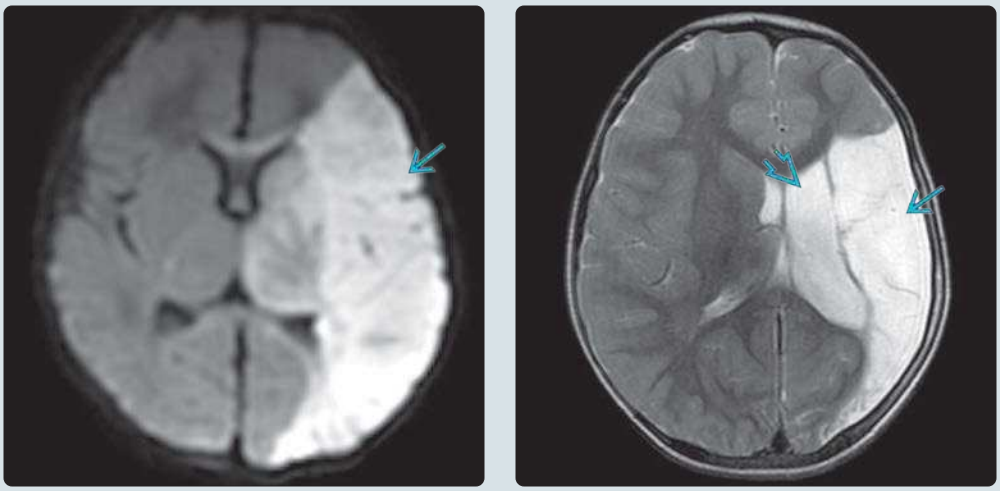
TERMINOLOGY

- Acute alteration of neurologic function due to loss of vascular integrity

IMAGING

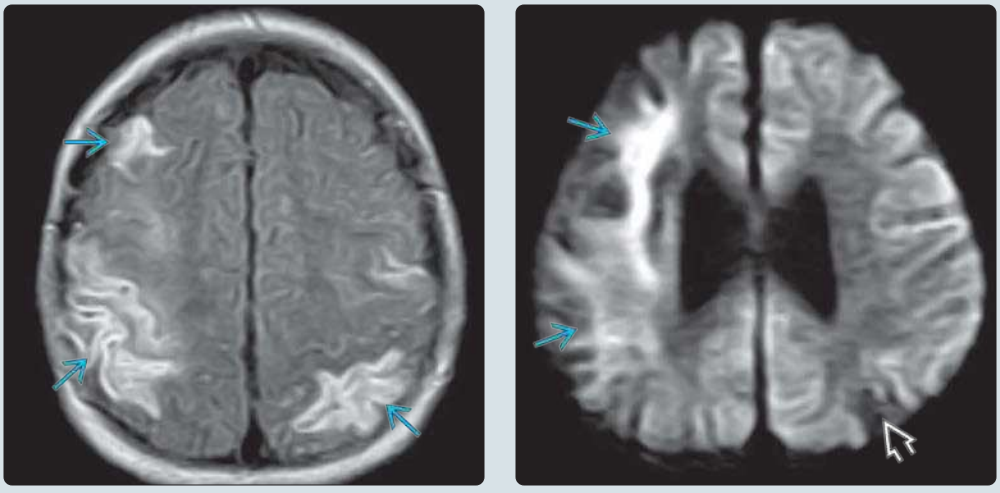
- NECT: ↓ attenuation of affected gray matter
  - Insular ribbon sign → loss of distinct insular cortex
  - Hyperdense middle cerebral artery (MCA) sign → thrombosed MCA
- MR: ↓ diffusion within ~ 30 minutes of arterial occlusion
  - Cytotoxic edema is evident in affected territory on FLAIR/T2 by 4-6 hours after arterial occlusion
  - Enhancement of infarct typically occurs after 5-7 days
- CTA/MRA: Critical for early evaluation & identification of possible etiology (e.g., dissection, arteriopathy)
- MR perfusion imaging can provide valuable information regarding region at risk in setting of acute stroke
- MR vessel wall imaging is helpful to identify inflammatory arteriopathy

TOP DIFFERENTIAL DIAGNOSES



- Complex migraine
- Seizure-related injury
- Acute encephalitis
- Mitochondrial encephalopathies
- Posterior reversible encephalopathy syndrome

PATHOLOGY



- Major causes: Cardiac disease (~ 25%), moyamoya-type arteriopathy, dissection, vasculitis, hematologic/metabolic
- No underlying cause discovered in ~ 25% of cases

CLINICAL ISSUES

- Incidence: 2-3/100,000 per year in USA
  - Mortality: 0.6/100,000
- Children typically present later than adults (> 24 hours)
- Focal deficit may be masked by lethargy, coma, irritability
- Treatment in pediatric acute stroke is often conservative
- Capacity for recovery in children much better than adults

(Left) *Axial DWI MR in a 4-day-old term neonate presenting with seizures shows diffusion restriction throughout the left middle cerebral artery (MCA) territory, consistent with a perinatal arterial ischemic stroke (PAIS).* **(Right)** *Axial T2 MR in the same patient 2 years later shows cystic encephalomalacia throughout left MCA territory & passive enlargement of the left lateral ventricle. Patients with PAIS who do not present near birth with seizures may later present with early hand preference or extremity weakness.*

(Left) *Axial FLAIR MR in a 2-year-old girl shows multiple areas of cytotoxic edema in both cerebral hemispheres in this patient with moyamoya-type vasculopathy.* **(Right)** *Axial DWI MR in the same patient with moyamoya-type vasculopathy shows diffusion restriction in the right frontoparietal foci of signal abnormality, suggesting an acute/subacute infarct. However, there is no diffusion restriction in the left parietal region, suggesting this infarct is of an older age. Acute stroke should prompt careful arterial evaluation.*

IMAGING

CT Findings

- NECT
  - ↓ attenuation of affected gray matter (GM) with loss of normal GM-white matter (WM) differentiation
    - ↓ in WM attenuation is less pronounced
    - Often wedge-shaped & localized to 1 arterial territory
  - Insular ribbon sign → loss of distinct insular cortex
  - Hyperdense middle cerebral artery (MCA) sign → ↑ density of acutely thrombosed MCA
  - Hemorrhagic transformation (HT)
    - Symptomatic HT in 3%; asymptomatic HT in 30%
- CTA
  - Invaluable for demonstrating focal vascular abnormalities in acute setting
    - Intimal flap in acutely dissected vessel
    - Major arterial occlusion may prompt thrombolysis or mechanical thrombectomy in appropriate setting

MR Findings

- **T1**: Acute: ↓ signal with gyral swelling
  - Chronic: ± ↑ signal in cortical laminar necrosis
- **T2**: Loss of flow void in thrombosed vessel
- **FLAIR**: ↑ signal with gyral swelling (within 4-6 hours)
  - Abnormal sulcal ↑ signal (climbing ivy sign) of chronic slow flow collaterals in setting of longstanding proximal vascular occlusion
- **DWI**: Most sensitive for early detection of ischemia
  - Acute: Restricted diffusion (↑ DWI, ↓ ADC signal) ≤ 30 minutes after ischemic insult
  - Subacute (7-14 days): Pseudonormalization of signal
  - Chronic: Facilitated diffusion in gliotic brain
- **T1 C+**: Cortical & leptomeningeal enhancement is seen after 5-7 days following acute infarct
  - Enhancing climbing ivy sign
- **MRA**: Can detect arterial occlusion & stenosis in large- & medium-sized cerebral vessels
- **PWI**: Provides valuable information about affected brain
  - Ischemic penumbra: ↓ perfusion, no DWI change (PWI-DWI mismatch)
- **MRS**: ↑ lactate is hallmark of ischemia/infarct
- **Vessel wall imaging**: Vessel wall enhancement suggests inflammatory arteriopathy

DIFFERENTIAL DIAGNOSIS

Complex Migraine

- ↓ (early) or ↑ (late) perfusion with normal DWI
- Engorgement of vessels on SWI

Seizure-Related Injury

- Swelling & restricted diffusion secondary to persistent seizure activity
- Differentiation by clinical presentation & EEG

Acute Encephalitis

- Acute parenchymal inflammation secondary to infectious agents, typically viral
- Slower onset with encephalopathy

Mitochondrial Encephalopathies

- Symmetric basal ganglia involvement is common
- Usually have manifestations beyond CNS

Posterior Reversible Encephalopathy Syndrome

- Patchy cortical/subcortical edema is most common in parietal & occipital lobes, typically in setting of hypertension
- Diffusion restriction is uncommon

PATHOLOGY

General Features

- 6 major causes of arterial stroke in children
  - Cardiac disease (~ 25%)
  - Moyamoya-type arteriopathy
  - Arterial dissection (e.g., trauma)
  - CNS vasculitis
  - Hematologic/metabolic (e.g., coagulopathy)
  - Idiopathic (~ 25%)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Depends on patient age, etiology, & involved artery
    - < 1 year: Seizures, encephalopathy > focal neurologic
    - > 1 year: Usually focal neurologic (e.g., hemiplegia)
    - Speech difficulties, gait abnormality, seizure
    - Embolic cause: Sudden onset of symptoms
    - Stenoocclusive cause: Gradual/intermittent (e.g., TIA)
  - Focal deficit may be masked by lethargy, coma, irritability
- Children typically present later than adults (> 24 hours)

Demographics

- Epidemiology
  - Incidence: 2-3/100,000 per year in USA
    - Mortality: 0.6/100,000
  - Underrecognized as significant source of morbidity in pediatric population

Natural History & Prognosis

- Capacity for recovery is better than in adults, due to
  - Better compensatory mechanisms, collateral recruitment, neuronal plasticity
  - Fewer concomitant risk factors

Treatment

- Clinical window of opportunity/benefit is not as well understood in children as compared to adults
- Mainstay of chronic therapy for fixed vascular lesions & vasculopathies: Aspirin
- Transfusion therapy for at-risk children with sickle cell disease

Moyamoya

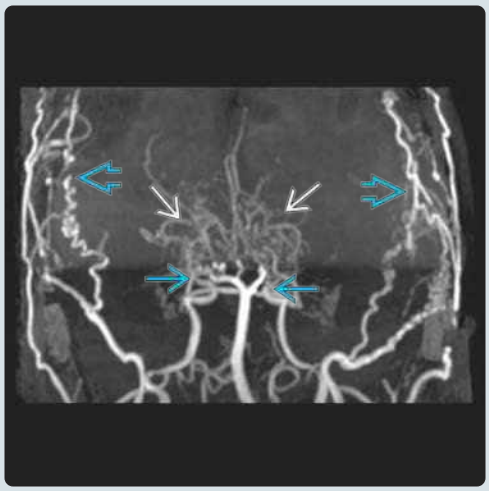
KEY FACTS

TERMINOLOGY

- Progressive narrowing of distal internal carotid artery (ICA) & proximal circle of Willis (COW) vessels → characteristic adjacent clusters of collateral flow appearing as puff of smoke on real-time angiography
- Moyamoya disease = primary (idiopathic) moyamoya
- Moyamoya arteriopathy (a.k.a. moyamoya syndrome or secondary moyamoya) is due to other disorders

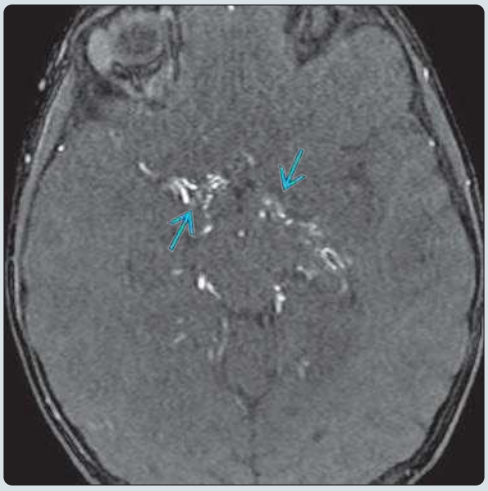
IMAGING

- Absent or narrowed distal ICA & abnormal COW
- Excessive tiny collaterals in basal ganglia & cisterns
  - "Puff of smoke" ("moyamoya" in Japanese) of lenticulostriate & thalamoperforator collaterals
- Prominent collaterals in sulci
  - Ivy sign on FLAIR & T1 C+ MR
- Acute & chronic infarcts
- CT/CTA: Acute use for ischemia or hemorrhage
- MR C+/MRA: Vascular protocol with DWI & perfusion
  - DWI: Helpful to identify acute-on-chronic injury

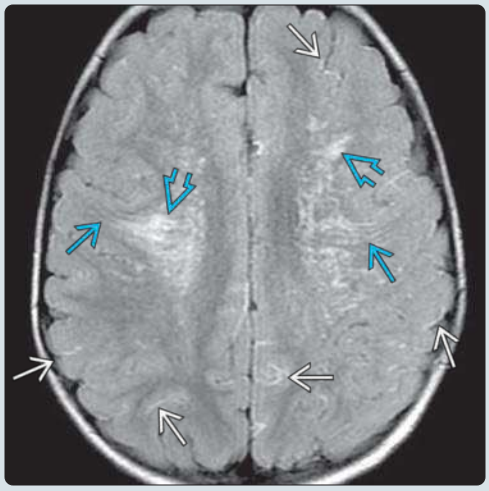


PATHOLOGY

- Moyamoya disease: Inherited idiopathic disorder
- Moyamoya arteriopathy: Secondary process
  - Sickle cell disease, neurofibromatosis type 1, radiation therapy, trisomy 21, Alagille syndrome, morning glory syndrome, TB meningitis, among others



CLINICAL ISSUES



- Bimodal age peaks: 6 & 35 years
- Most frequent cause of stroke in Asian children
- Presentation (children): Transient ischemic attacks (TIAs), alternating hemiplegia (exacerbated by crying), headache
- Presentation (adults): TIAs, hemorrhage (~ 30%), & cerebral infarct
- Prognosis depends on etiology, ability to form collaterals, age/stage at diagnosis
- Treatment: Indirect (more common in children) or direct (more common in adults) vascular bypass

(Left) *Axial DWI MR in a 13-month-old with increasing seizures shows left MCA distribution ischemia as well as a remote infarct in right MCA territory. This is a typical acute-on-chronic ischemic pattern of moyamoya.* **(Right)** *Anterior 3D TOF MRA in the same patient at 8 years of age shows occlusions of the small terminal ICAs, absence of the MCAs, & numerous lenticulostriate collaterals, forming a "puff of smoke." The PCAs are also occluded. Note the enlarged ECA collaterals status post synangiosis & dural inversion.*

(Left) *Axial 3D TOF MRA in a 5-year-old with idiopathic moyamoya arteriopathy shows multiple small collateral vessels where one would expect to see the proximal MCAs.* **(Right)** *Axial FLAIR MR in the same patient shows areas of gliosis from vascular insufficiency, multiple linear hyperintensities representing deep medullary collateral vessels, & hyperintensities conforming to the surface of the gyri & sulci representing pial collaterals (the leptomeningeal ivy sign).*

TERMINOLOGY

Definitions

- Progressive narrowing of distal internal carotid artery (ICA) & proximal circle of Willis (COW) vessels → characteristic adjacent clusters of collateral flow appearing as puff of smoke on real-time angiography
- Moyamoya disease: Primary (idiopathic) moyamoya
- Moyamoya arteriopathy (a.k.a. moyamoya syndrome or secondary moyamoya) occurs in association with other disorders or after radiation treatment

IMAGING

General Features

- Best diagnostic clue: Multiple enhancing punctate dots (CECT) & flow voids (MR) in basal ganglia & cisterns
- Arterial occlusions: Distal ICA, COW, branches
  - Anterior > posterior circulation
- Leads to prominent clusters of nearby collaterals
  - Cloud-like lenticulostriate & thalamoperforator collaterals on angiography: "Puff of smoke" ("moyamoya" in Japanese)
- Also leads to prominent sulcal collaterals distally

CT Findings

- NECT
  - Children: Acute ischemia ± old infarcts
  - Older children/adults: Usually ischemia but may present with intracranial hemorrhage
- CTA: Abnormal COW + basilar net-like collaterals

MR Findings

- **T2**: ↑ signal in gliotic areas from prior infarcts
  - Collateral vessels: Net-like cisternal flow voids
- **FLAIR**: Bright sulci = leptomeningeal ivy sign
  - Slow-flowing engorged pial collateral vessels, thickened arachnoid membranes
  - Correlates with ↓ cerebral vascular reserve
- **SWI/T2* GRE**: Hemosiderin if prior hemorrhage
- **DWI**: Very useful for acute-on-chronic infarcts
- **T1 C+**: Lenticulostriate collaterals → enhancing "dots" in basal ganglia & net-like thin vessels in cisterns
  - Leptomeningeal enhancement (ivy sign)
  - Vessel wall (spin-echo-based) imaging shows concentric enhancement of larger vessels
- **MRA**: Narrowed/occluded distal ICA & COW vessels
- **PWI**: ↓ perfusion in affected territories
  - May be used to measure response to revascularization

Angiographic Findings

- Predominantly (not exclusively) anterior circulation
  - Narrow proximal COW & ICA (early phase)
  - Lenticulostriate & thalamoperforator collaterals (intermediate phase)
  - Transdural/transosseous external carotid artery (ECA)-ICA collaterals (late phase)

Imaging Recommendations

- Best imaging tool: MR C+/MRA
- Catheter angiography defines anatomy prior to bypass

DIFFERENTIAL DIAGNOSIS

Ivy Sign

- Leptomeningeal metastases; subarachnoid hemorrhage; meningitis; ↑ inspired oxygen; collateral veins of Sturge-Weber or other chronic venous occlusion

Large Vessel Narrowing

- Vasculitis: Postvaricella vasculitis, lupus, & others; focal cerebral arteriopathy; arterial dissection; subarachnoid hemorrhage (spasm); meningitis; tumor encasement

PATHOLOGY

General Features

- Etiology
  - Moyamoya disease
    - Inherited polygenic or autosomal dominant
  - Moyamoya arteriopathy (a.k.a. moyamoya syndrome or secondary moyamoya)
    - Sickle cell disease, neurofibromatosis type 1, radiation therapy, trisomy 21, Alagille syndrome, morning glory syndrome, tuberculous meningitis, many others

Staging, Grading, & Classification

- Staging criteria (Suzuki)
  - Stage 1: Narrowing of ICA bifurcation
  - Stage 2: Anterior cerebral artery (ACA), middle cerebral artery (MCA), posterior cerebral artery (PCA) are dilated
  - Stage 3: Maximal basal collaterals; small ACA/MCA
  - Stage 4: Fewer collaterals (vessels); small PCA
  - Stage 5: Further ↓ in collaterals; absent ACA/MCA/PCA
  - Stage 6: Extensive ECA-pial collaterals

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Children: Transient ischemic attacks (TIAs), alternating hemiplegia (exacerbated by crying), headache
  - Adults: TIAs, hemorrhage (~ 30%), cerebral infarct

Natural History & Prognosis

- Pediatric cases usually advance to stage 5 in < 10 years
- Hemorrhagic moyamoya is more common in older patients

Treatment

- Aspirin therapy
- Direct bypass: Superficial temporal artery (STA)-MCA is more common in adults
- Indirect bypass
  - Pial synangiosis & encephaloduroarteriosynangiosis with STA is more common in children
  - Dural inversion with middle meningeal artery

Cerebral Venous Sinus Thrombosis

KEY FACTS

TERMINOLOGY

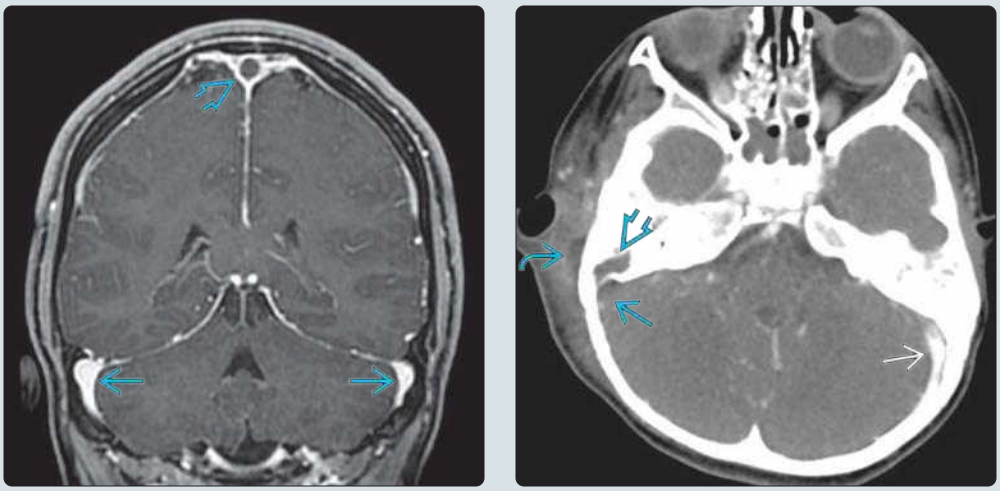
- Pathologic clot formation in cerebral veins & sinuses

IMAGING

- NECT: Acute thrombus is usually hyperdense (> 58 HU)
  - HU:hCT ratio > 1.4 ↑ sensitivity
  - Look for associated edema ± hemorrhage
- CTV: Filling defects or lack of opacification within sinus/vein
- MR: Be wary of artifacts [e.g., slow flow on spin-echo sequences, in-plane flow on time of flight (TOF)]
  - T2: Lack of flow void in affected vessels
  - FLAIR: May show edema within parenchyma
  - T2*/SWI: Blooming in areas of thrombosis
  - DWI: Look for areas of "venous infarct" within brain
  - 3D T1 GRE C+: Filling defects or nonopacification within sinus/vein, ± dural & leptomeningeal enhancement
  - PWI: ± altered areas of perfusion
  - MRV: Lack of flow-related signal in affected vessels
    - Helpful for chronic thrombus vs. recanalized vessel

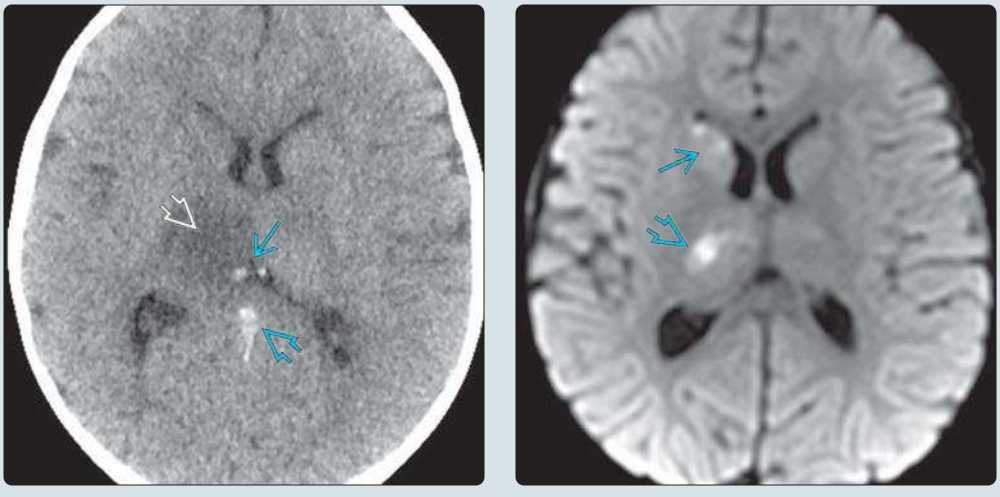
TOP DIFFERENTIAL DIAGNOSES

- Subdural hemorrhage
- Arachnoid granulation
- Normal asymmetry/hypoplasia of transverse sinuses
- Idiopathic intracranial hypertension
- Hemoconcentration



PATHOLOGY

- Virchow triad: (1) Stasis, (2) vessel injury, (3) ↑ coagulability
- Occlusive thrombus → inadequate collaterals → edema, ischemia, & hemorrhage



CLINICAL ISSUES

- Risk factors: Infection, acute systemic illness, thrombophilia, cancer, trauma, & medications
- Common symptoms: Headache, nausea/vomiting, seizures, visual disturbances

(Left) *Coronal 3D T1 C+ FS MR in a 17-year-old girl on oral contraceptives shows a lack of enhancement in the superior sagittal sinus (the empty delta sign), consistent with sinus thrombosis. Note the normal opacification of the sigmoid sinuses.* **(Right)** *Axial CECT in a 2-year-old with mastoiditis shows opacification of the right mastoid & a subperiosteal abscess. There is no contrast in the right sigmoid sinus, consistent with thrombosis. Compare to the normal left sigmoid sinus.*

(Left) *Axial NECT in a 1-year-old with left facial droop shows hyperattenuation in the bilateral internal cerebral veins & vein of Galen. Also note the ↓ attenuation & swelling of the right thalamus.* **(Right)** *Axial DWI MR in the same patient shows an enlarged right thalamus & caudate head with areas of diffusion restriction, often referred to as venous infarctions. This term should be used with caution, however, as the diffusion restriction can resolve without imaging sequelae.*

TERMINOLOGY

Definitions

- Pathologic clot formation in cerebral veins & sinuses

IMAGING

General Features

- Best diagnostic clue
  - Lack of flow or enhancement in cerebral veins & sinuses
- Location
  - Dural venous sinuses & cerebral veins
    - Transverse sinus (86%), superior sagittal sinus (62%), straight sinus (18%), cortical veins (17%), jugular veins (12%), & internal cerebral veins (11%)

CT Findings

- NECT
  - Acute thrombus is usually hyperdense; in cortical vein → dense cord sign
    - Acute thrombus detection: NECT is > 70% sensitive
      - Typically > 60 HU; suggested cutoff values range from 58-62
    - HU:hCT ratio of > 1.4 is advocated for higher sensitivity/specificity
  - Chronic thrombus is usually iso- or hypodense
- CT venography: Filling defects or lack of opacification within sinus/vein; empty delta sign in sagittal & transverse sinuses

MR Findings

- T1: Variable signal based on age of thrombus
- T2: Lack of flow void within affected sinus/vein
- FLAIR: May show edema within parenchyma
- T2*/SWI: Blooming in areas of thrombosis
  - Excellent for detection of cortical vein thrombus
- DWI: Diffusion restriction in areas of "venous infarct"
  - Changes may be reversible without permanent injury
- 3D GRE T1 C+: Filling defects within sinus/vein
  - Empty delta sign in sagittal & transverse sinuses
  - Chronic thrombus may enhance despite lack of flow
  - ± dural & leptomeningeal enhancement
- PWI: ± altered areas of perfusion due to venous congestion
- MRV: Lack of flow-related signal on time of flight (TOF) & PC sequences; T1 shortening in clot may mimic flow on TOF

Ultrasonographic Findings

- May use to evaluate sagittal & transverse sinuses in infants

Imaging Recommendations

- Best imaging tool
  - NECT + CTV: Excellent for detection of thrombus & gross parenchymal hemorrhage
  - MR + MRV: Superior to CTV in detection of parenchymal edema, infarct, & microhemorrhage
- Protocol advice
  - Use both flow-related venography (e.g., TOF or phase contrast) to distinguish chronic thrombus from patent recanalized vessel (both enhance on T1 C+)
  - 3D GRE-based T1 (e.g., BRAVO, MP-RAGE, SPGR) is best to avoid flow artifacts

DIFFERENTIAL DIAGNOSIS

Subdural Hemorrhage

- Subdural hemorrhage (SDH) along tentorium & falx may mimic thrombus
- Dense (CT) & T1 bright (MR) blood may mimic thrombus
- Multiplanar reconstructions help distinguish SDH vs. clot

Arachnoid Granulation

- Focal filling defects on CTV & MRV
- Most often occur in transverse & sagittal sinuses
- Follow CSF on MR ± small vessel within arachnoid granulation

Asymmetric or Hypoplastic Transverse Sinus

- Normal for transverse sinuses to be asymmetric in size
- If little/no flow on MRV, confirm hypoplasia with T1 C+ & T2

Idiopathic Intracranial Hypertension

- Identical symptoms of ↑ intracranial pressure (ICP)
- Look for flattening of lateral transverse sinuses

Hemoconcentration

- ↑ hCT→ ↑ blood density; may mimic thrombus
- Dense vessels throughout, including arteries
- Usually < 58 HU; HU:hCT ratio < 1.4; common in newborns

PATHOLOGY

General Features

- Virchow triad: (1) Stasis, (2) vessel injury, (3) ↑ coagulability
- ↓ venous outflow → ↑ venous pressure → ↑ ICP
- Inadequate collaterals → edema, infarction, & hemorrhage
- Chronic: Conversion of thrombus into fibrotic mass with multiple endothelial-lined channels

CLINICAL ISSUES

Presentation

- ↑ ICP: Headache, nausea/vomiting, visual symptoms, altered mental status;
- Parenchymal injury: Seizure, focal neurologic deficits

Demographics

- Risk factors: Infection (e.g., meningitis), acute illness (e.g., dehydration), thrombophilia, cancer, trauma, & medications

Natural History & Prognosis

- Neonates in general have poorer outcomes; vast majority have full recovery with appropriate therapy
- Permanent symptoms due to brain injury (e.g., hemorrhage)

Treatment

- Anticoagulation (heparin & low molecular weight heparin)

SELECTED REFERENCES

Childhood Aneurysms

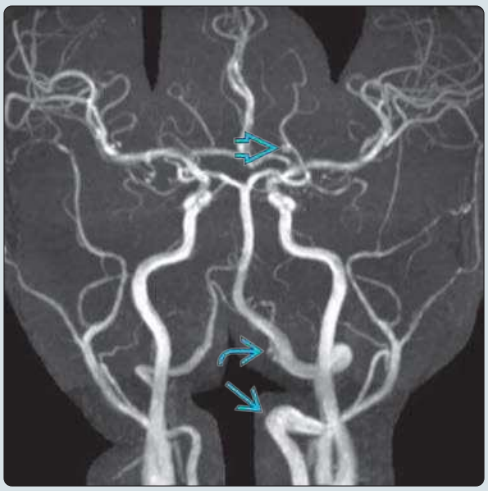
KEY FACTS

IMAGING

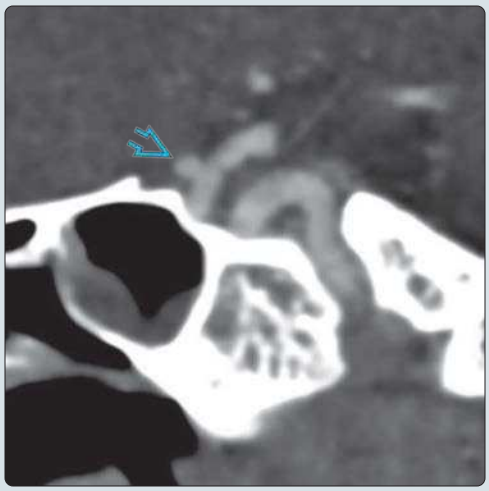
- Majority of pediatric cerebral aneurysms present with SAH
- Location: Most are located away from circle of Willis
  - ~ 80% anterior, ~ 20% posterior
- Morphology: Majority are saccular, but fusiform aneurysms are more common in children than adults
- Size: 15-20% "giant" (aneurysm > 2.5 cm)
  - May be partially thrombosed with "onion-skin" thrombus
- **NECT**: ± Ca^{2+}, especially giant aneurysms
- **CTA**: > 95% sensitivity for aneurysms > 2 mm
- **MR**: May be heterogeneous due to turbulent flow & layers of thrombus
  - Pulsation artifact (in-phase encoding direction) helps distinguish giant aneurysm from mass
- **3D TOF MRA**: > 90% sensitivity for aneurysms > 3 mm

TOP DIFFERENTIAL DIAGNOSES

- Arterial infundibulum
- Congenital cerebral aneurysmal arteriopathies

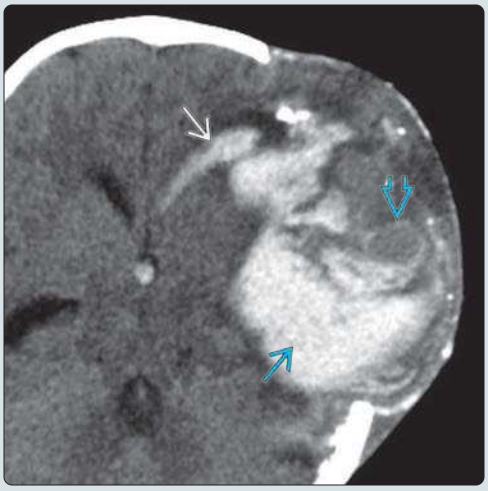


PATHOLOGY

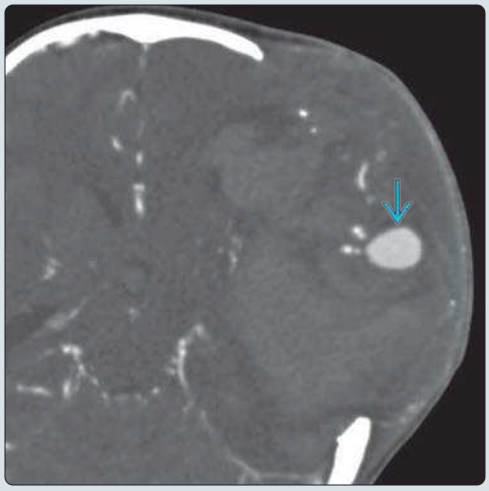


- Idiopathic (~ 45%)
- Traumatic (~ 20%)
- Vasculopathic (~ 10%)
- Infectious (mycotic) (~ 5%)
- Familial, excessive hemodynamic stress, noninfectious inflammatory, & oncotic aneurysms are less common

CLINICAL ISSUES



- < 5% of intracranial aneurysms occur < 18 years of age
- ~ 15% of hemorrhagic strokes occur in young patients
- Presentation: Sudden severe headache is most common
  - Seizure, loss of consciousness, limb weakness, & cranial nerve deficits are less common
- Prognosis: Severity of clinical presentation at time of rupture correlates with eventual outcome
- Treatment: Endovascular coiling or surgical clipping
  - Observation may be appropriate for certain types & locations of unruptured aneurysms



(Left) *Anterior 3D TOF MRA in a 16-year-old patient with sickle cell disease shows a 3-mm saccular aneurysm* ⇨ *that was arising from the C6 (ophthalmic segment) of the left internal carotid artery. Additionally, there is fusiform dilation* ⇨ *of the left V2/V3 vertebral artery segments. Protuberant foci* ⇨ *along the left posterior inferior cerebellar artery (PICA) were related to a bifid origin.* **(Right)** *Sagittal CTA in the same patient better details the neck of the 3-mm ophthalmic segment ICA saccular aneurysm* ⇨*.*

(Left) *Axial NECT in a 4-year-old girl status post gunshot wound & craniectomy shows a large intraparenchymal* ⇨ *& intraventricular* ➡ *hemorrhage. Patients with such a history are at high risk for traumatic pseudoaneurysm formation, necessitating CTA (though they may be suspected* ⇨ *prior to contrast).* **(Right)** *Axial CTA in the same patient shows a large, ovoid, contrast-opacified lesion* ⇨ *within the parenchymal hematoma, consistent with a traumatic pseudoaneurysm.*

TERMINOLOGY

Definitions

- Focal arterial outpouching or dilation presenting < 18 years

IMAGING

General Features

- Best diagnostic clue
  - Enlargement or focal deformity of artery on vascular imaging (CTA, MRA, catheter angiography)
- Location
  - Anterior circulation (~ 80%)
  - Posterior circulation (~ 20%)
- Size
  - Giant aneurysms (> 2.5 cm) are more common in children
    - ~ 15-20% in children vs. < 5% in adults
- Morphology
  - 27-78% saccular
  - 10-58% fusiform
- Multiple aneurysms are less common in children (~ 15%)
  - Usually vasculopathic or infectious when multiple

CT Findings

- NECT
  - ~ 50-70% present with hemorrhage, most commonly subarachnoid hemorrhage (SAH)
    - Intraventricular & parenchymal are much less common
  - ± Ca^{2+} (especially giant aneurysms)
- CTA
  - Excellent means of detecting & delineating aneurysms
    - CTA sensitivity for aneurysms > 2 mm: > 95%
  - Luminal imaging only; thrombosed aneurysms may be missed or mischaracterized

MR Findings

- Appearance may be heterogeneous due to turbulent flow, flow-related enhancement, or layered thrombus
- Partially thrombosed aneurysms may have lamellated appearance on MR
  - Central T1/T2 flow void (on spin-echo-based techniques) with peripheral layers of mixed signal
  - Central lumen & wall may enhance with contrast
- Pulsation artifact is key feature to distinguish giant aneurysms from other masses
- 3D TOF MRA sensitivity for aneurysms > 3 mm: > 90%

Angiographic Findings

- Most are diagnosed & characterized prior to angiography
- Catheter angiography is usually performed in concert with endovascular therapy
- Both carotid & vertebral arteries must be injected to search for additional aneurysms

Imaging Recommendations

- Best imaging tool
  - NECT & CTA for emergent evaluation of subarachnoid, intraventricular, or parenchymal hemorrhage
  - 3D TOF MRA may be used to follow known aneurysms
- Protocol advice
  - Thick MIP & 3D CTA reconstructions ↑ sensitivity for small peripheral aneurysms

DIFFERENTIAL DIAGNOSIS

Arterial Infundibulum

- Focal dilation at origin of arterial branch from circle of Willis
- Broad base, < 3-mm size, with vessel arising from apex

Congenital Cerebral Aneurysmal Arteriopathies

- Loeys-Dietz syndrome, Alagille syndrome, PHACE(S), autosomal dominant polycystic kidney disease, Ehlers-Danlos type IV, & others

PATHOLOGY

Staging, Grading, & Classification

- Classified by etiology
  - Idiopathic (~ 45%): No underlying predisposing factor
    - Usually distal to circle of Willis, saccular, & large
  - Traumatic (~ 20%): Blunt or penetrating head injury
    - Usually anterior circulation with saccular morphology
  - Vasculopathic (~ 10%): Disorders with vascular dysplasia
    - Often multiple, large, & fusiform
    - ↑ incidence in sickle cell disease, tuberous sclerosis, neurofibromatosis type 1
  - Infectious "mycotic" (~ 5%): Septicemia & endocarditis
    - Usually peripheral, saccular, & often multiple
  - Familial (~ 5%): Family history of nonsyndromic intracranial aneurysms
    - Small, anterior circulation, saccular aneurysms
  - Due to excessive hemodynamic stress (< 5%)
    - e.g., arteriovenous malformation, sickle cell disease
    - Usually small, solitary, & saccular in flow-loaded vessel
  - Noninfectious inflammatory (uncommon)
    - e.g., autoimmune vasculitis (lupus)
    - Usually multifocal, fusiform, & proximal

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - 10-15% of hemorrhagic strokes in children/young adults
  - Majority (32-89% in literature) present with SAH
    - Headache > seizure, loss of consciousness, limb weakness, & cranial nerve deficits

Demographics

- < 5% of intracranial aneurysms occur < 18 years of age

Treatment

- Endovascular coiling
- Surgical clipping

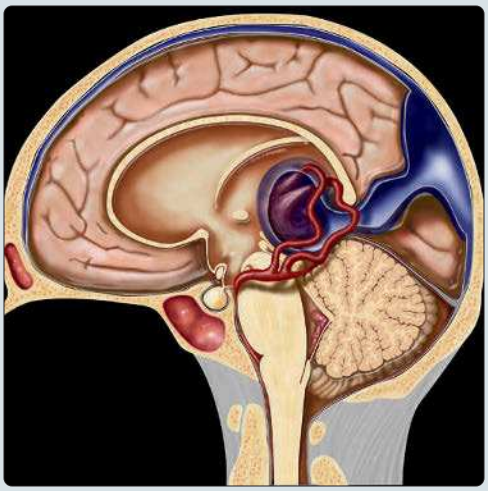
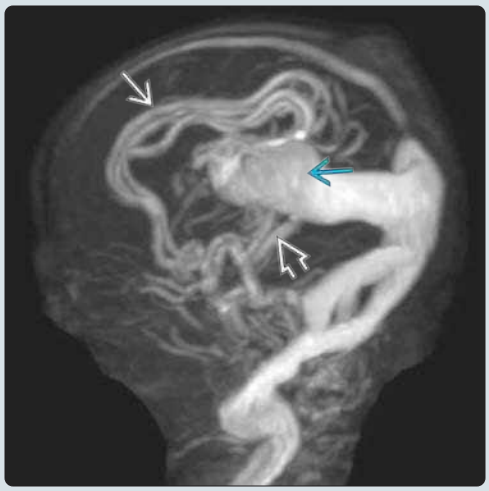
Vein of Galen Aneurysmal Malformation

KEY FACTS

TERMINOLOGY



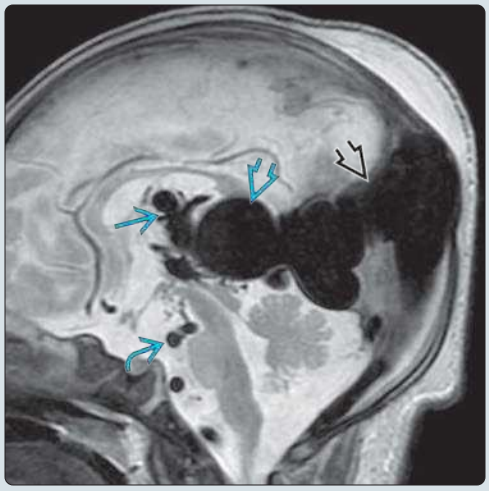
- Vein of Galen aneurysmal malformation (VGAM): High-flow arteriovenous fistula (AV) between deep choroidal arteries & median prosencephalic vein (MPV) of Markowski
- Not actually aneurysm of true vein of Galen, which fails to form because of fistula



IMAGING

- 2 major goals of imaging
  - Assess degree of brain injury
  - Define VGAM architecture to help plan embolization
- Some degree of ventriculomegaly is typical
  - ↓ CSF resorption due to venous hypertension
  - Chronic volume loss
    - Due to venous hypertension & arterial steal
  - Obstruction from compression of tectum
- Venous outflow stenosis affects end-organ damage
  - Sigmoid/jugular stenoses protect heart, injure brain
- Classification system for VGAMs (Lasjunias)
  - Choroidal type: Multiple primitive choroidal arteries pass through nidus before entering MPV
  - Mural type: 1 or more (usually multiple) direct AV fistulas within wall of MPV

CLINICAL ISSUES



- Most common extracardiac cause of high-output heart failure in newborn
- Preferred treatment: Transcatheter embolization at 4-6 months with occlusion of fistula, ideally from arterial side
  - May require staged embolizations
- Bicêtre neonatal evaluation score guides therapy
  - Assesses end-organ damage
- Prognosis is related to volume of shunt & timing/success of treatment
  - High-volume shunts requiring treatment in newborn period have worse prognosis
  - Ability to delay treatment until 4-6 months is associated with better outcome

(Left) *Sagittal graphic shows medial & lateral posterior choroidal arteries with a fistulous connection to an enlarged midline vein [median prosencephalic vein (MPV)], which drains through a persistent falcine sinus to the superior sagittal sinus. This would be a mural-type vein of Galen aneurysmal malformation (VGAM).* **(Right)** *Lateral 3D MRA with contrast in a newborn with high-output cardiac failure shows enlarged choroidal & pericallosal arteries feeding a large MPV & straight sinus. No venous outflow stenosis is identified.*

(Left) *Sagittal color Doppler US in a neonate with heart failure shows a large ovoid vascular lesion with turbulent flow located in the region of the MPV, characteristic for a VGAM.* **(Right)** *Sagittal T2 MR in the same patient shows a markedly dilated MPV & persistent falcine sinus with enlarged feeding arteries, including the basilar & internal carotid arteries (not shown). In this case, multiple feeding arteries fistulize directly into the wall of the MPV, consistent with a mural-type VGAM.*

TERMINOLOGY

Synonyms

- Vein of Galen aneurysmal malformation (VGAM), galenic varix

Definitions

- High-flow arteriovenous (AV) fistula between deep choroidal arteries & median prosencephalic vein (MPV) of Markowski
  - Not actually aneurysm of true vein of Galen, which fails to form because of fistula

IMAGING

General Features

- 2 major goals of imaging
  - Assess brain injury to determine if treatment is warranted
  - Delineate malformation architecture for embolization

CT Findings

- NECT
  - Hydrocephalus
  - Various stages of parenchymal injury, including cytoxic edema, volume loss, & white matter Ca^{2+} from chronic venous ischemia
- CTA
  - Excellent preangiography delineation of vessels

MR Findings

- Large flow void of varix
- Phase-encoding pulsation artifact from varix
- Prominent flow voids of feeding arteries around varix
- Some degree of ventriculomegaly is typical; ± ↑ T2 signal of white matter
  - ↓ CSF resorption due to venous hypertension
  - Obstruction from compression of tectum
  - Chronic volume loss
- Restricted diffusion in areas of acute ischemia/infarction
  - Due to venous hypertension & arterial steal phenomenon
  - ± focal or extensive loss of cortical ribbon on T2
- MRV: High flow through veins → venous stenoses
  - Affects end-organ damage
    - Venous stenosis protects heart at expense of brain
    - Jugular stenosis/atresia is associated with poor outcome
- MRA: Key to define architecture of lesion
  - Major arterial feeders: Targets for embolization
  - Unaffected by embolics (ideal for posttreatment evaluation)
- Perfusion: Arterial spin labeling can assess AV shunt reduction following embolization
- Fetal MR can identify malformation in 2nd & 3rd trimester & provide information about end-organ injury
  - Diameter of fetal or neonatal falcine or straight sinus may predict outcome

Angiographic Findings

- Choroidal or mural classification (Lasjunias) based on angioarchitecture of VGAM
  - Choroidal type: Primitive vessel morphology with multiple choroidal feeding arteries passing through nidus network before draining into MPV
  - Mural type: 1 or more (usually multiple) direct AV fistulas within wall of MPV
- Frequent venous abnormalities
  - Embryonic falcine sinus drains MPV in ~ 50%
  - Stenoses at sigmoid-jugular junction

PATHOLOGY

General Features

- Embryology
  - Abnormal connection of choroidal arteries to MPV occurs at 6- to 11-weeks gestation
  - Flow through fistula prevents normal regression of MPV

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Neonate: High-output CHF, cranial bruit
  - Infant: Macrocrania (hydrocephalus), seizures, or neurocognitive delay
  - Older children/adults: Usually compensated; may present with hemorrhage

Natural History & Prognosis

- Prognosis is related to volume of shunt & timing/success of treatment
  - High-volume shunts requiring treatment in newborn period have worse prognosis
- Severe cases → ischemia & cerebral atrophy: "Melting brain"
  - Due to venous insufficiency & arterial steal

Treatment

- Treatment in neonatal period is based upon Bicêtre neonatal evaluation score
  - 21-point system based upon cardiac (5), cerebral (5), respiratory (5), hepatic (3), & renal (3) function
  - High score: Good function; low score: Poor function
    - < 8: No treatment
    - 8-12: Emergent embolization
    - > 12: Medical management initially followed by delayed embolization at 4-6 months
- Transcatheter embolization
  - Permanent occlusion of fistula, ideally from arterial side
    - Liquid agents or coils
  - Outcome following embolization: 75% normal; 15% moderate impairment; 10% severe impairment

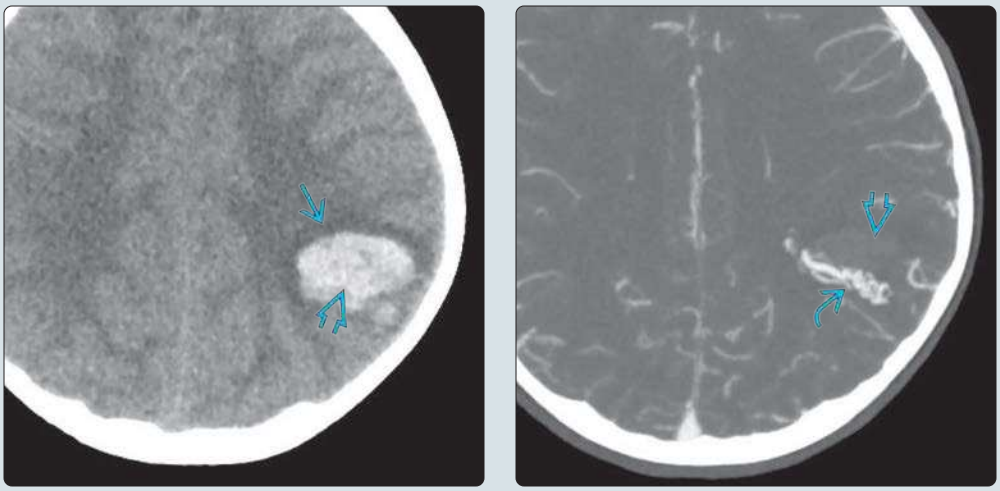
Arteriovenous Malformation

KEY FACTS

TERMINOLOGY

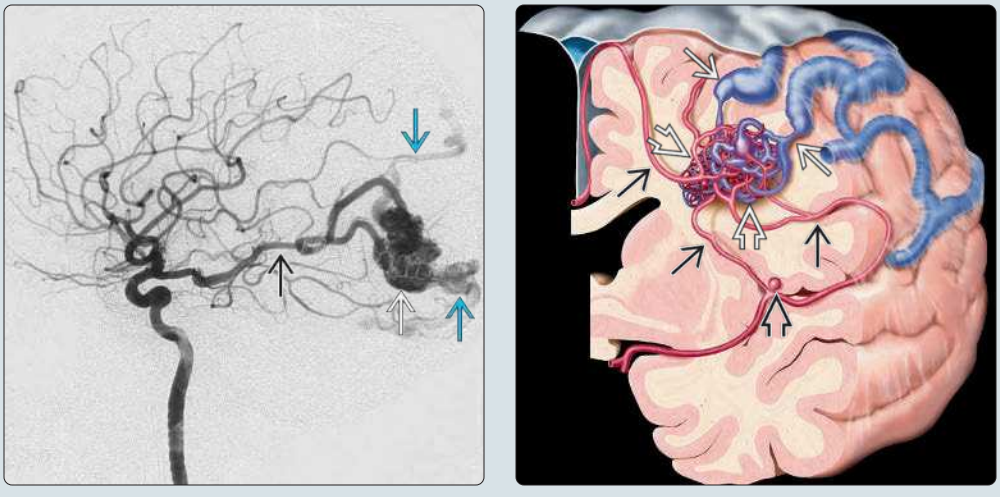
- High-flow vascular malformation with arteriovenous shunting through complex nidus of arterioles & venules (without intervening capillary bed)

IMAGING



- NECT: Parenchymal hematoma is most common
  - Small, unruptured AVMs are often not visible
- CTA: Enhancing feeding arteries, nidus, & draining veins
  - May be negative if AVM is compressed by hematoma
- MR
  - T1: Bright hemorrhage
  - T2: Prominent dark flow voids
  - T1 C+ (volumetric gradient): Enhancing abnormal vessels
- MRA: Gross depiction of AVM components
  - 3D TOF flow-related signal in draining veins from shunt
- Advanced MR
  - ASL: High signal in nidus & draining veins
  - SWI: High (arterial) signal in draining veins
- Digital subtraction catheter angiography
  - Best identifies all 3 components of AVM
    - Multiple arterial feeding vessels (internal-external carotid, vertebrobasilar)
    - Deep vs. superficial venous drainage
    - Associated arterial/nidus aneurysms, venous stenoses

PATHOLOGY



- Most AVMs are sporadic; micro-AVMs are typical in hereditary hemorrhagic telangiectasia (HHT)
- Spetzler-Martin surgical risk grading system (1-5 points)
  - Size: < 3 cm (1 point), 3-6 cm (2), > 6 cm (3)
  - Location: Eloquent (1) vs. noneloquent (0)
  - Venous drainage: Deep (1) vs. superficial (0)

CLINICAL ISSUES

- Spontaneous parenchymal hemorrhage in child should be considered AVM until proven otherwise
- Annual bleeding risk: 2-4%

(Left) *Axial NECT in a 5-year-old with new-onset seizures shows intraparenchymal hemorrhage in the left parietal lobe with surrounding low-attenuation vasogenic edema. Such a finding should prompt immediate evaluation with CTA to detect an AVM, which is the most likely underlying cause of spontaneous hemorrhage in children.* **(Right)** *Axial CTA MIP in the same patient shows a nidus of abnormal vessels along the posterior margin of the intraparenchymal hemorrhage, consistent with an AVM.*

(Left) *Lateral DSA (right ICA injection) in a 15-year-old girl shows an enlarged arterial feeder arising from the right ICA via the PCOM artery. The tightly packed nidus is well defined. Note the 2 enlarged superficial draining veins that opacify early during the arterial phase, typical of an AVM.* **(Right)** *Graphic shows a cerebral AVM with a centrum semiovale nidus fed from cortical & central arteries (with a proximal flow-related aneurysm) & drained by enlarged cortical veins.*

TERMINOLOGY

Definitions

- Arteriovenous malformation (AVM): High-flow vascular malformation with AV shunting through complex nidus of arterioles & venules (without intervening capillary bed)

IMAGING

CT Findings

- NECT: Unruptured AVM is often occult, unless large; ± Ca^{2+}
  - Ruptured AVM: Spontaneous parenchymal hemorrhage ± intraventricular extension
- CTA: Enlarged feeding arteries, nidus, draining veins
  - Nidus may be compressed by hematoma

MR Findings

- T1: Hematoma in ruptured AVM is typically of ↑ signal
- T2: Flow voids of arterial feeder, nidus, & draining veins
- FLAIR: May see adjacent gliosis, especially with prior bleed
- SWI/T2* GRE: Blooming with hemorrhagic blood products
  - Hyperintense (arterial) SWI signal in draining veins
- DWI: Usually normal on initial imaging studies
  - ± ischemic complications following intervention
- T1 C+: Avid enhancement of nidus & draining veins with GRE T1 (not spin echo)
  - Important for micro-AVMs as found in hereditary hemorrhagic telangiectasia (HHT)
- MRA/MRV: Gross depiction of AVM components
  - Flow-related signal in draining veins on 3D TOF MRA reflects AV shunt
- ASL: High signal in AVM nidus & draining veins
  - Sensitive sequence for detection of micro-AVMs

Angiographic Findings

- DSA provides high spatial & temporal resolution
  - Arterial feeders
    - Enlarged; often from multiple arteries (internal-external carotid, vertebrobasilar)
    - Feeding artery aneurysms in 10-15%
  - AVM nidus
    - Central tangle of vessels where AV shunting occurs
    - Small aneurysms within nidus (~ 50%)
  - Venous drainage
    - Must identify drainage as deep &/or superficial
    - ± venous varix, which suggests distal stenosis
    - Unbalanced inflow vs. outflow
      - Fast AV shunt + small outflow vein

Imaging Recommendations

- Best imaging tool
  - CTA for atraumatic intracranial hemorrhage on NECT
    - If initially negative, repeat when hematoma resolves as small AVM may be compressed by initial hematoma

DIFFERENTIAL DIAGNOSIS

Cavernous Malformation

- "Angiographically occult" lesion
- Popcorn appearance on MR with fluid-fluid levels, hemosiderin staining, ± Ca^{2+}

Arterial Aneurysm

- No nidus or enlarged draining veins
- Subarachnoid blood is common

Hemorrhagic Tumor

- Often enhances on MR; tumor blush on DSA
- No enlarged draining veins

Arteriovenous Fistula

- Direct AV shunting without nidus

PATHOLOGY

General Features

- Associated abnormalities
  - Syndromic AVMs (2% of cases)
    - HHT: 40-50% have micro-AVMs of brain
      - Additional lung & hepatic AVMs; cutaneous & mucosal telangiectasias

Staging, Grading, & Classification

- Spetzler-Martin scale predicts surgical morbidity: ↑ score = ↑ risk of open surgery
  - Size: < 3 cm (1 point), 3-6 cm (2), > 6 cm (3)
  - Location: Noneloquent (0) or eloquent (1)
  - Drainage: Superficial (0) or deep (1)

CLINICAL ISSUES

Presentation

- ~ 50% have acute hemorrhage (headache, ↓ consciousness), ~ 25% seizure, ~ 15% focal neurologic findings, ~ 10% incidental
  - Spontaneous parenchymal hemorrhage in child should be considered AVM until proven otherwise

Natural History & Prognosis

- Annual bleeding risk: 2-4%
- Factors that ↑ annual bleeding risk
  - Prior AVM rupture, exclusively deep venous drainage, small size (< 3 cm), single feeder, single outflow vein
- Possible factors that ↑ annual bleeding risk
  - Arterial or intranidal aneurysms
  - Unbalanced inflow vs. outflow
  - Size of outflow veins (controversial)

Treatment

- Acute surgical decompression may be required for mass effect from hematoma
- Optimal treatment for underlying AVM is based on variety of factors; options include
  - Microsurgical resection
  - Endovascular embolization
  - Stereotactic radiosurgery

Cavernous Malformation

KEY FACTS

TERMINOLOGY

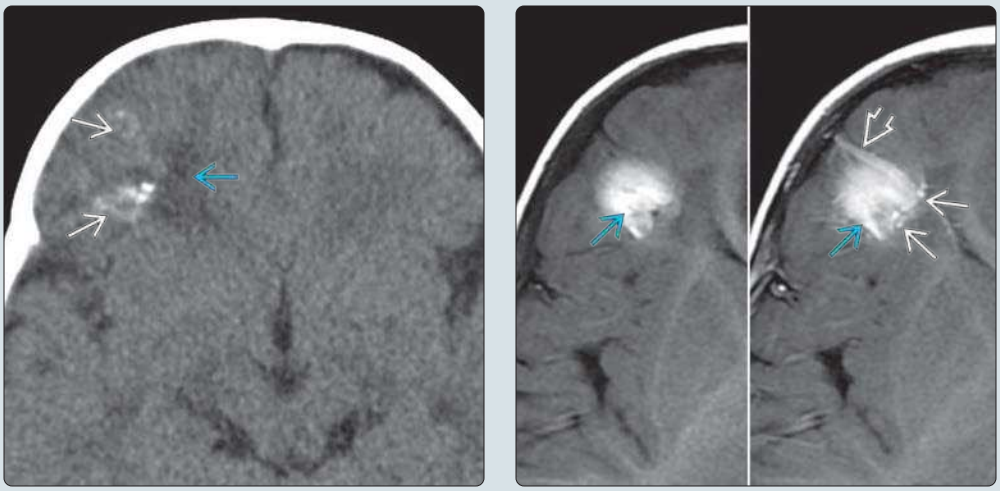
- Benign vascular lesion with dilated sinusoids lined by thin, immature walls & containing blood products of various ages

IMAGING

- Supratentorial > infratentorial > spinal cord
- Vary in size from microscopic to giant (> 6 cm)
- **CT**: Hyperdense lesion ± Ca^{2+}; 50% are not visible
- **MR**: Heterogeneous core with T2-hypointense rim
  - Popcorn ball appearance with internal fluid-fluid levels
  - Adjacent ↑ FLAIR signal suggests recent hemorrhage
  - SWI/T2* GRE is most sensitive for small lesions
  - Absent or minimal enhancement, except for associated developmental venous anomaly (DVA)

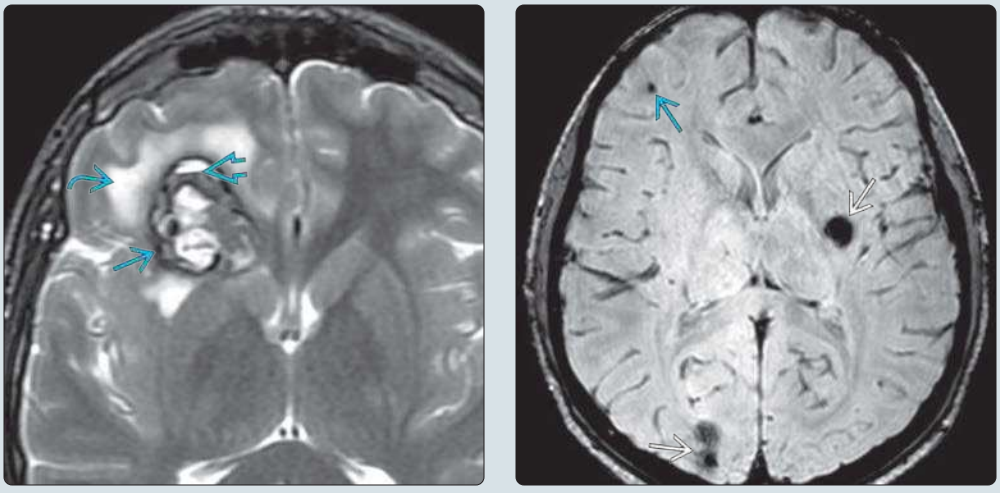
TOP DIFFERENTIAL DIAGNOSES

- Diffuse axonal injury
- Intracerebral hematoma
- Neoplasm



PATHOLOGY

- Etiology: Initial parenchymal microhemorrhage is followed by neoangiogenesis & recurrent hemorrhage
  - ↑ in size from recurring intralesional hemorrhages
- Multiple (familial) cavernous malformation syndrome: Autosomal dominant
  - *KRIT1* (CCM1), *CCM2, PDCD10* (CCM3) genes; variable penetrance
- 25% of CMs are associated with DVAs



CLINICAL ISSUES

- 0.6% incidence in children undergoing brain MR
- 50% incidental, 25% seizures, 25% neurologic deficits
- 70% solitary, 30% multiple (if familial or prior radiation)
- Factors that ↑ annual risk of hemorrhage are
  - Zabramski MR classification (I & II > III, IV)
  - Prior hemorrhage; brainstem location; associated DVA
- Treatment: Total surgical excision, sparing DVA

(Left) *Axial NECT in a 1-year-old patient with focal facial seizures shows heterogeneous high attenuation in the right frontal lobe with low attenuation (edema) deep to the lesion.* **(Right)** *Axial T1 (left) & T1 C+ (right) MR images in the same patient demonstrate intrinsically high signal (Zabramski type I) in the lesion. There are multiple small vessels along the medial margin coalescing into a draining vein, consistent with a developmental venous anomaly (DVA). DVAs are found in ~ 25% of cavernous malformations (CMs).*

(Left) *Axial T2 MR in a 16-year-old patient shows a characteristic CM with a hypointense rim & fluid level. The adjacent vasogenic edema suggests recent hemorrhage of the CM.* **(Right)** *Axial SWI MR in a 15-year-old patient with multiple familial CM syndrome shows 2 larger lesions in the left basal ganglia & right occipital lobe + a smaller lesion (Zabramski IV) in the right frontal lobe. The 2 larger lesions were visible on T2, but the smaller lesion was only visible on the more sensitive SWI sequence.*

TERMINOLOGY

Definitions

- Cavernous malformation (CM): Benign vascular lesion arising in CNS
- Consists of dilated sinusoids containing blood products of various ages & lined by thin, immature walls

IMAGING

General Features

- Location: Can be found throughout CNS
  - Supratentorial: ~ 80%
  - Infratentorial: ~ 20%
  - Rarely in spinal cord, except in multiple CMs
- Vary in size from microscopic to giant (> 6 cm)

CT Findings

- **NECT**: Round or irregular hyperdense lesion
  - ± hemorrhage & associated perilesional edema
  - Often shows small areas of Ca^{2+}
  - CT is negative in up to 50%, especially for small lesions
- **CECT**: No enhancement of actual lesion
  - ± associated developmental venous anomaly (DVA)

MR Findings

- **T1**: Heterogeneous with blood of varied ages & Ca^{2+}
- **T2**: Mixed signal core with complete hypointense rim corresponding to hemosiderin
  - Numerous septations or locules
  - ± fluid-fluid levels of layering blood products
  - Small lesions may appear as focal hypointensities
- **FLAIR**: Surrounding edema suggests recent hemorrhage
- **SWI/T2* GRE**: Exaggerated signal loss (blooming)
  - Most sensitive for detection of small CMs
    - Numerous punctate hypointense foci (black dots)
- **DWI**: Usually normal; may show susceptibility effect
- **T1 C+**: Minimal or no enhancement
  - Associated enhancing DVA in ~ 25% of cases
- **MRA**: Normal
  - CMs are "angiographically occult"

DIFFERENTIAL DIAGNOSIS

Diffuse Axonal Injury

- Multiple small foci of hemosiderin deposition
- History of prior trauma with severe neurologic impairment

Venous Infarction

- More often hemorrhagic compared to arterial infarction
- Less complex-appearing without hemosiderin rim if acute

Intracerebral Hematoma

- Usually more simple-appearing
- No hemosiderin at acute presentation

Neoplasm

- Hemorrhage or Ca^{2+} in primary brain tumor
- Often has enhancing soft tissue component

Neurocysticercosis

- May mimic familial CM with many small CNS Ca^{2+}

Capillary Telangiectasia

- Subtle enhancement following contrast administration

PATHOLOGY

General Features

- Etiology
  - Initial microhemorrhage from variety of conditions followed by neoangiogenesis & recurrent hemorrhage
    - ↑ vascular permeability (familial CMs); ↑ venous flow/pressure (CMs associated with DVAs); small vessel injury (CMs associated with radiation)
- Genetics
  - Multiple (familial) CM syndrome: Autosomal dominant
    - 3 separate loci implicated: *KRIT1* (CCM1), *CCM2*, *PDCD10* (CCM3)
- Associated abnormalities
  - DVA: 25% of CMs have associated DVA; < 5% of DVAs have associated CM

Staging, Grading, & Classification

- Zabramski classification of CMs
  - Type I: Subacute hemorrhage (↑ T1; ↑ or ↓ T2)
  - Type II: Reticulated mixed T1 & T2 with ↓ T2 rim
  - Type III: Chronic hemorrhage (iso/↓ T1; ↓ T2)
  - Type IV: Tiny microhemorrhages only seen on SWI/T2*

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Identified incidentally (40-50%)
  - Seizures (20-25%)
  - Neurologic deficit from hemorrhage (20-25%)

Demographics

- ~ 0.6% prevalence in all children undergoing brain MR
- ~ 70% solitary, 30% multiple

Natural History & Prognosis

- Factors that ↑ risk of symptomatic hemorrhage in children
  - Prior hemorrhage: 11.3% annually
  - Brainstem or spine location: 16.7% & 8.2% annually
  - Associated DVA: 9.7% annually
- Annual risk of hemorrhage also predicted by MR imaging
  - Zabramski I & II: 23.4% (5-60% in literature)
  - Zabramski III: 3.4% (0-6% in literature)
  - Zabramski IV: 1.3%

Treatment

- Total removal via microsurgical resection
- If DVA is present, venous drainage should be preserved
  - DVA removal → venous injury & venous infarct

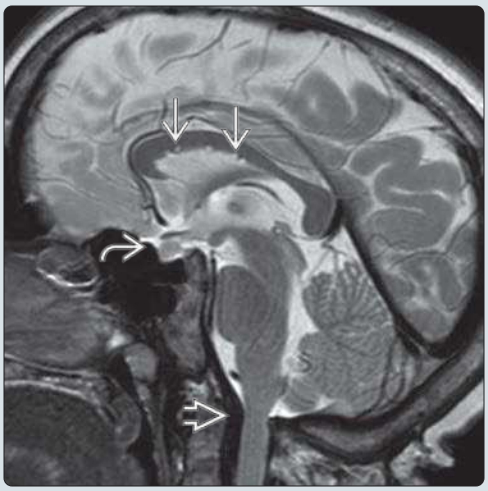
KEY FACTS

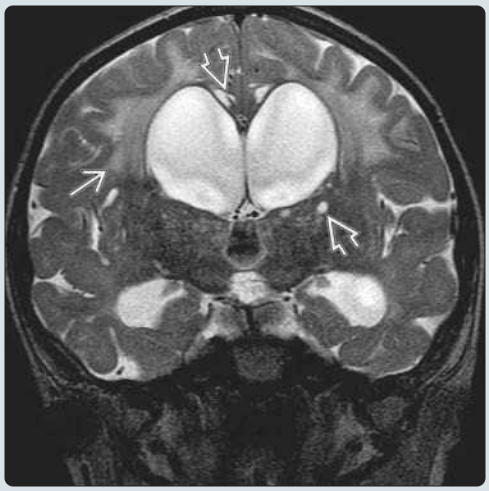
TERMINOLOGY

- Peroxisomal biogenesis disorders (PBD)
  - Zellweger syndrome (ZS)
- Mucopolysaccharidoses (MPS)
- Organic & aminoacidopathies
  - Molybdenum cofactor deficiency (MoCD)
  - Nonketotic hyperglycinemia (NKH)
- Urea cycle disorders
- Fatty acid oxidation disorders
  - Short-, medium-, & long-chain acyl-CoA dehydrogenase deficiency (SCAD, MCAD, LCAD)

IMAGING

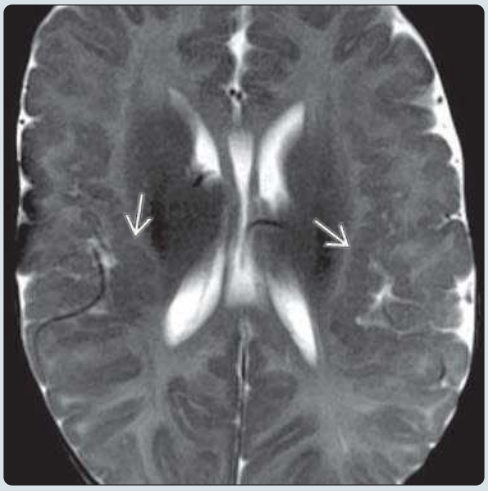


- ZS: Polymicrogyria is most severe in perisylvian region
- MPS: Enlarged perivascular spaces, confluent WM lesions
- MoCD: Hypoxic ischemic encephalopathy mimic
- NKH: Causes vacuolating myelinopathy, affecting structures that are myelinated at birth

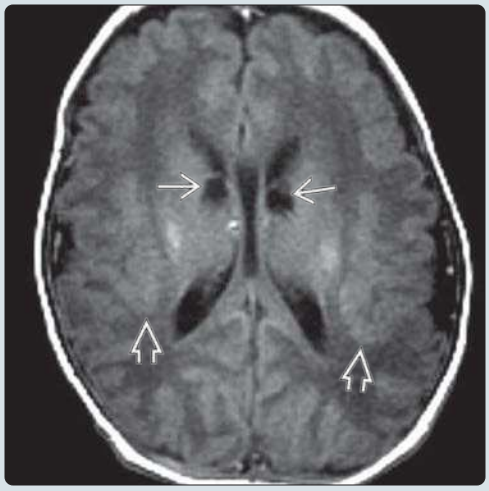


TOP DIFFERENTIAL DIAGNOSES

- Hypoxic ischemic encephalopathy
  - Many metabolic disorders are thought to represent perinatal asphyxia at 1st presentation
- Traumatic brain injury
- Mitochondrial encephalopathies
  - May present with encephalopathy or stroke-like symptoms
- Leukodystrophies
  - Do not have migrational abnormalities like PBD



DIAGNOSTIC CHECKLIST



- Remember to consider metabolic diseases when encountering acutely ill neonate
- Characteristic laboratory abnormalities may provide clue
  - Hyperammonemia → urea cycle disorder
  - Severe hypoglycemia → MCAD deficiency

(Left) *Sagittal T2 MR in a 12-year-old with Hurler syndrome shows dilated perivascular spaces, flattening of the anterior clinoids, & hypertrophy of the tectorial membrane.* **(Right)** *Coronal T2 MR shows confluent white matter (WM) lesions & dilated perivascular spaces in the corpus callosum & basal ganglia in this 5-year-old with Hunter syndrome (MPS 2). Perivascular space dilation is most pronounced in MPS 1 & 2 with WM lesions more common in 1, 2, 3, & 7.*

(Left) *Axial T2 MR in a 4-month-old with failure to thrive, hypotonia, & elevated liver enzymes shows polymicrogyria lining the sylvian fissure in each hemisphere. In combination with liver dysfunction, this is indicative of Zellweger syndrome.* **(Right)** *Axial T1 MR shows perisylvian polymicrogyria & germinolytic cysts in this 2-week-old with neonatal adrenoleukodystrophy, a peroxisomal biogenesis disorder with less severe enzymatic deficiencies than Zellweger syndrome.*

TERMINOLOGY

Definitions

- Inborn errors of metabolism affecting brain
  - Exclusive of mitochondrial encephalopathies & leukodystrophies
- Peroxisomal biogenesis disorders (PBD)
  - Severe: Zellweger syndrome (ZS)
  - Moderate: Neonatal adrenoleukodystrophy (NALD)
  - Mild: Infantile Refsum disease
- Mucopolysaccharidoses (MPS)
  - Lysosomal storage disease
  - Hunter, Hurler, Sanfilippo, Morquio, Maroteaux-Lamy, Sly, Natowicz syndromes
- Organic & aminoacidopathies
  - Molybdenum cofactor deficiency (MoCD)
  - Maple syrup urine disease (MSUD)
  - Phenylketonuria (PKU)
  - Nonketotic hyperglycinemia (NKH)
- Urea cycle disorders
  - Deficiency of enzymes in urea cycle
- Fatty acid oxidation disorders
  - Short-chain acyl-CoA dehydrogenase deficiency (SCAD)
  - Medium-chain acyl-CoA dehydrogenase deficiency (MCAD)
  - Long-chain acyl-CoA dehydrogenase deficiency (LCAD, VLCAD)
  - Carnitine palmitoyl transferase deficiencies (CPT1, CPT2)

IMAGING

Key Imaging Findings

- ZS
  - Leukoencephalopathy with abnormal myelin in corticospinal tracts & dentate nuclei
  - Polymicrogyria is most severe in perisylvian region
  - Germinolytic cysts near foramen of Monro
  - May see T1 shortening in globus pallidus from hyperbilirubinemia
  - May see enhancement of corticospinal tracts in brainstem
- MPS
  - CNS imaging abnormalities due to accumulated glycosaminoglycan (GAG)
  - Enlarged perivascular spaces
    - Pronounced in MPS 1 & 2
    - Not seen in MPS 4, 7, 9
  - Confluent WM lesions
    - Hypointense T1, hyperintense T2/FLAIR
    - Pronounced in MPS 1, 2, 3, & 7
  - Hydrocephalus & cortical atrophy
- MSUD
  - Edema prominently involving brainstem & cerebellar WM
  - Hypointense on T1, hyperintense on T2, hypodense on CT
  - Cytotoxic edema → markedly restricted diffusion
- MoCD
  - Diffuse cerebral edema/infarction
  - Diffusion restriction in globus pallidi & upper brainstem
  - Hypoxic-ischemic encephalopathy (HIE) mimic
- PKU
  - ↑ signal on T2 in periventricular WM
- NKH
  - Restricted diffusion & abnormal signal in posterior limb of internal capsule, dorsal midbrain, cerebellar WM in neonate
    - Causes vacuolating myelinopathy, affecting structures that are myelinated at birth
- Urea cycle disorders
  - Diffuse brain edema, not sparing basal ganglia or thalami
- MCAD deficiency
  - Cerebral cortical edema

DIFFERENTIAL DIAGNOSIS

Hypoxic Ischemic Encephalopathy

- Many metabolic disorders are thought to represent perinatal asphyxia at 1st presentation
- Atypical response to treatment raises concerns for metabolic disease

Traumatic Brain Injury

- May present with diffuse edema
- Close evaluation for signs of trauma is essential in obtunded neonate

Mitochondrial Encephalopathies

- May present with encephalopathy or stroke-like symptoms

Leukodystrophies

- Do not have migrational abnormalities like PBD

PATHOLOGY

PBD

- Defective transport of proteins into peroxisomal matrix → accumulation of very long chain fatty acids (VLCFA)
- ↓ peroxisomal function
  - Elevated plasma levels of sphingomyelin, VLCFA, pristanic acid, phytanic acid, pipecolic acid
- Caused by mutations in 1 of 14 known *PEX* genes
  - 70% associated with *PEX1* mutations
  - 15-20% associated with *PEX6* mutations

MPS

- Deficiencies of various enzymes required to break down GAG → accumulation of GAG in multiple organs, including brain & connective tissues
  - MPS 1 (Hurler): α-L-iduronidase
    - *IDUA* gene on chromosome 4
  - MPS 2 (Hunter): Iduronate 2-sulfatase
    - *IDS* gene on X chromosome
  - MPS 3 (Sanfilippo): Heparan sulfamidase
    - *SGSH* gene on chromosome 17
    - *NAGLU* gene on chromosome 17
    - *HGSNAT* gene on chromosome 8
    - *GNS* gene on chromosome 12
  - MPS 4 (Morquio): Galactose 6-sulfatase
    - *GALNS* gene on chromosome 16
    - *GLB1* gene on chromosome 3
  - MPS 6 (Maroteaux-Lamy): Arylsulfatase B
    - *ARSB* gene on chromosome 5

- MPS 7 (Sly): β-glucuronidase
  - *GUSB* gene on chromosome VII
- MPS 9 (Natowicz): Hyaluronidase
  - *HYAL1* gene on chromosome 3

Organic & Aminoacidopathies

- MoCD: Mutations in either *MOCS1*, *MOCS2*, or *GPHN* → inability to synthesize molybdopterin → deficiency of sulfite oxidase, xanthine dehydrogenase, aldehyde oxidase, & mitochondrial amidoxime reducing component
  - Enzyme deficiencies result in accumulation of sulfite, taurine, S-sulfocysteine, & thiosulfate
- MSUD: ↓ activity of branched chain α-keto acid dehydrogenase complex → accumulation of branched chain amino acids, particularly L-leucine
- PKU: ↓ phenylalanine dehydroxylase → accumulation of phenylalanine in brain (toxic to developing brain)
- NKH: Defect in 1 of 4 protein components (usually P-protein) of glycine cleavage system → accumulation of glycine (toxic to developing brain)

Urea Cycle Disorders

- Deficiencies of specific urea cycle enzymes
  - Ornithine transcarbamylase
  - Carbamoyl phosphate synthetase 1
  - Argininosuccinate synthetase (citrullinemia)
  - Arginase (argininemia)
  - N-acetylglutamate synthetase
  - Ornithine translocase (ORNT1 deficiency, hyperornithinemia-hyperammonemia-homocitrullinuria syndrome)
  - Citrin deficiency
- Enzyme deficiencies prevent conversion of ammonia into urea → hyperammonemia, neurotoxicity

Fatty Acid Oxidation Disorders

- MCAD deficiency: Enzyme deficiency prevents oxidization of medium-chain fatty acids → hypoketotic hypoglycemia when fatty acid oxidation is required to supplement cellular energy stores

CLINICAL ISSUES

PBD

- Severe hypotonia, seizures, poor sucking
- Elevated liver enzymes, hepatomegaly
- Characteristic facies in ZS: High forehead, broad nasal bridge, hypertelorism
- Renal cortical cysts

MPS

- Progressive coarsening of features, developmental delay
- Skeletal dysplasia: Dysostosis multiplex (**not** in MPS 3 or 9)
  - Flattening of anterior clinoid processes (J-shaped sella)
  - Inferior vertebral beaking (superior notch)
    - Middle of vertebral body in MPS 4
  - Rounded iliac wings
  - Thick diaphyses & metacarpals
  - Oar-shaped ribs
- Atlantoaxial instability
  - Result of odontoid hypoplasia & ligamentous laxity
  - Compensatory ligamentous hyperplasia contributes to craniocervical junction stenosis

Organic & Aminoacidopathies

- Catastrophic illness in neonatal period
- MoCD: Unremitting seizure activity
  - Type A, caused by mutations in *MOCS1*, amenable to treatment with *E. coli* derived cyclic PMP

Urea Cycle Disorders

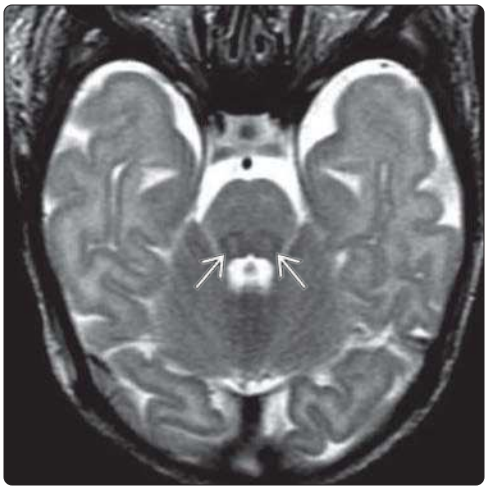
- Hyperammonemia & coma in neonatal period

Fatty Acid Oxidation Disorders

- Severe hypoglycemia in response to illness or fasting

DIAGNOSTIC CHECKLIST

Consider



- Remember to consider metabolic diseases when encountering acutely ill neonate

Image Interpretation Pearls

- Characteristic laboratory abnormalities may provide clue
  - Hyperammonemia → urea cycle disorder
  - Severe hypoglycemia → MCAD deficiency

(Left) *Axial T2 MR in a 3-day-old with nonketotic hyperglycinemia (NKH) shows the characteristic "owl's eye" paired signal abnormalities in the central tegmental tracts of the brainstem. Although this finding is not specific for NKH, it should raise the possibility of the diagnosis in the appropriate clinical setting.* **(Right)** *Axial T2 MR in an infant with maple syrup urine disease shows striking edema in the pons & cerebellar WM. This degree of brainstem edema should raise concern for metabolic brain disease.*

(Left) *Axial NECT in a 2-year-old presenting with severe hypoglycemia & seizures due to a medium-chain acyl-CoA dehydrogenase deficiency shows ↓ attenuation of the cerebrum with preservation of the basal ganglia.* **(Right)** *Axial NECT in a neonate with an inborn deficiency of ornithine transcarbamylase (a urea cycle enzyme) shows diffuse cerebral & basal ganglia low attenuation with loss of gray matter-white matter differentiation from cytotoxic edema brought on by hyperammonemia.*

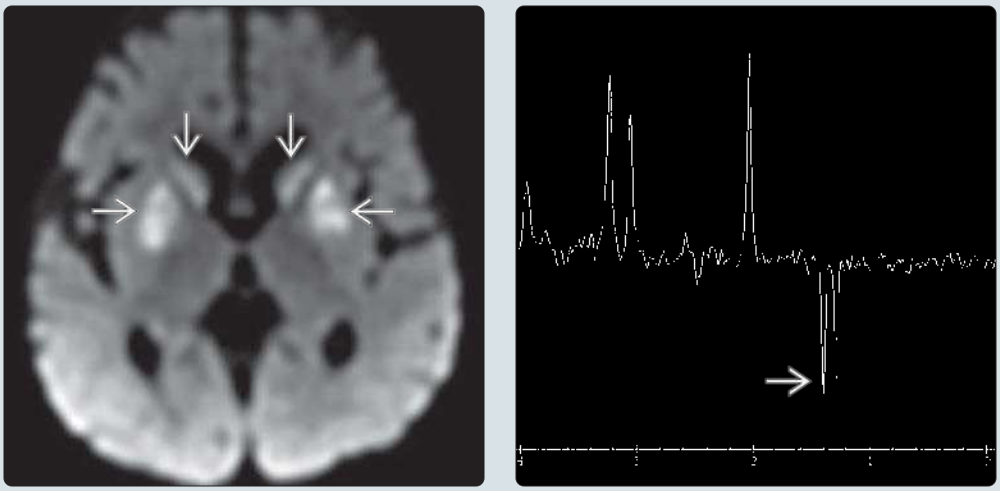
(Left) *Coronal FLAIR MR shows ill-defined, abnormal hyperintensity in the periventricular WM of this teenager with Sanfilippo syndrome (MPS 3).* **(Right)** *Axial T2 MR shows bilateral & symmetric volume loss & gliosis in the insular cortex & periventricular WM as a consequence of prior hyperammonemia in this 20-month-old with citrullinemia, a urea cycle disorder caused by deficiency of argininosuccinate synthetase.*

Mitochondrial Encephalopathies

KEY FACTS

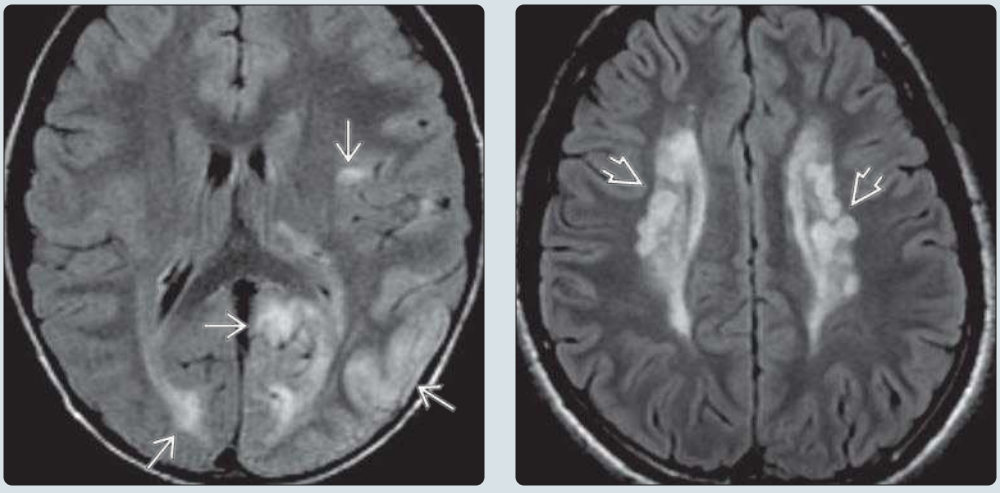
TERMINOLOGY

- Genetically based disorders of mitochondrial function resulting in progressive or intermittent brain injury
  - Leigh syndrome (LS)
  - Myopathy, encephalopathy, lactic acidosis, & stroke-like episodes (MELAS)
  - Kearns-Sayre syndrome (KSS)
  - DNA polymerase γ-related disorders (POLG-RD)
  - Disorders of pyruvate metabolism
    - Pyruvate dehydrogenase (PDH) deficiency
  - Mitochondrial aminoacyl tRNA synthetase deficiencies
    - Leukoencephalopathy with brainstem & spinal cord involvement & high lactate (LBSL)
- Mitochondrial dysfunction has been associated with myriad clinical pathologies, ranging from autism to Alzheimer dementia to normal aging



IMAGING

- Broad range of imaging appearances, characterized by regions of edema, brain destruction, volume loss, &/or mineralization
- Typically hyperintense lesions on T2 & FLAIR
  - LS typically causes speckled pattern in deep nuclei
- MRS can be helpful although often nonspecific
  - ↑ lactate & restricted diffusion can be clue to true etiology
    - Especially if found in normal-appearing regions
- Cerebellar atrophy is common feature



PATHOLOGY

- LS → associated with mutations in > 60 genes, both mitochondrial (mtDNA) & nuclear (nDNA)
  - As specific mutations affecting specific metabolic pathways are determined, enzymatic deficiencies resulting in LS are now diagnosed as separate entities

(Left) *Axial DWI MR in a 10-month-old with hypotonia & developmental delay shows restricting lesions in the basal ganglia that are bilateral & relatively symmetric, characteristic of mitochondrial encephalopathy.* **(Right)** *Intermediate (144 msec) echo proton MR spectroscopy acquired in one of the lesions in this patient shows a characteristic inverted doublet at 1.3 ppm, indicating elevated lactate. This child has Leigh disease caused by a mitochondrial DNA mutation.*

(Left) *Axial FLAIR MR in a 7-year-old with seizures shows numerous stroke-like lesions in both hemispheres, not correlating with arterial territories. A diagnosis of myopathy, encephalopathy, lactic acidosis, & stroke-like episodes (MELAS) was confirmed.* **(Right)** *Axial FLAIR MR in a teenager with LBSL shows extensive bilateral signal abnormalities in the corona radiata. The patient's only symptoms were transient paresthesias (tingling) in the lower extremities.*

TERMINOLOGY

Abbreviations

- Mitochondrial encephalopathies (MEs)

Definitions

- Genetically based disorders of mitochondrial function resulting in progressive or intermittent brain injury
  - Leigh syndrome (LS)
  - Myopathy, encephalopathy, lactic acidosis, & stroke-like episodes (MELAS)
  - Kearns-Sayre syndrome (KSS)
  - DNA polymerase γ-related disorders (POLG-RD)
  - Disorders of pyruvate metabolism
    - Pyruvate dehydrogenase (PDH) deficiency
  - Mitochondrial aminoacyl tRNA synthetase deficiencies
    - Leukoencephalopathy with brainstem & spinal cord involvement & high lactate (LBSL)
- Mitochondrial dysfunction has been associated with myriad clinical pathologies, ranging from autism to Alzheimer dementia to normal aging

IMAGING

General Features

- Best diagnostic clue
  - Broad range of imaging appearances, characterized by regions of edema, brain destruction, volume loss, &/or mineralization
    - LS, PDH deficiency: Symmetric speckled lesions in basal ganglia (BG)
    - MELAS: Peripheral, stroke-like lesions
    - KSS: Cerebellar atrophy, ↑ T2 in subcortical white matter (WM)
    - POLG-RD: Volume loss, asymmetric thalamic lesions with restricted diffusion
    - LBSL: ↑ T2 in WM, posterior limbs of internal capsules, dorsal columns of spinal cord
- Location
  - Variable: Most common in BG, brainstem, thalami, dentate nuclei

Imaging Recommendations

- Protocol advice
  - MRS can be helpful but is often nonspecific
  - ↑ lactate & restricted diffusion can be clue to true etiology, especially if found in normal-appearing brain

DIFFERENTIAL DIAGNOSIS

Hypoxic Ischemic Encephalopathy

- Central pattern of injury → ventrolateral thalamus & BG

Near Drowning

- History is generally definitive

Neurofibromatosis Type 1

- Signal abnormalities in globus pallidus (GP) are most common brain manifestation in children

Encephalitis

- Viral encephalitides can cause symmetric ↑ T2 of BG
- Acute disseminated encephalomyelitis can affect BG, mimic MELAS/myoclonic epilepsy with ragged red fibers (MERRF)

PATHOLOGY

General Features

- Genetics
  - Syndromes attributed to mutations in mtDNA
    - MELAS
    - KSS
    - LHON
    - MERRF
  - Syndromes attributed to mutations in nDNA
    - POLG-RD
      - Alpers-Huttenlocher syndrome
      - Myoclonic epilepsy, myopathy, sensory ataxia (MEMSA)
      - Ataxia neuropathy spectrum (ANS)
    - Mitochondrial neurogastrointestinal encephalomyopathy (MNGIE)
    - Coenzyme Q10 (CoQ10) deficiency
  - LS → associated with mutations in > 60 genes, both mtDNA & nDNA
- Associated abnormalities
  - KSS → ophthalmoplegia, heart block, retinitis pigmentosa
  - Alpers → micronodular cirrhosis
- Broad phenotypic presentations are due to varied distribution of mitochondria throughout various cell types

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Psychomotor delay/regression, hypotonia
  - Stroke-like episodes, episodic paresis
  - Metabolic stressors (e.g., infection) may unmask disease or cause deterioration

Demographics

- Age: Majority have clinical symptoms in infancy
  - MELAS usually presents in teenagers
  - Age at onset & severity correlates with degree of enzyme deficit

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Think of MEs when encountering atypical presentation of stroke, severe encephalitis, or seizure
- Bilateral, speckled, hyperintense lesions on T2 & FLAIR MR = LS or PDH deficiency
- Bilateral GP lesions = toxin exposure, hypoxic-ischemic injury (HIE), or mitochondrial dysfunction
- Cerebellar atrophy is common feature in MEs

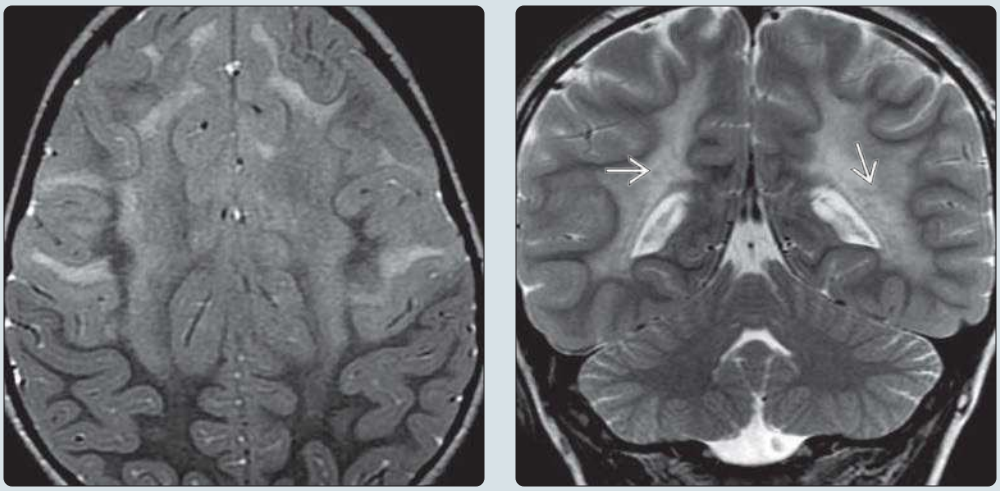
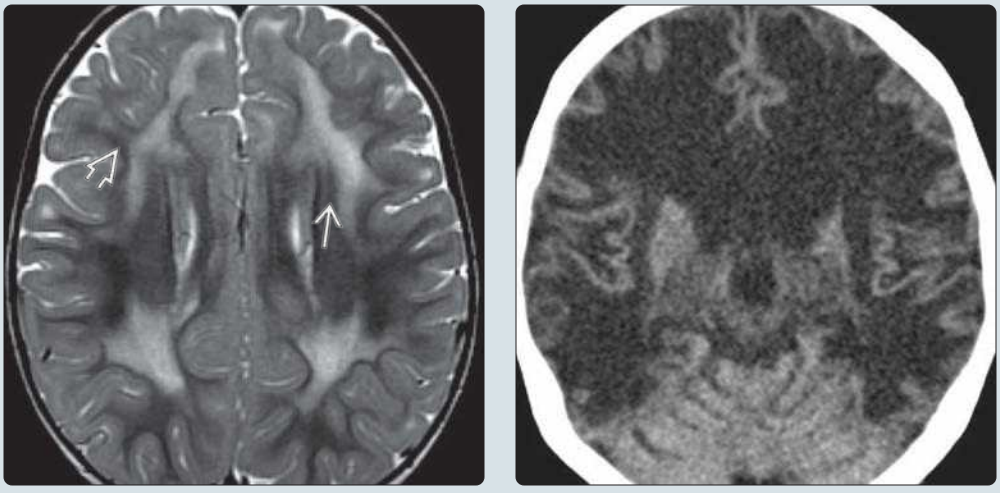
Leukodystrophies

KEY FACTS



TERMINOLOGY

- Heritable disorders primarily impacting structure & function of white matter (WM) in CNS
- Recent classification is based upon component of WM that is impacted
  - Myelin & oligodendrocytes
    - Metachromatic leukodystrophy (MLD), X-linked adrenoleukodystrophy (ALD), Canavan disease
  - Astrocytes
    - Alexander disease (AD), megalencephalic leukodystrophy with subcortical cysts (MLC), vanishing WM (VWM), globoid cell leukodystrophy (GLD, Krabbe disease)
  - Neurons & axons
    - POLR3-related leukodystrophies, hypomyelination with atrophy of basal ganglia & cerebellum (H-ABC)



IMAGING

- ALD
  - Characteristic early involvement of parietal periventricular WM
  - Enhancement of zone of active inflammation
- MLD
  - Early sparing of subcortical U fibers & perivascular WM → tigroid appearance
- GLD
  - ↑ density on CT in basal ganglia
- AD
  - Enhancement of ventricular lining, periventricular rim, frontal WM, & more
- Canavan disease
  - Megalencephaly with ↑ signal in occipital WM early, progressing to entire brain
  - ↑ NAA on MRS
- MLC
  - Subcortical cysts in anterior temporal &/or frontal WM

(Left) *Axial T2 MR in a 3-year-old with Alexander disease shows bilateral & symmetric abnormal signal in the cerebral white matter (WM). The frontal predominance is characteristic of this leukodystrophy caused by accumulation of GFAP.* **(Right)** *Coronal T2 MR in a 9-year-old with metachromatic leukodystrophy shows abnormal hyperintense cerebral WM signal interrupted by speckled/linear regions of preserved signal. The linear streaks of normal signal give rise to the phrase "tigroid demyelination."*

(Left) *Axial T2 MR in a 20-month-old with macrocephaly shows normal WM signal both proximal & distal to regions of myelin edema, confirming that this signal does not represent hypomyelination. This is MLC2B, a more benign phenotype of megalencephalic leukoencephalopathy caused by dominant mutations in the GLIALCAM gene.* **(Right)** *Axial NECT in a 9-year-old with vanishing WM shows marked hypoattenuation throughout the cerebral WM, caused by extensive myelin vacuolization & edema.*

TERMINOLOGY

Definitions

- Heritable disorders primarily impacting structure & function of white matter (WM) in CNS

Classification

- Multiple classification schemes have been proposed
  - Based on clinical phenotype, imaging phenotype, pathologic phenotype, &/or cellular organelle affected
- Recent classification is based upon component of WM impacted
  - Myelin & oligodendrocytes
    - Metachromatic leukodystrophy (MLD), X-linked adrenoleukodystrophy (ALD), Canavan disease
  - Astrocytes
    - Alexander disease (AD), megalencephalic leukodystrophy with subcortical cysts (MLC), vanishing WM (VWM), globoid cell leukodystrophy (GLD, Krabbe disease)
  - Neurons & axons
    - POLR3-related leukodystrophies, hypomyelination with atrophy of basal ganglia & cerebellum (H-ABC)

IMAGING

General Features

- Location
  - Some leukodystrophies have characteristic distributions, especially early in disease course
- ALD
  - Characteristic early involvement of parietal periventricular WM
  - Enhancement of zone of active inflammation
- MLD
  - ↑ signal in hemispheric WM on T2
  - Early sparing of subcortical U-fibers & perivascular WM
- GLD
  - ↑ density on CT in basal ganglia
- AD
  - Megalencephaly with ↑ signal in frontal WM, thalami, & brainstem structures on T2
  - Enhancement of ventricular lining, periventricular rim, frontal WM, & more
- Canavan disease
  - Megalencephaly with ↑ signal in occipital WM early, progressing to entire brain
  - ↑ NAA on MRS
- VWM
  - Diffuse ↑ WM signal on T2, ↓ on T1
- MLC
  - Megalencephaly with swelling & ↑ signal in cerebral > cerebellar WM
  - Subcortical cysts in anterior temporal &/or frontal WM
- POLR3
  - Hypomyelination & cerebellar atrophy

DIFFERENTIAL DIAGNOSIS

Periventricular Leukomalacia

- Static injury to periventricular WM in immature brain

Multiple Sclerosis

- Autoimmune demyelination

Anti-MOG Antibody Disease

- Autoimmune myelin inflammation & injury

PATHOLOGY

General Features

- Etiology
  - ALD: Absent/deficient peroxisomal enzyme acyl-CoA synthetase → accumulation of very long-chain fatty acids (VLCFA)
    - Mechanism by which VLCFA induces demyelination is still undetermined
  - MLD: Absent/deficient lysosomal enzyme arylsulfatase A → accumulation of sulfatide
    - Sulfatide accumulation triggers inflammation & demyelination
  - Canavan: Absence/deficiency of aspartoacylase → accumulation of NAA
  - Alexander: Mutations in gene for glial fibrillary acidic protein → excess GFAP
    - GFAP aggregates in Rosenthal fibers in astrocytes, prevent myelination
  - MLC: Mutations in genes encoding for astrocytic proteins *MLC1* or *GLIALCAM* genes
    - Normal myelin volumes with excessive vacuolization
  - GLD: Absent/deficient lysosomal enzyme galactosylceramidase I → accumulation of psychosine & cerebroside
    - Psychosine induces astrocytic apoptosis, secondarily causing demyelination
  - VWM: Defects in eukaryotic initiation factor 2B (eIF2B) → episodic WM cavitation after febrile infections or minor head trauma
    - Global protein synthesis regulated by eIF2B → abnormal cellular stress response
  - POLR3: Mutations in genes *POLR3A*, *POLR3B*, &/or *POLR1C* encoding for components of RNA polymerase III
    - Impacts function of oligodendrocyte, astrocyte, neuron, & microglia

TORCH Infections

KEY FACTS

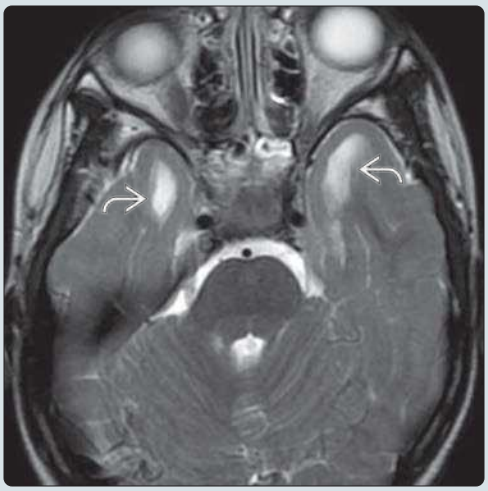
TERMINOLOGY

- TORCH/TORCHES: Acronym for congenital infections caused by transplacental transmission of pathogens
  - **T**oxoplasmosis (toxo) → *Toxoplasma gondii*
  - **O**ther (Zika → Zika virus)
  - **R**ubella → rubella virus
  - **C**ytomegalovirus (CMV) → most common TORCH infection
  - **He**rpes → herpes simplex virus 2 (HSV-2)
  - Human immunodeficiency virus (HIV)
  - **S**yphilis → *Treponema pallidum*

IMAGING

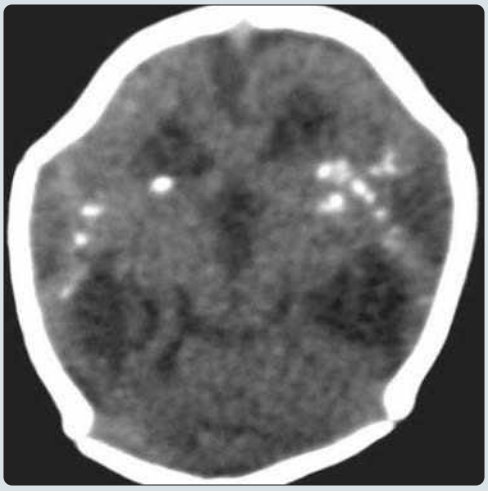
- Toxo, CMV, HIV, Zika, & rubella all cause parenchymal Ca^{2+}
- CMV causes migrational defects, white matter gliosis/hypomyelination, & cystic foci in temporal poles
- Rubella, Zika, & HSV cause lobar destruction/encephalomalacia
- ± microcephaly (not unique to Zika virus)

PATHOLOGY

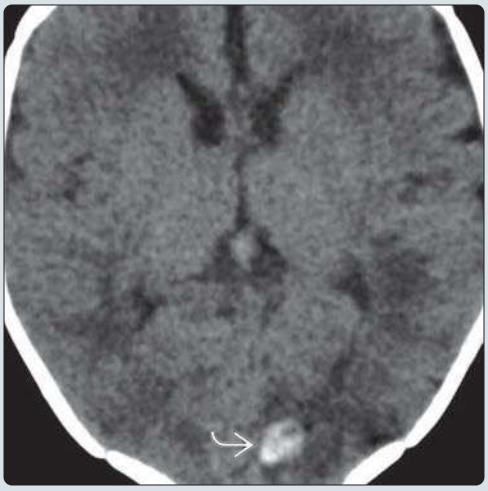


- CMV
  - Ubiquitous DNA virus of herpesvirus family
- Zika
  - Arbovirus of flavivirus family
- Herpes encephalitis
  - 75-90% of congenital herpes encephalitis
  - Most commonly from transmission during delivery
  - Transplacental infection can be from HSV-1 or HSV-2
- Toxoplasmosis
  - Active infection in pregnancy → 20-50% congenital infection
- HIV
  - 30% of pregnancies in HIV(+) women will result in transmission unless preventative measures are taken

DIAGNOSTIC CHECKLIST



- CMV is most frequently encountered TORCH infection in USA



(Left) *Axial NECT shows extensive periventricular Ca^{2+} in this 2-day-old, 32-weeks-premature infant with microcephaly, caused by in utero CMV infection.* **(Right)** *Axial T2 MR in a 14-year-old with seizures & developmental delay shows subcortical temporal lobe cysts. In combination with gliotic white matter lesions, such cysts are highly suggestive of congenital CMV.*

(Left) *Axial NECT in an infant with in utero Zika virus infection shows periventricular & subcortical Ca^{2+} with marked volume loss, resulting in microcephaly (despite the presence of ventriculomegaly). (Courtesy T. Fazecas, MD.)* **(Right)** *Axial NECT shows a focal parenchymal hemorrhage in a region of occipital pole cerebritis in this 3-week-old with disseminated herpes simplex virus (HSV) & lethargy. HSV acquired during delivery typically presents at 3-15 days.*

TERMINOLOGY

Synonyms

- Congenital infections, intrauterine infection, TORCHES

Definitions

- Acronym for congenital infections caused by transplacental transmission of pathogens
  - **T**oxoplasmosis (toxo) → *Toxoplasma gondii*
  - **O**ther (Zika → Zika virus)
  - **R**ubella → rubella virus
  - **C**ytomegalovirus (CMV) → most common TORCH infection
  - **He**rpes → herpes simplex virus 2 (HSV-2)
  - Human immunodeficiency virus (HIV)
  - **S**yphilis → *Treponema pallidum*

IMAGING

General Features

- Toxo, CMV, HIV, Zika, & rubella all cause parenchymal Ca^{2+}
  - Toxo Ca^{2+} is typically less extensive than CMV
  - HIV causes basal ganglia & frontal subcortical Ca^{2+}
- CMV causes migrational defects, white matter (WM) gliosis/hypomyelination, & cystic foci in temporal poles
- Rubella, Zika, & HSV cause lobar destruction/encephalomalacia; HSV is often hemorrhagic
- Syphilis causes basilar meningitis
- Unless complicated by hydrocephalus, volume loss caused by TORCH infections typically results in microcephaly
  - Zika is not unique in this regard
- Zika is also associated with macular atrophy

Imaging Recommendations

- Best imaging tool
  - MR brain to completely characterize abnormalities
  - CT is of benefit in confirming Ca^{2+}

DIFFERENTIAL DIAGNOSIS

Tuberous Sclerosis

- Subependymal Ca^{2+} is characteristic

Neurocysticercosis

- Most common cause of cerebral Ca^{2+} < 30 years of age

Chronic Venous Ischemia

- From arteriovenous fistula or venous malformation
- Subcortical Ca^{2+} with volume loss

Congenital Lymphocytic Choriomeningitis

- Produces necrotizing ependymitis, leading to aqueductal obstruction; macrocephaly (43%) > microcephaly (13%)
- NECT may perfectly mimic CMV

Pseudo-TORCH Syndromes

- Baraister-Reardon, Aicardi-Goutieres (CSF pleocytosis, ↑ CSF α-interferon)
  - Basal ganglia Ca^{2+}, ± periventricular Ca^{2+}

Megalencephalic Leukoencephalopathy With Subcortical Cysts

- Leukodystrophy with subcortical cysts in temporal lobes is similar to those seen in CMV

PATHOLOGY

General Features

- Etiology
  - CMV
    - Ubiquitous DNA virus of herpesvirus family
    - CMV is most common cause of intrauterine infection
  - Zika
    - Arbovirus of flavivirus family
    - Most commonly spread by *Aedes aegypti* mosquito
  - Herpes encephalitis
    - Active HSV-2 genital infection during delivery can pass directly to child
      - 75-90% of congenital herpes encephalitis
    - Transplacental infection can be from HSV-1 or HSV-2
  - Rubella
    - Togaviridae family of viruses
  - Toxoplasmosis
    - Active infection in pregnancy → 20-50% risk of congenital infection
  - HIV
    - 30% of pregnancies in HIV(+) women will result in transmission unless preventative measures are taken
  - Syphilis
    - Transplacental transmission from mother with primary or secondary syphilis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - CMV can present at birth (10%) with microcephaly, hepatosplenomegaly, petechial rash
    - 55% with systemic disease have CNS involvement
  - Congenital toxoplasmosis is usually inapparent at birth, presenting at 2-3 months
  - HSV acquired during delivery typically presents at 3-15 days with seizures, lethargy
    - HSV acquired in utero (5%) typically presents at birth
  - Zika is typically apparent at birth due to microcephaly

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Consider congenital CMV encephalitis when MR shows
  - Microcephaly & cerebellar hypoplasia
  - Cortical gyral abnormalities or schizencephaly with Ca^{2+}
  - WM gliosis & subcortical temporal cysts
- Zika virus causes brain destruction & dysmorphism in addition to microcephaly with Ca^{2+}

SELECTED REFERENCES

Brain Abscess

KEY FACTS

TERMINOLOGY

- Focal pyogenic infection of brain parenchyma

IMAGING

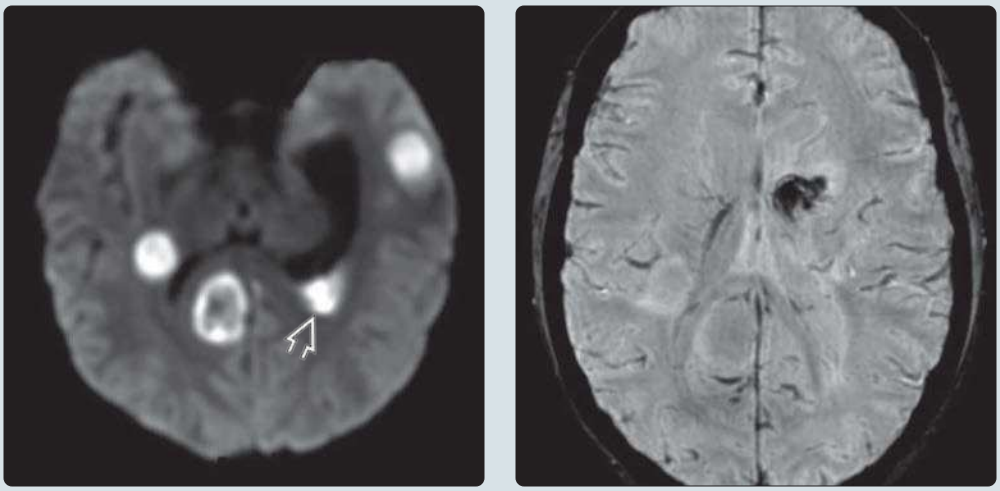
- Varies with stage of abscess development
- Early cerebritis: Ill-defined, hypodense (CT)/hyperintense (T2 MR) subcortical lesion with mass effect & patchy enhancement
- Late cerebritis: T2-hypointense rim (MR) with irregular, peripheral rim enhancement (CT/MR)
- Early capsule: T2-hypointense rim (MR) with well-defined, thin, enhancing wall (CT/MR)
- Late capsule: Cavity shrinks, edema & mass effect diminish, capsule thickens (CT/MR)
- DWI MR: Restricted diffusion in cerebritis & abscess

TOP DIFFERENTIAL DIAGNOSES

- Resolving hematoma
- Pilocytic astrocytoma
- Demyelinating disease

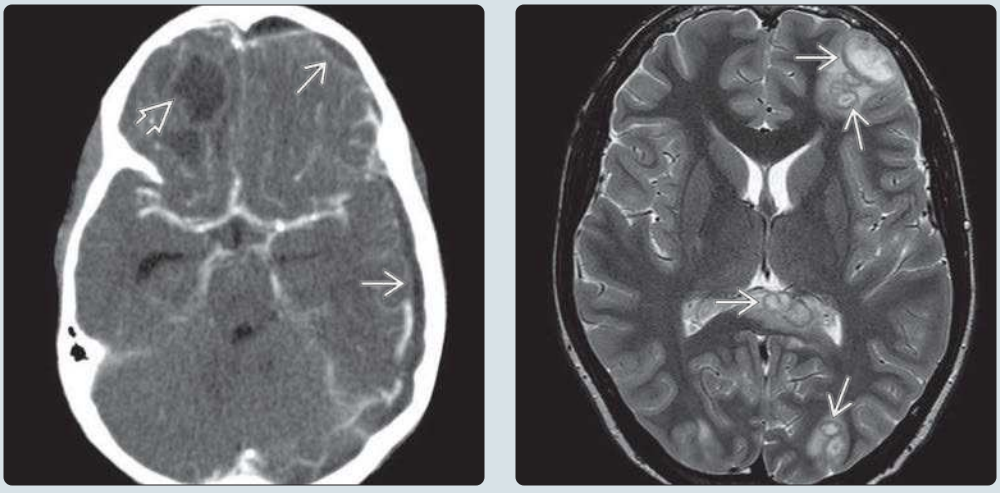
PATHOLOGY

- Early cerebritis (3-5 days)
  - Unencapsulated mass of leukocytes & edema
- Late cerebritis (4-5 days up to 2 weeks)
  - Necrotic foci coalesce
- Early capsule (begins ~ 2 weeks)
  - Well-delineated, collagenous capsule
- Late capsule (weeks to months)
  - Central cavity shrinks



CLINICAL ISSUES

- 25% occur in patients < 15 years
- Headache is most common symptom (up to 90%)
  - Fever in only 50%



DIAGNOSTIC CHECKLIST

- Search for local cause, such as sinusitis, mastoiditis

(Left) *Axial MR DWI in a teenager with a headache shows characteristic diffusion restriction in multiple intraparenchymal abscesses. Diffusion restriction layering in the left occipital horn ➡ reflects ventriculitis due to the intraventricular extension of a periventricular abscess, substantially increasing morbidity.* **(Right)** *Axial MR SWI in the same patient shows hemorrhage into an abscess in the left globus pallidus. Hemorrhagic changes in the walls of pyogenic abscesses are more frequently seen with SWI.*

(Left) *Axial CECT in a 5-year-old with fever & COVID-19 positive serology who developed right-sided weakness shows a large left subdural empyema ➡ & right frontal lobe abscess ➡ as a complication of bacterial sinusitis.* **(Right)** *Axial T2 MR in a previously healthy teenager with fever & altered mental status shows multiple clusters of abscesses in the frontal & occipital lobes + the splenium of the corpus callosum. The dark signal in the abscess walls ➡ is thought to reflect the presence of free radicals.*

TERMINOLOGY

Definitions

- Focal pyogenic infection of brain parenchyma
  - Typically bacterial; fungal or parasitic is less common

IMAGING

General Features

- Best diagnostic clue
  - Ring-enhancing lesion
  - T2-hypointense rim on MR with surrounding edema
  - High signal (restricted diffusion) on DWI MR with low ADC
- Location
  - Supratentorial > > infratentorial
    - Frontal & parietal lobes are most common

CT Findings

- Early cerebritis: Ill-defined, hypodense subcortical lesion with mass effect
- Late cerebritis: Irregular, peripheral rim enhancement
- Early capsule: Thin, distinct, enhancing capsule
  - Capsule is thickest near cortex
- Late capsule: Cavity shrinks, capsule thickens

MR Findings

- Early cerebritis: Ill-defined, T2-hyperintense mass with patchy enhancement
- Late cerebritis: Hypointense rim on T2; intense but irregular rim enhancement
- Early capsule: Hypointense rim on T2; well-defined, enhancing, thin wall
- Late capsule: Edema & mass effect ↓; ↑ of thick wall
- Restricted diffusion in cerebritis & abscess
  - Markedly ↓ signal centrally on ADC map
- Central necrotic area may show presence of acetate, lactate, alanine, succinate, pyruvate on MRS

Imaging Recommendations

- Best imaging tool
  - Contrast-enhanced MR + DWI

DIFFERENTIAL DIAGNOSIS

Resolving Hematoma

- Rim enhancement starts ~ 7 days after event

Pilocytic Astrocytoma

- Cyst with enhancing mural nodule
- Low signal of cyst contents on DWI

Demyelinating Disease

- Multiple sclerosis, acute disseminated encephalomyelopathy
- May have incomplete rim enhancement
- Characteristic lesions elsewhere in brain

Aging Infarction

- Enhancement at periphery of subacute to chronic infarction may mimic abscess

PATHOLOGY

General Features

- Etiology
  - Hematogenous from extracranial location
  - Extension from sinus infection via valveless emissary veins
  - Direct extension from calvarial or meningeal infection
  - Right-to-left shunts (congenital cardiac malformations, pulmonary arteriovenous fistulas)
  - 20-30% have no identifiable source → cryptogenic
  - Often polymicrobial → streptococci, staphylococci, anaerobes

Staging, Grading, & Classification

- Early cerebritis (3-5 days)
  - Unencapsulated mass of leukocytes & edema
- Late cerebritis (4-5 days up to 2 weeks)
  - Necrotic foci coalesce
- Early capsule (begins at ~ 2 weeks)
  - Well-delineated, collagenous capsule
  - Liquefied necrotic core
- Late capsule (weeks to months)
  - Central cavity shrinks

CLINICAL ISSUES

Presentation

- Headache is most common symptom (up to 90%)
  - Fever in only 50%

Demographics

- 25% occur in patients < 15 years

Natural History & Prognosis

- Complications of inadequately or untreated abscesses
  - Intraventricular rupture, ventriculitis (may be fatal)
  - Meningitis, daughter lesions
  - Mass effect, herniation
- Mortality is variable, 0-30%

Treatment

- Antibiotics only, if small (< 2.5 cm) or early cerebritis
- Steroids to treat edema & mass effect
- Surgical drainage or excision may be required
- Drainage of adjacent source (e.g., infected paranasal sinuses, mastoids)

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Search for local cause, such as sinusitis, mastoiditis
- T2-hypointense abscess rim resolves before enhancement in successfully treated patients

Acute Encephalitis

KEY FACTS

TERMINOLOGY

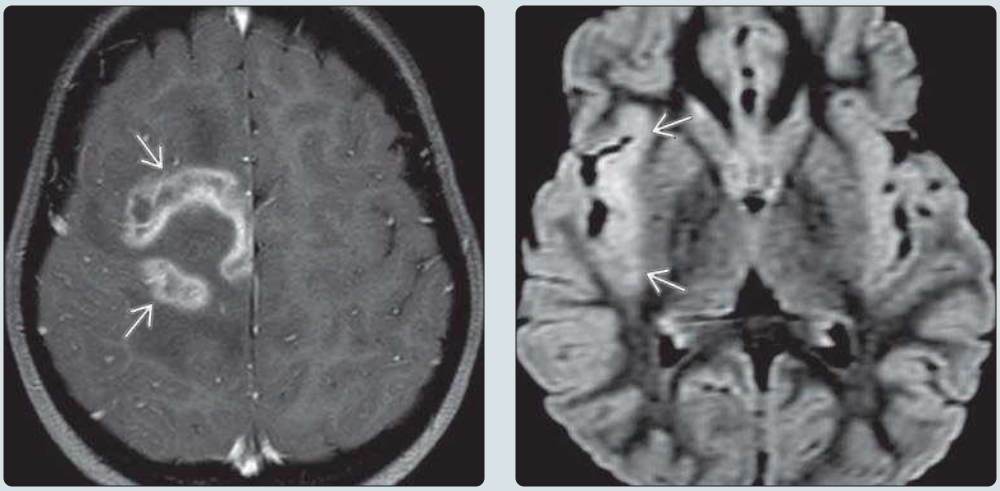
- Acute brain inflammation caused by infectious agents, most commonly viruses
- Noninfectious (autoimmune) brain inflammation

IMAGING

- Most viral encephalitides have wide ranging, nonspecific imaging findings
  - Poorly defined white matter signal abnormalities
  - Bilateral, symmetric basal ganglia &/or thalamic signal abnormalities
  - Minimal leptomeningeal enhancement
- Focal splenium signal abnormality
  - Influenza & other viral encephalitides
- Symmetric thalamic & basal ganglia necrosis
  - Acute necrotizing encephalitis of childhood (ANEC)
- Abnormal cranial nerve enhancement (neuritis)
  - COVID-19

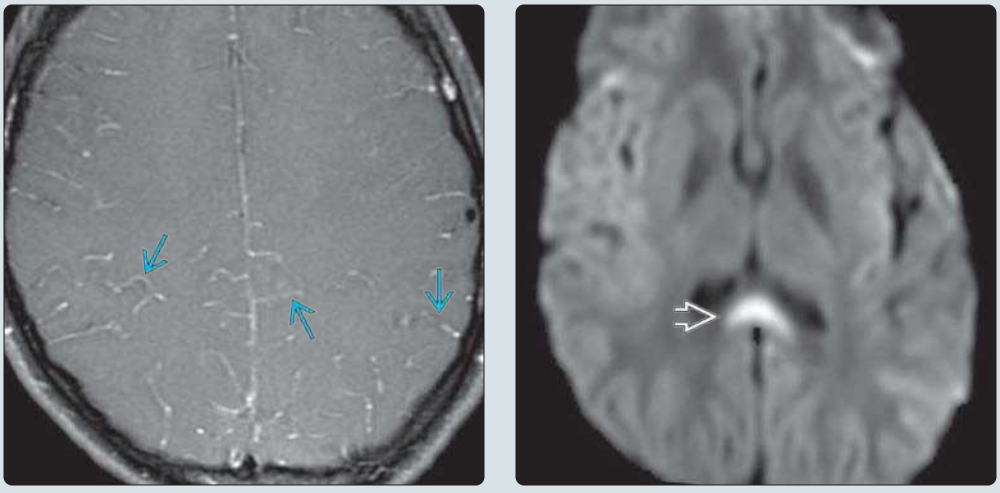
TOP DIFFERENTIAL DIAGNOSES

- Acute ischemia
- Gliomatosis cerebri
- Status epilepticus
- Mitochondrial encephalopathy



PATHOLOGY

- Herpesviruses include HSV1, HSV2, CMV, EBV, VZV, B virus, HSV6, HSV7
- Arboviruses transmitted by mosquitoes & ticks
  - Include Eastern & Western equine encephalitis, West Nile, Zika, St. Louis encephalitis, Lacrosse encephalitis, California encephalitis



CLINICAL ISSUES

- Presentation varies widely: Slight meningeal to severe encephalitic symptoms, ± fever, prodrome
- Rapid diagnosis & early treatment with antiviral or antibacterial agents can ↓ mortality, may improve outcome

(Left) *Axial T1 C+ FS MR in 9-year-old with left-sided weakness shows a right cerebral lesion with cortical enhancement ➡ & hemorrhagic necrosis due to COVID-19-associated vasculitis & infarction.* **(Right)** *Axial DWI MR in a 12-year-old with seizures shows abnormal signal & swelling of the right insular cortex ➡ due to GAD65 autoimmune encephalitis. GAD65 antibody is a biomarker of CNS & nonneurological autoimmune diseases.*

(Left) *Axial T1 C+ FS MR in a teenager presenting with nausea, headache, fever, & somnolence shows abnormal leptomeningeal enhancement in the frontal & parietal sulci ⇨. Serology was positive for West Nile virus.* **(Right)** *Axial DWI MR in a 14-year-old with seizures after 1 week of cough & fever shows restricted diffusion in the splenium of the corpus callosum ➡ due to influenza encephalitis.*

TERMINOLOGY

Definitions

- Acute brain inflammation caused by infectious agents, most commonly viruses
- Noninfectious (autoimmune) brain inflammation

IMAGING

General Features

- Most viral encephalitides have wide ranging, nonspecific imaging findings
  - West Nile, St. Louis, LaCrosse, California, Eastern equine
    - Poorly defined signal abnormalities in white matter
    - Bilateral, symmetric basal ganglia or thalamic signal abnormalities
      - ± diffusion restriction
    - Little or no parenchymal enhancement
    - Minimal leptomeningeal enhancement
- Some pathogens have characteristic imaging features
  - COVID-19
    - Abnormal cranial nerve enhancement (neuritis)
    - Vasculitic/thrombotic pattern with ischemic lesions
  - Herpetic encephalitis (HSV1) reactivation pattern
    - Temporal & subfrontal involvement, typically spares basal ganglia with early hemorrhagic conversion
      - Characteristic in adults
    - Majority of children with HSV1 encephalitis do not follow this pattern but have multilobar distribution instead
  - Rocky Mountain spotted fever (RMSF)
    - Multiple punctate foci of diffusion restriction in cerebral white matter
    - Minimal or no enhancement
  - Some features are associated with variety of pathogens
    - Focal splenium signal abnormality
      - Ovoid focus of diffusion restriction in splenium of corpus callosum
      - Associated with influenza & other viral encephalitides
      - Reported in COVID-19 infection
    - Acute necrotizing encephalitis of childhood (ANEC)
      - Symmetric thalamic & basal ganglia necrosis

Imaging Recommendations

- Best imaging tool
  - MR with FLAIR, DWI, & contrast is most sensitive
    - SWI or GRE to detect hemorrhage

DIFFERENTIAL DIAGNOSIS

Acute Ischemia

- Cytotoxic edema in typical vascular distribution; DWI positive

Gliomatosis Cerebri

- Lobar or hemispheric infiltration & expansion with subacute onset

Status Epilepticus

- Hyperintense on T2/FLAIR MR ± diffusion restriction

Mitochondrial Encephalopathy

- Symmetric basal ganglia or thalamic involvement common

PATHOLOGY

General Features

- Etiology
  - Herpesviruses include HSV1, HSV2, CMV, EBV, VZV, B virus, HSV6, HSV7
    - HSV2 is major cause of neonatal encephalitis
  - Arboviruses are transmitted by mosquitoes & ticks
    - Include Eastern & Western equine encephalitis, West Nile, Zika, St. Louis encephalitis, Lacrosse encephalitis, California encephalitis
  - Enteroviruses include Coxsackie viruses A & B, poliovirus, echoviruses, enteroviruses 68 to 71

Microscopic Features

- Infiltration by polymorphonuclear cells, lymphocytes, plasma cells, & mononuclear cells
- May see inclusion bodies (i.e., Negri bodies in rabies)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Varies widely: Slight meningeal to severe encephalitic symptoms; ± fever, prodrome
  - Varicella & herpes zoster: Different clinical manifestations of infection by same virus (VZV)
    - Varicella encephalitis: Fever, headache, vomiting, seizures, altered mental status days to weeks after onset of (chicken pox) rash
    - Zoster: Immunocompetent patient with cranial nerve & peripheral nerve palsies in dermatomes involved by skin lesions
  - EV71
    - Hand, foot, & mouth disease: Fever, vesicles on hands, feet, elbows, knees, lips

Demographics

- Epidemiology
  - Herpes: Most common cause of sporadic (nonepidemic) viral encephalitis
  - Japanese encephalitis: Most common endemic encephalitis in Asia

Natural History & Prognosis

- Many encephalitides have high morbidity, mortality
- Rapid diagnosis & early treatment with antiviral or antibacterial agents can ↓ mortality, may improve outcome

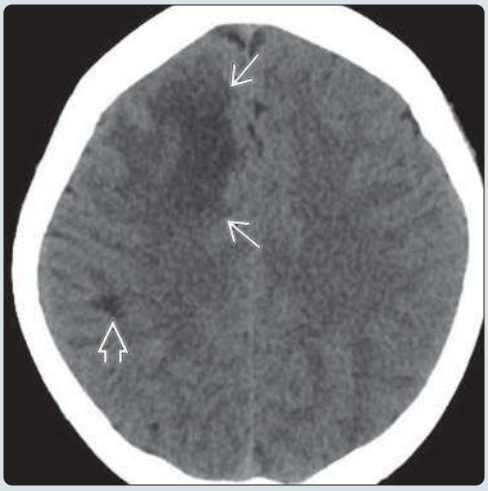
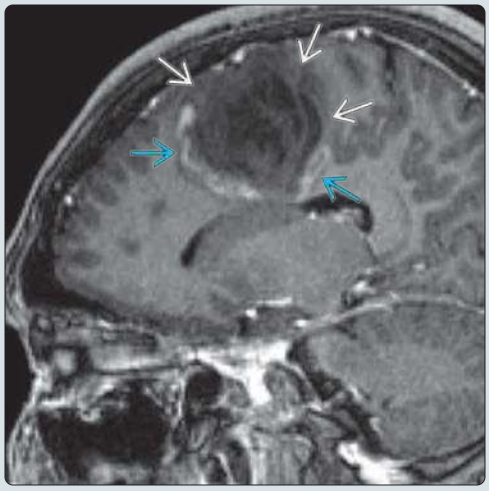
KEY FACTS



DIAGNOSTIC CHECKLIST



- Multiple sclerosis (MS)
  - Demyelinating disease characterized by multiple lesions disseminated in time & space
  - Brain lesions: Multiple T2- & FLAIR MR hyperintense foci, typically small (5-10 mm), ovoid, discrete, periventricular, & perpendicular to ventricular margins
  - Optic neuritis (ON): Unilateral, short segment, intraorbital; myelitis: < 2 vertebrae in length, < 50% of cross-sectional area, typically peripheral
- Acute disseminated encephalomyelitis (ADEM)
  - Acute demyelinating disease with encephalopathy, without NMOSD or anti-MOG associated antibodies
  - Characteristically arises subsequent to infection (viral respiratory) or vaccination
  - Brain: Ill-defined, larger T2-/FLAIR hyperintense lesions
- Neuromyelitis optica spectrum disorders (NMOSD)
  - Inflammatory CNS disease caused by antibodies to aquaporin-4 (AQP-4) on astrocytic end feet
  - ON & transverse myelitis predominate clinically
  - Brain: Commonly periventricular but parallel to ependymal lining; area postrema involvement is classic
  - ON: Bilateral, posterior predominant (including chiasm)
  - Myelitis: Longitudinally extensive transverse myelitis (LETM) (> 3 vertebrae), > 50% of cord cross section, central
- Anti-MOG syndromes
  - Acute demyelinating disease caused by antibodies to myelin oligodendrocyte glycoprotein (MOG)
  - Extensive clinical overlap with ADEM & NMOSD; encephalopathy in younger patients, ON in older
  - Brain: Similar to ADEM
  - ON: Bilateral anterior predominant (including optic disc) with perineural enhancement
  - Myelitis: LETM vs. short segment; conus involvement
- Lyme disease
  - May be accompanied by ON or other CN inflammation

(Left) *Sagittal T2 MR in a 9-year-old with optic neuritis shows multiple ill-defined hyperintensities in the medulla & cervical cord. Subsequent serum testing revealed antibodies to aquaporin 4, confirming a diagnosis of neuromyelitis optica spectrum disorders (NMOSD).* **(Right)** *Axial T1 C+ FS MR through the orbits shows diffuse bilateral optic nerve enhancement in this 9-year-old with vision loss. Clinical features were suggestive of NMOSD, but CSF analysis confirmed anti-myelin oligodendrocyte glycoprotein (MOG) disease.*

(Left) *Axial NECT in a 16-year-old with progressive left-sided weakness after minor trauma shows a large, low-attenuation white matter lesion in the anterior right frontal lobe & a smaller one near the right motor strip.* **(Right)** *Sagittal T1 C+ MR in the same patient shows the borders of the large lesion nearest to the cortex to be nonenhancing as compared to the other margins. This open ring appearance can help distinguish tumefactive MS from abscess or neoplasm (which more typically have complete ring enhancement).*

TERMINOLOGY

Definitions

- Acquired demyelinating processes characterized by inflammation
  - Multiple sclerosis (MS)
    - Demyelinating disease characterized by multiple lesions disseminated in time & space
  - Acute disseminated encephalomyelitis (ADEM)
    - Acute demyelinating disease with encephalopathy, without NMOSD or anti-MOG-associated antibodies
  - Neuromyelitis optica spectrum disorders (NMOSD)
    - Inflammatory CNS disease caused by antibodies to aquaporin-4 (AQP-4) on astrocytic end feet
    - Clinically characterized by optic neuritis & transverse myelitis
  - Antimyelin oligodendrocyte glycoprotein (MOG) syndromes
    - Acute demyelinating disease caused by antibodies to MOG
    - Extensive clinical overlap with ADEM & NMOSD
  - Lyme disease
    - CNS inflammation associated with *Borrelia burgdorferi* infection

IMAGING

General Features

- MS
  - Brain: Multiple T2- & FLAIR MR hyperintense lesions, typically small (5-10 mm), ovoid, discrete
    - > 85% are periventricular: Callosal involvement, hemispheric white matter; perpendicular to ventricle margin in perivenular distribution
    - Variable enhancement: Presumed to reflect active demyelination
      - Can be mass-like: Tumefactive MS
    - "Black holes" (due to axonal destruction) on T1 are much more likely to be seen in MS than ADEM
  - Optic neuritis (ON): Unilateral, short length, intraorbital
  - Myelitis: < 2 vertebral lengths, < 50% of cord cross section, cervical > thoracic
- ADEM
  - Brain: Ill-defined larger T2-/FLAIR hyperintense lesions
    - Lesions are more likely to be diffuse & bilateral
    - Frequent brainstem & thalamic involvement
  - ON: Less common; myelitis: Less common
- NMOSD
  - Brain: May have extensive lesions
    - Commonly periventricular but parallel
    - Dorsal brainstem (especially area postrema)
  - ON: Bilateral long segment
    - Posterior predominant, including chiasm
  - Myelitis: Longitudinally extensive transverse myelitis (LETM) (> 3 segments), typically central & > 50% circumference
- Anti-MOG syndromes
  - Brain: Similar in appearance to ADEM
    - Much less likely to involve corpus callosum
  - ON: Bilateral long length with perineural enhancement
    - Anterior predominant, including optic disc
  - Myelitis: LETM vs. short segment; conus often affected
- Lyme disease
  - May be accompanied by ON or other cranial nerve inflammation; Bell palsy is characteristic

DIFFERENTIAL DIAGNOSIS

Posterior Reversible Encephalopathy Syndrome

- Subcortical vasogenic edema associated with hypertension

Viral Encephalitis

- Widely variable, but often affects white matter & deep gray nuclei

Autoimmune-Mediated Vasculitis

- Reported in COVID-19 infection

Leukodystrophies

- Patterns vary by metabolic defect

Toxin-Induced Brain Injury

- Carbon monoxide or methanol poisoning

PATHOLOGY

General Features

- Etiology
  - MS
    - Activated T cells attack myelinated axons
    - B cells, antibodies, macrophages, & microglia all contribute to lesions
  - ADEM
    - Characteristically arises subsequent to infection (viral respiratory) or vaccination
  - NMOSD
    - Antibodies to aquaporin-4 (AQP-4) channels on astrocytic end feet
    - AQP-4 is dispersed throughout CNS
      - Highly expressed in optic nerves & spinal cord
  - Anti-MOG syndromes: Antibodies to MOG

CLINICAL ISSUES

Natural History & Prognosis

- MS: 45% of MS patients are not severely affected & are nearly normal
  - > 80% with "probable" MS & positive MR progress to clinically definite MS
- ADEM: Characteristically monophasic
  - Recurrence suggests anti-MOG
- Anti-MOG syndromes are more frequently seen in young
  - Encephalopathy is more common in younger patients, ON in older
- > 90% of NMOSD in pediatrics have relapsing disease
- Lyme disease: 11% develop neurologic manifestations

Craniosynostoses

KEY FACTS

TERMINOLOGY

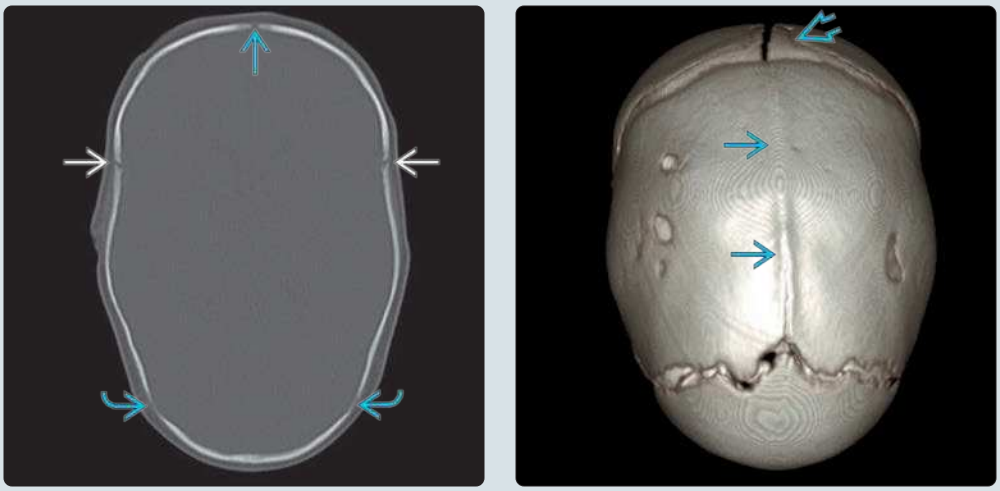
- Premature fusion of 1 or more cranial sutures, often resulting in abnormal cranial morphology &/or size
- Synonyms: Craniosynostosis, craniostenosis, sutural synostosis, premature sutural fusion

IMAGING

- Fibrous or osseous "bridging" ± ridging along suture
- Patterns of calvarial (& facial) dysmorphology depend on which suture(s) involved
  - Dolichocephaly: ↑ AP elongation, ↓ transverse dimension → sagittal synostosis
  - Trigonocephaly: Anterior pointing of frontal bone → metopic synostosis
  - Plagiocephaly: Calvarial asymmetry → unilateral coronal or lambdoid synostosis
  - Brachycephaly: ↑ transverse dimension, ↓ AP → bicoronal synostosis
  - Kleeblattschädel: Cloverleaf skull → sagittal & bilateral coronal ± bilateral lambdoid synostosis
  - Turricephaly (oxycephaly, acrocephaly): Towering skull → bilateral coronal, bilateral lambdoid, & sagittal synostosis
- Can be primary (nonsyndromic or syndromic) or secondary (e.g., shunt related, abnormally ↓ brain growth)

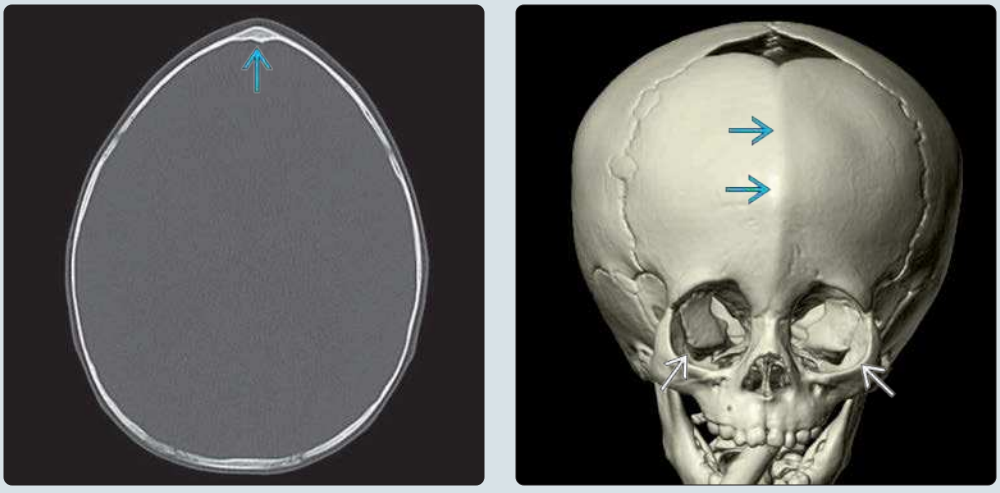
TOP DIFFERENTIAL DIAGNOSES

- Positional plagiocephaly or molding



CLINICAL ISSUES

- Nonsyndromic craniosynostosis: Most common, 1 or 2 sutures involved, typically normal outcomes
- Syndromic craniosynostosis: ↓ head growth, extremity anomalies, developmental delay
- Treatment with surgical cranial vault reconstruction or cranial vault distraction osteogenesis



DIAGNOSTIC CHECKLIST

- Low-dose head CT with 3D skull reformats is study of choice

(Left) *Axial NECT in bone windows of a 3-week-old girl with dolichocephaly demonstrates classic AP elongation of the skull with a shortened transverse dimension. Note that the metopic, coronal, & lambdoid sutures are patent.* **(Right)** *Vertex 3D skull reformatted CT in the same patient demonstrates osseous fusion & ridging of the sagittal suture. Note that the anterior fontanel is patent. The sagittal suture does not normally fuse until ~ 22 years of age.*

(Left) *Axial NECT in bone windows of a 6-month-old boy with trigonocephaly shows anterior pointing of the calvarium & osseous fusion of the metopic suture. The metopic suture typically fuses in the first 3-9 months of life but not with the abnormal ridging seen here.* **(Right)** *Anterior 3D skull reformatted CT in the same patient demonstrates anterior ridging of the fused metopic suture. There is associated hypotelorism.*

TERMINOLOGY

Synonyms

- Craniosynostosis, craniostenosis, sutural synostosis, premature sutural fusion

Definitions

- Premature fusion of 1 or more cranial sutures, often resulting in abnormal cranial morphology &/or size
- Can be primary or secondary
  - Primary: Underlying genetic abnormality; can be nonsyndromic (most common) or syndromic
    - Nonsyndromic (~ 85%): Usually sporadic
      - Simple or single-suture synostosis (~ 75-80%): Typically normal development, intelligence, & intracranial pressure (ICP)
      - Multisuture nonsyndromic (~ 20-25%): If > 2 sutures involved, high incidence of ↑ ICP, cerebellar tonsillar herniation, & developmental delay
    - Syndromic (~ 15%): > 200 associated syndromes; high incidence of other associated anomalies & developmental delay
      - Precise classification is difficult due to considerable overlap; patients with same gene mutations can have different phenotypic manifestations
  - Secondary: From external causes
    - Intrauterine skull compression (especially in oligohydramnios)
    - Teratogens: Phenytoin, valproic acid, retinoic acid
    - Lack of normal brain growth
    - Shunt induced
    - Metabolic disorders: Rickets, hyperthyroidism, lysosomal storage disorders

IMAGING

General Features

- Best diagnostic clue
  - Abnormal head shape &/or size
- Size
  - Part or all of suture may be fused, 1 or multiple sutures may be involved
- Morphology
  - Classic imaging appearance: Calvarial (& facial) dysmorphology based on suture(s) involved
    - Dolichocephaly (scaphocephaly): ↑ AP elongation, ↓ transverse dimension, frontal bossing → sagittal synostosis
    - Trigonocephaly: Anterior pointing of frontal bone, compensatory posterior widening, hypotelorism → metopic synostosis
    - Plagiocephaly: Calvarial asymmetry
      - Unilateral anterior plagiocephaly: Ipsilateral upturned orbit or "harlequin eye," ipsilateral forehead flattening, contralateral frontal bossing → unilateral coronal synostosis
      - Unilateral posterior plagiocephaly: Ipsilateral occipital flattening → unilateral lambdoid synostosis
    - Brachycephaly: ↑ transverse dimension, ↓ AP → bicoronal synostosis
    - Turricephaly (oxycephaly, acrocephaly): Upward growth of brain through enlarged anterior fontanelle ("towering skull"), disproportionately enlarged frontal horns of lateral ventricles, small skull base & posterior fossa → bilateral coronal, bilateral lambdoid, & sagittal synostosis
      - Conflicting literature as to whether turricephaly & oxycephaly are same or distinct entities
    - Kleeblattschädel (cloverleaf skull): Expansion of membranous bone between sutures, shallow orbits → sagittal & bilateral coronal ± bilateral lambdoid synostosis
    - Unclassified: Other combinations of sutural synostoses

Radiographic Findings

- Skull: Dense suture; "bone bridge," inner table scalloping
  - Can be useful screening tool
- Extremities: Many anomalies described, some specific
  - Apert: Hand/foot syndactyly
  - Pfeiffer: Wide "stub" thumbs
  - Saethre-Chotzen: Duplicated distal phalanx, cone-shaped hallux epiphysis
  - Muenke-type mutations: Calcaneocuboid fusion
  - Crouzon: Hands/feet normal

CT Findings

- Fibrous or bony "bridging" ± sutural ridging
- Head shape determined by involved suture(s)

MR Findings

- Syndromic: Abnormal head shape ± cerebellar tonsillar ectopia, hydrocephalus, agenesis of corpus callosum
- Nonsyndromic: Abnormal head shape; brain is usually normal
- ± congenital venous drainage anomalies
- Postoperative dural venous occlusion

Ultrasonographic Findings

- Fetal: Diagnosis suggested by calvarial dysmorphology, loss of normal sutural hypoechogenicity
- Post natal: Focused high-resolution linear transducer can determine suture patency; may be used in surgical planning

Imaging Recommendations

- Best imaging tool
  - Low-dose CT with 3D reconstructions best for evaluating relationship between sutural fusion & calvarial dysmorphology
  - MR for brain abnormalities

DIFFERENTIAL DIAGNOSIS

Positional Plagiocephaly or Molding

- Sutures normal
- Normal infants: Marked ↑ in incidence after 1994 pediatric "back to sleep" campaign
  - Parallelogram skull on axial images, ipsilateral anterior ear displacement
- Hypotonic infant: Lies on back → posterior flattening
- Premature infant: Lies on side → dolichocephaly

PATHOLOGY

General Features

- Etiology
  - Normal sutures permit skull growth perpendicular to long axis
    - Order of fusion: Metopic (3-9 months) > sagittal (~ 22 years) > coronal (~ 24 years) > lambdoid (~ 26 years) > squamosal (~ 60 years)
    - Sutures are often visible after head reaches adult size; normal head growth stops within 1st decade of life
  - Premature upregulation of growth factors signaling sutural fusion → anomalous skull base development, craniostenosis
    - Transforming growth factor (TGF) & fibroblast growth factor/receptor (FGF/FGFR) mutations are expressed in face, skull base, & limb buds
  - ↓ growth of 1 suture is compensated by ↑ growth of other sutures
    - Skull growth ↓ perpendicular & ↑ parallel to fused suture → abnormal head shape
- Genetics
  - Single sutural & nonsyndromic synostoses are believed to be caused by genetic abnormality
    - Recent identification of mutations in isolated sagittal, metopic, & unilateral coronal synostosis
    - Gene expression is often suture specific
  - Syndromic synostoses are usually autosomal dominant
    - *FGFR1* (Pfeiffer syndrome)
    - *FGFR2* (Apert, Pfeiffer, Crouzon, Jackson-Weiss)
    - *FGFR3* (Muenke, Crouzon)
    - *TWIST1* (Saethre-Chotzen syndrome)
    - *MSX2* (Boston-type craniosynostosis)
- Associated abnormalities
  - Limb anomalies: Syndactyly & polysyndactyly (30%), deficiencies (22%)
  - Neurologic abnormalities/complications
    - ↑ ICP: Mechanical brain distortion, hydrocephalus, dural & collateral venous outflow obstruction at skull base
    - Tonsillar herniation ± syringohydromyelia
    - Exophthalmos, visual loss, intellectual disabilities (secondary to ↑ ICP)

Gross Pathologic & Surgical Features

- Fibrous or osseous "bridging," ridging, or "beaking" along suture

Microscopic Features

- ↑ osteoblastic cell differentiation/maturation

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Asymmetric face/cranium, ↓ head growth
  - Affected patients with more severe abnormalities often present at birth
- Other signs/symptoms
  - Extremity anomalies, developmental delay
- Clinical profile
  - Craniofacial asymmetry ± extremity anomalies
  - More common in twins, perhaps related to mechanical forces

Demographics

- Age
  - Usually present at birth or in infancy
- Epidemiology
  - Overall: 1:2,500
  - Sagittal (55-60%), coronal (20-30%), plagiocephaly (5-10%), metopic (1-2%)
  - Isolated sagittal synostosis: 60% is nonsyndromic

Natural History & Prognosis

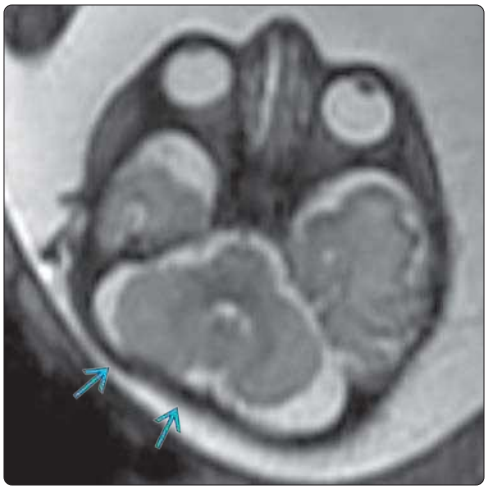
- Single suture → cosmetic only or secondary mandibular/maxillary deformities (suture dependent)
- Multiple sutures → cosmetic with secondary mandibular/maxillary deformities, ↑ ICP, ↓ cerebral blood flow; airway/aural/visual compromise
  - Craniofacial deformity is socially stigmatizing
- Nonsyndromic → typically normal cognitive & motor development
- Syndromic ± midline brain anomalies → developmental delay

Treatment

- Mild deformity or positional molding
  - Aggressive physiotherapy, head repositioning, orthotic headband/helmet therapy
- Moderate to severe deformity
  - Surgical cranial vault reconstruction or cranial vault distraction osteogenesis

DIAGNOSTIC CHECKLIST

Consider



- Nonsyndromic does not mean nongenetic: Single suture synostoses is also governed by genes
- Venous drainage anomalies are important in surgical planning (typically multisutural synostosis)

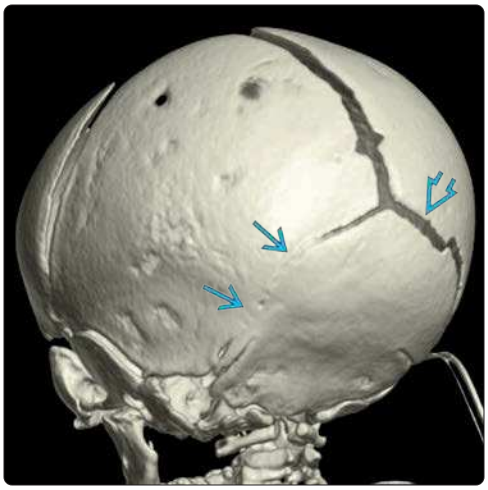


Image Interpretation Pearls

- 3D skull & maximum intensity projection (MIP) reformats from CT can be helpful, particularly in early or partial sutural fusion
- In patients with shunt, microcephaly, or abnormal bone mineralization → think of secondary craniosynostosis

(Left) *Axial T2 MR SSFSE of a 35-weeks gestational age male fetus with right pulmonary agenesis shows flattening of the left occipital calvarium, raising the possibility of unilateral lambdoid suture synostosis.* **(Right)** *Left posterior oblique 3D skull reformatted CT from the same patient at 1 month of age confirms partial osseous fusion of the left lambdoid suture. Note the patent right lambdoid suture.*

(Left) *Axial NECT in brain windows in a 2-month-old boy evaluated for scaphocephaly shows additional anterior bulging of the right frontal calvarium or plagiocephaly.* **(Right)** *Maximum intensity projection (MIP) CT from the same patient demonstrates osseous fusion of the sagittal suture & partial fusion of the left coronal suture. The right coronal suture remains open.*

(Left) *Axial NECT in a 1-day-old infant with Carpenter syndrome reveals marked irregularity of the calvarium. The intracranial compartment is small, producing brain compression with effacement of the posterior convexity sulci & bitemporal protrusion in a cloverleaf or Kleeblattschädel appearance.* **(Right)** *Anterior 3D skull reformatted CT in the same patient shows a very wide metopic suture with bilateral "harlequin eyes" & a small face due to premature closure of the bilateral coronal & squamosal sutures.*

CSF Shunts and Complications

KEY FACTS

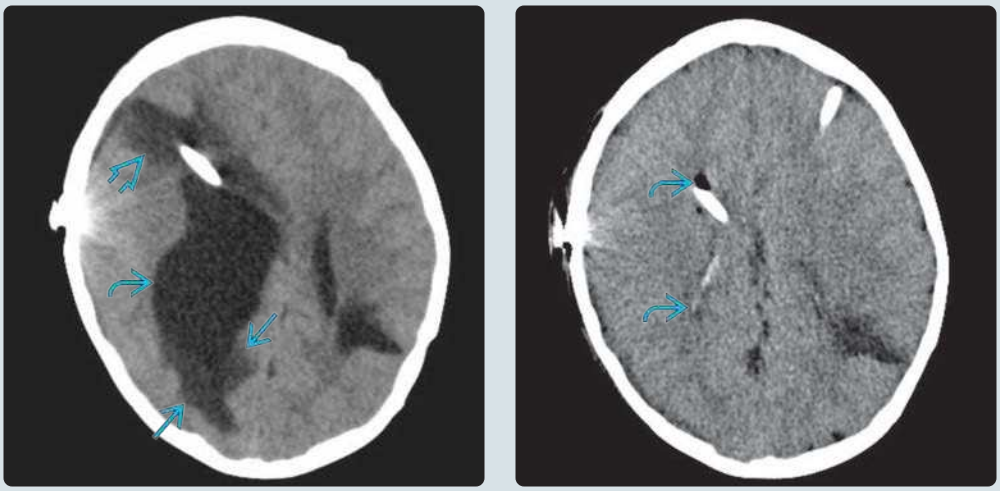
TERMINOLOGY

- Shunt malfunction comprises wide spectrum of potential complications associated with CSF diversion, mainly undershunting → acute hydrocephalus

IMAGING

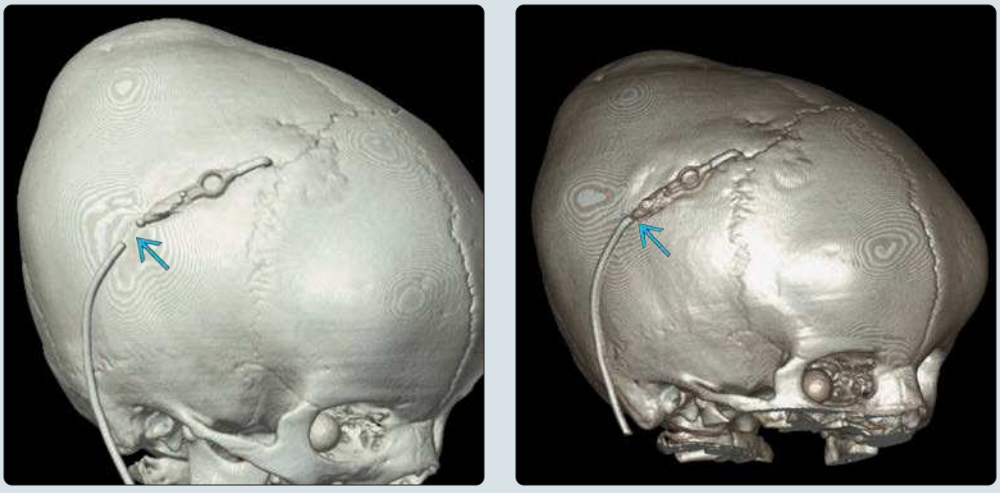
- Undershunting is most common: ↑ ventricular size, periventricular edema, extraaxial CSF space effacement, hindbrain herniation; widening of sutures in infants
- Overshunting: Largely clinical diagnosis; look for intracranial hypotension, slit-like ventricles, subdural fluid collections
- Additional complications: Shunt infection, intraparenchymal hemorrhages (neonates), abdominal pseudocyst

TOP DIFFERENTIAL DIAGNOSES



- Shunt failure with normal or stable ventricular size
  - Seen in up to 1/3 of patients with shunt malfunction
- Progressive cerebral volume loss in presence of shunt
  - ↑ size of ventricles & extraaxial CSF spaces

CLINICAL ISSUES



- Since patients with shunts often have impaired ventricular compliance, shunt malfunction requiring emergent revision may be present even when ventricles are normal or stable in size (i.e., diagnosis may be clinically based)
- Infants: Bulging fontanelle, ↑ head circumference, irritability, lethargy
- Older children/adults: Headache, vomiting, lethargy, seizure, neurocognitive symptoms

DIAGNOSTIC CHECKLIST

- Comparison to prior imaging studies is essential as patients with shunts often have abnormal ventricular size & morphology at baseline
  - Must understand clinical scenario from time that prior imaging was obtained
- Subtle changes in ventricular & extraaxial CSF space size can have significant clinical implications

(Left) *Axial NECT of the brain in a 4-year-old with Chiari 2 malformation & evidence of acute shunt malfunction shows significant interval ↑ in size of the right lateral ventricle with new periventricular hypodensity & hypodensity surrounding the shunt, consistent with acute hydrocephalus.* **(Right)** *Axial NECT in the same patient 1 month earlier (immediately after shunt placement) shows a nearly slit-like right lateral ventricle.*

(Left) *Oblique lateral 3D NECT skull reformat in an 8-year-old with Dandy-Walker malformation & shunted hydrocephalus presenting with concern for shunt malfunction shows focal separation of the peritoneal shunt catheter tubing from the shunt valve.* **(Right)** *Similar 3D NECT skull reformat performed 1 month earlier in the same patient shows a normal connection between the shunt catheter tubing & shunt valve. This is a common location for shunt disconnection.*

TERMINOLOGY

Abbreviations

- Shunt types: Ventriculoperitoneal (VP), ventriculoatrial (VA), ventriculopleural (VPL), lumboperitoneal (LP), externalized (draining outside body)
- Endoscopic 3r ventriculostomy (ETV)

Definitions

- Complications related to CSF diversion
  - Undershunting: Inadequate CSF drainage → ↑ intraventricular pressure → acute hydrocephalus
    - Can be secondary to shunt blockage or breakage (usually at sites of connection)
  - Overshunting can → intracranial hypotension
  - Subdural collections: Most often occur in severe hydrocephalus with early CSF overshunting
  - Infection: Usually from colonization of skin flora; also from distal end infection (such as bowel perforation) or hematogenous seeding
  - Relative catheter shortening related to patient growth
  - CSF egress around shunt
  - Craniocerebral disproportion: Chronic CSF shunting → lack of normal skull growth
  - Abdominal complications: Ascites, pseudocyst formation, viscus perforation, intestinal obstruction, granulomatous reaction
  - Multifocal intraparenchymal hemorrhages
    - Unique to infants, especially preterm

IMAGING

General Features

- Best diagnostic clue
  - Undershunting: Findings of acute hydrocephalus include ↑ ventricular size, periventricular edema, empty sella, dilated optic nerve sheaths (papilledema), depressed floor of 3rd ventricle, acute herniation, effacement of extraaxial CSF spaces over cerebral convexities; sutural widening in infants
- Location
  - Shunt components: Ventriculostomy catheter, ± reservoir (for CSF sampling or acutely relieving pressure), unidirectional valve (usually in scalp), & distal drainage catheter (usually peritoneal)
    - Programmable magnetic valves are MR compatible but must almost always be reset after MR exam
  - Tip of ventriculostomy catheter should ideally be within ventricles without contact of choroid plexus; frontal & occipital horns are preferred locations
    - Catheter has many sideholes; if tip has gone beyond ventricle, any sideholes remaining in ventricular system may result in adequate drainage
- Size
  - Ventricular size is relative; enlargement may indicate shunt failure in 1 patient vs. stable finding in another
    - Chronically shunted patients have ↓ ventricular compliance; small changes in ventricle size may be clinically significant
    - Up to 1/3 of patients with shunt failure will not have supportive imaging findings, leaving clinical presentation as key to diagnosis in many cases
- Morphology
  - Ventricular morphology varies greatly in patients based on underlying brain malformation, presence of prior brain injury, & how long patient has been shunted

Radiographic Findings

- Evaluate shunt catheter system integrity
  - Separation at connection points (most common), catheter breakage, migration
  - Distal catheter may retract out of abdomen if significant somatic growth has occurred since shunt placement
- Programmable shunt valve settings are often assessed using radiography or fluoroscopy
  - Can refer to individual manufacturer's guidelines for setting interpretation

CT Findings

- NECT
  - Evaluation of size & morphology of ventricles & extraaxial CSF spaces
  - High spatial resolution is ideal for evaluation of shunt catheter/tubing integrity
    - 3D skull reformats can be helpful in evaluating extracranial course of tubing
  - Periventricular hypodensity may reflect interstitial edema in acute hydrocephalus
    - Without prior studies, this can be difficult to differentiate from gliosis
- Intraventricular contrast injection through shunt + NECT→ identifies failure of contrast to disperse throughout CSF (ventricular isolation, which requires additional catheter placement)

MR Findings

- T1, T2, FLAIR
  - Periventricular T2-/FLAIR hyperintense signal in acute hydrocephalus
  - Midline structures in hydrocephalus
    - Upward bowing & thinning of corpus callosum
    - Anterior displacement of lamina terminalis
    - Depression of floor of 3rd ventricle
- T2-SSFSE/HASTE
  - Fast MR protocol can be performed to evaluate ventricular size without radiation or sedation

Ultrasonographic Findings

- Grayscale ultrasound
  - Head US: Useful in neonates for serial assessment of ventricular size (but requires open fontanelle)
  - Abdominal US: May identify localized collection (pseudocyst) restricting egress of CSF from catheter tip

Imaging Recommendations

- Best imaging tool
  - Brain NECT to assess for acute ventricular size change & catheter integrity
  - Nonsedated fast MR protocols (HASTE, SSFSE) to avoid cumulative radiation exposure & sedation
  - In neonatal period, US, MR, & CT may be used interchangeably; in conjunction with open sutures, this may create confusing assessment
    - Coronal US parameters correlate well with axial, coronal, or volumetric MR data

- Frontal occipital horn ratio (FOHR)
- Frontal temporal horn ratio (FTHR)

- Protocol advice
  - Brain CT or MR to evaluate ventricle size
  - 3D CT skull reformats to evaluate shunt course
  - Plain film shunt series to identify distal mechanical shunt fracture or disconnection

DIFFERENTIAL DIAGNOSIS

Shunt Failure With Normal or Stable Ventricle Size

- Seen in up to 1/3 of patients with shunt malfunction
- Diagnosis on clinical grounds

Progressive Cerebral Volume Loss in Presence of Shunt

- ↑ size of ventricles & extraaxial CSF spaces
- No periventricular edema
- Diagnosis is ultimately clinical

PATHOLOGY

General Features

- Etiology
  - CSF shunt establishes accessory drainage pathway to bypass obstructed natural CSF flow pathways
    - Restores or maintains normal ICP
  - Each shunt, valve, & device carries its own complications
    - All types → material degradation/fatigue, mechanical stress (especially craniocervical junction, inferior ribs)
    - VP → abdominal complications (CSF pseudocyst, ascites, bowel perforation)
    - VPL → symptomatic pleural effusion
    - VA → shunt nephritis, cor pulmonale, pulmonary embolus
    - LP → arachnoiditis, cerebellar tonsillar herniation, high catheter migration rate
    - ETV: Establishes alternate route of CSF egress from 3rd ventricle to suprasellar cistern; requires no residual internal device
      - ~ 5-10% complication rate (e.g., hemorrhage, hypothalamic injury, etc.)
      - 10-50% failure rate depending on indication, most within 1-2 weeks
      - Overshunting not possible

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Children, adults: Headache, vomiting, lethargy, seizure; neuropsychologic, cognitive, or behavioral
  - Infants: Bulging fontanelle, ↑ head circumference, irritability, lethargy
- Clinical profile
  - Depends on underlying clinical diagnosis necessitating CSF diversion, number of previous shunts, complications

Demographics

- Age: Shunts are placed early in life for aqueductal stenosis, intraventricular hemorrhage (typically grades 3-4)
  - Need for CSF diversion in Chiari 2 may be ↓ with in utero repair of myelomeningocele
  - Shunts are placed in older children following trauma, meningitis, tumor

Natural History & Prognosis

- Acute shunt failure in shunt-dependent patient is life-threatening emergency
- Majority of shunts eventually fail; complication rate: 25-37%
  - ≤ 40% shunts fail in 1st year, 80% fail by 10 years
  - 50% of patients need multiple revisions with progressively shorter time intervals between each failure

Treatment

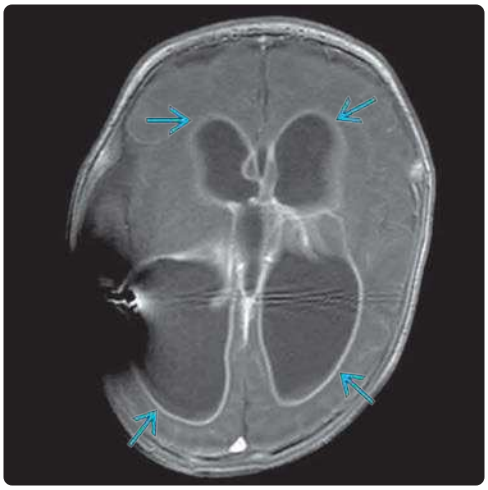
- Shunt revision
  - Replace intraventricular component/valve for proximal obstruction
  - Alter valve pressure setting/type if over- or undershunting
    - Programmable shunt valves permit transcutaneous adjustment of pressure setting
  - Lengthen distal shunt as child grows
- ETV to avoid indwelling shunt if blockage is distal to 3rd ventricle
  - Requires that suprasellar, interpeduncular, & prepontine cisterns are patent (which may not be true with recent/prior hemorrhage or meningitis)
- Laparoscopic or open abdominal procedure for distal obstruction related to CSF pseudocyst

DIAGNOSTIC CHECKLIST

Consider

- Unless there are overt imaging findings of acute hydrocephalus, shunt failure is clinical diagnosis ultimately
  - Significant number of patients with shunt failure have normal or stable ventricle size

Image Interpretation Pearls



- Comparison to priors is important as patients with shunts often have baseline abnormal ventricle size & morphology
  - Reviewing multiple prior exams (with awareness of clinical scenario at time of prior imaging, i.e., baseline vs. acute presentation for failure) can be helpful in understanding current imaging
- Subtle changes in ventricular & extraaxial CSF spaces can have significant clinical implications

Reporting Tips

- Be clear to exactly which prior studies you are comparing current exam
- Rapidly communicate clear acute shunt failure

Pathology-based Imaging Issues

In the newborn, the spine is most commonly imaged when a cutaneous lesion, such as a hemangioma or hairy patch, overlies the lumbosacral spine & implies the presence of an underlying spinal abnormality. Other findings on physical exam prompting investigation include a subcutaneous fatty mass, forked gluteal crease, or atypical dimple (above the gluteal crease). Within the first 4 months of life, US excels at imaging the spinal cord, CSF, & nerve roots, allowing for detection of a low-lying conus medullaris or intraspinal mass. Additionally, it has the advantage of requiring no sedation in the young infant. After ~ 4-6 months of age, too much of the pediatric vertebral cartilage has ossified to allow an adequate acoustic window into the spine. US can also provide vital real-time information in the operating suite to guide resection of intramedullary tumors & access syrinx cavities.

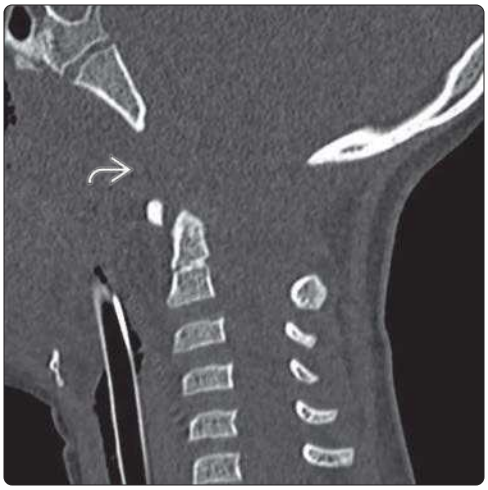
Conventional radiographs are fast, well tolerated, & relatively inexpensive but provide limited information for most pediatric spinal pathology. When combined with a good-quality clinical exam, radiographs are often sufficient for trauma evaluations. However, the negative predictive value of radiographs is low, so when clinical suspicion is high or if the clinical exam is positive or limited, further evaluation with CT &/or MR is imperative.

Speed, accessibility, & high bony detail make CT ideal for the initial evaluation of spinal trauma, but MR is essential for the assessment of neural & ligamentous injury. For chronic back pain in the older child, spondylolysis is a commonly encountered pathology that is often more confidently evaluated by CT, especially in combination with nuclear medicine SPECT. Primary osseous lesions can sometimes be more accurately characterized by investigation of their appearance on CT. Modern CT scanners allow for the rapid construction of multiplanar & volume-rendered images, which can be invaluable in the demonstration of pathology. High-quality CT images of the spine are routinely created from abdominal & thoracic CT acquisitions; therefore, dedicated CT imaging of the spine is typically not necessary if these studies have been performed.

MR provides the most complete & accurate assessment of congenital, inflammatory, & neoplastic disease of the spine. For the latter 2 categories, the administration of IV contrast is essential, but it rarely provides additional insight in congenital malformations. It is important to recognize that orthopedic stabilization devices may cause marked susceptibility artifact on MR, severely hampering the ability to evaluate the spine after surgery. This should not prevent the use of MR in evaluation of the postoperative instrumented spine; however, in many cases, the key features needed to make an accurate diagnosis can still be discerned despite the presence of marked image distortion.

Imaging Protocols

There is a temptation to always increase spatial resolution when performing medical imaging. This ignores the fact that increasing spatial resolution comes at the cost of decrease in signal-to-noise ratio. It is key to strike a balance between the best spatial resolution & image quality, so that the radiologist can not only see the lesion, but also confidently characterize it.



To that end, it can be counterproductive to image the pediatric spine with exceedingly small fields of view (FOVs). In neonates, you may achieve the best imaging quality with a single sagittal FOV, whereas 2 or even 3 overlapping FOVs are appropriate in older children. T2 should be the mainstay of most spine imaging protocols, providing the best assessment of both the spinal cord & the normal pediatric intervertebral disc. Fluid-sensitive sequences (such as STIR or T2 FS) diminish the signal of normal fat that may interfere with the assessment of pathologic fluid in fat-containing tissues; these sequences are essential for the detection of marrow & soft tissue edema in cases of trauma &/or pain. Precontrast spin-echo-based T1 provides an excellent assessment of normal bone marrow as well as any fat-containing intraspinal pathology. Postcontrast T1 should be performed with fat-saturation techniques whenever possible. High spatial resolution 3D sequences, such as CISS, T2 DRIVE, or FIESTA, are very helpful in the detection of smaller lesions & of arachnoid webs & adhesions. DWI of the spine is of most benefit in assessing for abscess & inclusion cysts (dermoid/epidermoid). The utility of DWI in the evaluation of subarachnoid tumor is still in evolution.

Embryology

In order to confidently & accurately diagnose congenital spinal abnormalities, it is necessary to have a working understanding of spinal embryology. Congenital spinal malformations can be classified into neural tube defects, split-cord or notochord malformations, & abnormalities of the caudal cell mass. Neural tube defects result from abnormalities in closure of the neural tube (neurulation), which occurs between 17-27 days of gestation. Failure of the neural ectoderm to separate from the cutaneous ectoderm will result in an open neural tube defect, which can be large in the case of a myelocele or myelomeningocele or small in the case of a dorsal dermal sinus. If disjunction occurs but is complicated by inclusion of mesoderm within the neural tube (perhaps a result of premature separation), a lipomatous malformation (lipomyelocele or lipomyelocystocele) will result. If the notochord splits during migration from the Hensen node (perhaps due to an adhesion of the ectoderm & endoderm), a split cord malformation, such as a diastematomyelia or neurenteric cyst, is the consequence. Finally, if there is a disruption of the normal canalization & retrogressive differentiation of the caudal cell mass, distal lesions, such as a terminal myelocystocele or syndrome of caudal regression, will develop. The nomenclature for these congenital lesions is confusing & often based on observations & assumptions that are no longer valid. Recognizing this, the neuroradiologist should take great care to identify & describe all the salient characteristics of the malformation, rather than assuming a diagnosis & adjusting the interpretation to fit.

(Left) *Coronal fused SPECT bone scan shows pars interarticularis defects & confirms reactive bony changes as a source of back pain.* **(Right)** *Sagittal T2 MR (left) in a teen with a Chiari 2 malformation shows a cystic lesion at the site of a prior lumbar myelomeningocele repair. The lesion has markedly restricted diffusion on DWI, confirming the diagnosis of epidermoid inclusion cyst. Recent advances have made diffusion a reasonable & useful tool in spinal imaging.*

Myelomeningocele

KEY FACTS

TERMINOLOGY

- Myelomeningocele (MMC) & myelocele (MC) comprise spectrum of open (not skin-covered) spinal dysraphisms
- MMC: Neural placode outside of spinal canal with measurable sac
- MC: Neural placode flush with skin surface or inside spinal canal

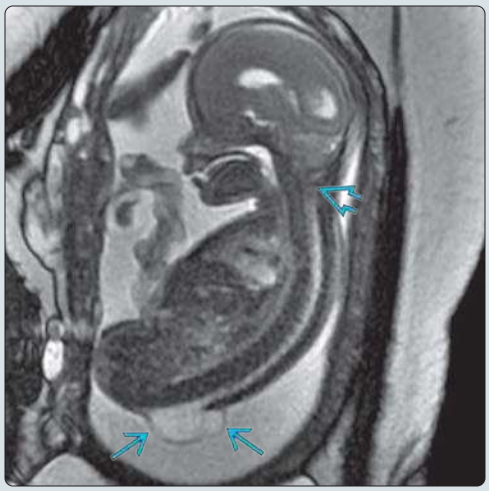
IMAGING

- Fetal US/MR: Lumbosacral dysraphism ± thin-walled MMC sac + intracranial findings of Chiari 2 (lemon sign, banana sign, ± ventriculomegaly)
- Postnatal spine imaging typically only performed after repair: Expect soft tissue covering of defect
  - Posterior osseous dysraphic defect & elongation of spinal cord persist
  - Neural placode (distal, nonneurulated segment of cord) inserts onto dorsal aspect of distal thecal sac

TOP DIFFERENTIAL DIAGNOSES

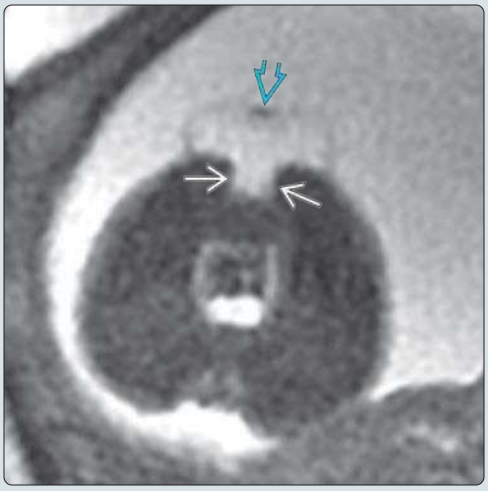
- Closed (skin-covered) spinal dysraphism
- Postoperative pseudomeningocele

CLINICAL ISSUES

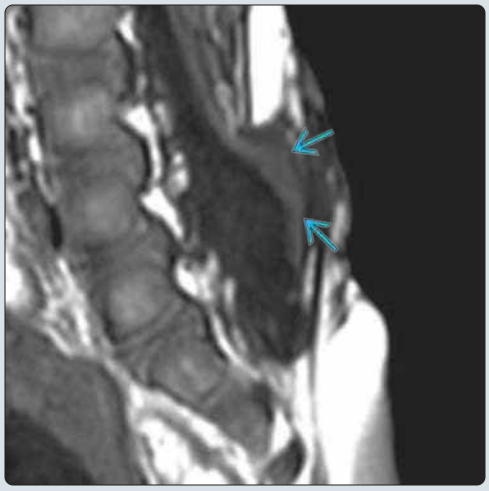


- Most common neurologic deficits: Lower extremities, bowel & bladder dysfunction
- ~ 80-85% have hydrocephalus requiring CSF diversion, though lower incidence reported after fetal repair
- Mortality: 10-30% die before adulthood
  - Brainstem/cerebellar dysfunction or shunt malfunction

DIAGNOSTIC CHECKLIST



- Most common spinal cause of delayed neurologic deterioration: Cord retethering (clinical diagnosis)
  - Spine MR (± brain imaging) to look for other causes
- For postnatal spine imaging, check clinical history to confirm history of open spinal dysraphism
  - MMC vs. MC on prenatal imaging only



(Left) *Longitudinal US of the spine in a 20-weeks-gestation fetus shows absence of posterior lumbosacral spinal elements & a measurable sac extending beyond the expected contours of the skin, consistent with a myelomeningocele (MMC)* ➡. **(Right)** *Sagittal 2D SSFP MR in the same fetus, now at 21-weeks gestation, shows the lumbosacral MMC* ⇨. *There is a small posterior fossa, caudal cerebellar herniation* ⇨, *& absence of the normal 4th ventricle, consistent with Chiari 2 malformation.*

(Left) *Axial 2D SSFP MR in the lumbosacral spine from the same fetus demonstrates the neural placode* ⇨ *outside of the open spinal canal* ➡, *consistent with an MMC.* **(Right)** *Sagittal T1 MR in the same patient at 10 months of age (status post-MMC closure) shows an expected skin-covered, postoperative appearance. The neural placode is attached to the dorsal thecal sac at the repair site* ⇨, *which is a typical finding.*

TERMINOLOGY

Definitions

- Myelomeningocele (MMC): Open (lacking skin covering) spinal dysraphism in which neural placode (exposed flattened end of elongated spinal cord) protrudes as sac beyond skin surface dorsal to spinal canal
- Myelocele (MC): Open spinal dysraphism with neural placode flush with skin surface or in spinal canal (no sac)
- Some authors refer to all open spinal dysraphisms as MMC (as MMC & MC fall along same pathologic spectrum)

IMAGING

General Features

- Best diagnostic clue
  - Absent posterior osseous elements, distorted low-lying spinal cord/roots, postoperative skin closure changes
    - Rarely imaged before repair in postnatal period due to infection risk
  - > 80% have significant hindbrain herniation in setting of Chiari 2 malformation

MR Findings

- Fetal MR
  - Abnormal elongation of spinal cord with neural placode extending into osseous dysraphism ± MMC sac
  - Intracranial findings of Chiari 2 malformation
- Postnatal MR: T1, T2
  - Postoperative soft tissue changes of MMC closure
  - Elongation of spinal cord extending to flat neural placode adherent to posterior thecal sac
    - Loss of normal posterior epidural fat at level of defect
  - Postoperative complications
    - Syringohydromyelia
    - Spinal cord compression by dermoid/epidermoid or arachnoid cyst
    - Constricting dural ring
    - Cord ischemia from vascular compromise
  - Associated anomalies: Split cord malformation (31-46%), dorsal dermal sinus, segmentation anomalies, caudal agenesis

DIFFERENTIAL DIAGNOSIS

Closed (Occult) Spinal Dysraphism

- Skin-covered osseous defect

Postoperative Pseudomeningocele

- History & clinical exam allow for differentiation

PATHOLOGY

General Features

- Etiology
  - Failure of neural tube closure in 3rd-gestational week
    - Due to lack of expression of specific receptors on surface of neuroectodermal cells
    - Likely multifactorial: Folate deficiency, toxins, genetics
  - Neurologic deficits are worsened by chronic mechanical injury & amniotic fluid exposure (chemical trauma)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Clinically obvious at birth: Exposed neural placode, usually leaking CSF
  - Dysfunction of bowel, bladder, & lower extremities
    - Higher level spine defect correlates with greater motor & somatosensory deficits
- Other signs/symptoms
  - ~ 80-85% of those that undergo postnatal repair have hydrocephalus requiring CSF diversion, though lower incidence is reported with in utero repair

Natural History & Prognosis

- Stable postoperative motor deficit in majority (~ 73%)
  - Neurologic deterioration suggests complication
- ~ 2/3 have normal intelligence, ~ 23% have ≥ 1 seizure
- Bladder, bowel, & sexual dysfunction
  - ~ 80% are bladder continent (most with catheterization)
  - ~ 38% require bowel regimen
- Lower extremity dysfunction
- Mortality: 10-30% die before adulthood
  - Majority die during infancy & early childhood from brainstem/cerebellar dysfunction
  - 2nd peak in early adulthood from shunt malfunction

Treatment

- MMC closure < 48 hours after delivery to stabilize neurologic deficits & prevent infection
- In utero surgical repair: ↓ need for shunting, ↓ Chiari 2 findings; may improve neurologic function
- Subsequent management of postoperative complications
  - Cord untethering, CSF diversion

DIAGNOSTIC CHECKLIST

Consider

- Open spinal dysraphisms are rarely imaged before repair postnatally
- Differentiation between MMC vs. MC is on prenatal imaging & has implications for fetal surgical approach
- Hindbrain herniation is seen in majority of open spinal dysraphisms after postnatal repair but not prenatal repair
- After repair, it cannot always be determined what type of spinal dysraphism was repaired (even open vs. closed spinal dysraphism) → must be correlated with clinical history

Image Interpretation Pearls

- Cord retethering is clinical diagnosis of exclusion as neural placode will always appear attached to operative site
  - Imaging is used to look for other complications causing symptoms, such as syrinx, arachnoid cyst, dermoid/epidermoid cyst

Lipomyelomeningocele

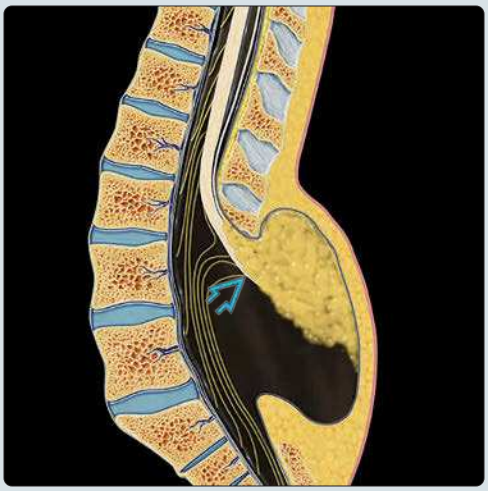
KEY FACTS

TERMINOLOGY

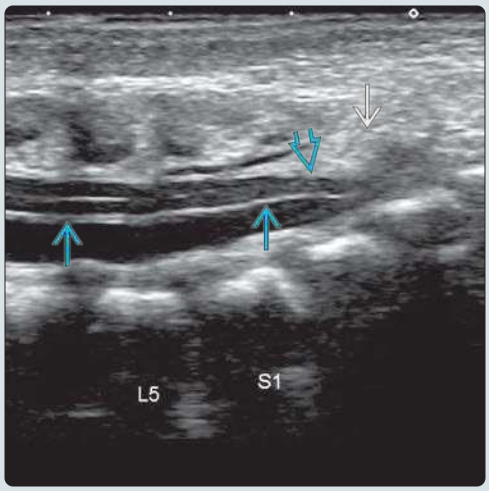
- Subtype of closed (skin-covered) spinal dysraphism characterized by lipoma extending through dorsal defect
  - Neural placode of elongated spinal cord attaches to lipomatous tissue that is continuous with dorsal subcutaneous fat through spinal dysraphic defect, forming placode-lipoma interface
  - Lipomyelomeningocele/lipomyelocele (LMMC/LMC) spectrum: Placode-lipoma interface can be within (LMC) or protrude outside (LMMC) spinal canal

IMAGING

- Elongated spinal cord ends in neural placode attached dorsally to lipomatous tissue
  - ± subarachnoid space expansion around neural placode
- ± syrinx, split cord malformation, segmentation anomalies, caudal agenesis (group 2)
- Anorectal & GU tract malformations in 5-10%

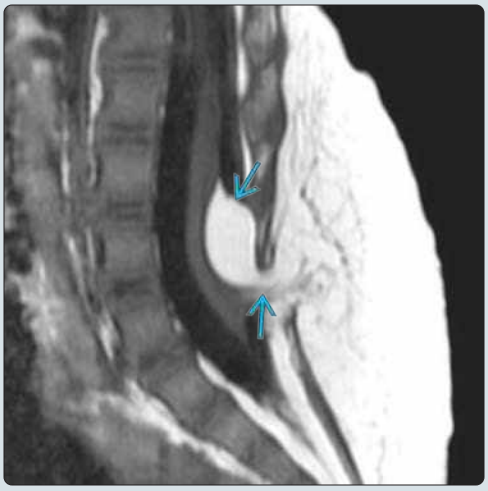


TOP DIFFERENTIAL DIAGNOSES

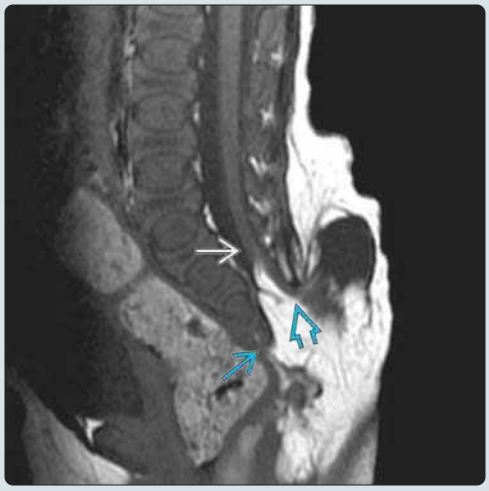


- Other closed spinal dysraphisms
  - With subcutaneous mass: Meningocele, terminal myelocystocele
  - Without subcutaneous mass: Intradural lipoma, dorsal dermal sinus
- Open spinal dysraphisms: Myelomeningocele, myelocele
- Sacrococcygeal teratoma

DIAGNOSTIC CHECKLIST



- Terminology is not uniformly adhered to in general clinical practice; precise anatomic descriptions involving placode-lipoma interface may be most helpful
- Check surgical history; accurate characterization of any spinal dysraphism is made prior to surgery
- LMMC/LMC spectrum can coexist with other closed spinal dysraphisms
- Careful evaluation for associated anomalies



(Left) *Graphic of a lumbar lipomyelomeningocele (LMMC) shows elongation of the spinal cord into a fatty mass with the placode-lipoma interface located outside the spinal canal due to the posterior spinal dysraphism.* **(Right)** *Sagittal US in a newborn shows an elongated, nondependent spinal cord attached to echogenic lipomatous tissue. The mass extends dorsally through dysraphic posterior elements, but the placode-lipoma interface remains in the spinal canal, consistent with a lipomyelocele (LMC).*

(Left) *Sagittal T1 MR of an 11-month-old with a LMMC/LMC lesion shows a low-lying conus attached to lipomatous tissue in direct communication with expanded subcutaneous fat through a spinal dysraphic defect.* **(Right)** *Sagittal T1 MR of an LMMC in a newborn shows a low-lying conus with the placode-lipoma interface extending dorsally through the deficient posterior elements. Associated sacral hypogenesis & coccygeal aplasia are noted, consistent with group 2 caudal agenesis.*

Dorsal Dermal Sinus

KEY FACTS

TERMINOLOGY

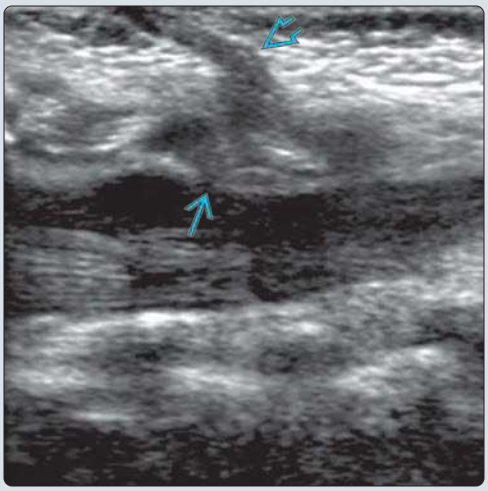
- Midline/paramidline subcutaneous sinus tract extending from skin surface toward spinal canal
- Located anywhere along neuraxis, from cranium to intergluteal cleft; most common location (~ 70%) is lumbosacral region above intergluteal cleft

IMAGING

- Linear, midline/paramidline, sagittal T1-hypointense tract in subcutaneous tissues
- Terminates anywhere from subcutaneous tissues (blind ending) to spine (epidural, intradural/intrathecal, or even intramedullary)
- ± (epi-)dermoid cysts along tract (~ 50%)
  - DWI or thin-section fluid-sensitive sequences are helpful for intrathecal mass visualization
- ± tethered cord with low-lying conus medullaris, intradural lipoma, or split cord malformation

TOP DIFFERENTIAL DIAGNOSES

- Coccygeal pit
- Pilonidal sinus/cyst
- (Epi-)dermoid without sinus tract
- Limited dorsal myeloschisis
- Lipomyelomeningocele (or other closed dysraphisms)



PATHOLOGY

- Closed spinal dysraphism due to incomplete disjunction of cutaneous & neural ectoderm at 3- to 8-weeks gestation

CLINICAL ISSUES

- Presentations include
  - Asymptomatic (incidentally noted skin dimple)
  - Infection (meningitis, abscess)
  - Neurologic deficits from cord tethering or compression
- Dorsal dermal sinus typically requires excision of entire tract
  - Intraspinal extension may be occult on imaging (necessitating operative exploration of dura)

(Left) *Sagittal graphic shows a dermal sinus extending from the skin surface into the spinal canal to terminate with epidermoid cysts at the conus medullaris. In this case, the sinus opening is marked by a skin dimple with a hairy tuft & capillary stain.* **(Right)** *Sagittal ultrasound of the spine in an infant with a cutaneous lumbar dimple demonstrates a hypoechoic dorsal dermal sinus tract ⇨ in the subcutaneous tissues. A dural defect ⇨ confirms communication of the tract with the thecal sac & subarachnoid space.*

(Left) *Sagittal T1 MR in the same patient shows a hypointense dorsal dermal sinus tract ⇨ in the subcutaneous tissues. The conus medullaris ⇨ is low-lying at the L4 level. No associated intraspinal mass or cyst is identified.* **(Right)** *Sagittal T1 C+ FS MR in the same patient at 3 years of age demonstrates the interval development of a rim-enhancing intraspinal abscess ⇨. Note that there is also enhancement along the dorsal dermal sinus tract ⇨ as it enters the spinal canal.*

Caudal Regression

KEY FACTS

TERMINOLOGY

- Sacral agenesis, caudal agenesis, caudal dysplasia, caudal dysgenesis

IMAGING

- Congenital absence of portion of caudal spine, frequently in conjunction with spinal cord malformations
- Spectrum ranges in severity from isolated coccygeal aplasia to complete lumbosacral (& even lower thoracic) spine agenesis
- 2 main types
  - Group 1: High (L1 or higher), blunted distal spinal cord
    - "Double-bundle" nerve roots
    - More severe distal osseous anomalies
  - Group 2: Tapered, low-lying distal cord
    - Other signs of cord tethering: ↓ nerve root movement, intradural lipoma, thick filum
    - Less severe osseous anomalies
- Coexisting anorectal & genitourinary anomalies are common (group 1 > group 2)

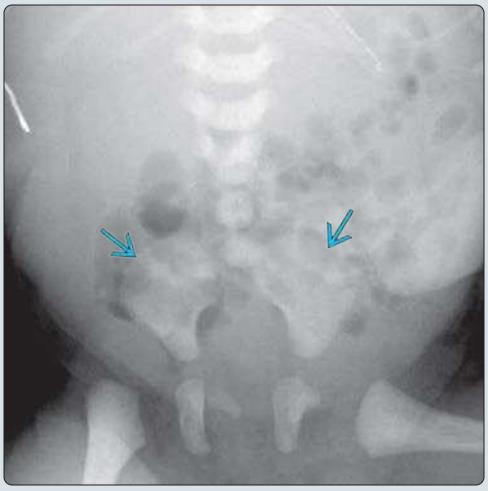
TOP DIFFERENTIAL DIAGNOSES

- Tethered spinal cord
- Other closed spinal dysraphisms
- Occult intrasacral meningocele
- Currarino triad

CLINICAL ISSUES

- ~ 200x more common in infants of diabetic mothers
- Clinical spectrum from normal to severely impaired
- Group 2 patients are more likely to require neurosurgical intervention (cord detethering) than group 1
- Usually sporadic but can be seen in various syndromes
  - OEIS, VACTERL, Currarino triad

DIAGNOSTIC CHECKLIST



- Look for caudal spine anomalies in patients with genitourinary &/or anorectal malformations

(Left) *Sagittal T2 SSFSE MR of a 24-weeks-gestation fetus with group 1 caudal regression shows absence of the sacrum with lumbar spine hypoplasia & a high, blunted conus terminating at the midthoracic spine. This fetus also had bilateral clubfeet (not shown).* **(Right)** *Sagittal T2 MR in an infant with group 1 caudal regression shows complete absence of the sacrum, a blunted, wedge-shaped conus, & a double-bundle appearance of the spinal nerve roots clumped anteriorly & posteriorly.*

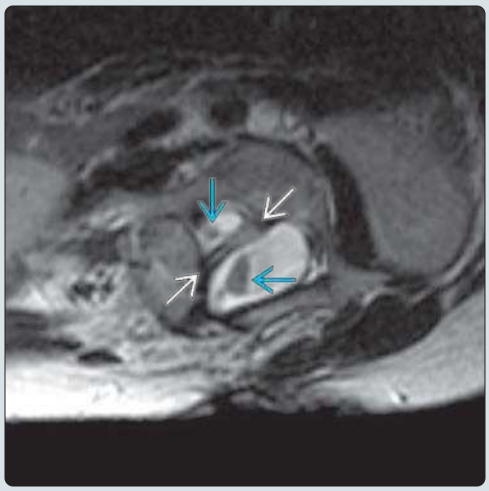
(Left) *AP radiograph in a newborn with group 1 caudal regression shows absence of the sacrum & medialization of the hypoplastic iliac bones. There is also hypoplasia of L3-L5.* **(Right)** *Sagittal T1 MR in a 5-year-old patient with group 2 caudal regression shows absence of the lower sacrum & coccyx with elongation of the spinal cord (which terminates in an intradural lipoma). Note the mild dilation of the central canal diffusely. Group 2 is suggested by less severe osseus aplasia & an elongated tethered cord.*

KEY FACTS

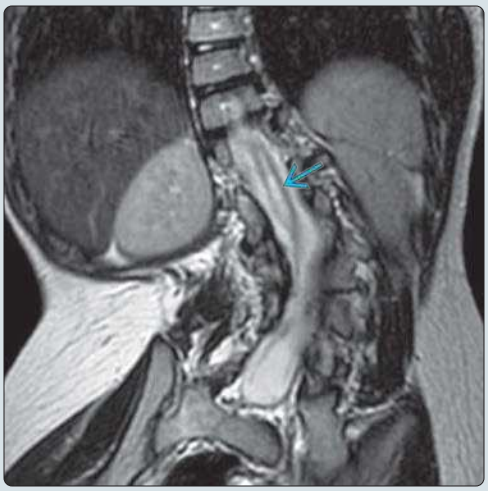
TERMINOLOGY

- Traditional terms diastematomyelia & diplomyelia are out of favor as these entities remain difficult to differentiate

IMAGING

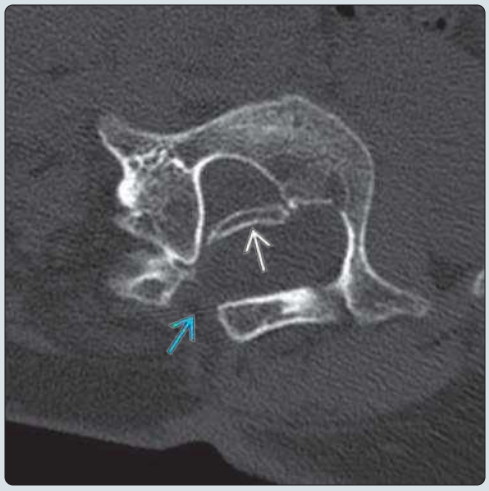


- Split cord malformation (SCM): Sagittal division of spinal cord into 2 hemicords
  - Hemicords have variable symmetry & may or may not unite below cleft
- Divided into 2 types
  - Type I SCM: 2 separate dural tubes, usually with bony/cartilaginous cleft
  - Type II SCM: Single dural sac, usually with thin, separating fibrous band
- Location is most commonly thoracolumbar (> 85%)
- Radiographs detect septum in < 50% of cases, may show widening of interpediculate distances
- ~ 85% of cases are associated with other spinal anomalies
  - Open or closed spinal dysraphisms
  - Hydromyelia, lipoma, dermal sinus, (epi-)dermoid, tethering adhesions (meningocele manqué)
  - Segmentation anomalies, kyphoscoliosis

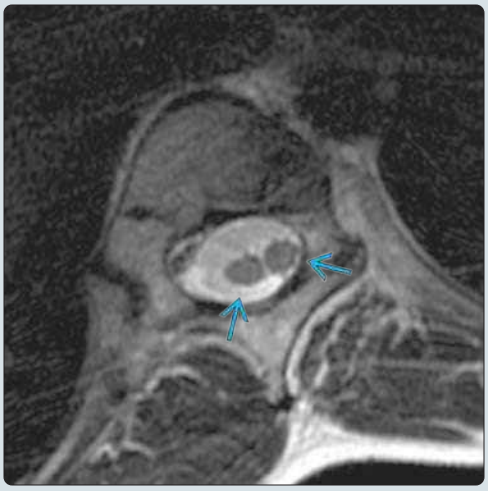


PATHOLOGY

- Believed to be result of splitting of notochord/neural plate around abnormal adhesion between ectoderm & endoderm during gastrulation



CLINICAL ISSUES



- Usually presents in early childhood
  - Cutaneous stigmata on back in > 50%
    - Hypertrichosis (hairy patch) is most common
  - Progressive kyphoscoliosis in older children & adults
  - Orthopedic foot problems (~ 50%)
  - Bladder & bowel dysfunction
- Prophylactic surgery to prevent symptom progression, especially type I SCM
  - Resection of spur, lysis of adhesions, detethering

(Left) *Axial T2 MR in a 6-year-old girl with a type I split cord malformation (SCM) at the level of the midlumbar spine demonstrates 2 hemicords within dural sacs that are separated by a bony spur. The hemicords are asymmetric in size.* **(Right)** *Coronal T2 MR in the same patient demonstrates a spinal cord syrinx above the level of the SCM. There is also marked left apex scoliosis. Associated abnormalities of the spinal cord (e.g., syrinx) & osseus spine (e.g., segmentation anomalies) are commonly seen with SCMs.*

(Left) *Axial bone CT in the same patient with a type I SCM at the level of the midlumbar spine more clearly delineates the bony septum separating the 2 dural sacs. Also note the associated dorsal spinal dysraphism, a common finding that is present in up to 85% of SCMs.* **(Right)** *Axial T2 MR in a 10-year-old with congenital scoliosis & clinical signs of tethered cord shows 2 separate hemicords of equal size within a single dural sac. Note the lack of a bony or fibrous septum in this type II SCM.*

Terminal Myelocystocele

KEY FACTS

IMAGING

- Closed (skin-covered) spinal dysraphism with bulging subcutaneous cystic mass
- Hydromyelic, low-lying spinal cord extends through osseous defect of lumbosacral spine into sac & attaches to subcutaneous fat
  - "Trumpet flaring" of distal cord
- ± T1-hyperintense lipoma or fatty thickening of sac wall (lipomyelocystocele), holocord syrinx, Chiari/hindbrain herniation (unlike other closed spinal dysraphisms)
- 3D SSFP MR images are helpful in diagnosis & delineating margins of terminal myelocystocele

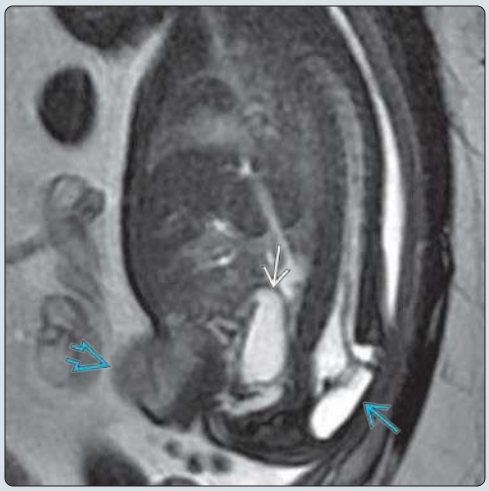
TOP DIFFERENTIAL DIAGNOSES

- Meningocele
- Lipomyelomeningocele
- Other closed spinal dysraphisms
- Sacrococcygeal teratoma

PATHOLOGY

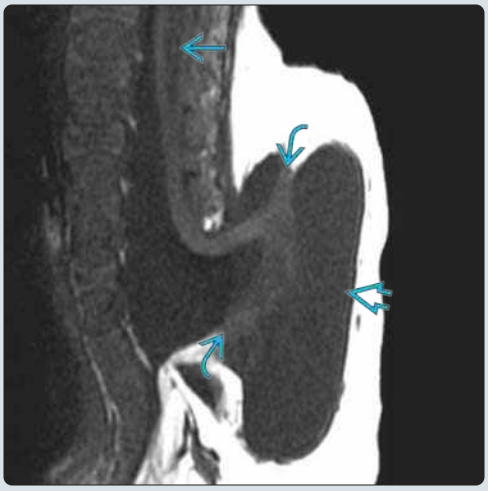
- Exact etiology is unclear; may be due to anomaly of caudal cell mass during secondary neurulation
- Associated malformations: OEIS [omphalocele, exstrophy (bladder/cloaca), imperforate anus, spinal anomalies], caudal agenesis (group 2), hindbrain herniation (not as common as seen in open spinal dysraphisms)

CLINICAL ISSUES

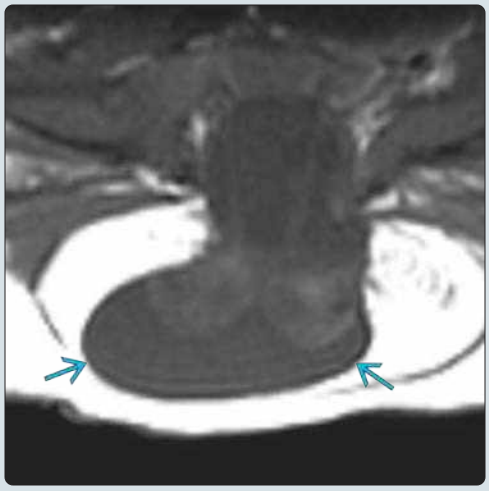


- Presents at birth with lumbosacral skin-covered mass
- Can have rapid neurologic deterioration early in life, more so than other closed spinal dysraphisms
- Early neurosurgical intervention is recommended

DIAGNOSTIC CHECKLIST



- Early diagnosis & surgery → best chance for normal neurological outcome
- Nonneurological prognosis is largely linked to severity of associated anomalies



(Left) *Sagittal graphic displays a closed (skin-covered) dysraphism with a low-lying, hydromyelic spinal cord piercing an expanded subarachnoid space (meningocele) & terminating in a myelocystocele, which is in continuity with the central canal of the spinal cord.* **(Right)** *Sagittal SSFP MR of a fetus at 28-weeks-gestational age demonstrates a terminal myelocystocele. There are additional findings of the OEIS complex, including a low omphalocele & a cloacal malformation.*

(Left) *Postnatal T1 MR in the same patient 11 weeks after delivery confirms the presence of a skin-covered terminal myelocystocele with splaying of the neural elements around a fluid collection that does not communicate with the surrounding subarachnoid space. There is also syringohydromyelia.* **(Right)** *Axial T1 MR in the same patient shows the terminal myelocystocele located superficial & posterior to the spinal dysraphism. The terminal myelocystocele is covered by skin & fat.*

Neurenteric Cyst

KEY FACTS

TERMINOLOGY

- Cyst along neuraxis is lined with mucin-secreting cuboidal or columnar epithelium resembling alimentary tract
  - Derived from displaced endodermal tissue
- Synonyms: Enteric, enterogenous, or endodermal cyst

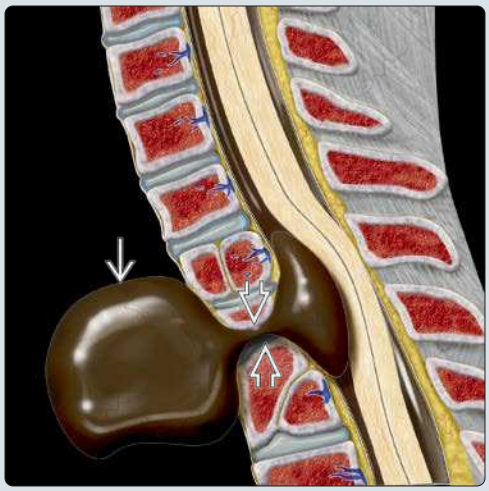
IMAGING

- Cyst along neuraxis (intraspinal/paraspinal) ± vertebral anomalies
  - Associated bony abnormalities in most cases
- Most are intradural extramedullary simple, unilocular cysts ventral to spinal cord
- Can be associated with other closed spinal dysraphisms
- ± associated fistulae & mediastinal/abdominal cysts

TOP DIFFERENTIAL DIAGNOSES

- Arachnoid cyst
- (Epi-)dermoid cyst
- Anterior spinal meningocele

PATHOLOGY



- Enteric & spinal structures are connected through persistent neurenteric canal (a.k.a. canal of Kovalevsky)
- Subgroup of split notochord syndrome spectrum
  - Sporadic or syndromic (Klippel-Feil, VACTERL, OEIS)
  - Associated with vertebral anomalies, split cord malformation, lipoma, dermal sinus tract, & tethered spinal cord

CLINICAL ISSUES

- Some are asymptomatic but most show progressive neurologic deterioration
- Best treatment (not always possible): Complete excision

DIAGNOSTIC CHECKLIST

- Location, size of cyst, degree of cord compression, & severity of associated anomalies determine prognosis
- Look for associated mediastinal or abdominal cysts, connecting fistulae, or vertebral anomalies

(Left) *Sagittal graphic shows a large mediastinal enteric cyst extending into the ventral spinal canal through a persistent neurenteric canal (a.k.a. canal of Kovalevsky). There is dorsal displacement & compression of the thoracic spinal cord. Associated bony abnormalities are present in most cases.* **(Right)** *Sagittal T2 MR of a 3-year-old boy with a remote history of a high-spinal dysraphism repair shows a ventral dysraphic defect of the lower cervical spine associated with a cyst in the paraspinal soft tissues.*

(Left) *Sagittal T1 MR in the same patient shows intermediate signal in the paraspinal cyst, hyperintense to CSF, making a neurenteric cyst the leading consideration. This was confirmed on pathology after resection.* **(Right)** *Coronal T2 MR in the same patient demonstrates the right paraspinal neurenteric cyst with multiple adjacent segmentation anomalies at the cervicothoracic junction.*

Syringomyelia

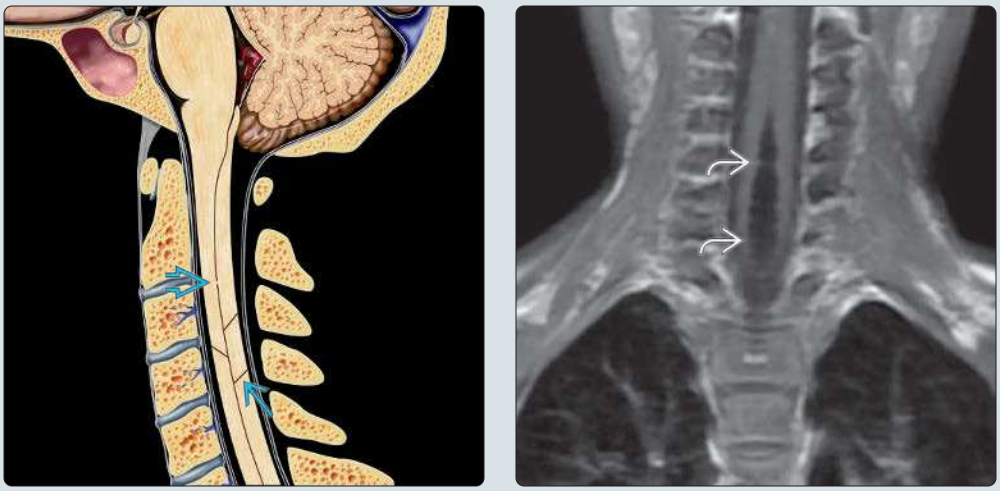
KEY FACTS

TERMINOLOGY

- Hydromyelia: Cystic dilation of spinal cord central canal
- Syringomyelia: Cystic spinal cord cavity not contiguous with central canal

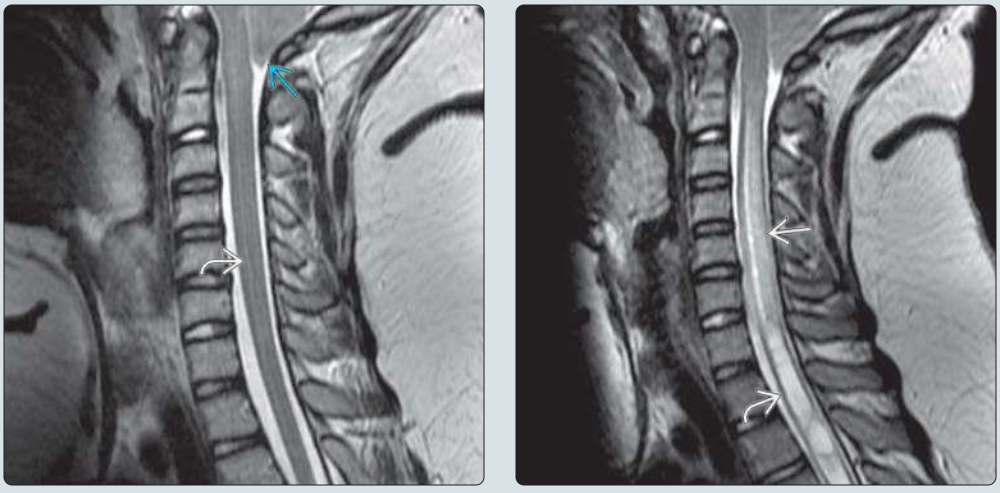
IMAGING

- Overlap between incidental (nonprogressive) & pathologic central canal dilation
- Incidental/nonprogressive central canal dilation may be up to 4 mm
  - True syrinx is associated with cord expansion
- Extent & morphology are best demonstrated on T2
  - Axial plane is most reliable for diameter measurement
- Volumetric/3D sequences may demonstrate adhesions
- Give contrast to look for underlying lesion if atypical features are present
  - Not needed in vast majority of cases



PATHOLOGY

- Central canal of spinal cord transmits CSF in rostral direction toward obex
- Lesions obstructing both central canal & subarachnoid space (SAS) → syrinx
  - Tumor, inflammation
  - Chiari malformation
- Congenital anomalies (frequent in children)
  - Chiari 1 malformation (not always congenital)
    - 10-15% of children with Chiari 1 present with syrinx
    - Combination of scoliosis + Chiari 1 is associated with larger cavities
  - Chiari 2 malformation



CLINICAL ISSUES

- Those associated with underlying malformations (Chiari 1 or 2, tethering lesions) are more likely to progress
- Suboccipital decompression can reverse/resolve syrinx associated with Chiari malformations

(Left) *Sagittal graphic shows that the normal central canal has multiple small obstructions ⇨ but also small channels ⇨ that lead from the central canal to the subarachnoid space. As a result, CSF flow must be impeded in both compartments for a syrinx to develop. Small obstructions may serve the same function as venous valves in the lower extremities, directing CSF flow cephalad to the obex.* **(Right)** *Coronal T1 MR shows resulting pseudohaustrations ⇨ in a syrinx.*

(Left) *Sagittal T2 MR in a teenager with a Chiari 1 malformation ⇨ of the craniocervical junction shows that the central canal ⇨ is barely visible.* **(Right)** *Sagittal T2 MR obtained 14 months later in the same patient because of right arm pain when sneezing shows development of a syrinx at the cervicothoracic junction ⇨ with dilation of the central canal cephalad & extensive presyrinx edema in the cervical cord ⇨. Subsequent suboccipital decompression resulted in complete resolution of the syrinx.*

TERMINOLOGY

Definitions

- Hydromyelia: Cystic dilation of spinal cord central canal
- Syringomyelia: Cystic spinal cord cavity not contiguous with central canal
- Syringohydromyelia: Features of both syringomyelia & hydromyelia
- Syringobulbia: Extension of syrinx/cavity into brainstem
- "Presyrinx" state: Reversible spinal cord edema produced by alterations in CSF flow dynamics

IMAGING

General Features

- Location
  - Intramedullary spinal cord
  - Typically centrally located on axial images
    - Off-midline location is of ↑ concern for neoplastic, traumatic, or inflammatory etiology
  - Thoracic > cervicothoracic > cervical
- Size
  - Cavity diameter: Small → markedly dilated
    - Overlap between incidental (nonprogressive) & pathologic, central canal dilation
      - Incidental/nonprogressive central canal dilation may be up to 4 mm
      - True syrinx is associated with cord expansion
  - Cavity length: Ranges from short segment (1 or 2 levels) to holocord
- Morphology
  - CSF-filled cavity in spinal cord
    - May have flow artifact (seen in larger lesions)
    - May be septated & lobulated or smooth & simple

MR Findings

- T2WI
  - Hyperintense, cystic, intramedullary cavity ± adjacent gliosis, myelomalacia
  - ± flow artifact with poorly defined, heterogeneously hypointense signal throughout larger cavities
  - ± adhesions on 3D/volumetric sequences
- T1WI C+
  - Simple syrinx does not enhance; enhancement suggests inflammatory or neoplastic lesion

Imaging Recommendations

- Protocol advice
  - Extent & morphology are best demonstrated on T2
    - Axial plane is most reliable for diameter measurement
  - Volumetric/3D sequences may demonstrate adhesions
  - Give contrast to look for underlying lesion if atypical features are present
    - Not needed in vast majority of cases

PATHOLOGY

General Features

- Etiology
  - Central canal of spinal cord transmits CSF in rostral direction toward obex
    - Normal canal has multiple sites of obstruction/adhesion/collapse (↑ with age)
      - May function like valves in venous system
    - Multiple microscopic channels lead from canal to subarachnoid space (SAS)
      - Similar to perivascular spaces in brain
      - Allow CSF to be driven into canal from SAS
    - Lesions obstructing both central canal & SAS → syrinx
      - Tumor, inflammation
      - Chiari malformation
    - Posttraumatic or postinflammatory myelomalacia can also cause cavitation
      - Analogous to porencephaly in brain
- Associated abnormalities
  - Congenital anomalies (frequent in children)
    - Chiari 1 malformation (not always congenital)
      - 10-15% of children with Chiari 1 present with syrinx
      - May develop syrinx over time
      - Combination of scoliosis + Chiari 1 is associated with larger cavities
    - Chiari 2 malformation
  - Scoliosis
  - Tumors
    - Up to 45% of primary spinal cord tumors have syrinx at presentation
      - More common in adults than children

CLINICAL ISSUES

Presentation

- Distal upper extremity weakness, gait instability
- Cloak-like pain & temperature sensory loss
  - Shock-like pain with Valsalva (sneezing)
- May be asymptomatic

Natural History & Prognosis

- Variable; dependent on underlying etiology
  - Those associated with underlying malformations (Chiari 1 or 2, tethering lesions) are more likely to progress

Treatment

- Suboccipital decompression can reverse/resolve syrinx associated with Chiari malformations

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Do not label central canal of 1- to 2-mm diameter as syrinx
- Simple syringomyelia does not require contrast
  - Give contrast for associated cord signal abnormalities, complex morphology, focal mass, or off-midline location

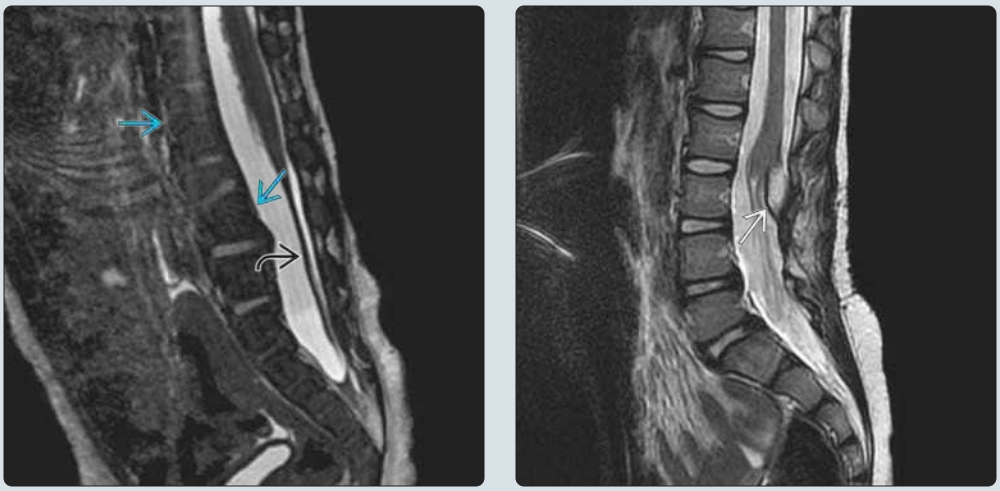
Tethered Spinal Cord

KEY FACTS

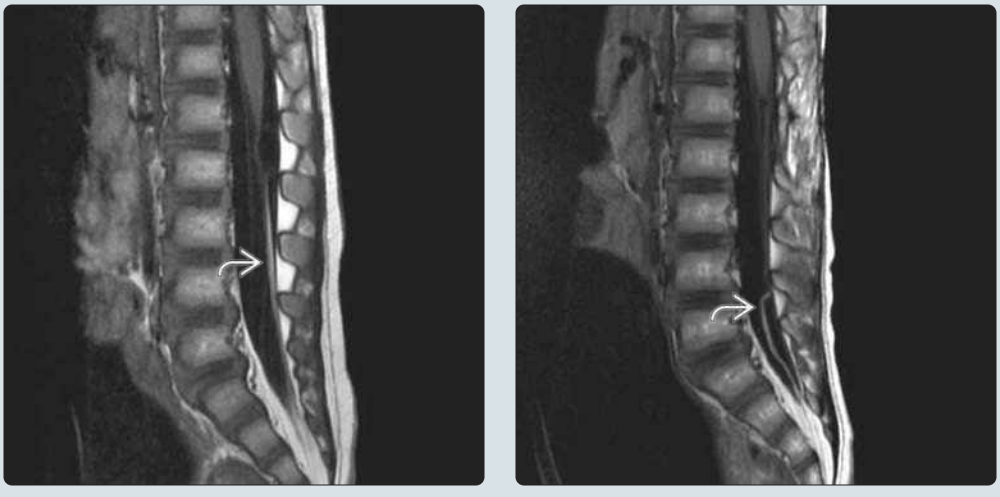
IMAGING

- Best clue: Low-lying conus medullaris
  - May have thickened filum terminale ± fatty infiltration or lipomatous mass
  - Accompanied by clinical signs & symptoms of tethering
    - Lower extremity weakness, spasticity, & ↓ sensation; abnormal gait; bladder dysfunction
- General imaging features
  - Conus below L2-L3 disc level
  - May appear taut or directly apposed to dorsal thecal sac
    - Lack of conus motion with CSF pulsations
    - Lack of dependent ventral shift of conus when prone
  - Filum > 2 mm thick (at L5-S1 on axial/transverse images)
    - ± echogenic (US) or T1 (MR) bright fatty mass at conus
    - ± bony/soft tissue dysraphism
- Ultrasound to screen infants (< 6 months old) at ↑ risk of spinal anomalies (as suggested by certain cutaneous stigmata or associated systemic anomalies)
- MR to define underlying anomalies for surgical planning in symptomatic patients



PATHOLOGY

- Cutaneous stigmata in up to 50%
  - Hairy patch, hemangioma, skin tag, atypical dimple
- Tethering also found in clinically apparent open & closed spinal dysraphisms
- Tethered filum is histologically abnormal
  - ↑ connective tissue with dense collagen fibers, hyalinization, & dilated capillaries



CLINICAL ISSUES

- Tethered cord syndrome: Clinical diagnosis; imaging in specific screening circumstances or to detect associated anomalies for surgical planning
- Symptomatic presentation is most common during rapid growth (4-8 years of age & adolescent growth spurt)
- Majority show improvement or stabilization of neurologic deficits following surgical untethering

(Left) *Sagittal 3D SSFP MR in a 6-month-old with bilateral clubfeet & multiple segmentation anomalies shows a taut & thickened filum terminale tethering the conus medullaris, which terminates at the level of L3.* **(Right)** *Sagittal T2 MR in a 4-year-old with a sacral dimple shows an intradural lipoma tethering the conus medullaris at the level of L3. Note the chemical shift artifact at the junction of the lipoma & the conus.*

(Left) *Sagittal T1 MR in an 18-month-old with motor delay, ↑ lower extremity tone, & plantar flexion shows fatty infiltration of the filum terminale (filar fibrolipoma), which is adherent to the dorsal aspect of the lumbar canal.* **(Right)** *Sagittal T1 MR in the same patient after surgical tethered cord release shows the slightly retracted distal limb of the sectioned filum, now fallen away from the dorsal canal.*

KEY FACTS

TERMINOLOGY

- 2016 WHO CNS tumor classification designation
- Low-grade glioneuronal tumor that presents with diffuse leptomeningeal dissemination

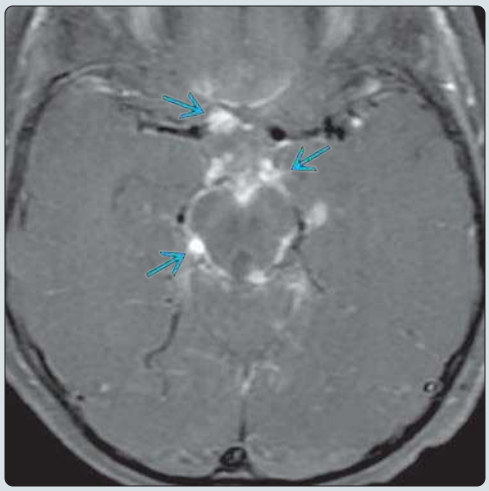
IMAGING

- Best clue: Diffuse leptomeningeal neoplastic disease without identifiable primary tumor
- Hydrocephalus in ~ 30%
- Location: 73% intracranial, 62% intraspinal
- Leptomeningeal thickening & enhancement
- ± leptomeningeal nonenhancing cystic foci
- ± nonenhancing intramedullary spinal lesions
- Best imaging: MR with contrast of entire neuraxis

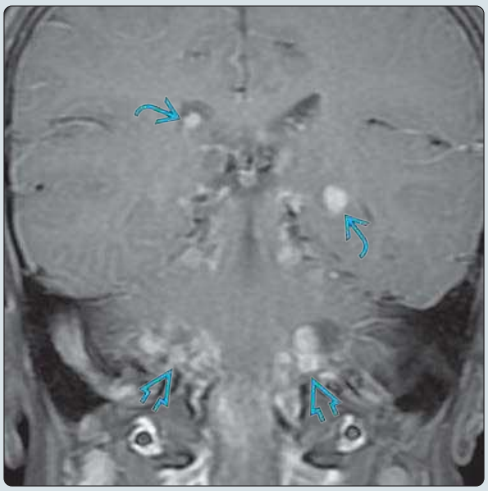
TOP DIFFERENTIAL DIAGNOSES

- Chronic infection
  - Tuberculosis
  - Neurocysticercosis (especially racemose type)
- Leptomeningeal metastatic disease
- Vascular disease (e.g., Sturge-Weber syndrome)
- Neurosarcoidosis
- Neurocutaneous melanosis

PATHOLOGY



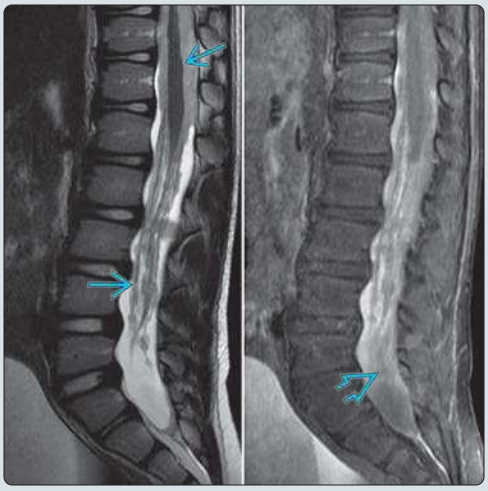
- Low-grade neoplasm of neuronal & glial populations with propensity for leptomeningeal dissemination
- Commonly show *BRAF* mutations



CLINICAL ISSUES

- Headache, seizures, cranial nerve dysfunction
- Variable prognosis with typical slow tumor growth
- No optimal evidence-based treatment strategy

DIAGNOSTIC CHECKLIST



- Consider in young patient with diffuse leptomeningeal disease, no primary tumor, & no clinical signs of infection

(Left) *Axial T1 C+ FS MR in a 6-year-old who presented years earlier with hydrocephalus of unknown etiology, later diagnosed with diffuse leptomeningeal glioneuronal tumor (DLGNT), shows extensive leptomeningeal enhancement & nodularity in the basilar cisterns, which is the most common area of intracranial involvement in DLGNT.* **(Right)** *Coronal T1 C+ FS MR in the same patient shows the heaviest burden of leptomeningeal disease in the inferior cerebellar regions with intraventricular disease as well.*

(Left) *Sagittal T2 (left) & T1 C+ FS (right) MR images in a 5-year-old with headaches & abnormal gait show extensive leptomeningeal disease within the posterior fossa & spine. Also note the sizable intramedullary lesion at the cervicothoracic junction, a finding seen in ~ 20% of DLGNT cases.* **(Right)** *Sagittal T2 (left) & T1 C+ FS (right) MR images in the same patient show disease along the distal cord & cauda equina. In cases of DLGNT with large tumor burden, contrast may leak into the thecal sac, as in this case.*

KEY FACTS

TERMINOLOGY

- Spinal cord neoplasm arising from ependymal cells

IMAGING

- Heterogeneous, intramedullary spinal cord mass
- Cervicothoracic, filum/conus
  - Most are intramedullary
  - Myxopapillary tumors are found at conus medullaris & arising from filum terminale
- Heterogeneous but mostly hyperintense on T2
  - Hemorrhage & cysts are common

TOP DIFFERENTIAL DIAGNOSES

- Astrocytoma
  - Less heterogeneous than ependymoma
  - Indistinct margins
- Cavernous malformation
- Hemangioblastoma

PATHOLOGY

- Most are WHO grade 2
  - 4 subtypes: Cellular, papillary, clear cell, tanycytic
- Myxopapillary are WHO grade 1
- Rare WHO grade 3: Anaplastic ependymoma
  - *MYCN* amplification is associated with anaplastic features, aggressive clinical behavior
- At least 1/3 of those with NF2 will eventually develop spinal cord ependymoma

CLINICAL ISSUES

- Neck or back pain, progressive paraparesis, paresthesias
- 2nd most common primary spinal cord tumor in children
- Prognosis of grade 1 & 2 tumors is largely dependent upon extent of resection
  - Most series report 5- & 10-year survival rates of 50-100% following combination of both surgery & postoperative radiation treatment

(Left) *Sagittal T2 MR in a 16-year-old with 2 weeks of back pain after minor trauma shows a complex hemorrhagic mass at the base of the cauda equina, consistent with the eventual histologic diagnosis of myxopapillary ependymoma.* **(Right)** *Sagittal T1 C+ FS MR in a teenager with NF2 shows a bilobed enhancing intramedullary mass, confirmed to be an ependymoma (grade 2). Any intramedullary cord tumor in NF2 is presumed to be an ependymoma, & they are diagnosed in at least 1/3 of those with NF2.*

(Left) *Sagittal T2 MR in a 13-year-old presenting with neck/back pain & subsequent gait abnormalities shows a well-defined, exophytic tumor at the cervicothoracic junction, with internal cysts.* **(Right)** *Sagittal T1 C+ FS MR in the same patient shows diffuse & heterogeneous enhancement of the tumor, which was an anaplastic ependymoma (grade 3) at surgery. Most spinal ependymomas are grade 1 or 2 lesions; higher grades are seen in < 10% of cases.*

TERMINOLOGY

Definitions

- Spinal cord neoplasm arising from ependymal cells

IMAGING

General Features

- Best diagnostic clue
  - Heterogeneous, intramedullary spinal cord mass
- Location
  - Cervicothoracic, filum/conus
  - Most are intramedullary
    - Myxopapillary tumors are found at conus medullaris, arising from filum terminale
      - More frequent in adults
- Morphology
  - Well circumscribed
  - May have exophytic component
- Typical MR features
  - Isointense to hypointense on T1
  - Heterogeneous but mostly hyperintense on T2
    - May have cystic foci
      - May be within tumor, at rostral & caudal margins, or due to reactive syrinx
  - Hemorrhagic foci in or at margins of tumor
  - Heterogeneous enhancement

Imaging Recommendations

- Best imaging tool
  - Sagittal & axial T2 & T1 C+

DIFFERENTIAL DIAGNOSIS

Astrocytoma

- Most common primary cord neoplasm in children
- Less heterogeneous than ependymoma
  - Hemorrhage & cysts are less common
- Often larger, can be holocord
- Indistinct margins

Cavernous Malformation

- Focal hemorrhagic lesion
- Little or no enhancement
- Rare below cervical cord

Hemangioblastoma

- Older patients
- 1/3 with von Hippel-Lindau disease
- Cyst with enhancing, highly vascular nodule
  - Flow voids may be present

Multiple Sclerosis

- Often multifocal; 90% have brain lesions
- Lesions are more often peripheral, posterolateral
- Typically < 2 vertebral segments in length
- < 1/2 cross-sectional area of cord involved on axial images

Idiopathic Transverse Myelitis

- Cord expansion is less pronounced
- Less well defined
- Diagnosis of exclusion

Cord Infarction

- Sudden onset of symptoms
- Central gray matter is typically involved

Cord Contusion

- History of trauma

PATHOLOGY

General Features

- Genetics
  - Different from intracranial ependymoma

Staging, Grading, & Classification

- Most are WHO grade 2
- Myxopapillary are WHO grade 1
- Rare WHO grade 3: Anaplastic ependymoma

Microscopic Features

- Arises from ependymal cells of central canal
- 4 subtypes (grade 2): Cellular, papillary, clear cell, tanycytic
  - Cellular is most common intramedullary tumor subtype
  - *MYCN* amplification is associated with anaplastic features, aggressive clinical behavior
  - H3K27me3 may predict better prognosis

CLINICAL ISSUES

Presentation

- Neck or back pain, progressive paraparesis, paresthesias
- Delay in diagnosis is due to slow growth

Demographics

- Epidemiology
  - 2nd most common primary spinal cord tumor in children
  - 30% of all ependymomas are spinal
  - At least 1/3 of those with neurofibromatosis type 2 (NF2) will eventually develop spinal cord ependymoma

Treatment

- Prognosis of grade 1 & 2 tumors is largely dependent upon extent of resection
  - Gross total resection in > 85% of cases
- Radiation for subtotal resection, grade 3, or recurrent disease
- Chemotherapy for failed surgery & radiotherapy
- Most series report 5- & 10-year survival rates of 50-100% following combination of both surgery & postoperative radiation treatment

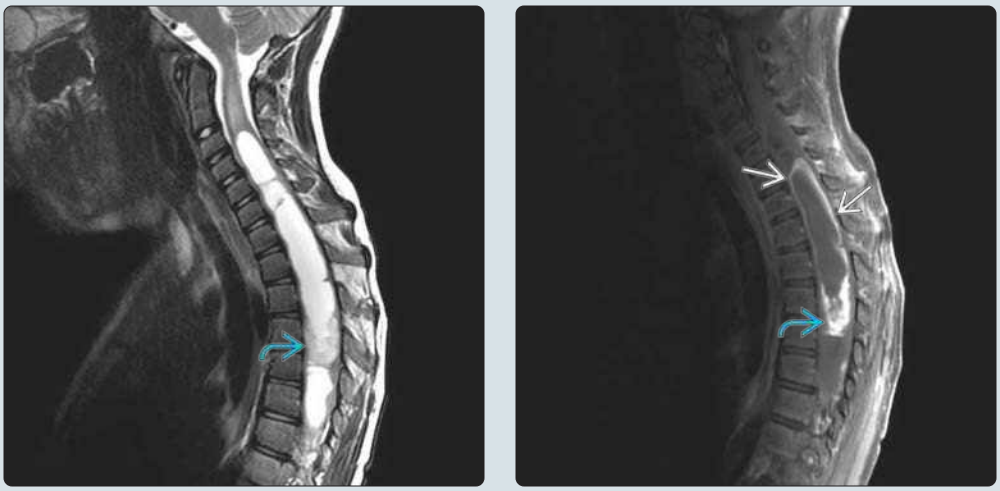
KEY FACTS

IMAGING

- Cervical > thoracic > lumbar locations
- Oblong, fusiform expansion of cord
  - 40% have tumor cysts or syringohydromyelia
- Variable enhancement
  - Pilocytic tumors (WHO grade 1) typically enhance avidly
  - Diffuse astrocytomas (WHO grade 2) typically have minimal, if any, enhancement

TOP DIFFERENTIAL DIAGNOSES

- Transverse myelitis
  - Similar imaging features
- Ganglioglioma
  - Similar imaging features
- Ependymoma
  - Less common in children than adults
- Multiple sclerosis
  - Short-segment lesions involving < 1/2 of cord cross section



PATHOLOGY

- 75-80% are low grade
  - Pilocytic astrocytoma = WHO grade 1
    - Rosenthal fibers
  - Diffuse astrocytoma = WHO grade 2
    - ↑ cellularity, variable atypia/mitoses
- 20-25% are high grade
  - Anaplastic astrocytomas = WHO grade 3
    - Dispersed anaplasia
  - Glioblastoma = WHO grade 4
    - Microvascular proliferation & palisading necrosis
  - Diffuse midline glioma = WHO grade 4
    - K27M mutation in histone 3

CLINICAL ISSUES

- Most common spinal cord tumor in children
- Survival varies with tumor histology/grade & degree of tumor resection; 80% 5-year survival for low grade

(Left) *Sagittal T2 MR in an 11-year-old with back pain & scoliosis shows a complex, intramedullary cyst in the cervicothoracic cord. Note the solid tissue at the caudal aspect of the lesion.* **(Right)** *Sagittal T1 C+ FS MR in the same patient demonstrates avid enhancement of the solid portions of the lesion as well as the walls of the cyst. Surgery confirmed a pilocytic astrocytoma (WHO grade 1).*

(Left) *Sagittal T2 MR in an infant initially treated for transverse myelitis at 6 months of age shows a residual, expansile, hyperintense mass of the cervicothoracic cord, shown to be a WHO grade 3 anaplastic astrocytoma upon biopsy.* **(Right)** *Sagittal T1 C+ FS MR in a 13-year-old who had 3 weeks of vomiting & headache followed by arm weakness shows a heterogeneously enhancing tumor extending from the cervicomedullary junction into the cord. Glioblastoma (WHO grade 4) was found at biopsy.*

TERMINOLOGY

Definitions

- Primary intramedullary neoplasm of spinal cord originating from astrocytes

IMAGING

General Features

- Location
  - Cervical > thoracic > lumbar
- Morphology
  - Oblong, fusiform expansion of cord
- Typical MR features
  - Up to 40% have tumor cysts or syringohydromyelia
  - Solid portion is hypo-/isointense on T1, hyperintense on T2; rarely hemorrhagic
  - Variable enhancement
    - Pilocytic tumors (WHO grade 1) typically enhance avidly
    - Diffuse astrocytomas (WHO grade 2) typically have minimal, if any, enhancement
  - Diffusion
    - Facilitated diffusion (↑ ADC values) if low grade
    - Restricted diffusion (↓ ADC values) if high grade

DIFFERENTIAL DIAGNOSIS

Transverse Myelitis

- Similar imaging features; absent or mild enhancement

Ganglioglioma

- Similar imaging features

Ependymoma

- Less common in children than adults
- Sharply delineated tumor, often with hemorrhage
  - May present as superficial siderosis

Multiple Sclerosis

- Short-segment lesions involving < 1/2 of cord cross section
- Predominantly in dorsal aspect of cord

Cord Infarct

- Central gray matter involvement is typical, may involve entire cord cross section

PATHOLOGY

General Features

- Associated abnormalities
  - Some ↑ risk with neurofibromatosis type 1 & 2 (NF1, NF2); ependymoma & extramedullary tumors are more common in NF2

Staging, Grading, & Classification

- 75-80% low grade
  - Pilocytic astrocytoma = WHO grade 1
  - Diffuse astrocytoma = WHO grade 2
- 20-25% high grade
  - Anaplastic astrocytomas = WHO grade 3
  - Glioblastoma = WHO grade 4
  - Diffuse midline glioma = WHO grade 4

Microscopic Features

- Pilocytic astrocytoma
  - Rosenthal fibers
  - Glomeruloid/hyalinized vessels
  - Low prevalence of nuclear atypia/mitoses
- Diffuse astrocytoma
  - ↑ cellularity, variable atypia/mitoses
  - Parenchymal infiltration
- Anaplastic astrocytoma
  - Dispersed anaplasia
  - Significant proliferative activity
- Glioblastoma
  - Highly cellular & heterogeneous
  - Microvascular proliferation & palisading necrosis
- Diffuse midline glioma
  - K27M mutation in histone 3
  - Resembles diffuse astrocytoma microscopically but far more infiltrative & aggressive

CLINICAL ISSUES

Presentation

- Scoliosis, pain, myelopathy, muscle wasting

Demographics

- Most common spinal cord tumor in children
  - 30-35% of intraspinal neoplasms in children
  - 60% of primary spinal cord tumors in children
  - Higher-grade lesions are much less frequent in children

Natural History & Prognosis

- Most are slow growing
- Survival varies with tumor histology/grade & degree of tumor resection
  - 80% 5-year survival for low grade

Treatment

- Gross total resection is goal in pilocytic & low-grade tumors
  - Definitive treatment for pilocytic tumors
  - Intraoperative evoked potentials are helpful for maximal resection without damaging normal tissue
  - Intraoperative US can show extent of tumor vs. syrinx

DIAGNOSTIC CHECKLIST

Consider

- Remember inflammatory lesions in differential

Image Interpretation Pearls

- Image entire spinal cord
- Subtotal surgical resection may be unimpressive on imaging
  - Residual lesion "fills in" resection cavity

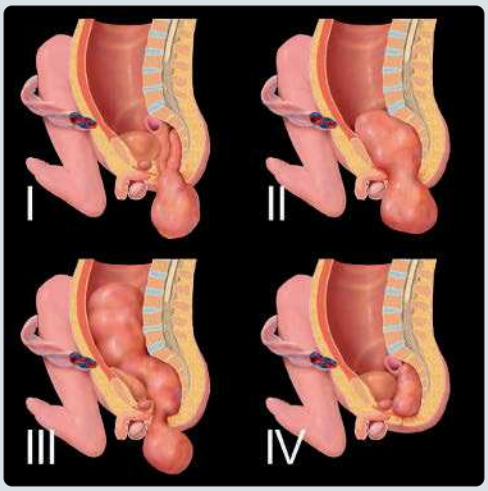
Sacrococcygeal Teratoma

KEY FACTS

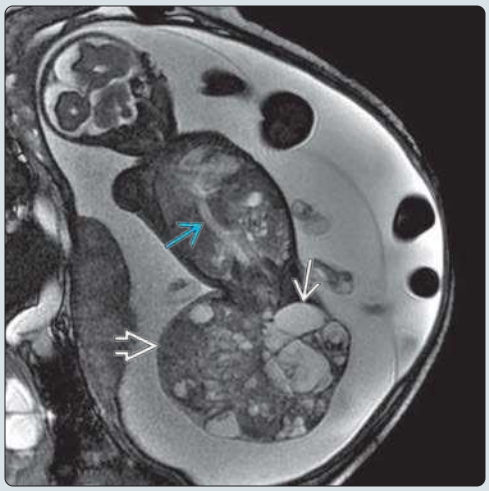
TERMINOLOGY

- Teratomas are made up of various parenchymal cell types from > 1 germ layer, usually all 3
- Sacrococcygeal teratoma (SCT) arises from coccyx, potentially grows both internally & externally
- Both benign & malignant (17%) varieties occur

IMAGING

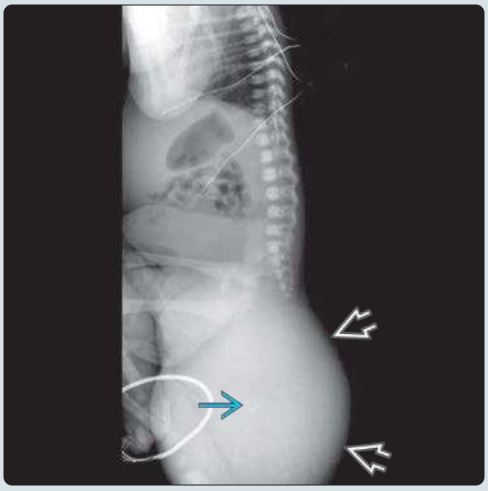


- Always has presacral component; exophytic extension is more common than internal growth
- Heterogeneous, mixed solid & cystic masses
  - Ca^{2+}, fat, hemorrhage, cysts, various soft tissues in mass
  - Solid components may show moderate to high vascularity
- MR is best for identifying intraspinal extension

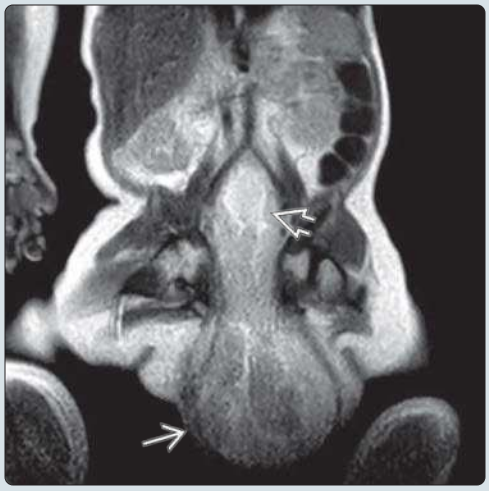


PATHOLOGY

- Malignant characteristics ↑ with age, type IV
- Currarino triad: Presacral mass (anterior meningocele or SCT), anorectal malformation, sacral anomalies
- American Academy of Pediatrics Surgical Section classification
  - Type I (47%): Primarily external in location
  - Type II (34%): Dumbbell, pelvic & external components
  - Type III (9%): Primarily located within abdomen/pelvis
  - Type IV (10%): Entirely internal, no external component



CLINICAL ISSUES



- Prognosis is variable: Fetal SCT can be quite vascular & grow rapidly → hydrops, intratumoral hemorrhage, rupture → demise
  - Hydrops before 30-weeks gestation > 90% mortality
  - Large tumors have > 25% perinatal mortality
- Excellent prognosis for patients with benign tumors & complete surgical resection
- Complete surgical resection must include coccyx
- 5-15% risk of recurrence

(Left) *Graphic shows the AAP tumor classification scheme: Type I is primarily exophytic, type II has equivalent-size internal & external masses, type III has a larger intraabdominal component, & type IV is entirely internal.* **(Right)** *Coronal SSFP MR of a twin gestation shows a fetus with a large, predominantly exophytic mass extending from the perineum. Note the solid ⇨ & cystic ⇨ areas within the mass. The inferior vena cava ⇨ is prominent due to the amount of blood flow coursing through this tumor. However, no hydrops is seen.*

(Left) *Lateral radiograph shows a newborn infant with a large, exophytic mass ⇨ extending from the sacrum & coccygeal region. A few Ca^{2+} ⇨ are visible within the mass, typical of a sacrococcygeal teratoma (SCT).* **(Right)** *Coronal T2 MR in a newborn infant shows a heterogeneous, solid mass protruding externally ⇨ with dumbbell extension internally ⇨, splaying the aortic bifurcation in this case of a type II SCT.*

TERMINOLOGY

Abbreviations

- Sacrococcygeal teratoma (SCT)

Synonyms

- Teratoma, germ cell tumor of coccyx

Definitions

- Teratomas are made up of various parenchymal cell types from > 1 germ layer, usually all 3
  - Tumors may contain hair, teeth, cartilage, & fat, among other tissues
- SCT arises from pluripotential cells at caudal tip of notochord (coccyx)
- Can grow both internally & externally (with latter being more common)
- Both benign & malignant varieties exist

IMAGING

General Features

- Best diagnostic clue
  - Large, solid, cystic, or mixed mass with exophytic perineal/buttock component & relatively small presacral component
  - May see Ca^{2+}, bone, fat, fluid levels, various soft tissues in mass
- Location
  - Origin from coccyx, but growth can occur in any direction
    - Presacral components are always present
  - Look for intraspinal extension
- Size
  - Ranges from small to massive in volume, potentially exceeding fetal weight
- Morphology
  - External components tend to be round &/or lobulated
  - Bilobed or dumbbell shape is often seen with large internal & external components
    - Lesion narrows passing through pelvis

Radiographic Findings

- Large mass extending outside infant
- Ca^{2+} may be present

Fluoroscopic Findings

- Type IV SCT may be found incidentally during fluoroscopy studies for constipation or voiding problems
- Patients rarely have long-term sequela of bladder outlet obstruction

CT Findings

- NECT
  - Demonstrates fatty components, Ca^{2+}, & fluid levels
  - Heterogeneous mass wrapped around coccyx but typically without bony destruction
- CECT
  - Variable enhancement pattern in solid & cystic components

Ultrasonographic Findings

- Grayscale ultrasound
  - Ultrasound may be limited due to large size & internal Ca^{2+}
  - Heterogeneous echotexture mass
    - Ca^{2+} & fat cause highly echogenic foci while cystic areas are hypo- to anechoic
    - Numerous interfaces are typically present in lesion
- Color Doppler
  - Solid components may show moderate to high vascularity
  - Arterial steal may be seen in nearby vessels to supply tumor

MR Findings

- Heterogeneous, similar to CT
- Fat is best confirmed on T1 ± FS
- Variable enhancement; does not predict malignancy
- Best study for identifying intraspinal extension (rare)

Nuclear Medicine Findings

- PET
  - Used more often in evaluation of malignant recurrence than in initial diagnosis

Imaging Recommendations

- Best imaging tool
  - Prenatal sonography is most common initial diagnostic modality
  - Prenatal or postnatal MR to determine full extent of mass & aid surgical planning

DIFFERENTIAL DIAGNOSIS

Pelvic Rhabdomyosarcoma

- Solid mass without Ca^{2+}, fat, or substantial cysts (usually)

Neuroblastoma

- May arise in pelvis at organ of Zuckerkandl
- Solid mass with Ca^{2+} & vascular encasement

Myelocystocele

- Skin-covered dorsal dysraphism
- Elongated spinal cord with dilated central canal & meninges ("cyst within cyst")

Other Intrapelvic Masses

- Consider Burkitt lymphoma, ovarian tumors, lymphatic malformation, hematometrocolpos

PATHOLOGY

General Features

- Etiology
  - Probably results from rests of pluripotential cells at caudal end of notochord/spine
- Genetics
  - Not inherited
    - Except Currarino type, which is autosomal dominant mutation in *MNX1* gene
  - Familial tendency is reported, prompting some to recommend screening asymptomatic siblings
- Associated abnormalities
  - 10% of SCTs are associated with other congenital anomalies

  - Primarily defects of hindgut & cloacal region, which exceeds baseline rate of 2.5% expected in general population
- SCT is 2nd most common lesion after anterior meningocele in familial disorder of Currarino
  - Autosomal dominant triad of presacral mass, partial sacral agenesis, & anorectal defects
- Malignant characteristics ↑ with
  - Age at diagnosis
  - Internal subtype (type IV is worst)
  - Male sex
  - Presence of necrosis or hemorrhage
- α-fetoprotein is often elevated

Staging, Grading, & Classification

- American Academy of Pediatrics (AAP) Surgical Section classification
  - Type I (47%)
    - Primarily external in location
  - Type II (34%)
    - Dumbbell shape, equal internal/external components
  - Type III (9%)
    - Primarily located within abdomen/pelvis
  - Type IV (10%)
    - Entirely internal, no external component visible

Gross Pathologic & Surgical Features

- Typical of all teratomas: Multiple tissue types in varying stages of maturation & differentiation
- Solid & cystic components are common

Microscopic Features

- Tumors can be mature or immature
- Only 17% of SCTs have malignant features

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Frequently diagnosed in utero
    - Large fetal tumors require C-section delivery or in utero surgical intervention (open fetal surgery, radiofrequency or thermal ablation of tumor)
  - Most others are diagnosed within 1st few days of life
    - Exophytic masses are easily diagnosed clinically
  - Type IV lesions can present in childhood with urinary retention, bowel issues, Ca^{2+} on scoliosis study, etc.
  - Arteriovenous shunting in tumor → high-output cardiac failure
- Other signs/symptoms
  - In utero complications: Fetal SCT can be quite vascular & grow rapidly → hydrops, intratumoral hemorrhage, or rupture → fetal demise
    - Hydrops before 30-weeks gestation: > 90% mortality rate
      - Solid masses are more likely to develop hydrops
      - Doppler parameters may help predict hydrops
    - Maternal mirror syndrome (preeclampsia) may develop

Demographics

- Age
  - Typically diagnosed in fetus or newborn
  - Delayed diagnoses are possible in childhood, rarely in adults
- Epidemiology
  - Prevalence: 1 in 14,000 (Sweden) to 40,000 births

Natural History & Prognosis

- Prognosis is excellent in patients with benign tumors resected after birth
  - Gait abnormalities & early arthrosis are reported with extensive pelvic muscle resection
  - Rarely long-term bladder & bowel issues
- 5-15% risk of recurrence
  - Intraoperative tumor spillage & incomplete resection ↑ risk
- Masses diagnosed after 1st birthday & located only internally have higher malignant potential
  - Prognosis is variable in malignant tumors
  - Serum α-fetoprotein is useful tumor marker postoperatively
- Malignant components may be found at presentation or at time of recurrence
  - Yolk sac tumor is most common
  - Embryonal carcinoma is 2nd most common
  - With intensive chemotherapy, 5-year relapse-free survival rate is reported 76-90%
- Study from Netherlands showed normal fertility in adult female survivors

Treatment

- Complete surgical resection to include coccyx
- Benign tumors do not require additional therapy
- Malignant tumors are treated with chemotherapy (platinum-based agents) & radiation
- Consideration of in utero intervention with development of early hydrops; must weigh benefits with risks of prematurity

(Left) *Clinical photograph shows an infant prior to resection of a type I SCT. Cross-sectional imaging is helpful to delineate the intrapelvic/intraabdominal extent of tumor & develop an appropriate surgical plan.* **(Right)** *Clinical photograph shows the immediate postoperative appearance of the buttocks following SCT resection. After several months, the gluteal crease & buttocks assumed a nearly normal appearance.*

(Left) *Sagittal SSFP MR of a fetus shows a primarily solid, lobulated, & exophytic mass ➡ extending out of the pelvis with only a small intrapelvic component abutting the coccyx ⇨, consistent with a type I SCT.* **(Right)** *Sagittal T2 FS MR in a 3-year-old boy (who was imaged for the changing appearance of his sacral dimple with firmness to palpation of the area) shows a high signal intensity solid mass ➡ surrounding the coccyx but not reaching the skin surface, a type IV SCT.*

(Left) *Sagittal T2 MR in a newborn shows a dumbbell-shaped, mixed solid & cystic, high signal intensity mass extending from the lower abdomen ⇨ into the external component ⇨. Note the elevation & dilation of the urinary bladder. The ascites ⇨ was secondary to hydrops at delivery.* **(Right)** *Sagittal T1 C+ FS MR in the same patient 6 months after complete surgical resection of the mature type II SCT shows minimal postsurgical changes in the pelvis ⇨ & truncated sacrum (minus the coccyx) ➡.*

Discitis/Osteomyelitis

KEY FACTS

TERMINOLOGY

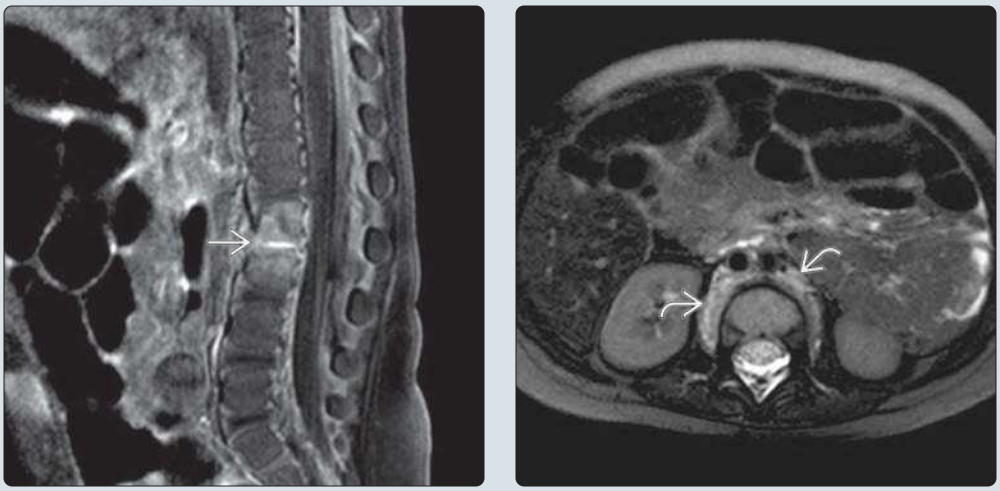
- Bacterial infection of intervertebral disc & adjacent vertebrae

IMAGING

- Disc-centered process: Disc space narrowing & adjacent endplate irregularity in young children
  - Lumbosacral (75%) > thoracic > cervical spine
- Early: MR is most sensitive & specific modality
  - Abnormal disc signal & enhancement
  - Ill-defined abnormal marrow signal & enhancement of adjacent vertebral bodies
  - Paraspinal & epidural phlegmon or abscess
- Subacute: Endplate destruction/erosion
- Chronic: ↑ bone density ± vertebral fusion with healing

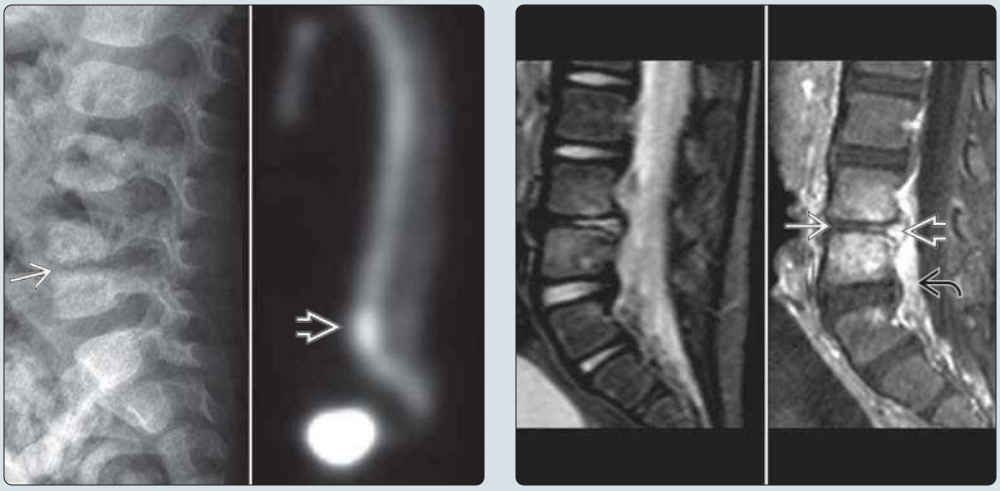
TOP DIFFERENTIAL DIAGNOSES

- Langerhans cell histiocytosis
- Chronic recurrent multifocal osteomyelitis (CRMO)
- Spinal metastases
- Tuberculous vertebral osteomyelitis
- Degenerative endplate changes



PATHOLOGY

- Hematogenous spread to vascularized disc or subchondral vertebral growth plate in children
- *Staphylococcus aureus* is most common pathogen
  - Consider *Kingella kingae* in young children



CLINICAL ISSUES

- Peak age: 6 months to 4 years
- Variable & nonspecific symptoms
  - May delay diagnosis for weeks in children
- Elevated ESR, CRP, WBC
- Treat early with empiric IV antibiotics until causative organism is identified

(Left) *Midline sagittal T1 C+ FS MR in a 7-month-old shows poor definition & abnormal enhancement of the L2-L3 disc space. Patchy abnormal enhancement is also noted in the marrow of the adjoining vertebral bodies. No drainable collection is identified within the adjacent paraspinal soft tissues or epidural space.* **(Right)** *Axial T2 MR in the same patient shows abnormal thickening & poorly defined fluid signal in the anterior & lateral paraspinal soft tissues in this patient with spondylodiscitis.*

(Left) *Lateral radiograph (left) shows L4-L5 disc space narrowing & endplate irregularity in this 1-year-old with back pain. Sagittal SPECT bone scan (right) confirms abnormal uptake in the vertebral bodies, typical of spondylodiscitis.* **(Right)** *Sagittal STIR (left) & T1 C+ FS (right) MR images in a 2-year-old show disc space narrowing & enhancement with abnormal signal/enhancement of the L4-L5 vertebral marrow. Enhancing soft tissue in the epidural space is due to contiguous inflammation.*

TERMINOLOGY

Definitions

- Bacterial suppurative infection of intervertebral disc & adjacent vertebrae

IMAGING

Radiographic Findings

- Negative up to 2-8 weeks after onset of symptoms
- Initial endplate & vertebral osteolysis
- Loss of intervening disc space height
- ↑ bone density ± intervertebral fusion with successful treatment
- Total vertebral destruction/collapse with treatment delay/failure

MR Findings

- Abnormal disc space
  - Loss of normal disc height, signal, & morphology
  - T1 hypointense, variable T2 signal intensity
  - Diffuse or rim enhancement with contrast
- Vertebral marrow signal abnormality abutting disc
  - T1 hypointense
  - Poorly defined ↑ fluid signal, most conspicuous on T2 FS or STIR images
  - Typically enhances with contrast unless necrotic
- Paraspinal & epidural phlegmon or abscess
  - Thickened T2-/STIR hyperintense tissues
  - Poorly defined fluid signal & stranding of fat
  - Diffuse enhancement vs. rim-enhancing collections
    - Abscess will restrict diffusion
- Follow-up: No single MR finding predicts clinical status
  - Abnormal imaging persists for months, does not necessarily equate residual/recurrent infection
  - Further bony destruction or new fluid collection can direct tissue sampling (if needed to direct treatment)

Nuclear Medicine Findings

- Bone scan
  - Tc-99m scan shows ↑ activity about affected disc space in all phases

Imaging Recommendations

- Best imaging tool
  - Targeted MR provides excellent diagnostic detail
  - Nuclear medicine bone scan or whole-body MR can localize nonspecific signs & symptoms
- Protocol advice
  - STIR or FS T2 MR for marrow & soft tissue involvement
  - T1 C+ FS MR to evaluate for drainable paraspinal & epidural fluid collections

DIFFERENTIAL DIAGNOSIS

Langerhans Cell Histiocytosis

- Enhancing marrow lesion ± lytic destruction, enhancing soft tissue mass; spares disc
- Single level vs. noncontiguous multifocal involvement
- Collapse of vertebra → vertebra plana

Chronic Recurrent Multifocal Osteomyelitis

- Autoimmune inflammatory disorder of bone
- Little disc involvement

Spinal Metastases

- Rare in children → neuroblastoma, leukemia
- Marrow abnormalities with disc space preservation
- Discrete or ill-defined vertebral lesions
- Noncontiguous vertebral involvement

Tuberculous Vertebral Osteomyelitis

- Usually centered in vertebral body rather than disc
- Midthoracic or thoracolumbar > lumbar or cervical
- Large dissecting paraspinal abscesses out of proportion to vertebral involvement
- Much more common in developing nations

Degenerative Changes

- Rare in children
- Normal marrow ± vertebral endplate preservation

PATHOLOGY

General Features

- Etiology
  - Pathophysiology
    - Intervertebral disc & adjacent vertebral growth plates are highly vascularized in young children
    - Hematogenous seeding of intervertebral disc/subchondral bone is most common source
      - Lumbosacral (75%) > thoracic > cervical spine
  - Most common pathogen: *Staphylococcus aureus*

CLINICAL ISSUES

Presentation

- Clinical profile
  - Peak age range: 6 months to 4 years
  - Clinical symptoms are variable & nonspecific in children
    - Difficulty walking, back/hip pain, fever (< 50%), irritability
  - Elevated ESR, CRP
    - WBC is often normal (~ 60%)

Treatment

- Early empiric IV antibiotics, broad-spectrum coverage until causative pathogen is isolated
- Organism-specific parenteral antibiotics for 6-8 weeks
- Spinal immobilization with bracing for 6-12 weeks
- CT-guided or open biopsy may be indicated if blood cultures are negative & conservative treatment fails
- Surgery is rarely indicated except in advanced infection

Inflammatory Myelopathies

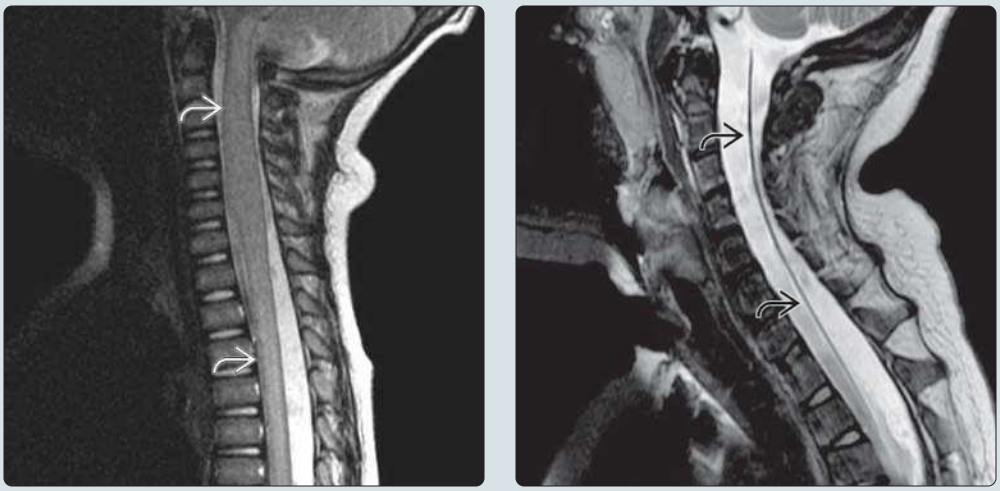
KEY FACTS

TERMINOLOGY

- Acute inflammatory pathologies of spinal cord, not secondary to other CNS inflammatory or demyelinating disease
  - Transverse myelitis (TM)
  - Acute flaccid myelitis (AFM)
  - Guillain-Barré syndrome (GBS)
  - Paralytic poliomyelitis

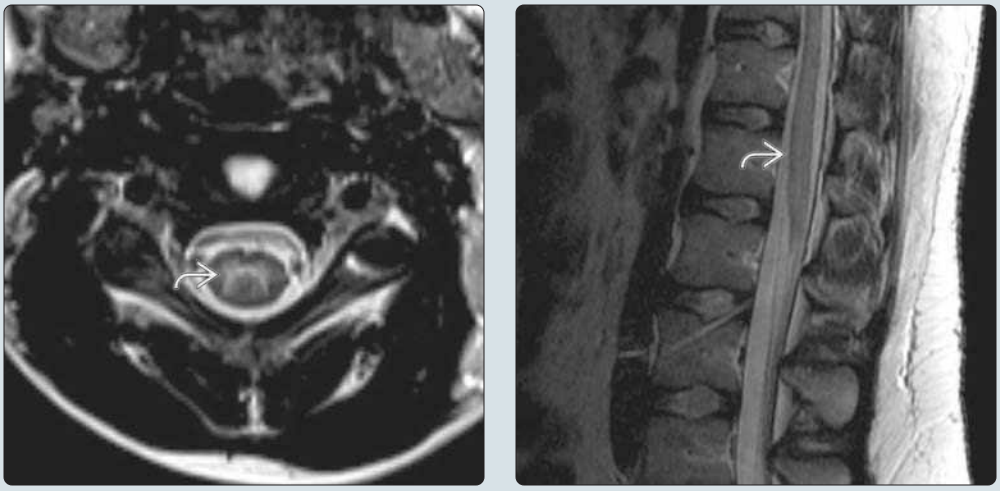
IMAGING

- TM: Diffuse cord swelling & abnormal signal > 2 vertebral segments in length
- AFM: Abnormal T2 hyperintensity in cord gray matter, often asymmetric
- GBS: Symmetric prominent enhancement of ventral nerve roots in cauda equina
- Poliomyelitis: Abnormal T2 hyperintensity in anterior horn cells



TOP DIFFERENTIAL DIAGNOSES

- Spinal cord astrocytoma
- Neuromyelitis optica
- Multiple sclerosis



PATHOLOGY

- TM: Many cases are associated with antimyelin oligodendrocyte glycoprotein (MOG) antibodies
  - COVID-19 can manifest as TM
- AFM: Majority are attributable to infection with enterovirus D68
- GBS: *Campylobacter jejuni* is most common preceding infection
  - Another CNS manifestation of pediatric COVID-19 infection
- Poliomyelitis: Caused by poliovirus, but West Nile virus can cause identical clinical syndrome

(Left) *Sagittal T2 MR in a 14-month-old who developed progressive upper then lower extremity weakness followed by respiratory failure shows diffuse swelling & hyperintensity of the entire cervical & upper thoracic cord, characteristic of transverse myelitis.* **(Right)** *Sagittal T2 MR of the same patient 8 years later shows severe atrophy of the entire cord. Approximately 25% of transverse myelitis cases will have permanent disability, with little or no recovery of function.*

(Left) *Axial T2 MR in a 4-year-old with left upper extremity weakness & cerebellar ataxia after a febrile illness shows abnormal hyperintense signal in the central gray matter of the cervical cord, especially the anterior horn cells, due to acute flaccid myelitis associated with enterovirus infection.* **(Right)** *Sagittal T2 MR in a teenager with West Nile myelitis who presented with fevers, bilateral lower extremity weakness, & urinary incontinence shows mild swelling & abnormal gray matter signal in the distal cord & conus.*

TERMINOLOGY

Definitions

- Acute inflammatory pathologies of spinal cord, not secondary to other CNS inflammatory or demyelinating disease
  - Transverse myelitis (TM)
  - Acute flaccid myelitis (AFM)
  - Guillain-Barré syndrome (GBS)
  - Paralytic poliomyelitis

IMAGING

General Features

- Best diagnostic clue
  - TM: Diffuse cord swelling & abnormal signal > 2 vertebral segments in length
  - AFM: Abnormal T2 hyperintensity in cord gray matter, often asymmetric
  - GBS: Symmetric prominent enhancement of ventral nerve roots in cauda equina
  - Poliomyelitis: Abnormal T2 hyperintensity in anterior horn cells
- Location
  - TM: Thoracic > cervical
  - AFM: Cervical > thoracic
  - GBS: Conus & cauda equina
  - Poliomyelitis: Cervical > thoracic
- Size
  - Cord involvement in TM & AFM is typically lengthy, covering 3 or more vertebral levels [longitudinally extensive TM (LETM)]

DIFFERENTIAL DIAGNOSIS

Spinal Cord Astrocytoma

- Homogeneous cord expansion
- Diffuse or nodular contrast enhancement

Neuromyelitis Optica

- LETM (> 3 vertebral segments) in central cord + optic nerve enhancement
- CSF with aquaporin 4-specific antibodies

Multiple Sclerosis

- Peripheral lesions ± central enhancement
- < 2 vertebral segments in length
- < 1/2 of cross-sectional area of cord
- 90% have intracranial lesions

PATHOLOGY

General Features

- Etiology
  - TM, AFM, & GBS are clinical syndromes, not diagnoses per se
    - Combinations of signs & symptoms
    - Variety of etiologies
  - TM: Many cases are associated with antimyelin oligodendrocyte glycoprotein (MOG) antibodies
    - COVID-19 can manifest as TM
  - AFM: Majority are attributable to infection with enterovirus D68
  - GBS: *Campylobacter jejuni* is most common preceding infection
    - Another CNS manifestation of pediatric COVID-19 infection
  - Poliomyelitis: Caused by poliovirus, but West Nile virus can cause identical clinical syndrome

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - TM: Sensory, motor, or autonomic dysfunction attributable to spinal cord, typically bilateral
  - AFM: Extremity weakness/paralysis following febrile illness, often asymmetric
  - GBS: Ascending weakness, 2-4 weeks after illness or immunization

Demographics

- Epidemiology
  - TM incidence: 2 per 500,000 population
    - 4.6 new cases of idiopathic acute TM per 1 million people per year in USA
    - 1,200 new cases per year in USA
    - Late winter through spring
  - AFM: 0.71 per million in patients ≤ 21 years old
    - Late summer through fall
  - GBS: 0.5-1.5 cases per 100,000 < 18 years old
    - Rare < 2 years of age

Natural History & Prognosis

- TM: Rule of 3s
  - 1/3 have good to complete recovery
  - 1/3 have fair recovery
    - Residual spasticity & urinary dysfunction
  - 1/3 have poor recovery
    - Persistent complete deficits
- AFM: < 10% recover completely
- GBS: 20% have persistent significant deficits

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Evaluate brain/orbits to exclude neuromyelitis optica, MS
- Document reduced swelling by imaging
  - Persistent cord enlargement suggests neoplasm (astrocytoma)

KEY FACTS

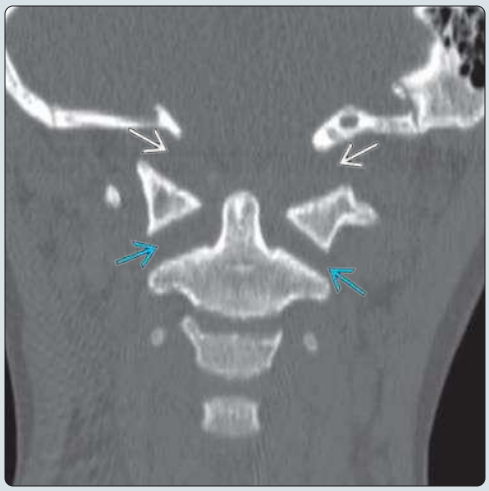
TERMINOLOGY

- Traumatic injury to upper cervical region: Occiput to C2

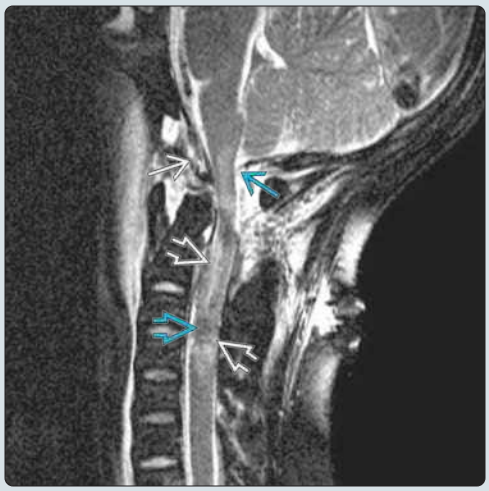
IMAGING

- Normal measurements in adults may not translate to children due to dynamic skeletal changes in early life
- Radiography: Initial screening test for most children
  - > 20% of cervical fractures are missed by radiography alone
  - 10% of craniocervical junction (CCJ) fractures are shown by CT, not radiography
- CT: Asymmetry & ↑ joint space measurements
- CT: Look for retroclival hematoma & perimedullary hemorrhage
- MR: T2 for ligament integrity & cord edema
- MR: STIR for bone marrow & soft tissue edema
- MR: SWI/T2* GRE for cord hemorrhage
- MRA: Vertebral artery injury may be associated with CCJ injuries; often clinically occult

TOP DIFFERENTIAL DIAGNOSES

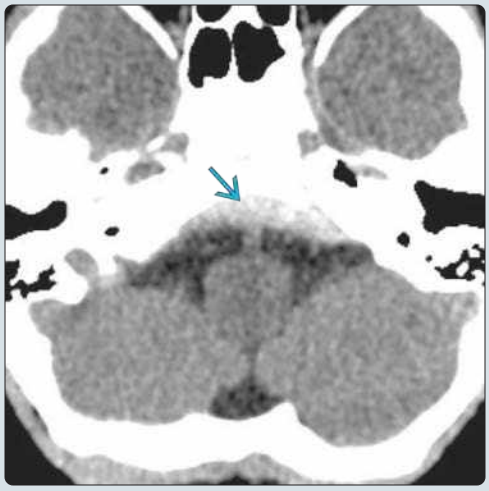


- Os odontoideum
- Nontraumatic ligamentous instability
- Congenital fusion & segmentation anomalies

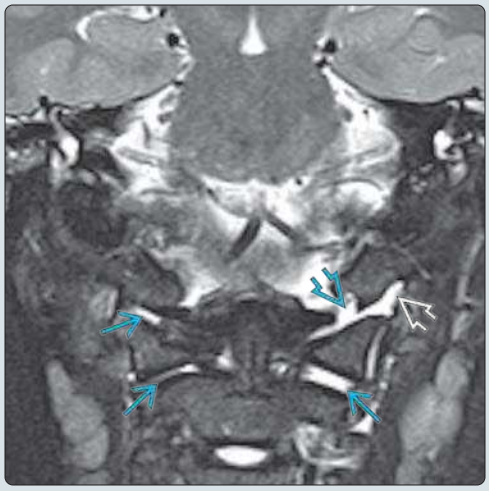


CLINICAL ISSUES

- Motor vehicle accidents, abusive head trauma, sports-related injuries, & falls
  - Higher mortality rate than adults
- Injury at CCJ is most common in 1st decade
  - Disproportionate head size, ligamentous laxity, & immature muscles may contribute
- Neurologic status at presentation predicts outcome



DIAGNOSTIC CHECKLIST



- Include C1-C2 on all head trauma CT studies
- MR in patients with normal radiographs/CT who continue to have neurologic symptoms
- STIR & MRA on all cervical spine trauma MR studies

(Left) *Coronal bone CT in a 9-year-old girl after an MVA shows ↑ of the condyle-C1 intervals (CCIs) as well as lateral mass intervals (LMIs), consistent with severe atlantooccipital dissociation (AOD) & atlantoaxial dissociation (AAD).* **(Right)** *Sagittal STIR MR in the same patient shows disruption of the tectorial membrane & transection of the posterior atlantooccipital ligament. The spinal cord shows hyperintense signal (likely contusion) as well as a few foci of low signal (possibly hemorrhage).*

(Left) *Axial NECT in a 7-year-old boy involved in an MVA shows a retroclival epidural hematoma. Such a finding should prompt imaging investigation for craniocervical injury.* **(Right)** *Coronal STIR MR in the same patient shows effusions in the bilateral occipital condyle-C1 & atlantoaxial joints as well as disruption of the left transverse ligament. Also note the extension of fluid beyond the left OC-C1 joint capsule, consistent with capsular rupture. These findings are consistent with AOD.*

TERMINOLOGY

Definitions

- Craniocervical junction (CCJ) injuries: Traumatic injury to upper cervical region: Occiput to C2
  - Much more common in 1st decade than in teens/adults

Types of Pediatric Craniocervical Junction Injuries

- Atlantooccipital dissociation (AOD)
- Atlantoaxial dissociation (AAD)
- Jefferson fracture (C1 ring)
- Odontoid (C2) fracture
- Hangman's (C2) fracture
- Atlantoaxial rotatory fixation (AARF)
- Spinal cord injury without radiographic abnormality (SCIWORA)

IMAGING

General Features

- Best diagnostic clue
  - Abnormal alignment, joint space widening, abnormal fluid collection, or fracture involving occiput to C2
- Size
  - Numerous normal measurements have been proposed as signs of CCJ injury
  - **Key point**: Most measurements have been shown to be helpful in severe injuries but insensitive for mild to moderate injuries
  - **Key point**: Normal measurements in children change significantly with age & normal osseous development
  - **Occipital condyle-C1 interval (CCI) > 4 mm → AOD**
    - Found to be superior (most sensitive & specific) to all other measures for diagnosis of AOD but still insensitive to mild/moderate injury
    - Requires averaging multiple CCI measurements
    - Normal CCI varies with age; largest (> 2 mm) at 2-4 years, smallest (< 1 mm) after late teenage years
    - Normal CCI joint is wider medially in young children, so single medial measurement > 4 mm will lead to false-positives
      - Avoid measuring in occipital condyle notch to avoid false-positives
  - **Powers ratio > 1.0 → AOD**
    - Powers ratio is calculated as BC/OA
      - BC: Basion to posterior C1 arch
      - OA: Opisthion to anterior C1 arch
    - Difficult to calculate in very young patients due to incomplete C1 ring ossification
  - **Basion-dens interval (BDI) > 1.2 cm or < 0 → AOD**
    - ↓ with age as dens ossifies
    - May cause false-positive in very young patients
  - **Interspinous ratio > 2.5 → AOD, AAD, or C2 dens fracture**
    - Interspinous ratio = C1-C2:C2-C3
  - **Lateral atlantodental space > 5-mm asymmetry → C1 ring fracture**
    - Some asymmetry is normal with head rotation/angulation
  - **Atlantodental interval > 6 mm → AAD**
    - Mean: ~ 2 mm in children
  - **Lateral mass interval (LMI) > 5 mm → AAD**
    - ↓ with age (mean: ~ 3 mm in children, ~ 1 mm in adults)

Radiographic Findings

- Prevertebral soft tissue thickening is often seen in severe CCJ injuries but is often absent in mild to moderate injuries
- AOD
  - Severe: ↑ CCI, Powers ratio > 1, abnormal BDI, ↑ interspinous ratio
  - Mild to moderate: Typically normal radiographs
- AAD
  - Severe: ↑ joint space; ± joint space asymmetry on frontal view
  - Mild to moderate: Typically normal radiographs
- Jefferson (C1 ring) fracture
  - Lateral displacement of C1 lateral mass in relation to C2 lateral mass on AP/open-mouth views
    - Highly specific sign, especially when bilateral
  - Lateral atlantodental space > 5-mm asymmetry
    - Usually due to positioning/rotation rather than fracture
    - Often leads to false-positive radiograph interpretation
- Odontoid (C2) fracture
  - Type 1, 2, or 3 based upon level of fracture
  - Typically occurs at C2 synchondroses in younger children
  - When severe, will lead to abnormal alignment at CCJ
- Hangman's (C2) fracture
  - Fracture of pars interarticularis on lateral radiographs
  - ± anterolisthesis of C2 on C3
- Rotation injuries & torticollis
  - Rotation of mandible over upper cervical spine on lateral view

CT Findings

- AOD
  - Abnormal measurements (especially CCI) & asymmetry
  - Retroclival hematoma
  - Perimedullary hemorrhage
- AAD
  - ↑ LMI ± asymmetric LMI
  - ↑ asymmetric distance between C1 & C2 lateral masses
- C1 & C2 fractures are clearly delineated
  - > 20% of cervical fractures are missed by radiography alone
  - 10% of CCJ fractures are shown by CT & not radiography
  - Sagittal & coronal reformats are essential
- Rotation injuries & torticollis
  - 3D reconstruction is ideal for rotational injuries
  - Dynamic CT for fixed atlantoaxial rotatory subluxation
    - Axial images through C1-C2 in neutral position & with maximal voluntary rotation in each direction
    - Measure degree of rotation of C1 relative to C2
    - If no significant change in C1/C2 relationship with rotation → fixed rotatory subluxation
- CTA if plane of injury affects vessel course

MR Findings

- T1WI
  - Helpful in identifying blood products

- Fat saturation to differentiate blood from fat in soft tissues
- Can identify vessel dissection

- T2WI
  - Best sequence for cord edema
    - Axial & sagittal to confirm subtle cases
  - Best conventional sequence for ligament integrity
    - Challenging in very young patients due to CSF flow artifact
- STIR
  - Best sequence for bone marrow & soft tissue edema
- 3D SSFP (CISS, FIESTA)
  - High spatial resolution with near-complete CSF flow artifact suppression
  - Ideal for detection of intraspinal nerve root avulsion
  - Ideal for ligamentous injury at CCJ
- DWI
  - ADC values correlate with severity of spinal cord injury & can predict cavity formation
- SWI/T2* GRE
  - Detects blood products in cord
- MRA
  - Key adjunct in cervical spine injuries
  - Vertebral artery injury in up to 25% of adults with cervical spine trauma; may be clinically occult

Imaging Recommendations

- Best imaging tool
  - Imaging algorithm is based upon ability to clinically clear cervical spine
  - Radiographs: Initial screening test in most children
  - NECT with reformats: Further evaluation of abnormal radiographs, high-risk mechanism, or persistent clinical symptoms in face of normal radiographs
  - Head/neck CTA: Fastest evaluation for any concern of vascular injury
  - MR + MRA: Optimal evaluation of ligamentous, spinal cord, & vascular injury
- Protocol advice
  - Include through C2 on all trauma head CT studies
  - Perform MR when clinical symptoms or subtle CT clues are present (even when CCJ measurements are normal on CT)

DIFFERENTIAL DIAGNOSIS

Os Odontoideum

- Result of aberrant embryogenesis vs. fracture through odontoid synchondrosis prior to fusion (5-6 years)
  - Can be source of instability
  - More common in children with skeletal dysplasias
- Ossiculum terminale → nonfusion of distal ossification center
  - Smaller & without clinical significance

Nontraumatic Ligamentous Instability

- Abnormal laxity of ligaments stabilizing C1-C2
- Grisel syndrome → atlantoaxial instability associated with inflammation in adjacent soft tissues
- Down syndrome → laxity of transverse ligament
  - 10-20% incidence

Congenital Fusion & Segmentation Anomalies

- C1-occiput, C1-C2
- Klippel-Feil spectrum

PATHOLOGY

General Features

- Etiology
  - Mechanism: Motor vehicle accidents (MVAs) are most common in young children
    - Also seen with falls & abusive head trauma
    - Sports-related injuries predominate in 2nd decade

CLINICAL ISSUES

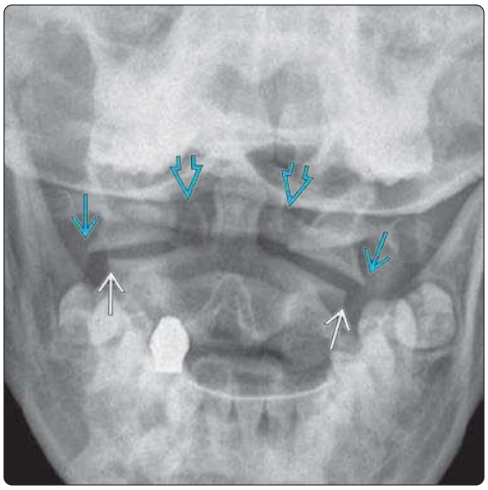
Presentation

- Most common signs/symptoms
  - AOD
    - Many die prior to reaching medical care
    - > 1/2 have cardiorespiratory arrest
    - 25-30% are neurologically intact at presentation
  - Jefferson (C1) fracture
    - Axial loading injury (e.g., diving into shallow pool)
  - Odontoid & hangman's fractures
    - Flexion or extension with distraction (usually MVA)
  - Rotational injuries
    - Present with painful torticollis

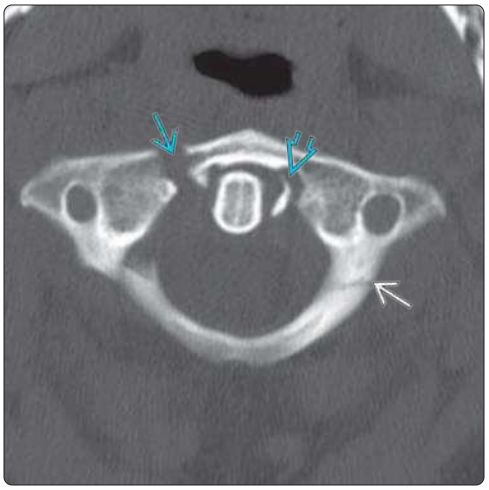
Demographics

- Age
  - 0-9 years: High incidence of upper cervical spine injury compared to adolescents & adults
    - Disproportionate head size, ligamentous laxity, & immature muscles have all been postulated as causes

Natural History & Prognosis



- Neurologic status at presentation is best predictor of outcome
  - Intact or incomplete injury → likely good outcome
  - Complete loss of function at level of injury → poor chance of recovery
- Spinal cord hemorrhage → worse potential for recovery



Treatment

- Support of impaired systemic function
- Stabilization of spine to prevent further injury
- Internal or external surgical stabilization
  - May impair ability to assess with MR
- Emergent decompression of spinal cord impingement
- Administration of steroids for acute spinal cord injury is controversial

(Left) *Frontal open-mouth radiograph in a 17-year-old girl who fell while performing a back flip shows the C1 lateral masses ⇨ extending lateral to the C2 lateral masses ➡ as well as widening of the lateral atlantodental spaces ⇨, consistent with a Jefferson fracture.* **(Right)** *Axial NECT in the same patient shows a displaced fracture of the right anterior arch of C1 ⇨, a nondisplaced fracture of the left posterior arch of C1 ➡, & a posterior cortical avulsion fracture of the left anterior arch of C1 ⇨.*

(Left) *Lateral radiograph in a 2-year-old girl in an MVA shows a displaced fracture ➡ of the odontoid at the synchondrosis, separating the odontoid & C2 body. Also note the extensive prevertebral soft tissue swelling ➡ with displacement of the nasoenteric tube ⇨ as well as widening of the C1-C2 interspinous distance ⇨.* **(Right)** *Sagittal T2 MR in the same patient shows disruption of the posterior longitudinal ligament ⇨, a commonly associated injury in the setting of an odontoid fracture.*

(Left) *Axial CTA in a 5-year-old with torticollis shows the left lateral mass of C1 ⇨ rotated anterior to the body of C2 ⇨, consistent with atlantoaxial rotatory subluxation. The left vertebral artery ⇨ is extremely small due to dissection related to the subluxation.* **(Right)** *Posterior oblique 3D surface rendering in the same CT shows the left C1 lateral mass ⇨ dislocated & rotated anterior to the left C2 lateral mass ⇨. The right C1 lateral mass ➡ is rotated superior & posterior to the right C2 lateral mass.*

Chance Fracture

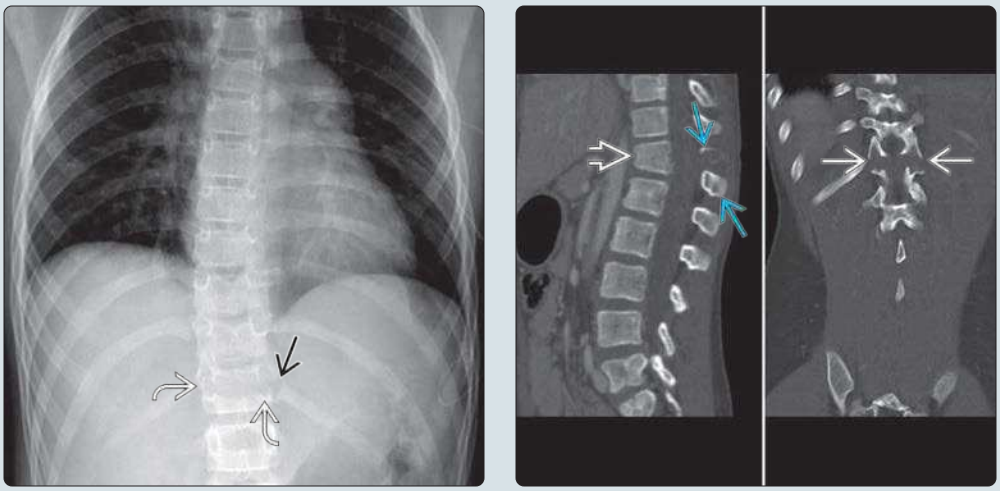
KEY FACTS

TERMINOLOGY

- Synonyms: Flexion-distraction injury, seat belt fracture
- Definition: Compression injury of anterior column of spine with distraction of middle & posterior columns
  - Anterior column: Anterior longitudinal ligament, anterior 1/2 of vertebral body, anterior anulus fibrosis
  - Middle column: Posterior longitudinal ligament, posterior 1/2 of vertebral body, posterior anulus fibrosis
  - Posterior column: Posterior neural arch, facet joint capsular ligaments, ligamentum flavum, inter- & supraspinous ligaments
- May be completely osseous, ligamentous (rare "Chance equivalent"), or mixed (most frequent)
- Extension across 3 columns may invoke osseous & soft tissue structures at multiple adjacent levels

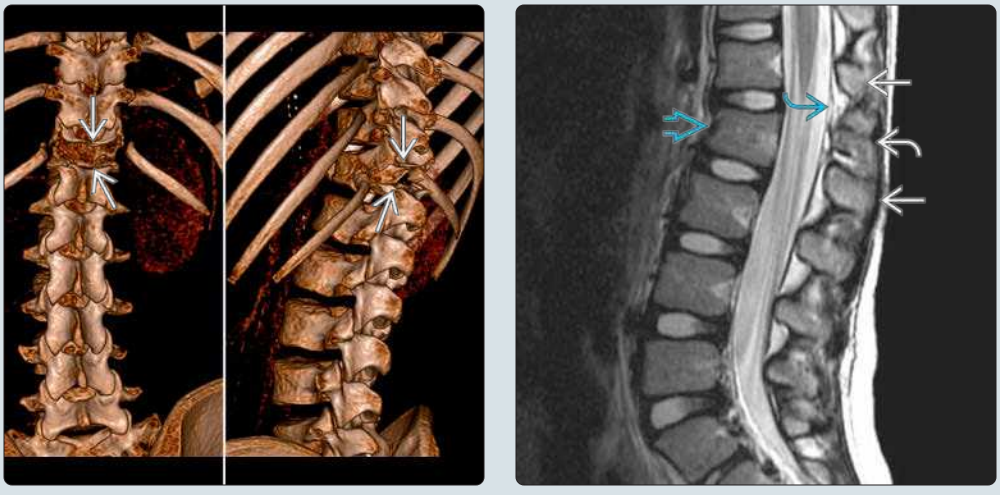
IMAGING

- 78% occur between T12-L2
- Wedging of anterior vertebral body
- Posterior bony & ligamentous distraction injuries result in
  - Focal kyphosis
  - Wide splitting of pedicles & laminae on AP view
  - Separation of facet joints with ↑ interspinous distance
  - Artifactual ↑ in radiolucency of vertebral body on AP radiograph secondary to splayed spinous processes
- Vertebral marrow edema & posterior ligamentous disruptions are best seen on STIR or T2 FS MR



CLINICAL ISSUES

- Classic history: Motor vehicle accident with lap belt restraint & cutaneous seat belt sign over abdomen
  - ~ 80% have significant abdominal injuries
    - Bowel/mesentery (most common), aorta



DIAGNOSTIC CHECKLIST

- Crucial to create sagittal & coronal bone reformatted images from abdominal CT exams in trauma patients

(Left) *AP chest radiograph of a teenager injured in a motor vehicle accident while wearing a seat belt shows a horizontal lucency splitting the T12 pedicles with widening of the costovertebral joints, indicative of a Chance fracture.* **(Right)** *Sagittal (left) & coronal (right) bone windowed CECT images in the same patient show anterior wedging of the T12 vertebral body with a horizontal fracture plane splitting the posterior elements. Note the splaying/distraction of the T12 spinous process fragments.*

(Left) *3D posterior oblique CT images in the same patient clearly show the horizontal splitting & distraction of the T12 posterior elements, characteristic of the posterior column injury in a Chance fracture.* **(Right)** *Sagittal T2 MR in a 7-year-old with a primarily ligamentous injury shows mild anterior wedging of the L2 vertebra with disruption of the ligamentum flavum & interspinous ligaments resulting in splaying of the L1 & L2 posterior elements.*

TERMINOLOGY

Synonyms

- Flexion-distraction injury, seat belt fracture

Definitions

- Compression injury of anterior column of spine with distraction of middle & posterior columns
  - Anterior column: Anterior longitudinal ligament (ALL), anterior 1/2 of vertebral body, anterior anulus fibrosis
  - Middle column: Posterior longitudinal ligament, posterior 1/2 of vertebral body, posterior anulus fibrosis
  - Posterior column: Posterior neural arch, facet joint capsular ligaments, ligamentum flavum, inter- & supraspinous ligaments

IMAGING

General Features

- Location
  - Usually occurs at T11-L3; 78% occur between T12-L2
  - May have anterior column injury at 1 level with posterior column injury (fracture &/or soft tissue disruption) at adjacent level

Radiographic Findings

- Wedging of anterior vertebral body with focal kyphosis
  - ± sclerotic transverse fracture line due to trabecular impaction
  - Vertebral body height loss is often > 40-50%
- Bony & ligamentous injuries to posterior column
  - Splitting of pedicles & laminae on AP view
  - Empty body sign on AP view: Artifactual ↑ in radiolucency of vertebral body secondary to splayed spinous processes
  - Separation of facet joints with ↑ interspinous distance
- No subluxation of vertebral body

CT Findings

- Vertebral body fracture may be comminuted
  - May have mild retropulsion of posterior cortex
- Transversely oriented posterior element fracture &/or posterior ligamentous injury
  - ↑ interspinous distance
  - Separation of facet joints: Naked facet sign

MR Findings

- Varying degrees of marrow edema (poorly defined ↑ T2/STIR signal intensity) surrounding fracture plane
  - May be seen in multiple adjacent vertebral bodies with radiographically occult fractures/contusions
- Low-signal ALL is not discontinuous
  - May be partially stripped from vertebral attachment
- Posterior element fractures are difficult to see if splaying is absent
- Low-signal interspinous & supraspinous ligaments are often disrupted by high fluid signal
- Poorly defined fluid in surrounding soft tissues

Imaging Recommendations

- Best imaging tool
  - CT scan
    - Data is typically acquired as part of abdominal CECT
  - MR is indicated to investigate neurologic deficit, ligamentous injuries

DIFFERENTIAL DIAGNOSIS

Distraction Injury

- Vertebral body displacement & ALL disruption distinguish from Chance fracture

Traumatic Compression Fracture

- No posterior element fracture

Burst Fracture

- Also involves posterior vertebral body cortex
- Vertically oriented fractures of posterior elements

PATHOLOGY

General Features

- Etiology
  - Typical setting: Motor vehicle accident or fall
  - Classic pattern: Lap seat belt without shoulder strap
    - Seat belt, in high position, serves as fulcrum anterior to vertebral column → compression of anterior column + distraction of posterior column
    - Up to 40% have 3-point restraint (not just lap belt), typically incorrectly positioned
- Associated abnormalities
  - Up to 80% of children with cutaneous seat belt sign have significant abdominal injuries
    - Bowel/mesentery (most common)
      - Look for unexplained mesenteric & peritoneal fluid with focal bowel wall thickening/dilation (± free air)
    - Aorta > solid organs

CLINICAL ISSUES

Presentation

- Traumatic back pain ± neurologic injury
- Seat belt sign of transverse low abdominal wall contusion/injury → up to 50% will have spine injuries

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Radiographic recognition is essential → prompts further evaluation for abdominal injury
- Search for spine injury on sagittal & coronal reformats from abdominal CT exams in trauma patients
  - Especially with clinical evidence of lap belt injury

KEY FACTS

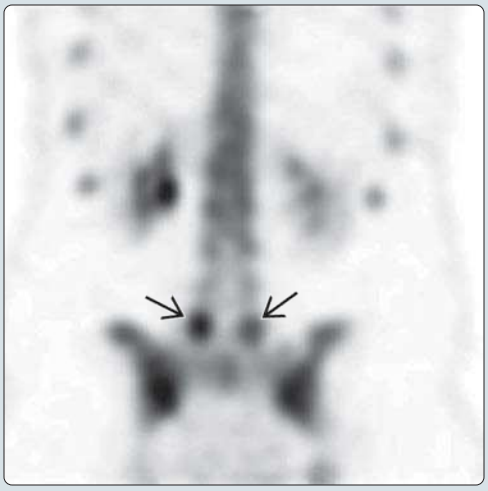
TERMINOLOGY

- Spondylolysis: Defect/break in pars interarticularis
  - Repetitive microtrauma is likely etiology
- Spondylolisthesis: Spondylolysis + anterior slippage of vertebra in relation to vertebra below

IMAGING

- Bone CT
  - Linear lucency or defect in pars interarticularis
    - Sagittal or oblique sagittal reformatted imaging is vital
  - Incomplete ring sign on axial imaging ± distraction
    - May simulate "extra" or double facet joints
    - May be confused with facet joint
      - Lysis is located anterior to facet joint
      - Lysis is more transverse in orientation on axial images compared to more oblique facet joint
      - Facet joint is smooth, while lysis typically is irregular/fragmented
  - Spondylolisthesis & foraminal narrowing on sagittal reformatted images
  - Secondary finding of sclerosis &/or hypertrophy of contralateral pedicle & lamina
  - May be insensitive to early stress injury (edema with microtrabecular fracture)
- SPECT bone scan imaging is helpful for diagnosis
  - Intense focal uptake in posterior elements, unilateral or bilateral
  - Triangular pattern of uptake on sagittal images
  - Remote or healed may be occult (normal)
- SPECT/CT: Confirms diagnosis with anatomy & physiology
- MR for lysis: Adjust spine protocol toward musculoskeletal system by adding STIR/T2 FS (↑ conspicuity of marrow & soft tissue edema)

CLINICAL ISSUES



- 40% incidence in children with lower back pain
  - L5: 85%; L4: 5-15%; rarely higher

(Left) *Lateral radiograph in a 15-year-old female basketball player with back pain shows a linear lucency at the L3 pars interarticularis. There is no anterior subluxation of L3 relative to L4 to suggest spondylolisthesis.* **(Right)** *Axial STIR MR in the same patient shows irregular low signal intensity pars interarticularis defects bilaterally at L3 with adjacent marrow & soft tissue edema.*

(Left) *Coronal SPECT bone scan in a 15-year-old who presents with lower back pain shows asymmetric uptake in the posterior elements of L5, R > L. NECT images (not shown) demonstrated right L5 spondylolysis with reactive stress changes at the left L5 pars interarticularis.* **(Right)** *Axial NECT in a 14-year-old girl who presents with severe left flank pain for a renal stone evaluation shows an incomplete osseous ring with bilateral distracted pars interarticularis defects at L5.*

TERMINOLOGY

Synonyms

- Lysis, isthmic spondylolysis

Definitions

- Spondylolysis: Defect/break in pars interarticularis
- Spondylolisthesis: Spondylolysis + anterior slippage of vertebral body in relation to vertebra below

IMAGING

General Features

- Location
  - L5: 85%; L4: 5-15%; rarely above
  - Cervical spine location is usually congenital
  - 10-15% are unilateral

Radiographic Findings

- Classic: Break in neck of "Scotty dog" (pars interarticularis defect on oblique views of standing lumbar spine)
  - ± anterolisthesis
  - Positive predictive value of 57%

CT Findings

- Bone CT: Lucent defect of pars interarticularis
  - Sagittal or oblique sagittal reformatted images are vital
  - Incomplete ring sign on axial imaging ± distraction
- High sensitivity with multiplanar reformats but often overlooked on abdominal/pelvic studies obtained for other reasons

MR Findings

- T1: Discontinuity (sagittal images best), ↓ signal in pars interarticularis
- T2: ↓ signal in pars interarticularis (reactive sclerosis), ↑ signal in pars interarticularis (marrow edema)
- STIR/T2 FS: ↑ conspicuity of surrounding marrow & soft tissue edema, suggesting spondylolysis at classic location even if fracture not seen
- MR for lysis: Sensitivity: 57-86%; specificity: 81-82%
- Additional sequences that may ↑ sensitivity
  - 3D GRE T1: Volumetric, thin slices
  - Ultrashort TE (UTE) or zero TE (ZTE): Improved visualization of cortical bone

Nuclear Medicine Findings

- ↑ uptake is best seen on SPECT bone scan
- Can be fused with bone CT

Imaging Recommendations

- Best imaging tool
  - Radiographs first
  - If source of back pain is not clear, consider MR
    - Include STIR or T2 FS for marrow & soft tissue edema
  - Targeted helical/volumetric bone CT with multiplanar reformats
  - Bone scan SPECT/CT is better than SPECT alone
    - Anatomic & physiologic confirmation
    - Helps differentiate completed lysis vs. uptake from stress changes

PATHOLOGY

General Features

- Etiology
  - Believed to be caused by repetitive microtrauma, particularly hyperextension → stress fracture
  - Common associated activities: Gymnastics, tennis, baseball, weightlifting, wrestling, cricket, & football at young age
- Associated abnormalities
  - Spondylolisthesis (50%), scoliosis, Scheuermann disease, spina bifida occulta

CLINICAL ISSUES

Presentation

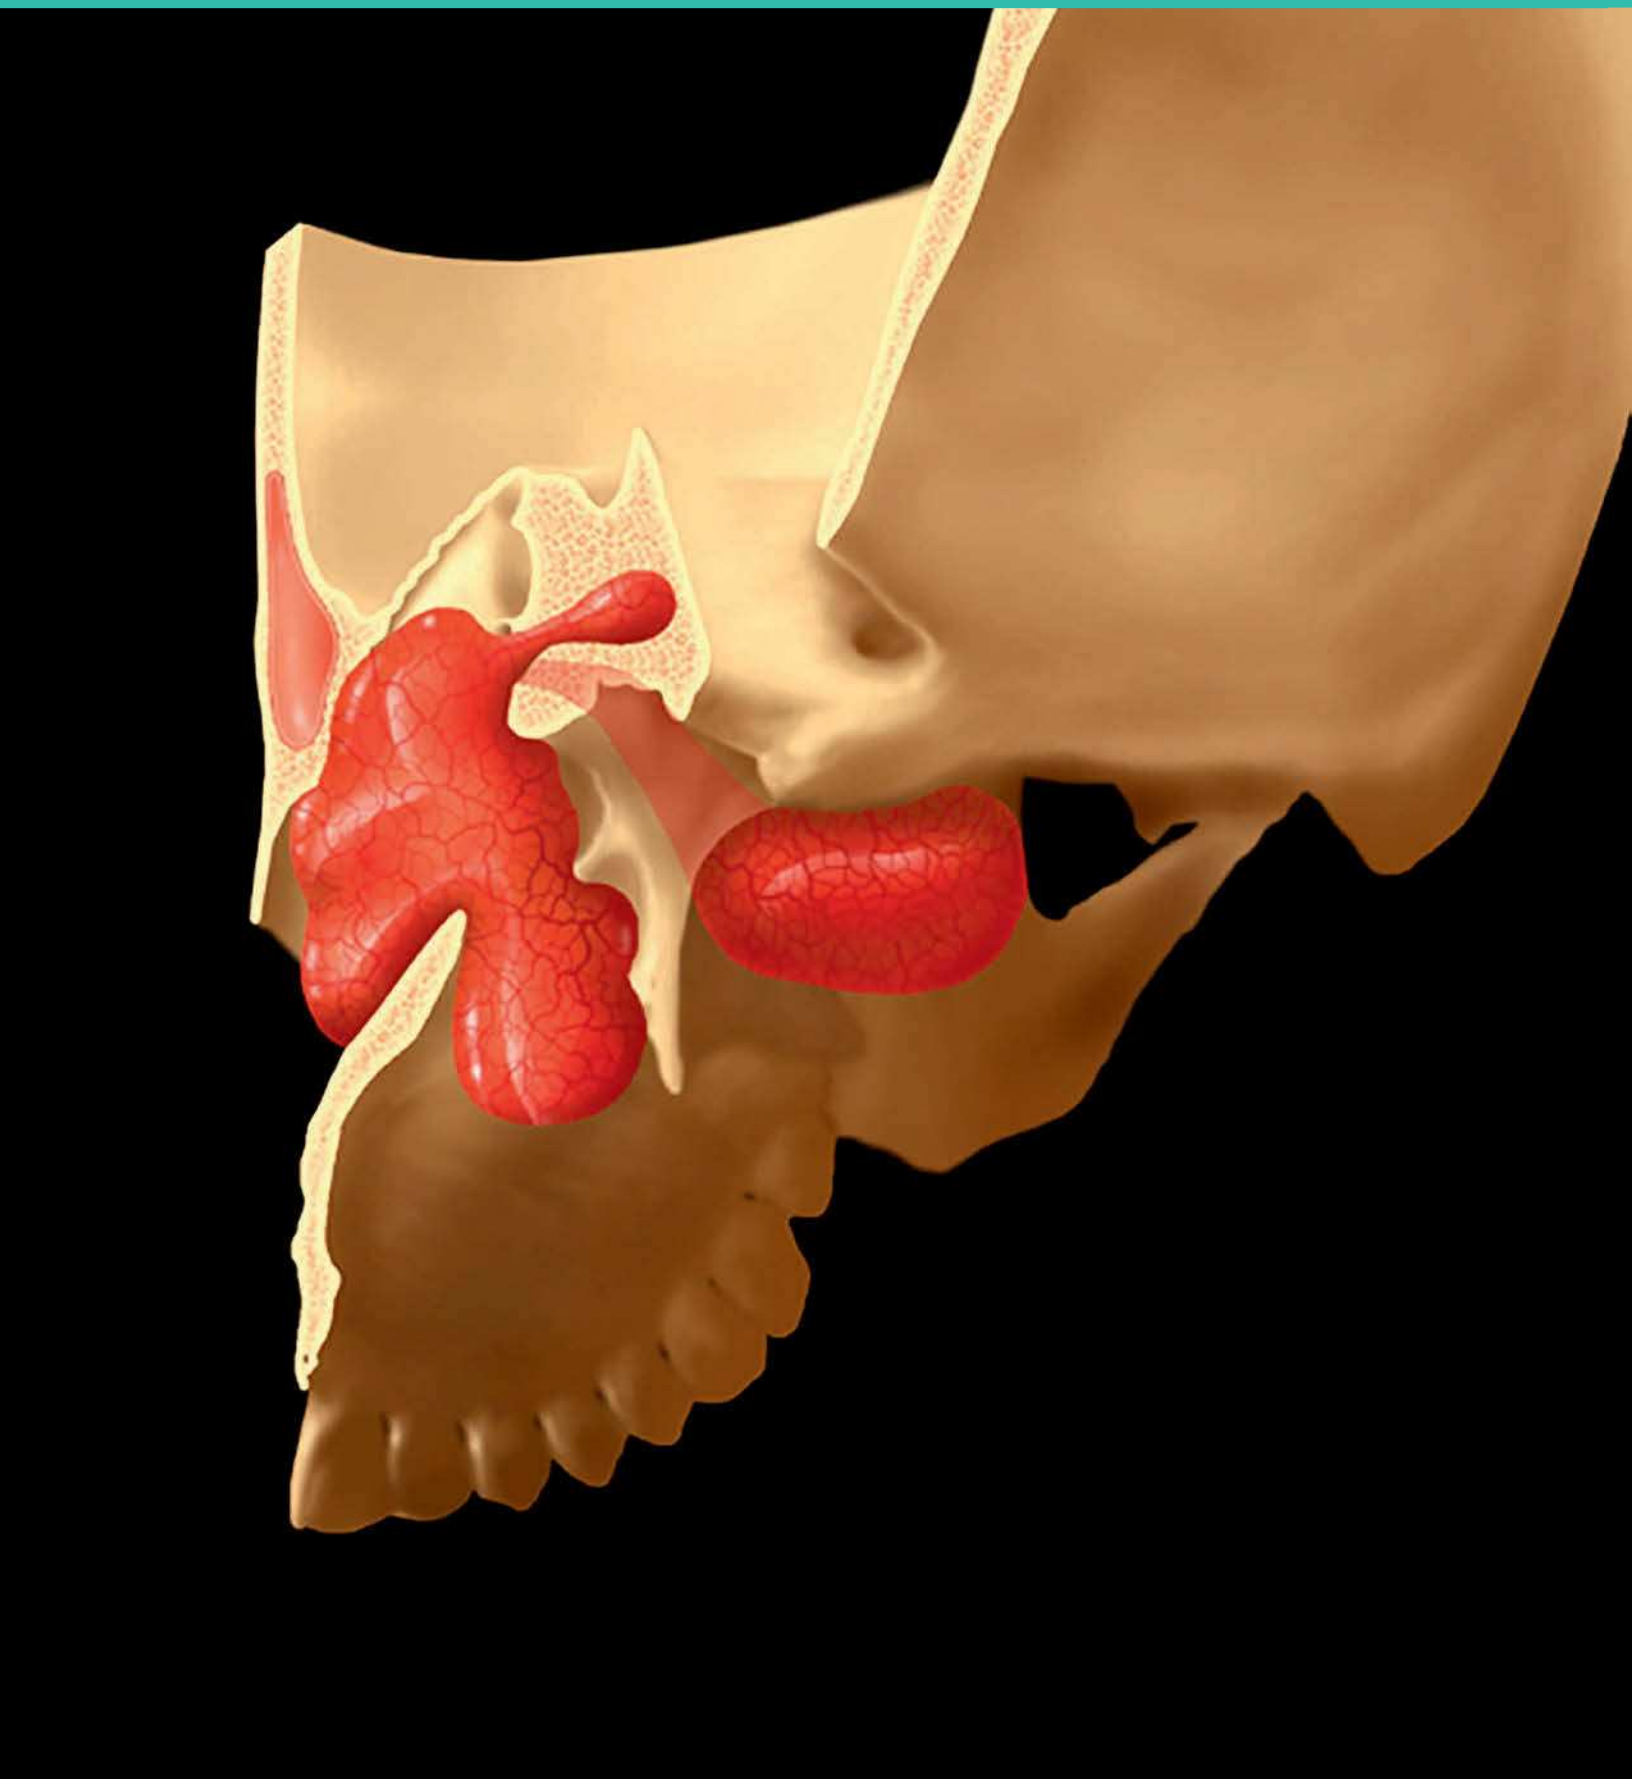
- Most common signs/symptoms
  - Asymptomatic (80%)
  - 40% incidence in children with lower back pain (LBP)
- Other signs/symptoms
  - Tight hamstring muscles
    - Waddling gait secondary to tight hamstring muscles
  - Back spasms or radiating pain
  - Chronic LBP in older children & adults
  - Back pain exacerbated by rigorous activities
  - Radiculopathy & cauda equina syndrome in lysis with high-grade spondylolisthesis

Demographics

- Epidemiology
  - Incidence: 3-10%
  - ↑ incidence in competitive athletes, especially males

Treatment

- Mainly conservative first; surgical if conservative treatment fails or subluxation progresses



DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Typical bone scan findings with normal radiographs or bone CT suggest stress reaction or early spondylolysis

Summary Thoughts: Congenital Cystic Neck Masses

Palpable masses are a common indication for imaging the pediatric head & neck (H&N). Most are congenital or inflammatory in children; only 5% of childhood neoplasms occur in the H&N (excluding the brain). The most common extrathyroid, nonneoplastic solid neck masses in children are related to inflammatory disease & do not require imaging unless there is concern for deep neck infection or abscess. The most common cystic masses in the pediatric H&N are congenital lesions secondary to abnormal embryogenesis involving the thyroglossal duct (TGD), the branchial apparatus, or the vascular endothelium. TGD cysts (TGDCs) account for 70-90% of all congenital neck abnormalities in children. The most common branchial apparatus lesion is the 2nd branchial cleft or apparatus cyst (BCC/BAC), & lymphatic malformations are the most common vascular malformations in the H&N.

Whenever a cystic neck mass is encountered on a pediatric imaging study, a very reasonable differential diagnosis can be made based on its location (midline, paramidline, or lateral, as well as location relative to carotid sheath), imaging appearance (simple cyst, complicated cyst, enhancement, ± solid component), & clinical presentation (present since birth or acute onset, ± clinical evidence of infection).

Terminology

A TGDC or tract is an anomalous remnant of the TGD that completely involutes during normal development. Cysts are located anywhere from the midline posterior tongue at the foramen cecum to the thyroid bed in the lower neck.

Branchial apparatus anomalies can be cysts, sinus tracts, or fistulae. Cysts are fluid filled with well-defined walls secondary to the failure of obliteration of a branchial cleft or pouch. Sinus tracts are congenital tracts with 1 opening, either externally to the skin surface (or external auditory canal) or internally to the pharynx (2nd branchial cleft), superolateral hypopharynx (3rd branchial cleft), or pyriform sinus (4th or 3rd branchial pouch). Fistulae are congenital tracts with 2 openings (1 internally & 1 externally) secondary to failure of obliteration of the branchial cleft & pouch.

Imaging Techniques & Indications

US, CT, & MR are all reasonable options for the initial imaging of neck masses in children. Modality choice depends on the clinical presentation, the referring clinical service, & the modalities available at the time. For instance, if there is concern that a child with cellulitis & cervical adenitis has a drainable abscess deep to a palpable neck mass, US may be very helpful in determining the presence of underlying drainable fluid. Likewise, if a child is thought to have a TGDC, US is the imaging modality of choice to evaluate the suspected TGDC & prove the presence of a normal-appearing thyroid gland in the lower neck. US is also the modality of choice in patients with suspected infantile hemangioma, as color Doppler findings can be quite characteristic. However, CECT is the initial imaging modality of choice to evaluate the total extent of disease in children with suspected deep neck infection & to assess for a possible underlying pyriform sinus tract in children with left-sided neck abscesses that involve the left thyroid lobe.

In children not presenting with signs & symptoms of infection, CT or MR may be used as the initial imaging modality. The choice of which modality may depend on the need for sedation/anesthesia, which is usually required for MR in children under 5 or 6 years of age. MR is the preferred imaging modality for children with suspected vascular malformations due to its excellent soft tissue contrast resolution, variety of methods of interrogation, & lack of limitations regarding depth.

Embryology

The thyroid gland migrates from the foramen cecum at the midline posterior tongue to the paramidline location in the lower neck via the path of the TGD. The TGD normally involutes during the 5th or 6th week of gestation. However, remnant epithelium anywhere along the tract may persist & form a TGDC. As the TGD diverticulum descends caudally, it passes along the anterior surface of the developing hyoid bone; therefore, remnants may be found anterior to the preepiglottic space of the larynx.

Branchial apparatus structures develop between the 4th & 6th week of gestation & consist of 6 pairs of mesodermal arches separated by 5 paired endodermal pouches internally & 5 paired ectodermal clefts externally. During the 6th week of gestation, the 2nd branchial arch overgrows the 3rd & 4th branchial arches, resulting in a combined 2nd, 3rd, & 4th branchial cleft, termed the "cervical sinus of His." Anomalies of the branchial apparatus include cysts, sinus tracts, & fistulae. The most common lesions for which imaging is indicated are BCCs/BACs, & most of these are related to anomalous development of a branchial cleft. However, a few are related to anomalous development of a branchial pouch.

The location of the lesion is the best clue to the origin of a branchial apparatus anomaly. First BCCs account for ~ 8% of all branchial anomalies. They are located in or around the external auditory canal, ear lobe, or parotid gland & may extend inferiorly to the angle of the mandible. Second BCCs account for up to 95% of all branchial apparatus anomalies & are subclassified by location using the Bailey system: Type I cysts are located deep to the platysma muscle/anterior to the sternocleidomastoid (SCM) muscle; type II cysts are posterior to the submandibular gland/anterior to the SCM (& are the most common); type III cysts protrude between the external & internal carotid arteries; & type IV cysts are directly adjacent to the pharyngeal wall (thought to be a remnant of the 2nd pouch). Fistulas are rare; however, a 2nd branchial apparatus fistula is occasionally identified with an internal opening at the level of the pharynx & an external skin opening anterior to the lower aspect of the SCM.

Third BCCs are rare & located in the posterior compartment of the upper neck or anterior compartment of the lower neck. Third pharyngeal pouch remnants are more common than cleft remnants & are related to descent of the thymic primordium from the lateral margins of the pharynx to the upper anterior mediastinum (via the thymopharyngeal duct) during the 6th-9th weeks of gestation. If the duct does not undergo normal involution, a cervical thymic cyst may form that is in close association with the anterior margin of the carotid sheath. The cyst formation is from interactions between the endodermal primordia & neural crest cells during normal thymic development & migration. Histologically, Hassall corpuscles will be identifiable within the cyst wall. Ectopic foci of solid thymic tissue may also be deposited along the remnant duct.

Types of Congenital Cystic Neck Masses

Thyroglossal Duct Lesions
Thyroglossal duct cyst: Tongue base to thyroid bed; embedded in strap muscles when infrahyoid
Ectopic thyroid tissue: Lingual location is most common
Branchial Apparatus Lesions
1st branchial cleft cyst (type I): Located anterior, inferior, or posterior to external auditory canal
1st branchial cleft cyst (type II): Located in or adjacent to parotid gland; may extend inferiorly to angle of mandible
2nd branchial cleft cyst: Most common location is posterior to submandibular gland, lateral to carotid space, & anteromedial to SCM muscle
3rd branchial cleft cyst: Posterior cervical space in upper neck or anterior to SCM in lower neck
3rd branchial pouch remnant → thymopharyngeal duct cyst or ectopic thymus: Along course from pharynx to upper mediastinum
4th branchial pouch remnant → pyriform sinus tract: Patients present with left-sided abscess involving thyroid gland
Vascular Malformations
Venous malformation: Patchy, gradual enhancement; phleboliths are common; ± fluid-fluid levels
Lymphatic malformation: Multilocular cyst ± fluid-fluid levels; rim/septal enhancement
Venolymphatic malformation: Mixed enhancing venous & nonenhancing lymphatic components

SCM = sternocleidomastoid.

Pyriform sinus tracts, or rarely fistulae, represent a unique congenital anomaly of the 4th (or 3rd) pharyngeal pouch. This lesion should be suspected in any child presenting with neck infection involving the left thyroid lobe. The inflammation can frequently be traced superiorly to an asymmetric pyriform sinus apex. A postbarium swallow CT study is frequently helpful to define the barium-filled tract extending from the pyriform sinus to the anterior lower neck.

Vascular malformations are congenital malformations of endothelial development that can be divided into simple or combined lesions with combined lesions containing 2 or more vessel types in 1 lesion. Simple lesions can be divided based on the predominant endothelial characteristics of the lesion into capillary malformations, lymphatic malformations, venous malformations, arteriovenous malformations, & arteriovenous fistulae. The most common vascular malformations identified in the H&N are lymphatic, venous, & combined venolymphatic lesions.

Imaging Anatomy

Recognizing the defined location of a congenital abnormality, particularly congenital cysts, is key to arriving at the correct diagnosis or differential diagnosis. TGD remnants may be in the form of cysts or solid ectopic thyroid tissue anywhere from the midline tongue base to the infrahyoid paramidline thyroid bed. First BCCs are in or around the external auditory canal or parotid gland. Second BCCs are most commonly posteromedial to the submandibular gland & anteromedial to the SCM. Cysts in the posterior triangle of the upper neck may be 3rd BCCs or lymphatic malformations. Cysts along the lower anterior margin of the SCM may be from the 2nd or 3rd branchial cleft or may be lymphatic malformations. Cysts or solid masses in close association with the carotid sheath along the tract of the thymopharyngeal duct (from the angle of the mandible to the upper mediastinum) should raise the question of cervical thymic cyst or ectopic thymus.

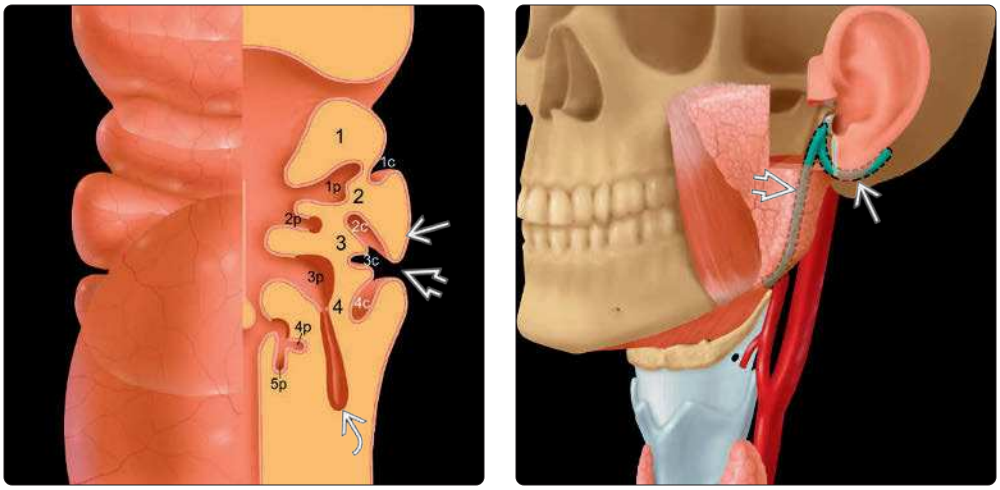
Differential Diagnosis

Thyroglossal Duct Lesions

- TGDC: Tongue base to thyroid bed
- Ectopic thyroid: Lingual thyroid is most common

Branchial Apparatus Lesions

- 1st BCC: Type I cysts lie anterior, inferior, or posterior to external auditory canal
- 1st BCC: Type II cysts in superficial, parotid, or parapharyngeal space may extend as low as posterior submandibular space
- 2nd BCC: Most common posterolateral to submandibular gland, lateral to carotid space, & anteromedial to SCM
- 3rd BCC: Posterior cervical space of upper neck or along anterior border of SCM in mid- & lower neck
- 3rd branchial pouch remnant: Thymopharyngeal duct cyst or ectopic thymus
- 4th branchial pouch remnant: Pyriform sinus tract → recurrent thyroiditis or thyroid abscess, usually left sided; recent literature suggests this may be 3rd branchial pouch remnant



Vascular Malformations

- Venous malformations: Patchy, gradual enhancement; ± fluid-fluid levels & phleboliths
- Lymphatic malformations: Classically multilocular & transspatial with fluid-fluid levels & minimal rim/septal enhancement
- Venolymphatic malformations: Nonenhancing lymphatic & enhancing venous elements ± phleboliths

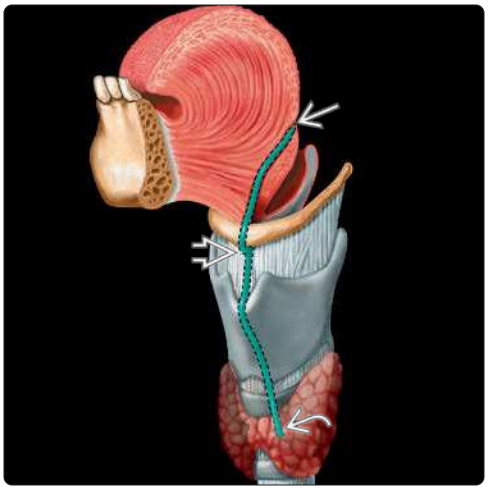
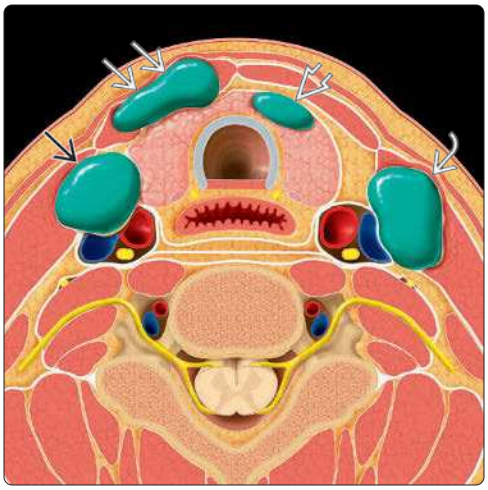
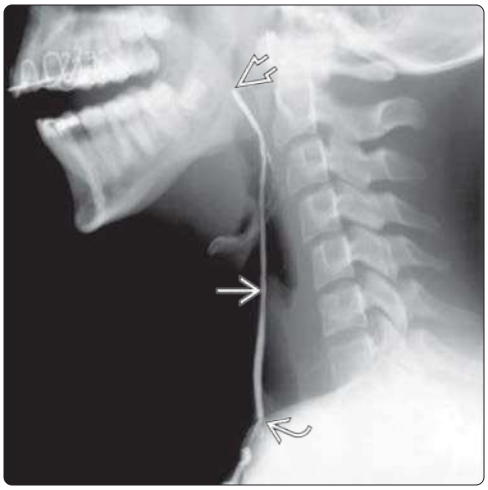
(Left) *Anterior graphic of a 6-week embryo shows the 2nd branchial arch ➡ growing inferiorly over the 3rd & 4th arches, resulting in the cervical sinus of His ➡ that combines the 2nd, 3rd, & 4th branchial clefts (BCs). Note that the thymopharyngeal duct is a remnant of the 3rd branchial pouch ➡.* **(Right)** *Oblique graphic shows the tract of a type I 1st BC anomaly ➡ from the medial bony external auditory canal (EAC) toward the retroauricular area. The tract of a type II 1st BC anomaly ➡ connects the EAC to the angle of the mandible.*

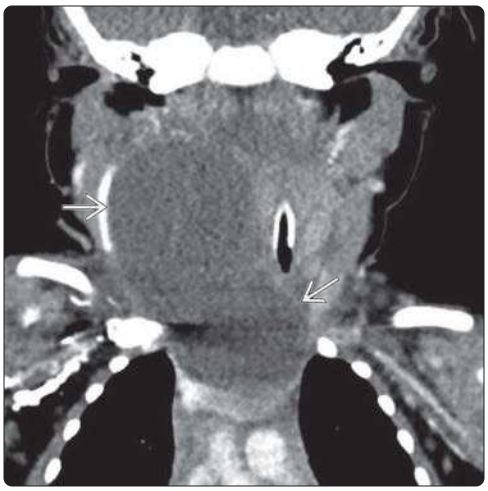


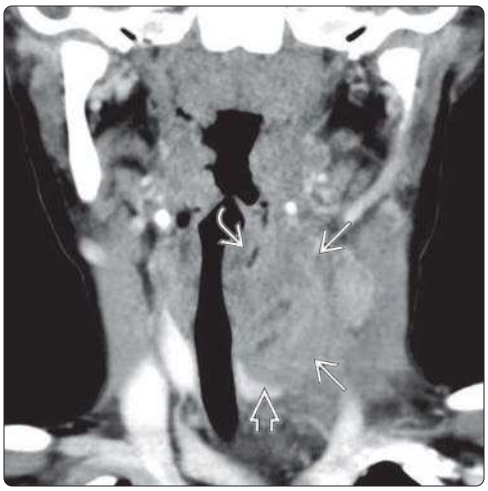


(Left) *Oblique graphic of the tract of a 2nd BC fistula ➡ shows a proximal opening ➡ in the faucial tonsil & a distal opening in the anterior supraclavicular neck ➡.* **(Right)** *Oblique graphic illustrates the tract of a 3rd BC anomaly ➡ extending from the cephalad aspect of the lateral hypopharynx ➡ to the supraclavicular anterior neck skin ➡.*

(Left) *Anterior graphic shows both thymopharyngeal duct tracts ➡ extending from the lateral hypopharyngeal area ➡ to the location of the normal lobes of the thymus ➡ in the superior mediastinum.* **(Right)** *Oblique graphic of the neck shows the tract of a 4th BC anomaly ➡ extending from the hypopharynx ➡ to the location of the left thyroid lobe ➡. This relationship explains why this lesion often presents with thyroiditis.*







(Left) *Oblique graphic illustrates the tract of the thyroglossal duct descending from the foramen cecum (at the tongue base) to the midline hyoid bone before tracking off midline to the thyroid lobe.* **(Right)** *Axial graphic demonstrates the locations of 4 major congenital cystic lesions of the head & neck. Shown here are the infrahyoid 2nd & 3rd BC cysts, the infrahyoid thyroglossal duct cyst, the cervical thymic cysts, & the 4th branchial apparatus sinus tracts.*

(Left) *Coronal CECT shows a bilobed, cystic mass, the largest portion lying within the left parotid gland & the smaller portion extending toward the junction of the cartilaginous & osseous EAC, typical of a 1st BC cyst.* **(Right)** *Lipiodol fistulagram of a 2nd BC fistula shows the proximal opening into the lateral oropharynx & the distal opening in the anterior supraclavicular neck.*

(Left) *Coronal CECT in a 4-month-old shows the typical appearance of a 3rd branchial pouch remnant cervical thymic cyst extending from the anterior neck to the mediastinum.* **(Right)** *Coronal CECT in a 4-year-old boy shows a phlegmonous mass in the left neck involving the left thyroid lobe. There is a tract of inflammation coursing toward the left pyriform sinus, consistent with an inflamed 4th (or 3rd) branchial sinus tract.*

Nasal Dermal Sinus

KEY FACTS

TERMINOLOGY

- Defective embryogenesis of anterior neuropore
- Results in any mixture of dermoid cyst, epidermoid cyst, &/or sinus tract in frontonasal region

IMAGING

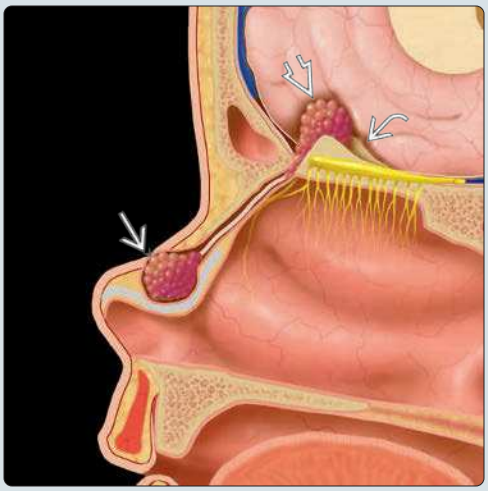
- Midline location, anywhere from nasal tip to anterior skull base at foramen cecum
- MR
  - T2: Fluid-signal tract in septum from nasal dorsum to skull base (sinus)
  - T1: Focal low-signal (epidermoid or nonfatty dermoid) or high-signal (dermoid) mass between tip of nose & apex of crista galli
- CT
  - Bifid crista galli with large foramen cecum
  - Fluid-attenuation tract (sinus)/cyst (epidermoid) or fat-containing mass (dermoid)
    - From nasal dorsum to skull base within nasal septum

TOP DIFFERENTIAL DIAGNOSES

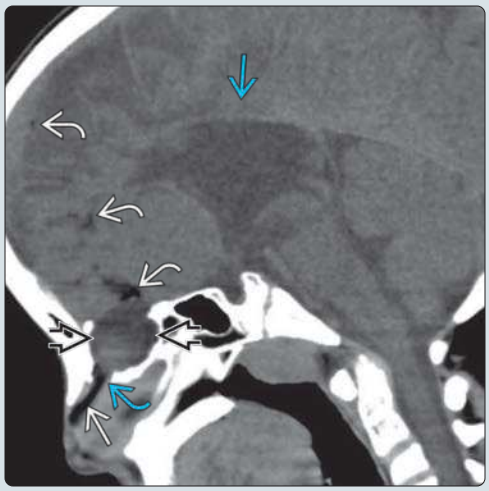
- Yellow marrow in crista galli
- Unossified foramen cecum
- Frontoethmoidal cephalocele
- Nasal glioma (nasal glial heterotopia/cerebral heterotopia)

PATHOLOGY

- Intracranial extension of nasal dermal sinus (NDS) in 20%
  - May rarely lead to meningitis
- Associated craniofacial anomalies in 15%

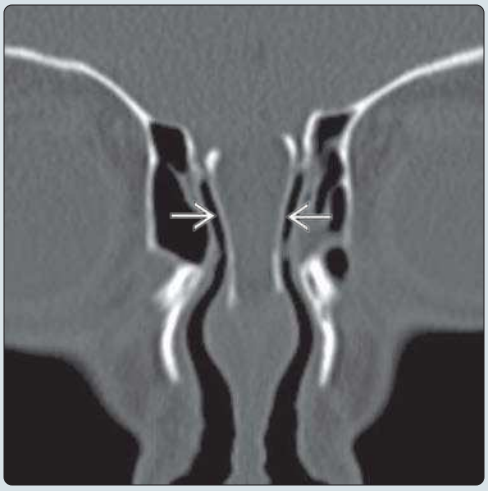


CLINICAL ISSUES

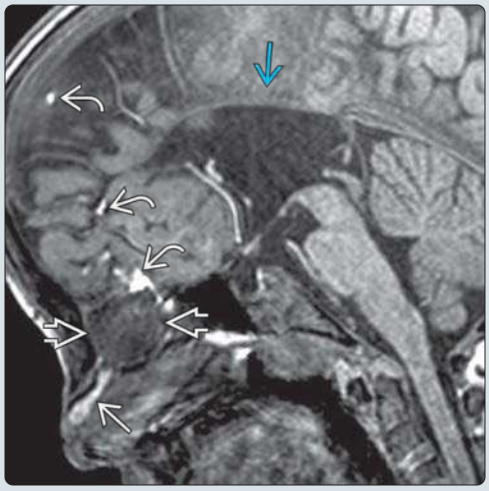


- Nasoglabellar mass (30%)
- Pit (± protruding hair) on skin of nasal bridge at osteocartilaginous nasal junction

DIAGNOSTIC CHECKLIST



- Nasoglabellar mass or pit on nose leads clinician to search for NDS with intracranial extension



(Left) *Lateral graphic depicts a nasal dermal sinus with 2 dermoids. An extracranial dermoid is present just deep to a cutaneous nasal pit. An intracranial dermoid splits a bifid crista galli.* **(Right)** *Sagittal NECT in an 8-year-old with known midline anomalies shows a fat-lined nasal dermal sinus deep to the nasal bones. The sinus leads to a large fat- & fluid-attenuation dermoid. There is a wide foramen cecum with fatty foci extending along the falx. Agenesis of the corpus callosum is also noted.*

(Left) *Coronal bone CT in the same patient shows the bony nasal septum split by a large fat & fluid-attenuation dermoid.* **(Right)** *Sagittal T1 MR in the same patient shows the fat-lined nasal dermal sinus, large mixed signal intensity dermoid, & falcine foci of fat (consistent with intracranial extension & rupture). Agenesis of the corpus callosum is again noted. The dermoid was ultimately resected. Note that the size & extent of findings in this case is greater than typically seen.*

TERMINOLOGY

Abbreviations

- Nasal dermal sinus (NDS)

Synonyms

- Nasal dermoid, nasal dermal cyst, anterior neuropore anomaly

Definitions

- Defective embryogenesis of anterior neuropore
- Results in any mixture of dermoid cyst, epidermoid cyst, &/or sinus tract in frontonasal region

IMAGING

General Features

- Best diagnostic clue
  - CT
    - Bifid crista galli with large foramen cecum
    - Fluid-attenuation tract (sinus)/cyst (epidermoid) or fat-containing mass (dermoid)
      - From nasal dorsum to skull base within nasal septum
  - MR
    - Fluid-signal tract in septum from nasal dorsum to skull base (sinus)
    - Focal T1 low-signal (epidermoid) or high-signal (dermoid) between tip of nose & apex of crista galli
- Location
  - Midline lesion anywhere from nasal tip to anterior skull base at foramen cecum
- Size
  - 5 mm to 2 cm for dermoid/epidermoid
- Morphology
  - Ovoid mass ± tubular sinus tract

CT Findings

- Bone CT
  - Focal tract (sinus) or mass (dermoid or epidermoid) anywhere from nasal bridge to crista galli
    - Fluid-density tract = sinus
    - Fluid-density mass = epidermoid
    - Fat-density mass = dermoid
  - Large foramen cecum with bifid or deformed crista galli or cribriform plate suggests intracranial extension
    - Caution: Anterior skull base ossification is widely variable in 1st few years of life
    - Wide foramen cecum alone is not strong indicator of intracranial extension; correlate with MR

MR Findings

- T1WI
  - ↓ signal tract = sinus
  - ↑ signal mass = dermoid (with ↓ signal on fat-suppressed images)
  - ↓ signal mass = epidermoid or dermoid without fat
- T2WI
  - ↑ signal in sinus, epidermoid, or dermoid
  - Coronal plane shows septal lesions to best advantage
- DWI
  - ↑ signal = epidermoid usually, dermoid rarely
  - Susceptibility artifacts at skull base may obscure signal from epidermoid

Imaging Recommendations

- Best imaging tool
  - MR is more sensitive for delineating sinus tract & detecting intracranial extension
    - MR characterizes epidermoid/dermoid lesions better
  - Bone CT is optimal for identifying skull base defect & crista galli deformity
- Protocol advice
  - Imaging "sweet spot" is small & anterior
    - Focus imaging from tip of nose to back of crista galli
    - Inferior end of axial imaging is hard palate
    - Contrast helps with infectious complications or consideration of other differential diagnoses
      - Not for primary dermoid/epidermoid diagnosis
  - CT
    - Thin-section (1-2 mm) bone & soft tissue images
  - MR
    - Sagittal plane displays course of sinus tract from nasal dorsum to skull base
    - Fat-suppressed T1 images confirm presence of fat in dermoids
    - DWI raises sensitivity for lesion
    - 3D T2/SSFP sequences, such as CISS, FIESTA, or SPACE
      - May demonstrate sinus tract, intracranial continuity, & associated tiny epidermoid/dermoid

DIFFERENTIAL DIAGNOSIS

Yellow Marrow in Crista Galli

- No nasoglabellar mass or pit on nose
- CT & MR are otherwise normal

Unossified Foramen Cecum

- Cartilaginous small midline bone "defect" lying between frontal & ethmoid bones, just anterior to crista galli of ethmoid
- ~ 4-mm diameter at birth
- Foramen cecum ossification usually completes by 2 years
  - Sometimes delayed until 5 years
- Crista galli is not deformed or bifid

Frontoethmoidal Cephalocele

- Bone dehiscence is typically larger, involving broader area of midline cribriform plate or frontal bone
- Direct extension of meninges & subarachnoid space ± brain in cephalocele on sagittal MR

Nasal Glioma

- Solid mass of dysplastic glial tissue separated from brain by subarachnoid space & meninges
- Preferred terms: Nasal glial heterotopia, nasal cerebral heterotopia
- Most commonly projects extranasally onto paramedian bridge of nose
- Less commonly lies intranasal along anterior nasal septum, off midline

PATHOLOGY

General Features

- Etiology
  - Anterior neuropore anomaly: General term for anomalous anterior neuropore regression; 3 main types
    - NDS
    - Nasal glioma (preferred term: Nasal glial/cerebral heterotopia)
    - Frontoethmoidal (sincipital) cephalocele
  - Embryology-anatomy: Development of anterior neuropore in 4th-gestational week
    - Dural stalk passes from area of future foramen cecum to area of osteocartilaginous nasal junction
      - Later regresses completely
    - Failure of involution may leave neuroectodermal remnants along tract of dural stalk
    - Results in dermoid or epidermoid alone or in association with NDS tract
- Associated abnormalities
  - Intracranial extension of NDS is seen in 20%
  - Craniofacial anomalies is seen in 15%

Gross Pathologic & Surgical Features

- Sinus = tract can be followed through bones
- Epidermoid = well-defined cyst; dermoid = lobular, well-defined mass

Microscopic Features

- Sinus = midline epithelial-lined tract
- Epidermoid cyst contains desquamated epithelium
- Dermoid cyst contains epithelium, keratin debris, skin adnexa

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Nasoglabellar mass (30%)
  - Pit on skin of nasal bridge at osteocartilaginous nasal junction
    - ± protruding hair
- Other signs/symptoms
  - Intermittent discharge of sebaceous material from pit
  - < 50% have broadening of nasal root & bridge
  - Nasal sinus tract rarely leads to recurrent meningitis
- Clinical profile
  - Child (mean age: 32 months) with nasal pit ± nasoglabellar mass
  - Rarely presents in adult population
    - Meningitis may be 1st problem leading to diagnosis

Demographics

- Age
  - Newborn to 5 years old
- Sex
  - Male patients with dermal sinus are more likely to have intracranial extension
- Epidemiology
  - Congenital midline nasal lesions are rare (1 in 20,000-40,000 births)
    - Nasal dermoid is most common

Natural History & Prognosis

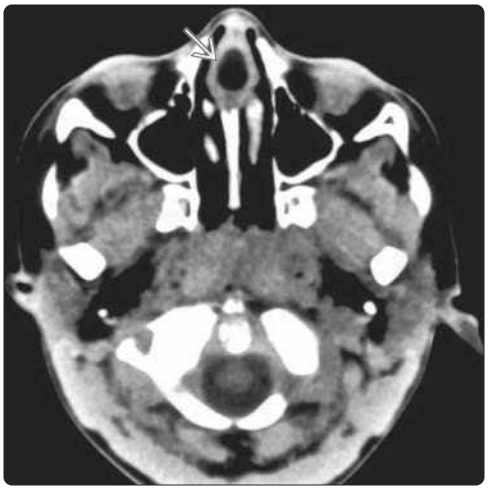
- Isolated problem when surgical correction is successful
- Untreated patients have nasal bridge broadening ± recurrent meningitis

Treatment

- 80% require extracranial excision only
  - Local procedure to remove pit
  - Any associated dermoid or epidermoid is simultaneously removed from nasal bridge
    - Open rhinoplasty vs. transnasal endoscopic excision
- 20% undergo combined extracranial & intracranial resection
  - Biorbitofrontal nasal craniotomy approach
    - Dermoid or epidermoid removed along with involved dura & crista galli
    - Primary closure of surgical margins of dura
  - Midline approach via keyhole frontal craniotomy has been recently described → less blood loss & shorter hospital stay

DIAGNOSTIC CHECKLIST

Consider



- Nasoglabellar mass or pit on nose leads clinician in search of NDS with intracranial extension
- Focused thin-section MR is key to radiologic diagnosis
  - Axial coverage from cephalad margin of crista galli to hard palate
  - Coronal coverage from tip of nose to posterior aspect of crista galli
- Some surgeons prefer to add bone CT if NDS with intracranial extension is found on MR

Image Interpretation Pearls

- If dermal sinus tract reaches dura of anterior cranial fossa, crista galli will be bifid with large foramen cecum
- If foramen cecum is large but crista galli is not bifid & tract is not seen, foramen cecum is normal & not yet closed
  - Foramen cecum may not close before age of 5 years
  - Do not overcall "large foramen cecum" or unnecessary craniotomy may result
  - Repeat imaging in 6-12 months to confirm foramen cecum closure may be acceptable in difficult cases

(Left) *Axial NECT demonstrates a characteristic low-attenuation dermoid ➡ centered in the cartilaginous portion of the nasal septum. The mass is slightly higher in attenuation than adjacent fat.* **(Right)** *Axial T1 C+ FS MR in a 4-month-old infant with a glabellar mass demonstrates a nonenhancing, fluid-signal intensity dermoid cyst ➡ with mild remodeling of the underlying nasal bones ➡. Although dermoid cysts may contain fat, the majority of them do not.*

(Left) *Axial bone CT demonstrates a bifid crista galli ➡ surrounding an intracranial dermoid ➡ at a persistently large foramen cecum.* **(Right)** *Sagittal T2 MR in a 1-year-old with a mass at the tip of his nose shows an ovoid, hyperintense mass ➡ & a tubular lesion ➡ traversing the nasal septum to the foramen cecum without intracranial extension. At the level of the foramen cecum, the lesion demonstrated diffusion restriction (not shown), typical of a dermoid.*

(Left) *Sagittal T1 C+ MR in a 1-year-old with a nasal dorsum mass shows the subcutaneous, nonenhancing midline mass ➡ with a fluid-filled lesion extending to the foramen cecum ➡, imaging characteristics consistent with dermoid or epidermoid cysts.* **(Right)** *Axial DWI MR in the same patient demonstrates restricted diffusion in the lesion at the level of the foramen cecum ➡, typical of a dermoid cyst.*

Juvenile Angiofibroma

KEY FACTS

TERMINOLOGY

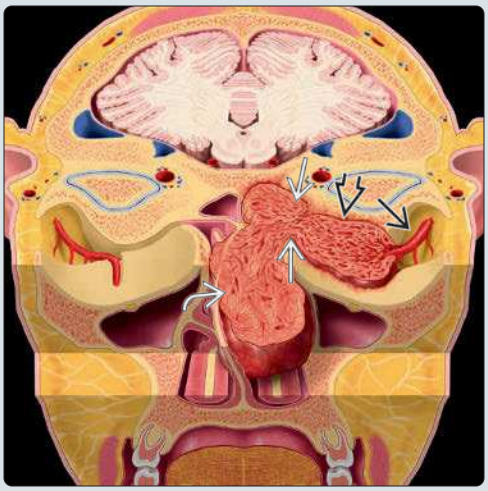
- Benign, vascular, nonencapsulated, locally invasive mass originating in nasal cavity

IMAGING

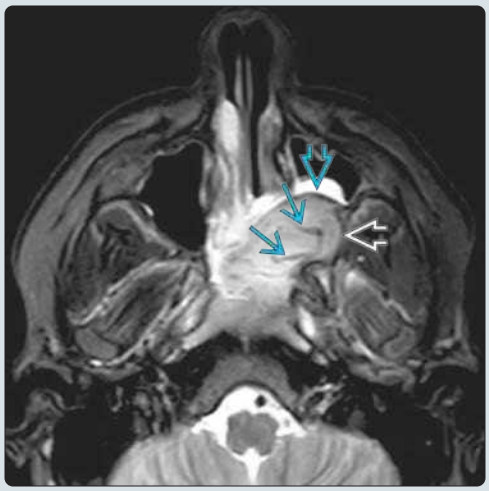
- Centered in posterior nasal cavity arising at sphenopalatine foramen; extends into nasopharynx, sphenoid sinus, pterygopalatine fossa, masticator space, orbit, skull base
- CT findings in juvenile angiofibroma (JAF)
  - Heterogeneous vs. diffuse, avid enhancement
  - Bone remodeling & destruction
    - Posterior wall of maxillary sinus bowed anteriorly
    - ± skull base invasion, intracranial extension
- MR findings in JAF
  - Tubular signal voids on spin echo-based sequences due to fast flow in enlarged vessels
  - Intense enhancement, diffuse or heterogeneous
- Angiography is typically performed at time of preoperative embolization; shows tumor blush
  - Most common feeding artery: Internal maxillary branch of external carotid artery

TOP DIFFERENTIAL DIAGNOSES

- Rhabdomyosarcoma
- Childhood nasopharyngeal carcinoma
- Antrochoanal polyp
- Esthesioneuroblastoma

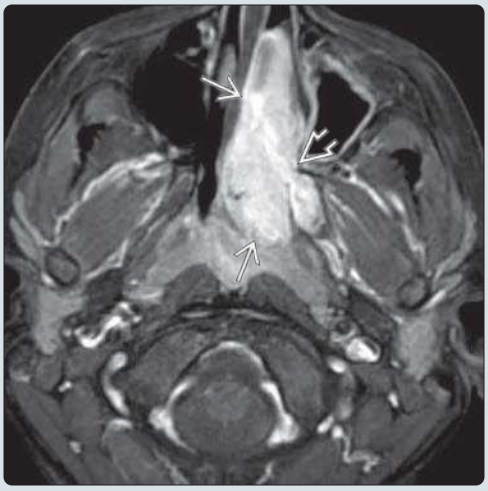


CLINICAL ISSUES

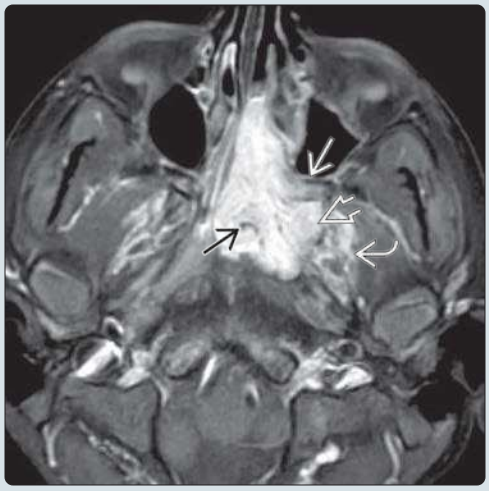


- Occurs almost exclusively in adolescent males
- Unilateral nasal obstruction (90%), epistaxis (60%)
- Preferred treatment: Complete surgical resection using preoperative embolization to ↓ blood loss
  - ± adjuvant radiation therapy after surgery or as primary treatment in some cases

DIAGNOSTIC CHECKLIST



- Look for JAF extension into surrounding structures
- Consider other diagnoses (or genetic testing) in females



(Left) *Tiered graphic shows the classic features & location of a juvenile angiofibroma (JAF). The site of origin is the sphenopalatine foramen (SPF) ➡ with extension into the pterygopalatine fossa (PPF) ⇨ & nasal cavity ➡. The internal maxillary artery ⇨ is the dominant feeding vessel of this vascular mass.* **(Right)** *Axial STIR MR in a teenager shows a well-defined mass with intralesional flow voids ⇨ widening the left PPF, deviating the posterior wall of the maxillary sinus ⇨, & extending into the left infratemporal fossa ➡.*

(Left) *Axial T1 C+ FS MR in a 15-year-old boy with nasal obstruction shows an enhancing JAF ➡ filling the left nasal cavity & extending into the nasopharynx. The presumed site of origin is the SPF ➡.* **(Right)** *Axial T1 C+ FS MR in the same patient shows a few intralesional, high-flow vessels ⇨ with extension of the JAF into the widened PPF ➡. There is destruction of the left pterygoid ➡ with extension of the mass into the masticator space ➡.*

TERMINOLOGY

Abbreviations

- Juvenile angiofibroma (JAF)

Synonyms

- Juvenile nasopharyngeal angiofibroma (JNA); fibromatous or angiofibromatous hamartoma
  - JAF of nasal cavity is more correct terminology
  - JNA is commonly used term, but tumor begins in nasal cavity, not in nasopharynx

Definitions

- Benign, vascular, nonencapsulated, locally invasive nasal cavity mass

IMAGING

General Features

- Best diagnostic clue
  - Intensely enhancing soft tissue mass originating at sphenopalatine foramen (SPF) in adolescent boy
- Location
  - Centered in posterior wall of nasal cavity off midline, at margin of SPF
    - SPF is medial opening of pterygopalatine fossa (PPF) into superior meatus of nose
    - Extends more anteriorly into nasal cavity, posteriorly into nasopharynx, & laterally into PPF
      - Penetrates PPF early (90%) with involvement of upper medial pterygoid lamina
    - Sphenoid sinus extension (60%)
    - May extend into maxillary (43%) & ethmoid sinuses (35%), masticator space, inferior orbital fissure
    - 5-20% extend into middle cranial fossa via vidian canal or foramen rotundum
  - Extranasopharyngeal angiofibroma: Entity showing pathologic findings of JAF but with other differences
    - Located at nasal septum, turbinate, etc.
    - M:F 2.1:1.0; mean age: 28.7 years
    - Mainly nasal obstruction; epistaxis in 25% only
    - Female sex or normal vascularity does not exclude
- Size
  - Usually 2-6 cm but may become massive
- Morphology
  - Lobular, usually well-circumscribed mass
    - Large lesions have infiltrating margins

Radiographic Findings

- Lateral skull radiograph shows anterior displacement of posterior wall of maxillary antrum
  - Called antral sign, bow sign, or Holman-Miller sign
  - Nonspecific sign denoting any slow-growing mass
- Associated with nasal cavity opacification
- ± nasal cavity/nasopharyngeal soft tissue mass

CT Findings

- CECT
  - Heterogeneous vs. diffuse, avid enhancement of soft tissue mass in nasal cavity originating near SPF
  - Frequent extension into adjacent nasopharynx & PPF
  - ± opacified sphenoid sinus (obstructed, nonenhancing secretions vs. enhancing tumor infiltration)
  - ± intracranial & rare orbital extension
- Bone CT
  - Bone remodeling ± destruction
    - Antral sign is nonspecific
    - Ipsilateral nasal cavity & PPF are enlarged
    - ± skull base invasion; pterygoid lamina erosion is specific
- CTA
  - Enlarged, ipsilateral external carotid artery (ECA) & internal maxillary artery (IMAX)

MR Findings

- T1WI
  - Heterogeneous, intermediate signal
  - Signal voids represent flow in enlarged vessels
- T2WI
  - Heterogeneous, intermediate- to high-signal mass
  - Punctate & serpentine flow voids within tumor
- T1WI C+
  - Intense enhancement ± flow voids
- T1WI C+ FS
  - Coronal plane shows cavernous sinus, sphenoid sinus, or skull base extension
- MRA
  - Enlarged ipsilateral ECA & IMAX artery
  - Lesional vessels may be too small to evaluate with MRA

Angiographic Findings

- Conventional angiography is typically performed at time of preoperative embolization
- Intense capillary tumor blush is fed by enlarged feeding vessels from ECA
  - Most common feeding vessels: IMAX & ascending pharyngeal arteries from ECA
  - With skull base or cavernous sinus extension, internal carotid artery (ICA) supply is common
  - ± supply from contralateral ECA branches

Imaging Recommendations

- Best imaging tool
  - Maxillofacial bone-only NECT in axial & coronal planes for evaluating bone remodeling vs. destruction
  - Postcontrast MR is optimal for mapping lesion extent & determining vascularity
  - Catheter angiography of both ECA & ICA
    - Often in conjunction with embolization therapy
    - Helps plan surgery & ↓ intraoperative blood loss
- Protocol advice
  - Maxillofacial MR with T1 C+ FS in axial & coronal planes
    - Multiplanar imaging for evaluating extension into sphenoid sinus, orbit, skull base
  - Precontrast T1 without fat suppression is vital in evaluating infiltration of normal fat in PPF & adjacent bone
  - CECT may be helpful for evaluating residual disease in postoperative period

DIFFERENTIAL DIAGNOSIS

Rhabdomyosarcoma

- Intermediate to mildly high T2 signal mass with variable enhancement (often mild to moderate) & restricted diffusion, ± bone destruction
- Can arise in many locations (not necessarily nasal cavity)
- Rarely penetrates SPF into PPF

Childhood Nasopharyngeal Carcinoma

- Mostly EBV-related, undifferentiated carcinoma
- Invasive mass of lateral nasopharynx
- Mild to moderate enhancement
- 90% with nodal metastases, usually diagnosed at advanced stage

Antrochoanal Polyp

- Maxillary antrum is opacified
- Homogeneous mass herniates into anterior nasal cavity, then nasopharynx; PPF is not involved
- Peripheral enhancement only

Encephalocele

- Nasoethmoidal type presents as intranasal mass
- Connection to intracranial cavity **is** seen on imaging
- No enhancement
- Usually more anterior in position

Esthesioneuroblastoma

- 1st incidence peaks in 2nd decade; F > M
- Presenting symptoms are same as JAF
- Nasal cavity mass near cribriform plate
- Cystic intracranial components are characteristic

PATHOLOGY

General Features

- Etiology
  - Source of fibrovascular tissue of JAF is not known
  - Best current hypothesis: Primitive mesenchyme of SPF is source of JAF

Staging, Grading, & Classification

- Staging systems are based on tumor size (< or > 6 cm), invasion to PPF anterior &/or posterior to pterygoid plates, & skull base/intracranial invasion

Gross Pathologic & Surgical Features

- Reddish-purple, compressible, mucosa-covered mass
- Cut surface has spongy appearance

Microscopic Features

- Unencapsulated, highly vascular polypoid mass of angiomatous tissue in fibrous stroma
- Myofibroblast thought to be cell of origin
- ± estrogen, testosterone, or progesterone receptors

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Unilateral nasal obstruction (90%), epistaxis (60%)
- Other signs/symptoms
  - Nasal voice, nasal discharge, anosmia, pain or swelling in cheek, proptosis, serous otitis media

Demographics

- Age range: 10-25 years reported
  - Average age at onset: 15 years
- Sex: Almost exclusively occurs in male patients
  - If found in female, may have genetic mosaicism
- Epidemiology: 0.5% of all head & neck neoplasms

Natural History & Prognosis

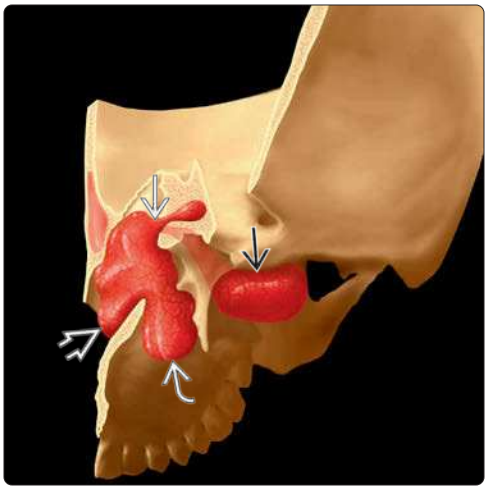
- May rarely spontaneously regress
- Local recurrence rate with surgery: 6-24%
  - Local recurrence is more common with large lesions (> 6 cm), intracranial spread, previous treatment

Treatment

- Preferred: Complete surgical resection using preoperative embolization to ↓ blood loss
  - Biopsy in outpatient setting should be avoided due to risk of hemorrhage
- Multiple surgical approaches
  - Open resection (midface degloving) vs. endoscopic removal ± laser assistance
    - Endoscopic resection is associated with ↓ bleeding & shorter hospital stay
- Radiation therapy (RT)
  - Adjuvant to surgery for unresectable intracranial disease & cavernous sinus involvement
    - 78% control rates are reported
  - RT is used alone for cure in some institutions
  - Used with caution in young patients due to potential to induce malignancies
- Hormonal therapy (estrogen) is controversial
  - Not routine as complete tumor regression is not achieved
  - Feminization side effects are undesirable in adolescent male

DIAGNOSTIC CHECKLIST

Consider



- JAF in adolescent male patient with epistaxis & enhancing posterior nasal cavity mass
- Consider other diagnoses (or genetic testing) in females

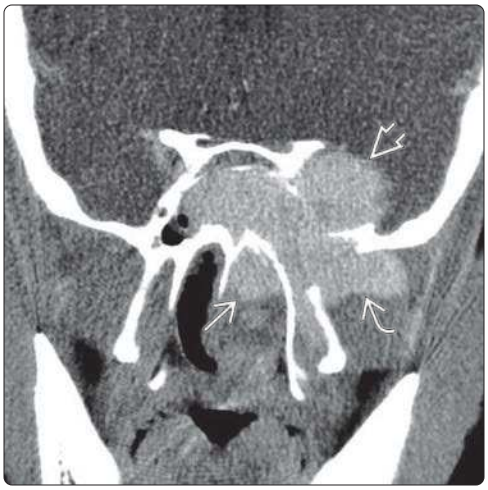


Image Interpretation Pearls

- Evaluate JAF extension into surrounding structures
  - Orbit, infratemporal fossa, sphenoid sinus, & skull base
  - Failure to identify subtle deep growth will result in incomplete surgical resection

(Left) *Posterior oblique sagittal graphic shows the spread patterns of a JAF. The lesion originates at the SPF & extends into the nasal cavity, nasopharynx/oropharynx, & infratemporal fossa.* **(Right)** *Coronal CECT shows a large JAF extending into the nasopharynx, infratemporal fossa, & middle cranial fossa. The sphenoid sinus is replaced by the tumor. As seen in this case, the JAF classically shows avid enhancement.*

(Left) *Axial CECT in bone windows shows anterior bowing of the left maxillary sinus posterior wall & erosion of left medial pterygoid plate & pterygoid process by a JAF in the nasal cavity, nasopharynx, & PPF. Note the normal right PPF & pterygoid.* **(Right)** *Coronal CECT in bone windows in the same patient shows the left pterygoid erosions. The left vidian canal (VC) is invaded by the JAF, & the margin of the left foramen rotundum (FR) shows fine erosions. Note the normal right VC & FR.*

(Left) *Axial T1 C+ FS MR shows avid enhancement throughout a JAF. The mass is centered at the SPF & extends laterally into the masticator space & medially into the nasopharynx. Several serpiginous flow voids are noted in the mass, consistent with enlarged feeding vessels.* **(Right)** *Lateral DSA from an external carotid artery injection shows areas of dense tumor blush within a JAF prior to embolization. As is typical, the main arterial feeding vessel for this JAF is the internal maxillary artery.*

Acute Rhinosinusitis

KEY FACTS

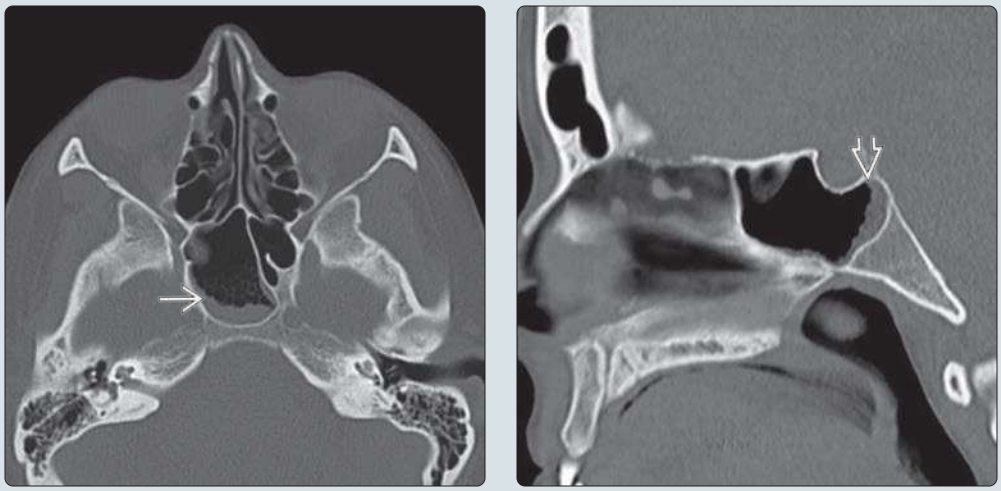
TERMINOLOGY

- Pediatric acute rhinosinusitis (ARS): Sinonasal inflammation lasting < 12 weeks with sudden onset of symptoms
  - ≥ 2 of nasal congestion/obstruction, discolored nasal discharge, or cough
- Classified into acute bacterial rhinosinusitis (ABRS) vs. viral (VRS) based on clinical presentation

IMAGING

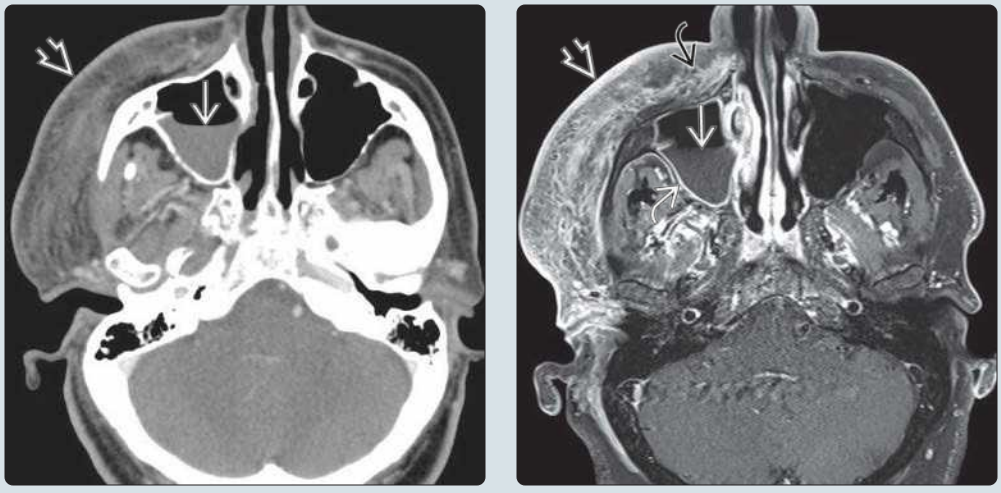
- ARS is clinical diagnosis & imaging is rarely necessary
- Radiography: Mucosal thickening, complete opacification, air-fluid level
- NECT: Can suggest ARS but lacks specificity & should not be performed routinely for diagnosis
  - May be considered to evaluate complications or if diagnosis remains uncertain on clinical grounds
  - Best sign = air-fluid level (nonspecific) ± bubbly secretions with mucosal thickening
  - Most common in ethmoid & maxillary sinuses
  - Often shows asymmetric sinus involvement
- CECT/MR: Indicated for suspected complications

TOP DIFFERENTIAL DIAGNOSES



- Pseudofluid level from large maxillary polyp/cyst
- Posttraumatic blood level
- Postobstructive noninfected secretions

PATHOLOGY



- Most cases follow viral upper respiratory infection

CLINICAL ISSUES

- Purulent nasal drainage, nasal obstruction, & facial pain, pressure, fullness
- VRS: Signs/symptoms last < 10 days, do not progress
- ABRS: Signs/symptoms fail to improve within 10 days **or** worsen within 10 days after initial improvement
- ABRS complications are rare but important to identify
  - Orbital cellulitis, subperiosteal abscess, meningitis, subdural empyema, brain abscess, venous thrombosis

(Left) *Axial NECT in a patient with headache, fever, & purulent nasal discharge shows a bubbly air-fluid level in the right sphenoid sinus, corroborating a clinical history of acute bacterial rhinosinusitis (ABRS).* **(Right)** *Sagittal reconstruction NECT in the same patient delineates a frothy air-fluid level, which layers dependently in the sphenoid sinus.*

(Left) *Axial CECT in a patient with ABRS complicated by facial cellulitis shows a right maxillary sinus air-fluid level as well as skin thickening & subcutaneous edema of the right cheek.* **(Right)** *Axial T1 C+ FS MR in the same patient shows circumferential mucosal thickening of the right maxillary sinus with an air-fluid level. MR better delineates complications, including diffuse right facial cellulitis with skin thickening, subcutaneous edema, & thickening of the superficial musculoaponeurotic system.*

TERMINOLOGY

Abbreviations

- Acute rhinosinusitis (ARS)
- Acute bacterial rhinosinusitis (ABRS)
- Viral rhinosinusitis (VRS)

Definitions

- Adult ARS: Sinonasal inflammation lasting < 4 weeks & demonstrating sudden onset of symptoms
  - Symptoms: **Both** nasal congestion/obstruction **or** nasal discharge & facial pain/pressure **or** reduced smell
- Pediatric ARS: Sinonasal inflammation lasting < 12 weeks & demonstrating sudden onset of symptoms
  - Symptoms: 2 or more of nasal congestion/obstruction, discolored nasal discharge, or cough
- ARS is clinical diagnosis, which does not require imaging or endoscopy to make initial diagnosis
  - Image to assess for complications, surgical planning, or unclear clinical diagnosis (uncommon)
- Classified into VRS vs. ABRS based on clinical presentation

IMAGING

General Features

- Best diagnostic clue
  - Imaging findings are imperfect & lack specificity → need appropriate clinical history
  - Air-fluid level (nonspecific) ± bubbly/frothy secretions within sinus with mucosal thickening
- Location
  - Ethmoid & maxillary sinuses are most common, typically asymmetric

Radiographic Findings

- Mucosal thickening, complete opacification, air-fluid levels

CT Findings

- NECT
  - Air-fluid level, bubbly- or frothy-appearing secretions
    - Air-fluid level is nonspecific & can also be seen with recent sinus irrigation
  - Moderate mucosal thickening, generally > 1 cm in sinus cavity, ostium, or nasal cavity
  - May see polypoid inflammatory tissue obstructing drainage pathways
- CECT
  - Indicated when orbital or intracranial complications are suspected clinically
  - Inflamed sinus mucosa enhances but thin, linear soft tissue deep to mucosa does not
    - Central secretions do not enhance
  - Invasive fungal sinusitis (in immunocompromised host) is suggested by
    - Induration of perimaxillary fat
    - Nonenhancement of mucosa
- Bone CT
  - Bone destruction is not typical for acute infection
    - If present, suspect aggressive invasive sinus infection or neoplasm
  - Osteoneogenesis with sinus wall sclerosis & thickening usually indicates chronic inflammation

MR Findings

- T1WI
  - Mucosal thickening is isointense to soft tissue
  - Air-fluid level
  - Hyperintense secretions if chronic sinusitis is present
- T2WI
  - Thickened edematous mucosa, especially in maxillary & ethmoids
  - Air-fluid level
    - Anterior ethmoid cells are generally too small for discrete fluid level
  - Low signal intensity secretions if proteinaceous or chronic
- T1WI C+
  - Enhancing mucosa lines sinus cavity
  - Central secretions do not enhance

Imaging Recommendations

- Best imaging tool
  - ARS is clinical diagnosis
  - Radiographic findings are nonspecific
    - Not recommended in evaluation of acute disease
  - CT: Consider only if evaluating for complications, failed medical therapy, alternative diagnoses, or surgical candidacy
    - NECT delineates anatomic variants prior to endoscopic sinus surgery
    - CECT is indicated with concern for complications
  - MR is superior for evaluating orbital or intracranial complications, invasive fungal disease, neoplasm
- Protocol advice
  - Bone CT
    - Axial ≤ 1-mm slice thickness with coronal & sagittal reconstructions to evaluate drainage pathways
  - MR
    - Multiplanar T1 & T2 sequences are necessary
    - T1 C+ FS & DWI are best for intracranial/orbital complications

DIFFERENTIAL DIAGNOSIS

Pseudofluid Level

- Mucus retention cyst mimics air-fluid level
- Rounded contour with incomplete fluid level

Posttraumatic Blood Level

- Clinical history of recent facial injury
- ↑ attenuation of layering fluid (blood)
- Associated sinus wall fractures

Postobstructive Secretions

- Lesion obstructs sinus drainage pathway, resulting in noninfected trapped sinus cavity fluid
- MR differentiates tumor from obstructed secretions
  - Neoplasm is generally of ↓ SI on T2 compared to hyperintense secretions & frequently hypoenhancing relative to sinonasal mucosa

PATHOLOGY

General Features

- Etiology

- ABRS uncommonly follows VRS (0.5-2.0% of cases) in adults but more commonly follows upper respiratory infection (URI) in children (4-7%)
  - URI (typically viral) → mucosal swelling → sinus outflow obstruction → static secretions in sinus → infection
  - Viral symptoms usually improve in 7-10 days
  - Symptoms > 10 days or worsening after 5-7 days suggest bacterial superinfection
    - Common organisms: *Streptococcus pneumonia*, *Haemophilus influenzae*, *Moraxella catarrhalis*
- Odontogenic rhinosinusitis: Apical periodontitis with dehiscence or transosseous spread of infection into maxillary sinus
  - Likely underdiagnosed (reported prevalence of 10-15% but may be as high as 45%)
- Genetics
  - Cystic fibrosis (autosomal recessive disorder) predisposes to rhinosinusitis & polyps
- Associated abnormalities
  - Structural abnormalities may narrow drainage pathways
    - Anatomic variants of septum, uncinate process, middle turbinate, frontal recess, ethmoid sinuses
    - Polyps, either isolated or associated with allergic sinusitis with diffuse polyposis
    - Benign or malignant neoplasms
  - Predisposing systemic disorders: Allergies, immunoglobulin deficiency, immotile cilia syndrome, cystic fibrosis, vitamin D deficiency

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Cardinal signs/symptoms of ARS: < 4 weeks of purulent nasal drainage & obstruction, facial pain, or pressure
    - VRS: Signs/symptoms last < 10 days, do not progress
    - ABRS: Signs/symptoms fail to improve within 10 days or worsen within 10 days after initial improvement
- Other signs/symptoms
  - Fever, cough, malaise, hyposmia, anosmia, dental pain, ear pressure/fullness
    - Facial/dental pain predicts ABRS, but location correlates poorly with site of involvement
- Clinical profile
  - Nasal discharge & obstruction following viral URI lasting < 4 weeks (adult) or < 12 weeks (child)
  - Laboratory results
    - Nasal/nasopharynx cultures poorly correlate with sinus cultures, do not differentiate ABRS from VRS
    - Endoscopic middle meatus aspiration is more specific but generally not necessary in uncomplicated ARS

Demographics

- Age
  - Children & adults
    - Typically follows viral URI in children
- Epidemiology
  - Sinonasal inflammatory disease is ubiquitous
  - Rhinosinusitis affects nearly 31 million patients in USA annually
  - VRS & ARS often follow/coexist with common cold

Natural History & Prognosis

- VRS is usually self-limited
- ABRS may resolve without antibiotics
- ABRS course may be shortened by medical therapy, surgical drainage, & possibly saline irrigation
- If ABRS is untreated, complications rarely ensue
  - Orbital cellulitis, subperiosteal abscess, meningitis, subdural empyema, brain abscess, venous sinus thrombosis

Treatment

- Medical therapy
  - Antibiotics (in uncomplicated cases with worsening after 7 days, earlier if extenuating circumstances)
  - Intranasal corticosteroids
  - Topical saline irrigation (adjunct to antibiotics for ABRS)
- Surgical therapy
  - More often performed for chronic rhinosinusitis
  - Drainage procedures performed in acute disease (frontal & sphenoid) to prevent development of complications

DIAGNOSTIC CHECKLIST

Consider

- Bone CT for suspected alternative diagnoses, failed therapy, complications, or surgical candidate
  - Acquire ≤ 1-mm axial slices with coronal & sagittal reformations
- CT limitations
  - Cannot differentiate viral from bacterial disease
  - High incidence of sinus mucosal abnormalities in asymptomatic patients

Image Interpretation Pearls

- Air-fluid level is not always present & not highly specific
- In correct clinical setting, even severe mucosal thickening can indicate ABRS
- Normal nasal mucosal cycle may be impossible to distinguish from ARS mucosal thickening
- Look for signs of invasive fungal sinusitis in immunocompromised patient

(Left) *Axial NECT performed for headache & fever reveals frothy air-fluid levels in both frontal sinuses. Although ABRS is a clinical diagnosis, imaging may be performed to rule out suspected complications.* **(Right)** *Axial NECT in patient with a clinical diagnosis of ABRS demonstrates an air-fluid level in the left sphenoid sinus. Note osteoneogenesis, or a sclerotic sinus wall, suggesting chronic sinus inflammatory disease, as well as an acute ABRS component.*

(Left) *Axial NECT in a patient with facial pain & purulent nasal discharge shows a partially opacified right maxillary sinus with bubbly air-fluid level, consistent with clinical history of acute rhinosinusitis (ARS).* **(Right)** *Sagittal NECT reconstruction in a patient with clinical ARS shows corroborating air-fluid level in the maxillary sinus. Careful inspection reveals periapical lucencies of the maxillary teeth, an easily overlooked finding that may contribute an odontogenic component to the maxillary sinusitis.*

(Left) *Axial CECT in a child shows right ethmoid sinusitis complicated by postseptal orbital cellulitis with a medial orbital subperiosteal abscess. Orbital disease may be the initial presentation of sinusitis in children.* **(Right)** *Axial CECT in a 5-year-old with fever & COVID-19 positive serology who developed right-sided weakness shows a large left subdural empyema & right frontal lobe abscess as a complications of ABRS (not shown).*

Orbital Cellulitis

KEY FACTS

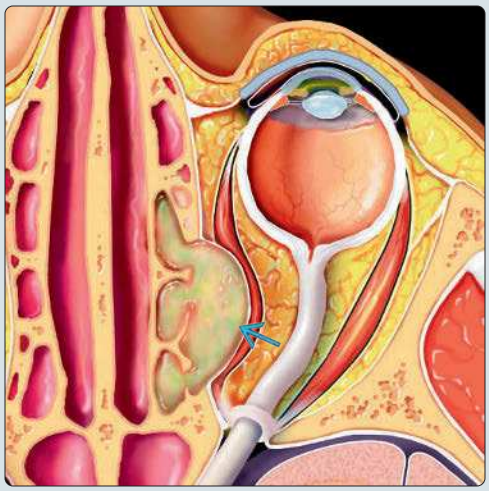
TERMINOLOGY

- Preseptal cellulitis: Infection anterior to orbital septum
- Postseptal cellulitis: Infection posterior to orbital septum
- Orbital septum: Periosteal reflection of bony orbit → upper lid levator aponeurosis & lower lid tarsal plate

IMAGING

- Thickening & edema of orbital/periorbital soft tissues
- Preseptal cellulitis: Limited to anterior tissues
- Postseptal cellulitis
  - Low-attenuation, rim-enhancing collection
    - Drainable subperiosteal abscess (SPA) in majority
    - 20% without drainable abscess (phlegmon)
  - Associated myositis is common with swollen extraocular muscles, ± abnormal enhancement
  - ± thrombosed superior ophthalmic vein
- ± extraorbital complications of sinusitis
  - Frontal osteomyelitis, meningitis, subdural/epidural effusion or empyema, cerebritis, parenchymal abscess

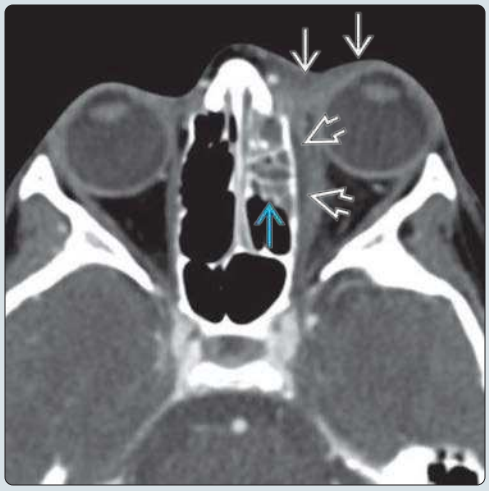
TOP DIFFERENTIAL DIAGNOSES



- Idiopathic orbital inflammation
- Langerhans cell histiocytosis
- Orbital soft tissue or osseous neoplasm
  - Rhabdomyosarcoma
  - Metastatic neuroblastoma
- Orbital vascular anomaly
  - Infantile hemangioma
  - Venous malformation

PATHOLOGY

- Preseptal/periorbital cellulitis: Typically due to trauma (skin infection, insect bites, etc.)
- Postseptal cellulitis: Most common cause is sinusitis



CLINICAL ISSUES

- Treatment: Intravenous antibiotics ± sinus drainage procedures, SPA drainage

(Left) *Axial graphic shows the spread of infection from the ethmoid sinuses through the lamina papyracea into the medial orbit, resulting in a subperiosteal abscess (SPA) that places the optic nerve at risk.* **(Right)** *Axial CECT in a 7-year-old with neutropenia & left eyelid swelling demonstrates marked preseptal periorbital soft tissue edema. There is a low-attenuation crescent with rim enhancement marginating the anterolateral globe, consistent with chemosis. The postseptal orbit is normal.*

(Left) *Axial CECT in a 6-year-old boy demonstrates moderate preseptal cellulitis, a medial subperiosteal fluid collection deviating the left medial rectus muscle, & ipsilateral left ethmoid sinus disease, which is the typical cause of postseptal inflammation. There is also mild associated proptosis.* **(Right)** *Axial CECT shows diffuse enlargement & lack of central enhancement in a thrombosed left superior ophthalmic vein. There is associated ethmoid sinus disease with preseptal & postseptal orbital cellulitis.*

TERMINOLOGY

Definitions

- Preseptal cellulitis: Inflammation anterior to orbital septum
- Postseptal cellulitis: Inflammation posterior to orbital septum
- Orbital septum: Periosteal reflection bony orbit → upper lid levator aponeurosis & lower lid tarsal plate

IMAGING

General Features

- Best diagnostic clue
  - Thickening & edema of periorbital &/or orbital soft tissues = cellulitis
  - Low-attenuation, rim-enhancing subperiosteal collection in medial or superior orbit
    - Drainable subperiosteal abscess (SPA) in majority
    - Phlegmon in 20% without drainable abscess
- Location
  - Preseptal: Disease limited to periorbital soft tissues, anterior to orbital septum
  - Postseptal: Disease posterior to orbital septum
    - Intraconal: Within cone formed by extraocular muscles (EOMs)
    - Extraconal: Between bony orbit & EOMs
    - Subperiosteal: Between bony orbit & orbital periosteum
    - Associated myositis is common
      - Swollen EOMs ± abnormal enhancement
  - ± extraorbital complications of sinusitis
    - Frontal osteomyelitis, meningitis, subdural/epidural effusion or empyema, cerebritis, parenchymal abscess

CT Findings

- CECT
  - Infiltration of periorbital &/or intraorbital fat with poorly defined diffuse mild enhancement
  - ± focal elongated/lentiform rim-enhancing SPA or intraorbital abscess
    - Medial > > superior orbit
    - ± foci of gas in abscess
  - ± EOM enlargement due to myositis; EOM deviation by inflammatory collections
  - ± enlarged, centrally nonenhancing superior ophthalmic vein due to thrombosis
  - Careful review of anterior & middle cranial fossae for fluid collection or findings of parenchymal edema

MR Findings

- T1: Hypointense infiltration of normal fat
- T2 FS: Heterogeneous hyperintensity of fat ± fluid in focal collection
- DWI: Restricted diffusion suggests abscess
- T1 C+ FS: Heterogeneous enhancement of inflamed tissues ± rim-enhancing SPA

Imaging Recommendations

- Best imaging tool
  - CECT: Axial & coronal reformatted images
  - MR with contrast: Best for evaluation of intracranial complications of sinusitis

DIFFERENTIAL DIAGNOSIS

Idiopathic Orbital Inflammation

- Acute to subacute orbital pain, swelling, restricted motion, diplopia, proptosis, & impaired vision
- Poorly marginated, mass-like enhancing soft tissue involving any region of orbit
  - Unilateral or bilateral

Langerhans Cell Histiocytosis

- Classic punched-out round or geographic lytic bone lesion
- Bone lesion is often filled with homogeneously enhancing soft tissue mass ± intra- & extracranial extension

Orbital Neoplasm

- Variably enhancing mass originating in bone or soft tissues
- Bone-centered lesions (primary or metastatic) show aggressive permeative destruction & periosteal reaction, particularly in superolateral orbit
  - Metastatic neuroblastoma: Perpendicular radiating spicules of new bone; may show mild osseous expansion
- Soft tissue neoplasms are often well-defined without surrounding edema

Orbital Vascular Anomaly

- Infantile hemangioma
  - Well-circumscribed, lobular, diffusely enhancing mass
  - Superficial lesions typically show characteristic cutaneous features (raised red "strawberry mark")
    - Appear in 1st days-weeks of life with rapid growth prior to gradual involution
- Venous malformation
  - Infiltrative pre- &/or postseptal fluid signal lesion with septated mass-like components &/or tubular channels
  - ± fluid-fluid levels, low-signal thrombi, patchy gradual enhancement
  - ± bluish skin discoloration that bulges with Valsalva
    - Present at birth
    - May ↑ at puberty/pregnancy or with thrombosis

PATHOLOGY

General Features

- Etiology
  - Most common causes of preseptal or periorbital cellulitis
    - Trauma (skin infection, insect bites, foreign body), sinusitis, & primary bacteremia (< 36 months of age)
  - Most common cause of postseptal cellulitis: Sinusitis
    - Up to 3% of sinusitis patients develop cellulitis (most common complication)
      - May precede signs & symptoms of sinusitis
      - Usually secondary to ethmoiditis
    - Spread of sinus infection to orbit
      - Direct extension via thin bone with acquired dehiscence &/or normal foramina in lamina papyracea
      - Valveless venous system (diploic veins of Breschet) connects orbital circulation with ethmoid, frontal, & maxillary sinus circulation
    - Occasional underlying cause of sinusitis
      - Antrochoanal polyp
      - Sinonasal foreign body

        - Odontogenic sinusitis
    - Other causes: Nasolacrimal duct mucocele or dacryocystocele may lead to periorbital cellulitis; retinoblastoma rarely presents as periorbital cellulitis
- Associated abnormalities
    - Superior ophthalmic vein &/or cavernous sinus thrombosis
        - Expanded with central heterogeneous or nonenhancing thrombus
    - Frontal osteomyelitis (Pott puffy tumor)
        - Forehead cellulitis, phlegmon ± subgaleal abscess
        - Frontal bone lytic lesion may be difficult to detect
    - Meningitis
        - ± abnormal meningeal contrast enhancement
            - Absence of enhancement does not exclude meningitis with clinical suspicion
    - Effusions
        - Epidural (lenticular) or subdural (crescentic) fluid collections without rim enhancement or restricted diffusion
    - Empyema
        - Epidural (lenticular) or subdural (crescentic) collection of pus
        - Usually shows peripheral dural enhancement
        - Restricted diffusion on MR (↑ signal on DWI with ↓ signal on ADC map)
    - Cerebritis
        - Amorphous parenchymal edema without rim-enhancing collection
    - Brain abscess
        - Round or ovoid collection of pus within brain
        - Ring-enhancing wall may be thicker superficially; ± low T2 signal rim on MR
        - Hyperintense DWI, hypointense ADC on MR

Staging, Grading, & Classification

- Chandler classification: Orbital complications of sinusitis
    - Preseptal cellulitis
        - Inflammation anterior to orbital septum
        - Eyelid edema
        - No tenderness, visual loss, or impaired EOM motility (ophthalmoplegia)
    - Orbital cellulitis without abscess
        - Diffuse postseptal edema of orbital fat
    - Orbital cellulitis with SPA
        - ± proptosis, impaired vision, or ophthalmoplegia
    - Orbital cellulitis with abscess in orbital fat
        - Usually severe proptosis, ↓ vision, & ophthalmoplegia
    - Cavernous sinus thrombosis secondary to orbital phlebitis: Unilateral or bilateral

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
    - Depends on degree of inflammation
        - Fever, eyelid swelling, erythema, tenderness, chemosis, proptosis, ophthalmoplegia resulting in diplopia, ↓ visual acuity
- Other signs/symptoms
    - Cranial nerve palsies (III-VI) with cavernous sinus thrombosis
    - Seizures, mental status changes with intracranial complications

Demographics

- 50% of affected children < 4 years of age

Natural History & Prognosis

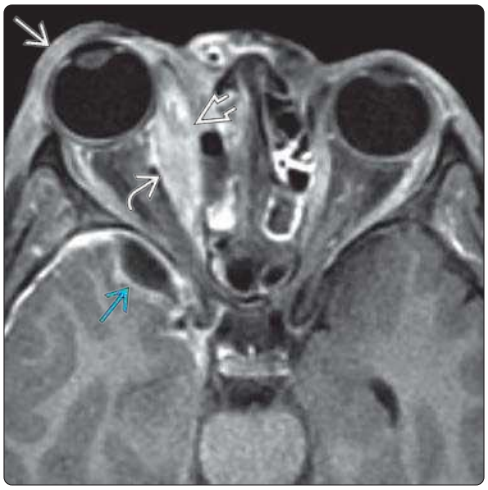
- Excellent with appropriate treatment
- Rare cause of blindness if untreated

Treatment

- Medical management: Intravenous antibiotics
- Surgical management
    - Chandler classification + imaging characteristics ↑ ability to predict surgical need
    - SPA: Not absolute surgical indication
        - Younger children may only require antibiotics with more aggressive surgical drainage in older children
        - Emergent surgery if visual disturbance develops from optic nerve or retinal compromise
    - Drainage of orbital fat abscess
    - Sinus drainage procedures
    - Intracranial empyema is classically considered surgical emergency, particularly with neurologic signs/symptoms
        - Collection may resolve with antibiotics

DIAGNOSTIC CHECKLIST

Consider



- Imaging indications: CECT
    - Impairment in visual acuity or ophthalmoplegia
    - No improvement or worsening of symptoms on appropriate antibiotics
    - Severe eyelid edema prohibiting evaluation of vision & EOM motility
- Imaging indications: MR with contrast
    - Suspected intracranial complications
        - Fluid collection is presumed infected if neurologic symptoms (seizure, altered mental status) are present
        - Clinical & CT findings may dictate operative intervention before MR

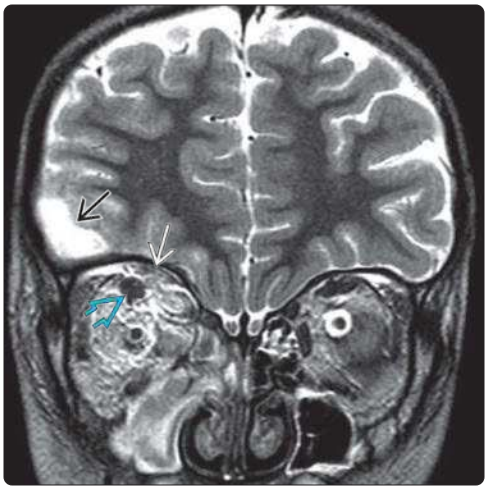


Image Interpretation Pearls

- Distinguishing SPA from phlegmon may be difficult
- Cavernous sinus thrombosis may be subtle
- Look for underlying cause of sinusitis & extraorbital complications

(Left) *Axial T1 C+ FS MR in a 5-year-old with right proptosis & seizures shows ethmoid sinus disease, preseptal orbital cellulitis, medial extraconal postseptal phlegmon with an enlarged medial rectus muscle, & a middle cranial fossa epidural abscess.* **(Right)** *Coronal T2 MR in the same child shows additional extraconal disease in the superior right orbit with inferior displacement of the superior rectus muscle complex. There is an extraaxial fluid collection in the right anterior cranial fossa.*

(Left) *Axial CECT in a 9-day-old presenting with eye swelling shows left preseptal orbital edema in the setting of a nasolacrimal duct mucocele. The lacrimal sac & lacrimal fossa/proximal canal are enlarged. There was an associated distal intranasal component to the mucocele (not shown).* **(Right)** *Axial T1 C+ FS MR in a 7 year old imaged for follow-up of an intracranial abnormality demonstrates new, unsuspected left preseptal cellulitis. In this case, the cellulitis was secondary to a bee sting 1 day prior.*

(Left) *Coronal T1 C+ FS MR in a child with extensive sinusitis shows hazy ↑ enhancement of the right intraconal fat, thickening of the superior & lateral rectus muscles (consistent with myositis), & enlargement of a nonenhancing superior ophthalmic vein, consistent with thrombosis.* **(Right)** *Coronal CECT in a child with left ethmoid sinusitis shows an ipsilateral superior orbital gas-containing SPA. The left superior rectus muscle complex & globe are deviated inferiorly.*

Retinoblastoma

KEY FACTS

TERMINOLOGY

- Retinoblastoma (RB): Malignant primary retinal neoplasm
- Trilateral/quadrilateral RB: Bilateral ocular RB + pineal tumor ± suprasellar tumor

IMAGING

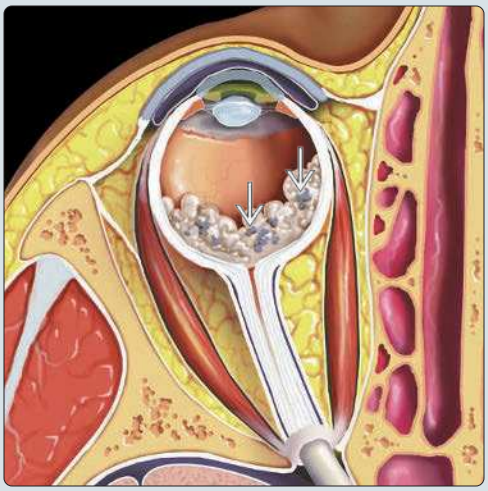
- Unilateral in 60%, bilateral in 40%
- Trilateral or quadrilateral disease is rare
- Extraocular extension in < 10%: Poor prognosis
- CT: Ca^{2+} in > 90%
- MR: Assess extent of intraocular tumor + presence of optic nerve, orbital, &/or intracranial involvement
  - T1: Mild hyperintensity
  - T2: Moderate to marked hypointensity
  - T1 C+: Moderate to marked heterogeneous enhancement

TOP DIFFERENTIAL DIAGNOSES

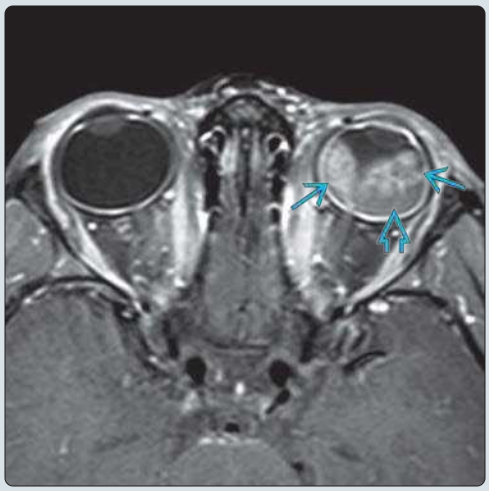
- Persistent hyperplastic primary vitreous
- Coats disease
- Retinopathy of prematurity
- Orbital toxocariasis

PATHOLOGY

- Primitive neuroectodermal tumor
- Sporadic (nongermline) *RB1* mutation: Most are unilateral
- Inherited (germline) *RB1* mutation: Multilateral > unilateral
  - ↑ risk of 2nd remote malignancy

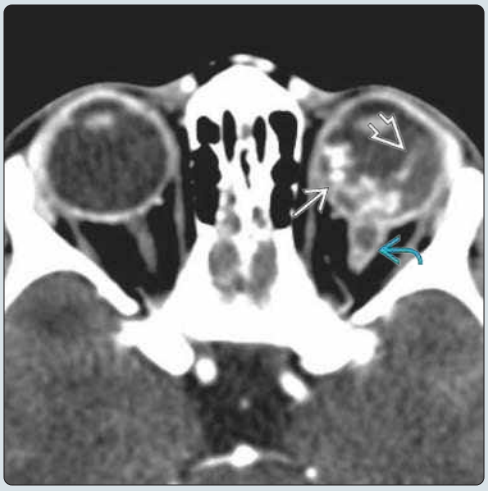


CLINICAL ISSUES

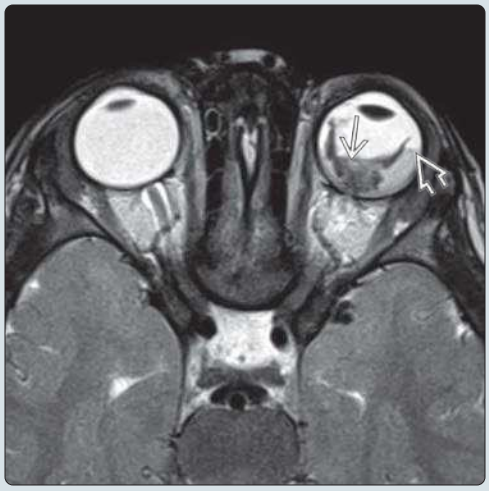


- Most common intraocular tumor of childhood
- Leukocoria in 50-60%
- 90-95% are diagnosed by age 5 years

DIAGNOSTIC CHECKLIST



- Calcified intraocular mass in child: RB until proven otherwise



(Left) *Axial graphic depicts a retinoblastoma (RB) with lobulated tumor extending through the limiting membrane into the vitreous. Characteristic punctate Ca^{2+} are shown.* **(Right)** *Axial T1 C+ FS MR in a 3-year-old with leukocoria demonstrates a large, moderately enhancing, bilobed left RB. Mild ↓ signal intensity posteriorly represents subretinal fluid secondary to retinal detachment.*

(Left) *Axial CECT in a 3-year-old with leukocoria shows a partially calcified RB in the left globe with a focus of retinal detachment &/or noncalcified subretinal tumor at the temporal aspect of the globe. There is also postlaminar optic nerve/sheath invasion.* **(Right)** *Axial T2 MR in the same child shows hypointensity in the calcified portions of the ocular mass with a lateral subretinal fluid level secondary to retinal detachment.*

TERMINOLOGY

Abbreviations

- Retinoblastoma (RB)

Definitions

- Malignant primary retinal neoplasm
- Trilateral RB: Bilateral ocular tumors + midline intracranial neuroblastic tumor, typically pineal
- Quadrilateral/tetralateral RB: Bilateral disease + pineal & suprasellar tumors

IMAGING

General Features

- Best diagnostic clue
  - Intraocular, calcified mass in young child
  - Diagnosed typically with ophthalmoscopy & ultrasound
    - MR for tumor mapping & prognostication
- Location
  - Unilateral in 60%, bilateral in 40%
  - Trilateral or quadrilateral disease is rare
  - Extraocular extension in < 10%
    - Spreads along scleral vessels into orbit & along optic nerve to subarachnoid space
  - Predictors for metastatic disease: Involvement of optic nerve, choroid, anterior chamber, or orbit
    - Anterior chamber enhancement reflects neoangiogenesis → associated with more aggressive tumor behavior
  - Role of MR imaging
    - Exclude pseudoneoplastic lesions
    - Assess intraocular (choroid, sclera, prelaminar optic nerve), extraocular (postlaminar optic nerve, orbital), & intracranial (pineal, parasellar, metastatic) involvement
- Morphology
  - Irregular & heterogeneous mass within normal or small globe
- Growth patterns
  - Endophytic form (45%)
    - Inward protrusion into vitreous
    - Associated with vitreous seeding
  - Exophytic form (45%)
    - Outward growth into subretinal space, typically with hemispherical configuration
    - Associated retinal detachment & subretinal exudate
  - Mixed endophytic & exophytic (10%)
  - Diffuse infiltrating form (rare, older children)
    - Plaque-like growth along retina; often no Ca^{2+}
    - Simulates inflammatory or other conditions

CT Findings

- Punctate, coarse or finely speckled Ca^{2+} (> 90-95%)
- Moderate to marked heterogeneous enhancement

MR Findings

- T1: Variable, mildly hyperintense (relative to vitreous)
- T2: Moderate to marked hypointensity (vs. vitreous)
  - Helps distinguish from hyperintense lesions (e.g., persistent hyperplastic primary vitreous, Coats disease)
  - Best to identify subretinal fluid ± vitreous hemorrhage
- T1 C+: Moderate to marked heterogeneous enhancement
  - Best to assess extent of intraocular disease & presence of optic nerve or extraocular invasion
    - Choroidal invasion: Localized thickening & heterogeneous contrast enhancement near tumor
    - Scleral invasion: Interruption in thin, hypointense zone surrounding enhancing choroid
    - Optic nerve invasion: Thickening of optic disc (prelaminar), enhancement of nerve (postlaminar)
- Imaging of orbital prosthesis
  - Fibrovascularization secures prosthesis & provides surface for muscular attachment
    - Progressive ↓ T2 signal & ↑ peripheral enhancement

Ultrasonographic Findings

- A-scan: Highly reflective spikes at Ca^{2+}
- B-scan: Echogenic, irregular mass with focal shadows

Imaging Recommendations

- Best imaging tool
  - MR: T1 C+ FS & T2 are best for tumor mapping
  - CT: Intraocular Ca^{2+} is relatively specific in child
- Protocol advice
  - Include whole brain to assess for intracranial disease

DIFFERENTIAL DIAGNOSIS

Persistent Hyperplastic Primary Vitreous

- Small globe, hyperdense tissue, no Ca^{2+}
- Hyperintense on T2 MR with enhancing retrolental stalk

Coats Disease

- Normal-sized globe, hyperdense exudate, rare Ca^{2+}
- Hyperintense on T1 & T2 MR

Retinopathy of Prematurity

- Retrolental fibroplasia; associated with excess oxygen & premature retinal vessels
- Bilateral, small globes; hyperdense tissue, Ca^{2+} if advanced

Retinal Astrocytic Hamartoma

- Rare lesion often associated with tuberous sclerosis; ± Ca^{2+}

Toxocariasis

- Uveoscleral enhancement with no Ca^{2+} in acute phase
- Moderately enhancing retinal nodule
- Intravitreal membranes & retinal detachment

Other Causes of Leukocoria

- Retinal detachment
  - Subretinal hemorrhage, retinal folds
- Choroidal osteoma, choroidal angioma
- Retinal dysplasia

PATHOLOGY

General Features

- Etiology
  - Primitive neuroectodermal tumor
  - Sporadic (nongermline): 60% of RB
    - Spontaneous somatic mutation or deletion of both copies of *RB1* in retinoblasts
    - Majority (85%) of unilateral disease

- Inherited (germline): 40% of RB
  - Germline mutation or deletion of 1 copy of *RB1* + spontaneous mutation of other copy
  - Essentially all bilateral & multilateral disease
    - Minority (15%) of unilateral disease
  - Autosomal dominant with 90% penetrance
  - Positive family history in 5-10%
  - New germline mutations in 30-35%
- Genetics
  - *RB1* gene (chromosome 13q14) codes for pRB tumor suppressor protein
    - Lack of both *RB1* alleles in embryonic retinoblasts leads to absence of pRB, resulting in malignancy
  - Somatic mosaicism in 10-20% of RB patients
- Associated abnormalities
  - ↑ risk of 2nd malignancy in germline disease
    - Sarcoma, melanoma, CNS tumors, epithelial tumors (lung, bladder, breast)
    - 20-30% in nonirradiated patients
    - 50-60% in irradiated patients
    - Occurs within 30 years; average 10-13 years
  - 13q deletion syndrome: RB + multiple organ anomalies

Staging, Grading, & Classification

- Reese-Ellsworth classification
  - Groups 1-5
  - Based on size, location, & multifocality
  - More useful in radiation therapy management
- International (Murphree) classification of retinoblastoma
  - Groups A-E
  - Based on size, retinal location, subretinal or vitreous seeding, & several specific prognostic features
  - More useful in chemotherapy management

Microscopic Features

- Small round cells, scant cytoplasm, & large nuclei
- Flexner-Wintersteiner rosettes & fleurettes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Leukocoria in 50-60%
- Other signs/symptoms
  - Severe vision loss
  - Strabismus with macular involvement or retinal detachment
  - Proptosis with significant orbital disease
  - Rubeosis iridis (redness of iris secondary to neovascularization) correlates with anterior chamber enhancement on MR
  - Inflammatory signs in 10%
  - Less common: Anisocoria, heterochromia, glaucoma, cataract, nystagmus

Demographics

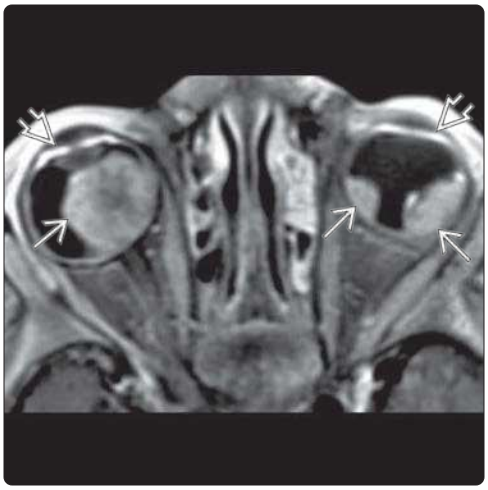
- Age
  - Average age of RB diagnosis: 18 months
    - Unilateral: 24 months; bilateral: 13 months
    - Earlier with family history & routine screening
  - 90-95% are diagnosed by age 5 years
- Epidemiology
  - Most common intraocular tumor of childhood
  - Incidence of 1:17,000 live births (↑ in past 60 years)
  - 3% of cancers in children < 15 years old
  - 1% of cancer deaths; 5% of childhood blindness

Natural History & Prognosis

- Degree of nerve involvement correlates with survival
  - Superficial or no invasion: 90%
  - Invasion to lamina cribrosa (prelaminar): 70%
  - Invasion beyond lamina cribrosa (postlaminar): 60%
  - Involvement at surgical margin: 20%
- Poor prognosis for extraocular disease
  - < 10% 5-year disease-free survival
- Poor prognosis for trilateral disease or CSF spread
  - < 24-month survival

Treatment

- > 95% of children with RB in USA are cured with modern techniques
  - Maintaining eye & vision remains problematic
- Therapy is based on tumor volume & localization, intraocular tumor extent, & extraocular stage of disease
- Enucleation: Used in advanced disease with no chance of preserving useful vision
- External beam radiation therapy: Bulky tumors with seeding
  - Unfavorable complications (e.g., arrested bone growth, radiation-induced tumors)
- Chemotherapy ("chemoreduction"): Currently favored 1st-line therapy for lower grade intraocular tumors
  - Intraarterial & intravitreous chemotherapy are gaining traction with high globe salvage rates
    - Limits need for systemic chemotherapy, external radiation, & enucleation
- Plaque radiotherapy: Locally directed I-125 or other isotope
  - Selected solitary or small tumors
- Cryotherapy: Primary local treatment small anterior tumors
- Photocoagulation: Primary local treatment of small posterior tumors



DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Calcified intraocular mass in child: RB until proven otherwise
- Assess for intraocular & extraocular spread
- Check for intracranial trilateral or quadrilateral disease in pineal & suprasellar regions

(Left) *Axial T1 C+ FS MR shows bulky, enhancing intraocular masses compatible with bilateral RB. Note the prominent enhancement of each iris. Anterior segment enhancement is associated with more aggressive tumor behavior.* **(Right)** *Axial T2 FS MR reveals a lobular, hypointense mass filling much of the vitreous compartment of the left globe. Note the posterior fluid level indicating vitreous hemorrhage associated with an endophytic form of RB.*

(Left) *Axial T1 C+ FS MR shows a moderately enhancing RB associated with prominent anterior segment enhancement. Note the intact thin lines of enhancing choroid & hypointense sclera, indicating absence of invasion.* **(Right)** *Axial T1 C+ FS MR shows interruption of linear hypointensity posteriorly with focal contour abnormality, indicating scleral invasion by RB on the right. The left postlaminar optic nerve demonstrates asymmetric enlargement & enhancement, consistent with tumor extension.*

(Left) *Sagittal T1 C+ FS MR in a 3-year-old with bilateral RB demonstrates a lobulated, enhancing mass in the region of the pineal gland. This mass was proven to represent pineoblastoma/PNET, typical of trilateral RB.* **(Right)** *Axial T1 C+ FS MR in a child after left globe enucleation for treatment of a large RB shows the hydroxyapatite intraorbital component with a well-defined, spherical prosthesis. There is typical moderate, heterogeneous postcontrast enhancement secondary to fibrovascular tissue infiltration.*

Congenital Auricle Malformations

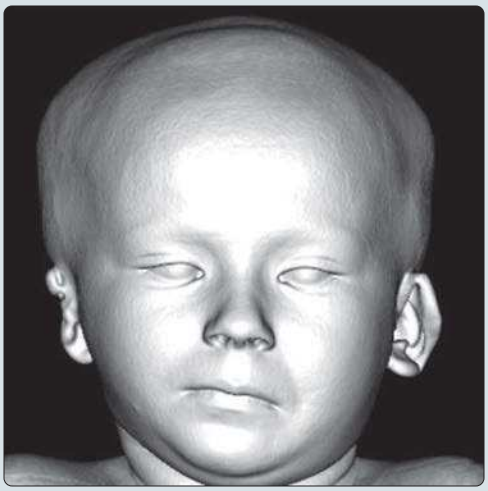
KEY FACTS

TERMINOLOGY

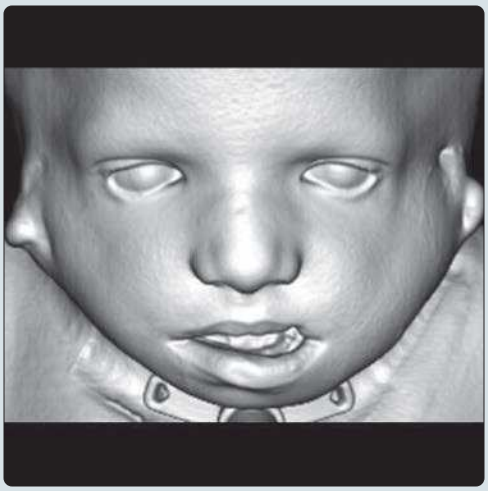
- Congenital aural dysplasia (CAD): Congenital external ear malformation
- Outer ear: Auricle (pinna) & external auditory canal (EAC)
- Microtia: Congenital malformation with underdeveloped, misshapen auricle

IMAGING

- Small, malformed, ± low-set pinna
- EAC stenosis/atresia & middle ear (ME)/ossicular anomalies
- Degree of microtia correlates with degree of EAC stenosis/atresia & ME anomalies



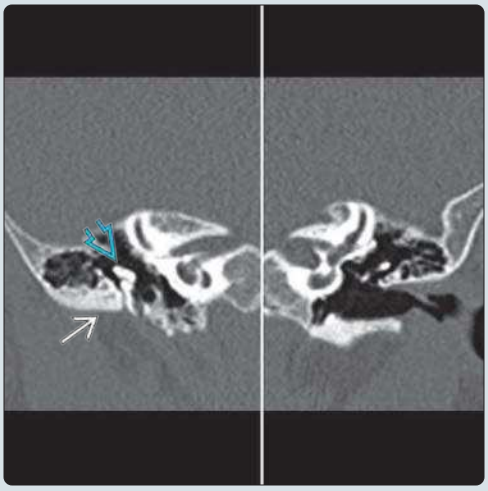
TOP DIFFERENTIAL DIAGNOSES



- Syndromes with auricle malformations
  - Treacher Collins syndrome
  - Hemifacial microsomia
  - Branchiootorenal syndrome
  - CHARGE syndrome

PATHOLOGY

- Weerda classification of auricular dysplasia
  - 1st-degree dysplasia: Macrotia, prominent ear, pocket ear, absence of upper helix, absence of tragus, clefts, lobular deformities, & cup ear types I & II
  - 2nd-degree dysplasia: Cup ear type III, miniear
  - 3rd-degree dysplasia: Auricular remnant with no recognizable structures of normal auricle
- Minor microtia: 1st & 2nd degree
  - Associated with EAC stenosis
- Major microtia: 3rd degree
  - Associated with EAC atresia (75%)
- Associated temporal bone abnormalities
  - EAC stenosis or atresia & malformed ossicles
  - ± ↓ ME & mastoid pneumatization
  - 1/3 with CAD have inner ear malformations
  - Anomalous CNVII canal ± oval window anomaly
  - Congenital or acquired ME cholesteatoma



(Left) *Frontal 3D soft tissue surface-rendered NECT reformation in a 3-year-old girl with hemifacial microsomia demonstrates a right-sided 2nd-degree microtia, a small right mandible, & a normal left pinna.* **(Right)** *Frontal 3D soft tissue surface-rendered NECT reformation in a child with Treacher Collins syndrome shows bilateral 3rd-degree microtia, downward-slanting palpebral fissures, & symmetric micrognathia.*

(Left) *Lateral 3D soft tissue surface-rendered NECT reformation shows a moderately deformed right pinna (2nd-degree malformation) in a 10-month-old with right congenital external & middle ear malformation.* **(Right)** *Coronal CT images of the temporal bones in the same patient show the atretic right EAC ⇨. The deformed right malleus & incus ⇨ are fused to the lateral epitympanic cavity, & the middle ear cavity is underdeveloped. The normal left temporal bone is shown for comparison.*

TERMINOLOGY

Synonyms

- Congenital aural dysplasia: Congenital external ear malformation
- Outer ear: Auricle & external auditory canal (EAC)
- Auricle: Pinna

Definitions

- Microtia: Congenital malformation with underdeveloped & misshapen auricle
- Anotia: Absent auricle

IMAGING

General Features

- Best diagnostic clue
  - Small, malformed, ± low-set pinna
    - Associated EAC stenosis/atresia, middle ear (ME) & ossicular malformation
  - Degree of microtia correlates with degree of EAC stenosis/atresia & ME anomalies
- Location
  - Auricle, EAC, ME, ± inner ear (IE)
  - R > L (60:40); 1/3 of cases are bilateral

CT Findings

- Bone CT
  - Identifies congenital external & ME malformation (CEMEM)
  - 3D soft tissue reconstruction demonstrates microtia

Imaging Recommendations

- Best imaging tool
  - Temporal bone CT with multiplanar & 3D reconstruction

DIFFERENTIAL DIAGNOSIS

Syndromes With Auricle Malformations

- Treacher Collins syndrome
- Hemifacial microsomia
- Branchiootorenal syndrome
- Pierre Robin sequence
- CHARGE syndrome

PATHOLOGY

General Features

- Etiology
  - CEMEM is secondary to anomalous 1st & 2nd branchial arch development during 1st trimester
  - Genetic or teratogenic insult
- Associated abnormalities
  - < 30% of CEMEM have IE malformations
  - Up to 30% of CEMEM have syndromic etiology
  - ↓ ME & mastoid pneumatization in 25% of minor & 66% of major microtia
  - Abnormal course of CNVII canal ± oval window atresia
  - Congenital or acquired cholesteatoma lies behind atretic plate in up to 10% of patients with CEMEM
  - Micrognathia with low-set pinna in syndromic cases

Staging, Grading, & Classification

- Weerda classification of auricular dysplasia
  - Minor microtia
    - 1st-degree dysplasia: Macrotia, prominent ear, pocket ear, absence of upper helix, absence of tragus, clefts, lobular deformities, & cup ear types I & II
    - 2nd-degree dysplasia: Cup ear type III, miniear
      - ± low, anterior position of pinnae
      - 75% of minor microtia patients have EAC stenosis
  - Major microtia
    - 3rd-degree dysplasia: Auricular remnant with no recognizable structures of normal auricle
      - Includes anotia
      - Severely dysplastic ears are frequently anterior & inferior in position secondary to incomplete embryologic ascent in neck
      - 75% of patients with major microtia have EAC atresia; remainder have EAC stenosis

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Microtia or anotia & stenotic/absent EAC
  - Conductive or mixed hearing loss
- Other signs/symptoms
  - Micrognathia: Unilateral (hemifacial microsomia) or bilateral (Treacher Collins) with low-set pinna

Demographics

- Overall incidence of CEMEM: 1/3,300-10,000 live births

Treatment

- Complicated surgical correction of pinna
  - Autogenous rib construction: 2 or more stages
    - More durable, less prone to infection
  - Alloplastic porous high-density polyethylene reconstruction: 2 stages
    - More aesthetic, less morbidity, & can be done at younger age
- ± drilling of new EAC &/or ossicle reconstruction

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- Degree of microtia correlates with underdevelopment of EAC, ME, & mastoid air cells
- Look for erosive opacity due to associated cholesteatoma

Large Vestibular Aqueduct

KEY FACTS

TERMINOLOGY

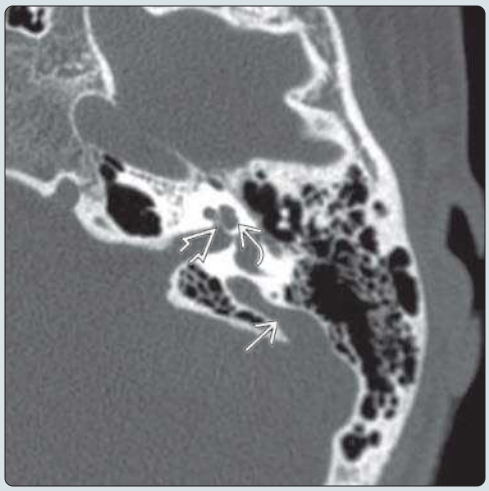
- Large vestibular aqueduct (LVA): Bony VA houses large endolymphatic sac (ES) & duct (ED)
- Incomplete partition type II (IP-II): Between middle & apical cochlear turns; often seen with LVA
- IP-II + LVA + minimally dilated vestibule: Mondini deformity

IMAGING

- Axial CT: Midpoint of VA (between posterior labyrinth & operculum) > 1.5 mm
- MR: Enlarged ES & ED
- Cochlea: Abnormal in ~ 75% of LVA cases
  - Absent interscalar septum between middle & apical turns with deficient modiolus (IP-II) → enlarged scala vestibuli
- 2nd interscalar ridge notch angle ↑ & depth ↓
- Vestibule: Normal or minimally enlarged

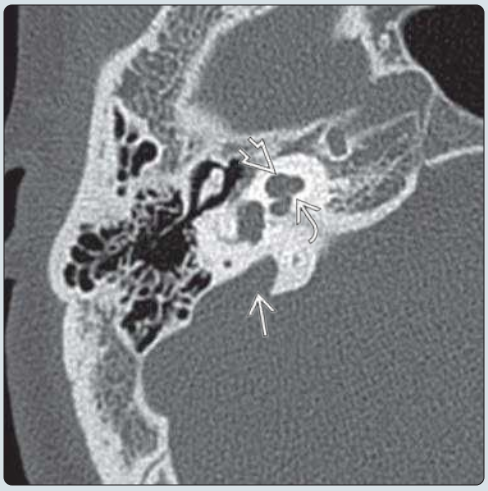
TOP DIFFERENTIAL DIAGNOSES

- Cystic cochleovestibular malformation (IP-I)
- Cochlear hypoplasia
- CHARGE syndrome (funnel-shaped LVA)
- Branchiootorenal syndrome (funnel-shaped LVA)

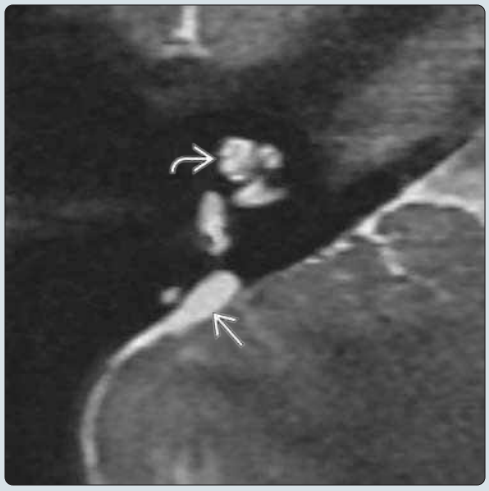


PATHOLOGY

- *SLC26A4* mutations in ~ 50% of LVA patients
  - Pendred syndrome: Sensorineural hearing loss (SNHL) + thyroid organification defect ± goiter



CLINICAL ISSUES



- Most common imaging abnormality in pediatric SNHL
- Bilateral anomaly (most); initially normal hearing
  - Progressive/fluctuating SNHL due to high pulsating CSF pressure or head trauma
- Avoid contact sports & try to prevent head trauma
- Hearing aid first, cochlear implantation later
  - Cochlear nerve is present in IP-II

(Left) *Left inner ear graphic shows large endolymphatic sac (ES) epidural ➡ & intraosseous ➡ components. The cochlea is malformed with absent septation between middle & apical turns, which appear bulbous ➡.* **(Right)** *Axial bone CT in a 15-year-old boy with sensorineural hearing loss (SNHL) shows a large vestibular aqueduct (LVA) ➡. The modiolus is defective toward the apex & present at the base ➡. Note that the scalar chambers are asymmetric (anterior scala vestibuli > posterior scala tympani) ➡.*

(Left) *Axial bone CT in a 17-year-old girl with Pendred syndrome shows a LVA ➡ & absent septation between the middle & apical cochlear turns ➡ with a deficient modiolus ➡. This is typical of incomplete partition type II (IP-II), which results in a baseball cap-shaped cochlea.* **(Right)** *Axial T2 MR in a 12-year-old girl with right SNHL shows a large endolymphatic sac anomaly (LESA) ➡ & typical IP-II cochlear anomaly. Note deficiency of the ISS, resulting in plump cochlear middle & apical turns ➡, resembling a baseball cap.*

TERMINOLOGY

Abbreviations

- Large vestibular aqueduct (LVA)

Synonyms

- Large endolymphatic sac anomaly (LESA): T2/SSFP MR term
- Enlarged vestibular aqueduct (EVA): CT term
- Mondini deformity (historic terminology): LVA + minimally dilated vestibule + incomplete partition type II (IP-II)

Definitions

- LVA: Enlarged, bony VA houses large endolymphatic sac (ES) & duct (ED)
  - Associated with variable cochlear malformation
- IP-II: Deficient modiolus & interscalar septum (ISS) between middle & apical cochlear turns, + LVA
  - IP-II has normal cochlear external dimensions
    - Not correct to call IP-II if cochlea has 1.5 turns
    - Term "cochlea with 1.5 turns" should be used only for cochlear hypoplasia (CH)

IMAGING

General Features

- Best diagnostic clue
  - CT: EVA ± IP-II; 3D T2/SSFP MR: LESA ± IP-II
- Size
  - Valvassori criteria: Vertical & axial VA width > 1.5 mm at midpoint of labyrinth & operculum (most accepted)
  - Additional criteria in literature
    - Cincinnati criteria: LVA ≥ 1 mm at midpoint (more sensitive), ± ≥ 2 mm at operculum on axial images
    - Pöschl 45° oblique plane: 0.8 mm at midpoint is borderline enlarged

CT Findings

- Bone CT
  - LVA: May scallop posterior margin of petrous bone
  - Cochlea: Abnormal on CT in ~ 75% of LVA cases
    - Normal or deficient ISS between plump apical & middle turns (IP-II); normal basal turn
      - Results in baseball cap appearance of cochlea
    - Asymmetric scalar chambers: Anterior > posterior
    - Deficient (typical), absent, or normal modiolus
  - Vestibule: Normal or minimally enlarged
  - Semicircular canals (SCCs): Normal or mildly dilated
    - Reduced size of lateral SCC bone island with enlargement of lateral SCC may be seen in IP-II
  - Middle ear space & ossicles: Normal

MR Findings

- 3D T2 SPACE or 3D SSFP (FIESTA, CISS or equivalent)
  - ES & ED: Enlarged, variable hyperintense signal
  - Cochlea: Deficient ISS between plump apical & middle turns (IP-II); normal in LVA only
  - Interscalar R2 notch angle > 114° & depth ≤ 0.31 mm suggests IP-II & scala communis
  - In IP-II, 2nd part of ISS bulges anteriorly due to enlarged scala vestibuli in 3D T2 MR

DIFFERENTIAL DIAGNOSIS

Cystic Cochleovestibular Malformation (IP-I)

- Cystic cochlea & vestibule without internal structure

Cochlear Hypoplasia

- Small cochlea; usually < 2 turns

CHARGE Syndrome

- Funnel-shaped LVA, small vestibule, & small/absent SCC
- Cochlear nerve canal stenosis/atresia & thickened modiolus; occasional CH

Branchiootorenal Syndrome

- Funnel-shaped LVA, tapered basal turn, & small offset middle & apical turns

High-Riding Jugular Bulb

- Communicates with jugular foramen, not vestibule

PATHOLOGY

General Features

- Genetics
  - *SLC26A4* mutations (*PDS* gene, chromosome 7)
    - ~ 50% of LVA patients have *SLC26A4* mutations
  - Syndromic deafness: Pendred syndrome
    - Sensorineural hearing loss (SNHL) + thyroid organification defect ± goiter
    - Autosomal recessive; biallelic *SLC26A4* mutation; ~ 10% of hereditary deafness

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - SNHL (or MHL due to "3rd window" effect)
    - Bilateral or unilateral
    - Fluctuating or progressive course
    - SNHL precipitated by minor head trauma
- Other signs/symptoms
  - Tinnitus, vertigo, dizziness
  - Pendred syndrome: Hypothyroidism in ~ 50%, ± goiter in adolescence

Treatment

- Avoid contact sports & try to prevent head trauma
- Hearing aid first, cochlear implantation later in IP-II
  - Cochlear nerve is present in IP-II

Congenital Cholesteatoma

KEY FACTS

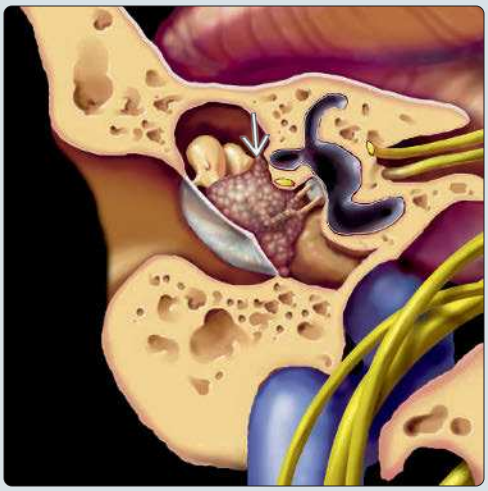
TERMINOLOGY

- Congenital cholesteatoma (CCh): Benign mass secondary to epithelial rests of embryonal origin
- CCh most commonly occurs in middle ear (ME), behind intact tympanic membrane (TM) in patient without history of surgery, chronic otitis media (COM), or otorrhea

IMAGING

- Majority are in ME (CCh-ME)
  - Anterosuperior tympanic cavity near eustachian tube or stapes is most common
  - Posterior epitympanum at tympanic isthmus
  - Other sites include EAC, petrous apex, & mastoid
- Temporal bone CT findings
  - Small, well-circumscribed ME lesion medial to ossicles
  - Large mass may erode ossicles, ME wall, lateral semicircular canal, or tegmen tympani
- MR findings: Peripherally enhancing ME mass with diffusion restriction in larger lesions

TOP DIFFERENTIAL DIAGNOSES



- Acquired cholesteatoma
- Rhabdomyosarcoma
- Langerhans cell histiocytosis
- Glomus tympanicum paraganglioma
- ME cholesterol granuloma

CLINICAL ISSUES

- Avascular pearly white ME mass behind intact TM without prior history of inflammation or trauma
- Unilateral conductive hearing loss in 30%
- Large ME lesions can obstruct eustachian tube → ME effusion & infection
- Complete surgical extirpation = treatment of choice

DIAGNOSTIC CHECKLIST

- Child with ME mass medial to ossicles, normal mastoid aeration, & no history of COM = CCh-ME

(Left) *Coronal graphic shows a congenital cholesteatoma (CCh) involving the middle ear (ME) cavity. Note that the lesion has extended medially to the ossicles as it engulfs the entire ossicular chain. The tympanic membrane (TM) is intact, a typical finding in congenital lesions, as opposed to acquired cholesteatomas (which are associated with TM perforation).* **(Right)** *Axial bone CT in a 3-year-old child without a history of chronic otitis media shows a typical round, well-circumscribed CCh anteromedial to the malleus manubrium.*

(Left) *Axial T2 MR in the same patient shows the CCh as an intermediate signal intensity, well-defined ME mass anterolateral to the basal turn of the right cochlea.* **(Right)** *Axial T1 C+ FS MR in the same patient shows the centrally nonenhancing CCh with a thin rim of peripheral enhancement adjacent to the cochlea. This is a typical appearance & location for a CCh.*

TERMINOLOGY

Synonyms

- Primary cholesteatoma, epidermoid

Definitions

- Congenital cholesteatoma (CCh): Benign mass secondary to epithelial rests of embryonal origin
- Most commonly occurs in middle ear (ME), behind intact tympanic membrane (TM) in patient without history of surgery, chronic otitis media, or otorrhea

IMAGING

General Features

- Best diagnostic clue
  - Smooth, well-circumscribed ME mass ± ossicular erosions
- Location
  - Majority in ME (CCh-ME)
  - Other locations: External auditory canal (EAC), mastoid, petrous apex, cerebellopontine angle, facial nerve canal, incudostapedial joint

CT Findings

- Bone CT
  - Appearance depends on size of lesion & location
  - Small CCh-ME: Well-circumscribed lesion
  - Large CCh-ME: Mass may erode ossicles, ME wall, lateral semicircular canal, or tegmen tympani [similar to acquired cholesteatoma (ACh)]
    - Bone erosion < ACh; occurs late in disease
    - Long process of incus & stapes superstructure are most commonly destroyed ossicles
    - If aditus ad antrum is occluded, mastoid air cells opacify with retained secretions
  - Petrous apex CCh: Expansile mass with smooth bone remodeling/erosion
    - May become very large before discovered
  - Mastoid CCh: Expansile mass with smooth bone erosion; may exit mastoid into EAC, parotid space, carotid space
  - EAC CCh: Rare; ↑ with EAC malformations

MR Findings

- T1: Iso- to hypointense mass
- T2: Intermediate signal intensity mass
  - Larger ME lesions → aditus ad antrum obstruction → high-signal retained secretions in mastoid air cells
- DWI: Larger lesions demonstrate diffusion restriction
- T1 C+: Peripherally enhancing ME mass
  - CCh-ME shows nonenhancing material surrounded by thin, subtle rim enhancement

DIFFERENTIAL DIAGNOSIS

Acquired Cholesteatoma Acquired Cholesteatoma

- Pars flaccida-ACh
- Pars tensa-ACh

Rhabdomyosarcoma

- Destructive mass in petrous apex, ME, or mastoid

Langerhans Cell Histiocytosis

- Enhancing soft tissue mass with bone destruction

Glomus Tympanicum Paraganglioma

- Pulsatile, vascular mass behind TM
- Enhancing mass on cochlear promontory; no bone erosion
- Unusual in pediatric & adolescent patients

Middle Ear Cholesterol Granuloma

- ME mass with high signal intensity on T1 MR

Facial Nerve Schwannoma

- Enlarged bony facial nerve canal

PATHOLOGY

General Features

- Etiology
  - 2 principal theories of CCh-ME
    - Congenital ectodermal rest in ME cavity left behind at time of neural tube closure
    - Lack of regression of epidermoid formation
      - Epidermoid formation: Point of epithelial transformation between tympanic cavity & eustachian tube
- Associated abnormalities
  - EAC atresia may have associated CCh of ME or EAC

Staging, Grading, & Classification

- CCh-ME staging system
  - Stage 1: Single quadrant; no ossicular involvement or mastoid extension
  - Stage 2: Multiple quadrants; no ossicular involvement or mastoid extension
  - Stage 3: Ossicular involvement; no mastoid extension
  - Stage 4: Mastoid extension

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Avascular pearly white ME mass behind intact TM without prior history of inflammation or trauma

Demographics

- Age
  - Average age of presentation or detection
    - Anterior or anterosuperior: 4 years
    - Posterosuperior & mesotympanum: 12 years
    - Attic & mastoid antrum: 20 years or older
- Epidemiology
  - 2-5% of temporal bone cholesteatomas are congenital

Natural History & Prognosis

- CCh-ME: Smaller anterior lesions have better outcome with complete surgical resection
- Large lesions or posterior epitympanic CCh have recurrence rates as high as 20%

SELECTED REFERENCES

Acquired Cholesteatoma

KEY FACTS

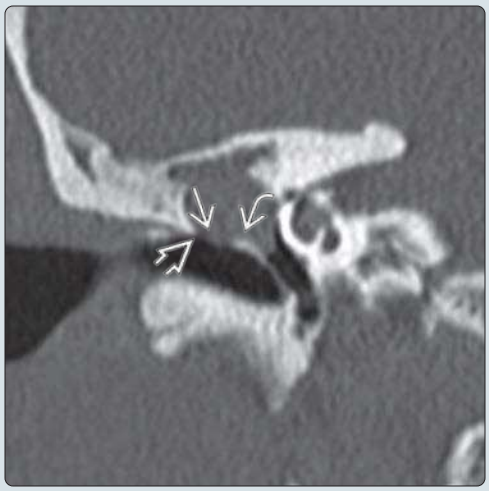
TERMINOLOGY

- Secondary or acquired cholesteatoma (ACh)
  - Tympanic membrane (TM) retraction or perforation → accumulation of stratified squamous epithelial cells in middle ear (ME) → mass-like keratin ball
- Pars flaccida cholesteatoma (PFCh): 80%
- Pars tensa cholesteatoma (PTCh): 15%
  - Sinus cholesteatoma = PTCh in sinus tympani

IMAGING

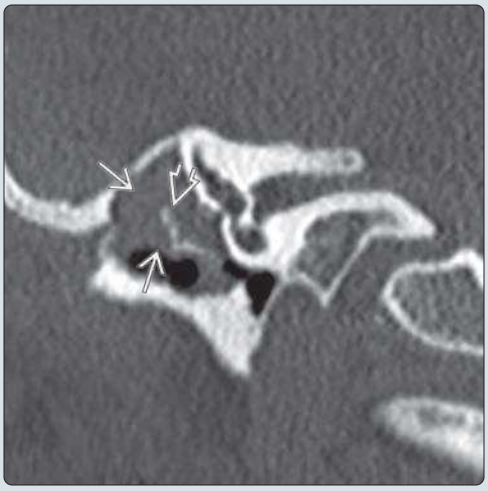
- Nonenhancing ME soft tissue mass + ossicular erosion
  - PFCh: In Prussak space with scutum erosion
    - ± tegmen tympani, lateral semicircular canal, facial nerve canal, or sigmoid sinus plate dehiscence
  - PTCh: In posterior mesotympanum medial to ossicles
    - ± ossicular erosion, involvement of sinus tympani, facial recess, aditus ad antrum, or mastoid
- Restricts diffusion on DWI MR
- Associated granulation tissue or scar may enhance
- Best modalities
  - Noncontrast bone CT: Axial & coronal
    - Ossicular & adjacent bone evaluation
  - Coronal T1 C+ FS MR
    - Suspected intracranial extension/infection

TOP DIFFERENTIAL DIAGNOSES

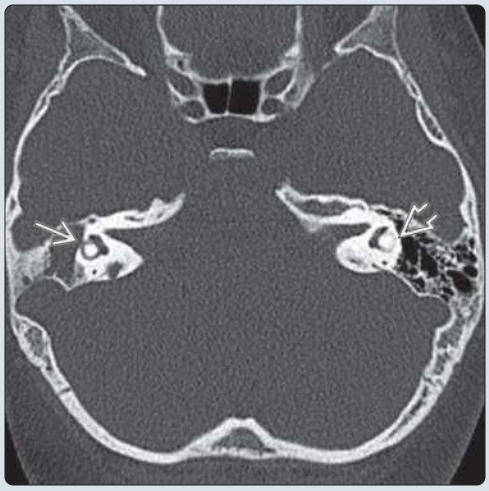


- Chronic otitis media
- Congenital cholesteatoma
- Acute coalescent otomastoiditis with abscess
- Langerhans cell histiocytosis
- Rhabdomyosarcoma

CLINICAL ISSUES



- Recurrent or chronic ME infections with TM perforation or retraction pocket
- Conductive hearing loss
- Affects children & adults
  - Unusual in children < 4 years of age



(Left) *Coronal graphic shows a large acquired cholesteatoma of the pars flaccida (PF). Complications include erosion of the ossicles & lateral semicircular canal (SCC) ➡ + thinning of the tegmen tympani ➡.* **(Right)** *Coronal bone CT in a 7-year-old patient shows a large middle ear mass filling the upper mesotympanum with opacification of the epitympanum & Prussak space ➡, blunting of the scutum ➡, & near-complete erosion of the ossicles ➡, typical of a PF cholesteatoma (PFCh).*

(Left) *Coronal bone CT in a 10-year-old patient with chronic right otitis media & otorrhea shows a large PFCh ➡ nearly filling the mesotympanum & epitympanum. The demineralized/partially eroded ossicles ➡ are deviated inferior & medial.* **(Right)** *Axial bone CT in the same patient demonstrates focal dehiscence of the right lateral SCC ➡ compared to the normal covering of the left lateral SCC ➡. Also note the underdevelopment of the right mastoid air cells relative to the left, a common finding in chronic inflammatory disease.*

TERMINOLOGY

Definitions

- Secondary or acquired cholesteatoma (ACh): Stratified squamous epithelium-lined sac filled with exfoliated keratin debris in middle ear (ME)
  - Attic or Prussak space ACh = pars flaccida cholesteatoma (PFCh)
  - Pars tensa ACh (PTCh) lies in posterior mesotympanum, medial to ossicles
- Due to abnormal migration of ectoderm in external auditory canal (EAC) spontaneously or 2° to surgery/trauma

IMAGING

General Features

- Location
  - PFCh: 80% of all cholesteatomas
    - 2° to tympanic membrane (TM) perforation or retraction pocket in anterior superior pars flaccida portion of TM (also called Shrapnell membrane)
  - PTCh: 15% of all cholesteatomas
    - Secondary to TM perforation or retraction pocket in inferior pars tensa portion of TM

CT Findings

- Bone CT
  - PFCh: Soft tissue mass in Prussak space, lateral to malleus head; scutum erosion is characteristic
    - Ossicular erosion in 70%: Most commonly involves incus long process; less commonly involves incus body & malleus head
    - ± posterolateral extension to aditus ad antrum & mastoid antrum or inferiorly to posterior ME recesses
    - May also erode lateral semicircular canal, facial nerve canal, tegmen tympani, &/or sigmoid sinus plate
  - PTCh: Erosive mass in posterior mesotympanum medial to ossicles
    - ± sinus tympani, facial recess, aditus ad antrum, &/or mastoid involvement
    - Ossicular erosion is common (90%): Especially at medial aspect of incus long process, stapes suprastructure, & malleus manubrium
  - EACCh: Soft tissue mass with scalloping of EAC ± bone flecks

MR Findings

- ↓ T1, mildly ↑ T2 (< trapped secretions) ME mass
- PFCh & PTCh do not enhance; ± rim-enhancement of EACCh
- Associated granulation tissue or scar may enhance
- If tegmen tympani is dehiscent, coronal may show dural enhancement adjacent to bony defect
- ± cephalocele, intracranial extension or infection
- Restricted diffusion on DWI

Imaging Recommendations

- Noncontrast bone CT: Axial & coronal
- Coronal T1 C+ MR is useful adjunct when cephalocele, intracranial extension, or intracranial infection is suspected
- Nonecho planar DWI MR can help detect ACh amidst chronic inflammation

DIFFERENTIAL DIAGNOSIS

Chronic Otitis Media

- Soft tissue/fluid density may be indistinguishable from ACh on CT
- Erosions favor ACh but may be seen with chronic inflammation (especially at distal incus)

Congenital Cholesteatoma

- Well-defined ME mass behind intact TM, medial to ossicles
- Osseous erosion is similar to ACh if large
- Usually lacks history of recurrent infection or TM perforation

Acute Coalescent Otomastoiditis With Abscess

- Fever, periauricular erythema, pain, fluctuance
- Rim-enhancing fluid collection adjacent to opacified mastoid air cells = intracranial or extracranial abscess

Langerhans Cell Histiocytosis

- Enhancing mass + mastoid > petrous apex bone destruction

Rhabdomyosarcoma

- Soft tissue mass with variable contrast enhancement + petrous apex > mastoid permeative bone destruction

PATHOLOGY

General Features

- Etiology
  - TM retraction or perforation → accumulation of stratified squamous epithelial cells in ME → mass-like keratin ball

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Recurrent or chronic ME infections with TM perforation or retraction pocket
  - Conductive hearing loss (CHL)
  - ME mass with TM perforation on otoscopy

Demographics

- Unusual in children < 4 years of age

Treatment

- Surgical excision, mastoidectomy, & ossicular chain reconstruction if needed

DIAGNOSTIC CHECKLIST

Image Interpretation Pearls

- When ME & mastoid are opacified, difficult to differentiate effusion from ACh
- Presence of ossicular erosion favors ACh (but may rarely occur in noncholesteatomatous chronic otitis media)

Acute Otomastoiditis With Abscess

KEY FACTS

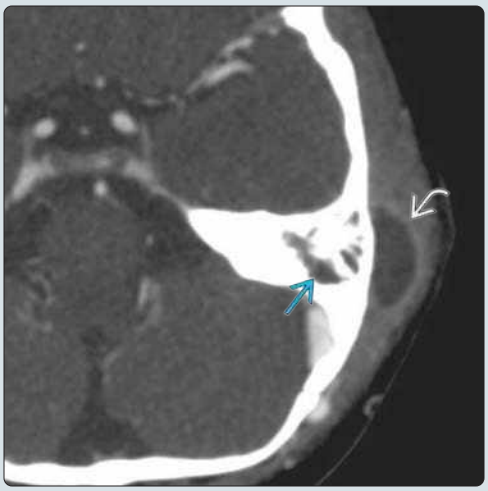
TERMINOLOGY

- Acute coalescent (or confluent) otomastoiditis (ACOM)
- Definition: Acute middle ear-mastoid infection with progressive bony resorption & demineralization due to intramastoid empyema

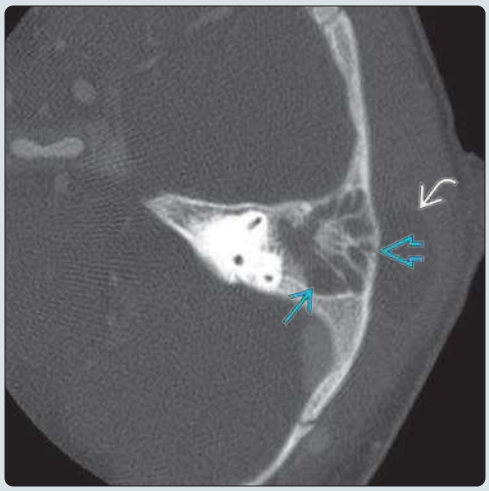
IMAGING

- Bone CT findings
  - Opacified mastoid cells
  - Erosion of mastoid cortex ± trabecula (confluent mastoiditis)
- Contrast-enhanced CT or MR findings
  - Subperiosteal abscess: Periauricular fluid collection
  - Bezold abscess: Walled-off pus in & around sternocleidomastoid muscle
  - Middle cranial fossa abscess (epidural or temporal lobe abscess)
  - Posterior fossa abscess (epidural or cerebellar abscess)
  - Dural sinus thrombosis: Adjacent venous filling defect

TOP DIFFERENTIAL DIAGNOSES

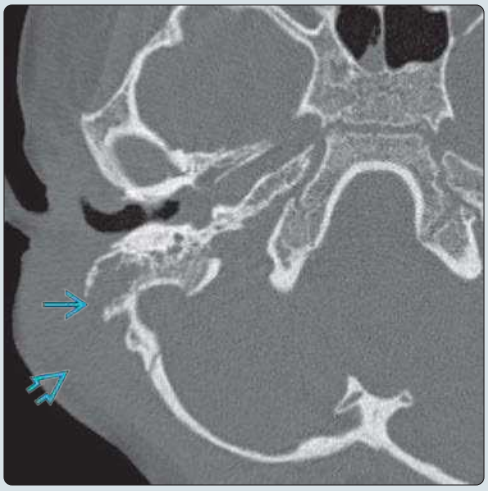


- Acquired cholesteatoma
- Apical petrositis
- Langerhans cell histiocytosis
- Rhabdomyosarcoma

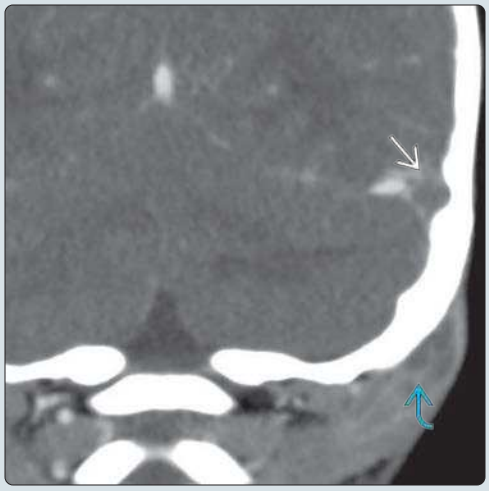


PATHOLOGY

- Common pathophysiology
  - Granulation tissue or cholesteatoma blocks aditus ad antrum & prevents mastoid air cell drainage
- Less common pathophysiology
  - Mastoid cortex remains intact with septic thrombophlebitis of emissary veins seeding periosteum



CLINICAL ISSUES



- Young child with 1 day to 1 week history of otalgia, posterior auricular swelling, fever, & otorrhea
- Identify associated complications → appropriate treatment

(Left) *Axial CECT in an 8-month-old girl shows a rim-enhancing fluid collection superficial to opacified left mastoid air cells, consistent with a subperiosteal abscess. There is edema of the surrounding soft tissues.* **(Right)** *Axial bone CT in the same patient shows opacification of the mastoid air cells without septal destruction. Subtle bony dehiscence is suggested deep to the abscess. However, bony destruction need not be present to establish a diagnosis of acute mastoiditis.*

(Left) *Axial bone CT in a 3-year-old shows bony dehiscence of the posterolateral wall of the mastoid with overlying soft tissue swelling. Acute otomastoiditis may be diagnosed with or without bony dehiscence. Overlying soft tissue inflammation is very common.* **(Right)** *Coronal CECT venogram in a 4-year-old shows an empty delta sign with lack of contrast opacification in the left transverse sinus secondary to acute otomastoiditis. Note the subperiosteal abscess inferior to the left mastoid.*

TERMINOLOGY

Synonyms

- Coalescent (or confluent) otomastoiditis with abscess

Definitions

- Acute mastoiditis (AM): Active infection in mastoid without destruction of mastoid septations or cortex
- Acute otitis media (AOM): Acute middle ear-mastoid infection with progressive bony resorption & demineralization due to intramastoid empyema
- Acute coalescent (or confluent) otomastoiditis (ACOM) + abscess: Coalescent mastoiditis with resultant intracranial or extracranial abscess

IMAGING

General Features

- Best diagnostic clue
  - Rim-enhancing fluid collection adjacent to opacified mastoid cells with eroded cortex
- Location
  - Abscess location depends on direction of mastoid cortical dehiscence
    - Lateral mastoid wall
      - Postauricular abscess (cortical bone is thin here)
      - Pre- or periauricular abscess
    - Inferior mastoid wall
      - Mastoid tip → Bezold abscess
      - Other inferior mastoid cortical dehiscence → transspatial abscess
    - Tegmen mastoideum → temporal lobe abscess
    - Medial mastoid wall → epidural or cerebellar abscess

CT Findings

- CECT
  - Subperiosteal abscess
    - Periauricular fluid collection
      - Thick, enhancing lateral wall represents inflamed periosteum
  - Bezold abscess
    - Walled-off pus in & around sternocleidomastoid muscle
  - Middle cranial fossa abscess (epidural or temporal lobe abscess)
    - Epidural or intratemporal lobe rim-enhancing fluid
  - Posterior fossa abscess (epidural or cerebellar abscess)
    - Epidural or intracerebellar rim-enhancing fluid
  - Dural sinus thrombosis (DST)
    - Filling defect within venous sinus
- Bone CT
  - Middle ear & mastoid opacification
  - Variable trabecular & cortical erosions (confluent disease)
  - Subtle to obvious cortical dehiscence deep to abscess
    - Lateral mastoid cortex → subperiosteal abscess
    - Mastoid tip cortex → Bezold abscess
    - Tegmen mastoideum cortex → epidural or temporal lobe abscess
    - Medial mastoid cortex → epidural or cerebellar abscess

MR Findings

- T2WI
  - High signal fills middle ear & mastoid
    - Complete opacification is more common in children (90%)
  - High signal fluid in epidural or parenchymal abscess
- DWI
  - Restricted diffusion in abscess
- T1WI C+
  - Variable enhancement of middle ear & mastoid
    - More common in children (90%)
  - Perimastoid dural enhancement
    - More common in children (80%)
  - Rim-enhancing pus in subperiosteal, epidural, or brain parenchymal abscess
    - Subperiosteal abscess is more common in children (50%)
  - 3D volumetric gradient-echo T1 C+ imaging allows optimal detection of venous sinus thrombosis
- MRV
  - May show DST
    - Focus of diminished or absent vascular signal on flow-sensitive sequences

Imaging Recommendations

- Best imaging tool
  - Temporal bone CT defines bony changes (confluence, cortical dehiscence)
    - CECT will define most infectious complications
  - Enhanced temporal bone MR is more sensitive for intracranial complications (DST, meningitis, subdural empyema, abscess)
- Protocol advice
  - Thin-section SE T1 MR with FS gives best evaluation of bone
  - 3D gradient-echo T1 C+ allows optimal delineation of epidural abscess & venous sinus thrombosis
  - Non-EPI DWI techniques ↓ susceptibility artifact from bone & air in skull base

DIFFERENTIAL DIAGNOSIS

Acquired Cholesteatoma

- Clinical: Retraction or rupture of tympanic membrane; may be superinfected
- Imaging: CT shows erosive mass with poor enhancement
- May lead to ACOM & associated complications
- Important to identify underlying cholesteatoma as it may alter surgical management strategy

Apical Petrositis

- Clinical: CNIV palsy, retroauricular pain, AOM
- Imaging: CT shows coalescent changes in petrous apex
  - T1 C+ MR shows enhancing meninges & focal, walled-off fluid in petrous apex
- Usually no associated intracranial abscess

Langerhans Cell Histiocytosis

- Clinical: Child with draining ear & periauricular mass
- Imaging: Extensive, often bilateral, mastoid destruction with homogeneously enhancing soft tissue

- Look for additional lesions (e.g., punched-out, well-defined lytic calvarial lesions)

Rhabdomyosarcoma

- Clinical: Neurologic deficits common, including CNVII palsy
- Imaging: CT shows extensive bone lysis & permeation, intracranial extension
  - T1 C+ MR shows variably enhancing soft tissue mass emanating from middle ear

PATHOLOGY

General Features

- Etiology
  - Inflammation, granulation tissue, or cholesteatoma block aditus ad antrum & prevent mastoid air cell drainage
  - Local hyperemia-acidosis creates enzymatic resorption of trabeculae (confluent mastoiditis)
  - Subtle or obvious cortical dehiscence conveys infection into adjacent tissues
  - Less common pathophysiology: Mastoid cortex remains intact with septic thrombophlebitis of emissary veins seeding periosteum
- Macewen triangle
  - Surgical access point to mastoid antrum at posterosuperior EAC
  - Weak bone, loose periosteum allow breakout of infection in postauricular location

Gross Pathologic & Surgical Features

- Pus in mastoid, adjacent abscess cavity
- Granulation tissue or cholesteatoma is occasionally identified in middle ear-mastoid

Microscopic Features

- *Streptococcus* species is most common
- Polymicrobial aerobes & anaerobes are less common

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Otalgia (ear pain)
  - Other signs/symptoms
    - Fever
    - Otorrhea (ear drainage)
    - Postauricular pain & swelling
    - Lateralized auricle (ear pushed outward by abscess)
    - Conductive > sensorineural hearing loss
    - ↑ WBC, ↑ ESR
- Clinical profile
  - Young child with 1 day to 1 week history of otalgia, postauricular swelling, fever, & otorrhea
  - 35-70% of patients have received antibiotics for AOM
  - Postauricular edema (Griesinger sign) is common in uncomplicated acute mastoiditis (85%)
    - Enhancing fluid collection confirms subperiosteal abscess

Demographics

- Age
  - Infants & young children
  - Older age group is typical when ACOM results from acquired cholesteatoma
- Epidemiology
  - 46% of children have > 2 episodes of AOM by age 3
  - 0.24% of patients with AOM develop ACOM

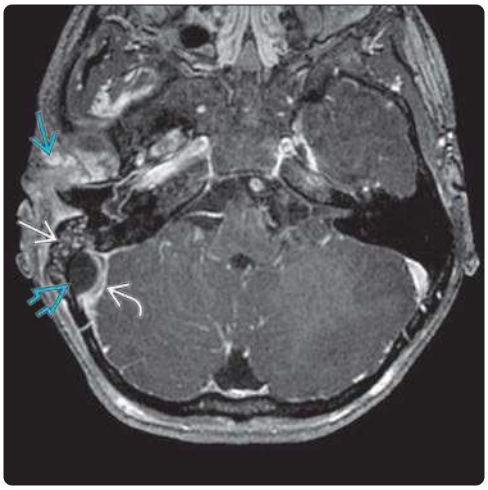
Natural History & Prognosis

- Isolated extracranial subperiosteal abscess
  - Excellent prognosis with prompt therapy
  - Worse if prior incomplete antibiotic therapy, virulent organism, or immunocompromised host
- Intracranial abscess (temporal lobe is most common)
  - Worse prognosis, particularly with concomitant complications
    - Venous sinus thrombosis
    - Epidural abscess or subdural empyema

Treatment

- Intravenous antibiotics ± tympanocentesis with myringotomy tube placement
- Surgical treatment
  - I&D of extracranial subperiosteal abscess
  - Simple mastoidectomy is typically reserved for patients that fail initial conservative management
  - Radical mastoidectomy if cholesteatoma is present

DIAGNOSTIC CHECKLIST



Consider

- Look for other complications of ACOM
  - Temporal bone findings (T1 C+ MR)
    - Facial nerve paralysis: Enhancing CNVII
    - Labyrinthitis: Enhancement within membranous labyrinth
    - Apical petrositis: Enhancing apical air cells on MR
  - Intracranial findings (T1 C+ MR)
    - Epidural or brain abscess
    - Subdural empyema, meningitis ± DST

(Left) *Axial T2 MR in a 7-year-old boy with acute mastoiditis shows an epidural abscess in the right jugular fossa. Note the internal fluid-fluid level, which is most frequently due to blood products.* **(Right)** *Axial T1 C+ FS 3D SPGR MR in the same patient shows enhancement of the right mastoid air cells with right periauricular soft tissue swelling. There is an epidural abscess in the right sigmoid fossa. The dura is medially displaced with narrowing & thrombosis of the right sigmoid sinus.*

(Left) *Axial T1 C+ FS MR in a 14-year-old boy with right acute otomastoiditis & petrous apicitis shows extensive mastoid & petrous apex enhancement with an intraparenchymal abscess involving the right cerebellar flocculus.* **(Right)** *Axial DWI MR in the same patient demonstrates restricted diffusion in the right mastoid & petrous apex as well as the right flocculus intraparenchymal abscess. DWI can be a helpful sequence in determining the full extent of purulent material in acute otomastoiditis.*

(Left) *Axial T1 C+ FS MR in an adult with ↓ consciousness & fever demonstrates a bilobed, rim-enhancing temporal lobe abscess along with meningeal enhancement, consistent with meningitis.* **(Right)** *Coronal T1 C+ MR in the same patient reveals the source of infection to be acute otomastoiditis with extension of infection from the mastoid to the temporal lobe across the tegmen tympani. Associated meningitis is again noted.*

CHARGE Syndrome

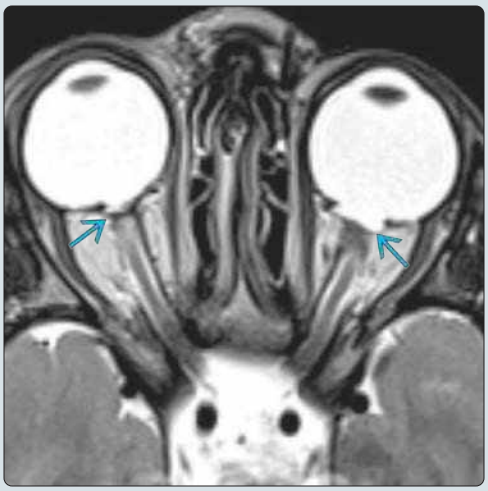
KEY FACTS

TERMINOLOGY

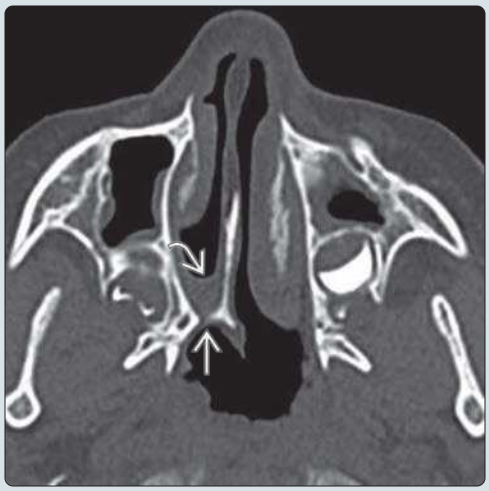
- **CHARGE**
  - **C**oloboma
  - **H**eart anomaly
  - **A**tresia of choanae
  - **R**estriction: Mental & somatic development
  - **G**enital hypoplasia
  - **E**ar abnormalities
- Major signs: Coloboma, choanal atresia, semicircular canal (SCC) hypoplasia/aplasia, cranial nerve (CN) involvement
- Minor signs: Hindbrain, external/middle ear, cardiac/esophageal malformations, hypothalamo-hypophyseal dysfunction, intellectual disability

IMAGING

- Choanal atresia, coloboma (variable), cleft lip/palate
- Hypoplastic vestibule & hypoplastic/absent SCC
- Mildly flattened apical ± middle turns + thickened modiolus or single cochlear turn/hypoplasia
- Stenotic/atretic cochlear nerve canal
- Stenotic/atretic oval window ± overlying anomalous tympanic segment of CNVII
- Large emissary veins, hypoplasia of basiocciput, basilar invagination, & vertebral anomalies
- Hypoplastic pons, uplifted vermis ± cerebellar malformation
- CN hypoplasia/aplasia (mainly CNI, CNVII, & CNVIII)

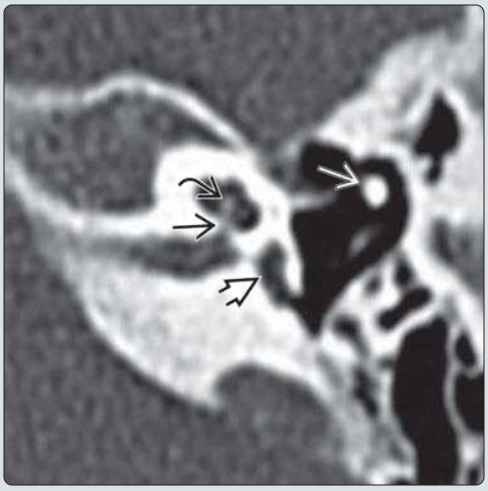


TOP DIFFERENTIAL DIAGNOSES

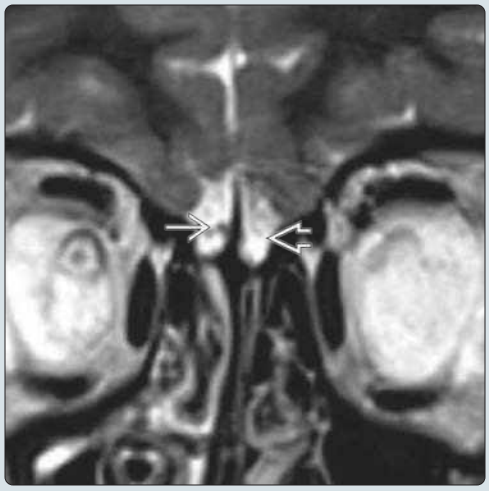


- VACTERL association
- Kallmann syndrome
- Branchiootorenal syndrome

PATHOLOGY



- *CHD7* mutation in 60-90%
- Highly predictive of CHARGE: Cup-shaped pinna, agenesis/hypoplasia of SCC, arrhinencephaly



(Left) *Axial T2 MR in a 3-year-old girl with multiple congenital anomalies & a CHD7 gene mutation reveals bilateral colobomas near the optic nerve insertions onto the globes.* **(Right)** *Axial bone CT in the same child shows right-sided, predominantly osseous choanal atresia with a fluid level within the nasal cavity. This combination of findings should raise the question of CHARGE syndrome & alert the imager to closely assess the temporal bones & skull base for additional abnormalities.*

(Left) *Axial bone CT in the same child with CHARGE syndrome reveals a hypoplastic vestibule with absence of the semicircular canals (SCCs). The cochlea is hypoplastic with prominence of the modiolus & narrowing of the cochlear nerve canal, suggesting cochlear nerve deficiency. Dysmorphic ossicles are partially visualized.* **(Right)** *Coronal T2 MR in the same child shows absent left & diminutive right olfactory bulbs.*

KEY FACTS

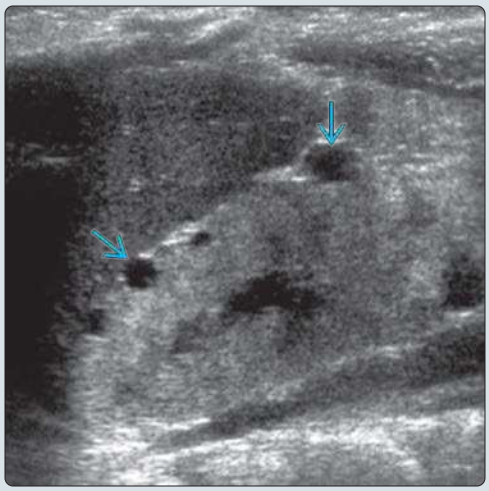
TERMINOLOGY

- Branchiootorenal syndrome (BOR): Autosomal dominant
  - Deafness & ear anomalies
  - Branchial anomalies/preauricular pits
  - Renal abnormalities

IMAGING

- Neck: Branchial cleft cyst/fistula
- Temporal bone CT findings
  - Dilated eustachian tubes
  - External ear: Variable stenosis/atresia
  - Middle ear: Dysmorphic; fused, malformed ossicles
  - Cochlea: Tapered basal turn, hypoplastic & offset middle/apical turns
  - Semicircular canal anomalies
  - Dilated, bulbous vestibular aqueduct
  - Flared internal auditory canal; anomalous CNVII canal
- Abdominal ultrasound/CT/MR findings: Renal cysts, dysplasia, agenesis
- Variable, asymmetric micrognathia

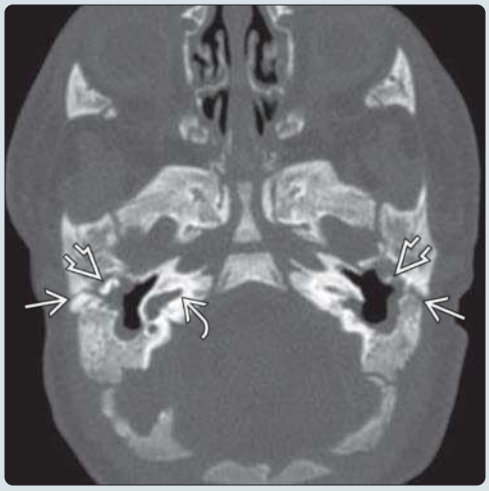
TOP DIFFERENTIAL DIAGNOSES



- Branchiootic syndrome
  - Normal kidneys; BOR genetic overlap
- Otofaciocervical syndrome: BOR genetic overlap
- Congenital nonsyndromic external ear & middle ear malformation

PATHOLOGY

- BOR 1: 8q13.3 locus, *EYA1* gene mutation
- BOR 2: 19q13.3 locus, *SIX5* mutation



CLINICAL ISSUES

- Clinical presentation
  - Hearing loss (sensorineural, conductive, or mixed): ~ 98%
  - Preauricular tag, pit: ~ 84%
  - Branchial anomalies: ~ 70%
  - Renal anomalies: ~ 40%

(Left) *Longitudinal ultrasound in a 4-month-old boy presenting with Potter syndrome shows a solitary, echogenic left kidney with numerous peripheral cysts. This patient with branchiootorenal syndrome (BOR) also had a branchial cleft cyst & microtia.* **(Right)** *Axial CECT in a 5-month-old boy with preauricular pits & a family history of renal & ear anomalies shows a hypodense, rim-enhancing, cystic lesion, consistent with a 2nd branchial cleft cyst. The patient also had ear anomalies characteristic of BOR.*

(Left) *Axial bone CT in the same patient imaged at 10 days of age (to evaluate microtia) shows bilateral external auditory canal (EAC) atresia. The ossicles are malformed, fused, & laterally located. Note the tapered basal turn of the right cochlea.* **(Right)** *Axial bone CT in the same patient shows unwound or offset hypoplastic middle & apical cochlear turns & deficiency of the right cochlear modiolus. The posterior semicircular canals (SCCs) & ossicles are malformed. The CT findings are characteristic of BOR.*

Treacher Collins Syndrome

KEY FACTS

TERMINOLOGY

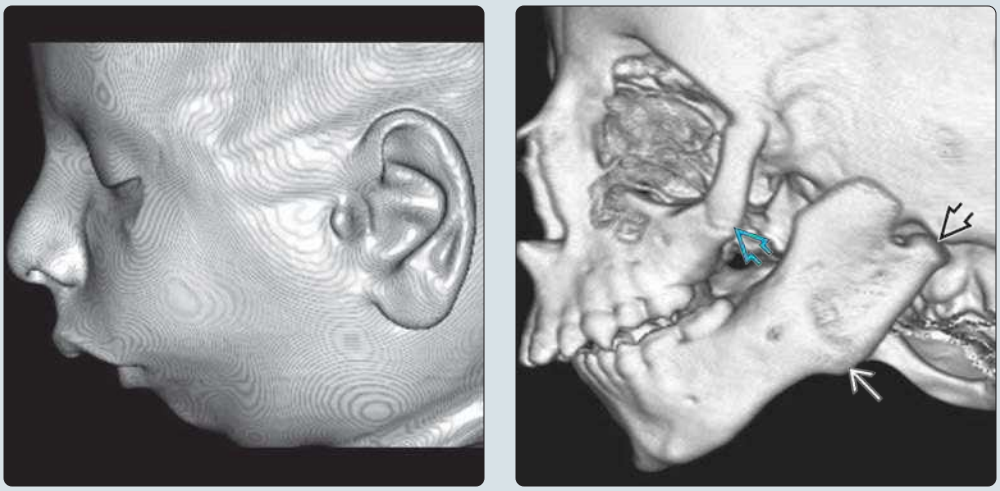
- Treacher Collins syndrome (TCS)
- Nager syndrome: TCS + limb anomalies
- Craniofacial malformation: Downslanting palpebral fissures, micrognathia, zygomatic & malar hypoplasia, microtia/anotia, ± limb defects

IMAGING

- Temporal bone findings
  - EAC: Stenosis/atresia, small/absent tympanic plate
  - ↓/absent mastoid pneumatization
  - Hypoplastic/atretic middle ear space
  - Malformed or absent ossicles ± fixation
  - Oval window stenosis/atresia
  - Facial nerve canal anomalies/dehiscence
  - Normal or malformed cochlea (flattened turns)
  - Normal or malformed lateral SCC ± vestibule
- Relatively symmetric micrognathia, zygomatic/malar hypoplasia
- Coloboma, hypoplastic muscles of mastication, absent or hypoplastic parotid glands

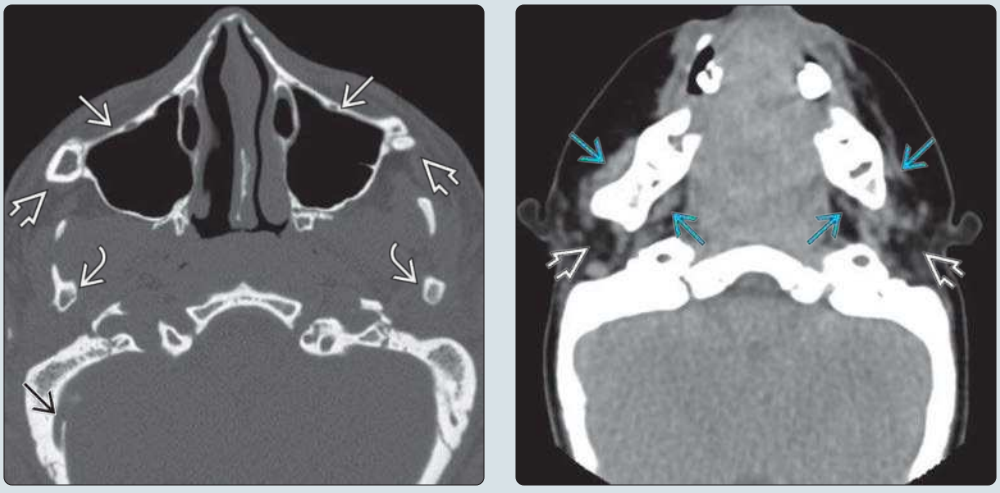
TOP DIFFERENTIAL DIAGNOSES

- Bilateral facial microsomia
- Nonsyndromic congenital external & middle ear malformation
- Branchiootorenal syndrome



PATHOLOGY

- Autosomal dominant > > recessive, phenotypic variability & genetic heterogeneity, "ribosomopathy"
- TCS: *TCOF1*, *POLR1D*, & *POLR1C* gene mutations
- Nager syndrome: *SF3B4* gene mutation



CLINICAL ISSUES

- Airway obstruction, deafness
- Treatment: Airway support, reconstructive surgery, hearing aids, developmental support

(Left) *Lateral 3D soft tissue surface-rendered CT in an infant with Nager syndrome shows micrognathia, malar flattening, mildly low-set ears, & external auditory meatus atresia.* **(Right)** *Lateral 3D bone CT in the same infant with Nager syndrome shows micrognathia with an obtuse mandibular angle & marked hypoplasia of the neck & condyle of the mandible. There is hypoplasia of the midface & zygomatic complex with absence of the zygomatic arch. There is also EAC atresia.*

(Left) *Axial bone CT in a 13-year-old girl with Treacher Collins syndrome (TCS) shows zygomatic complex hypoplasia with posteriorly slanted maxillae, absent zygomatic arches, & hypoplastic mandibular condyles. Note the EAC atresia, absent mastoid pneumatization, & an enlarged mastoid emissary vein.* **(Right)** *Axial soft tissue NECT in a 1-year-old with TCS shows bilateral mandibular hypoplasia, EAC atresia, microtia with hypoplastic muscles of mastication, & aplasia of the parotid glands.*

KEY FACTS

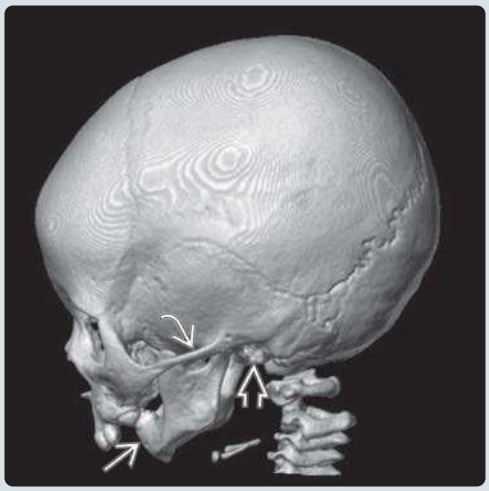
TERMINOLOGY

- Pierre Robin sequence (PRS) triad: Micrognathia, glossoptosis, airway obstruction

IMAGING

- Micrognathia: Bilateral, usually symmetric
- Glossoptosis: Elevated, posteriorly displaced tongue
- Posterior, U-shaped cleft palate
- Additional features depend on syndromic etiology
- Temporal bone
  - EAC: Normal, stenotic (e.g., Stickler syndrome), or atretic [e.g., Treacher Collins syndrome (TCS), Nager syndrome]
  - Middle ear & mastoid: Normal or hypoplastic ± opacification
  - Ossicles: Normal, mildly malformed [e.g., stapes in velocardiofacial syndrome (VCFS)], or severely malformed ± fixation (e.g., TCS)
  - Inner ear: Normal or malformed (e.g., small semicircular canal bone island/anlage anomaly in VCFS & TCS)

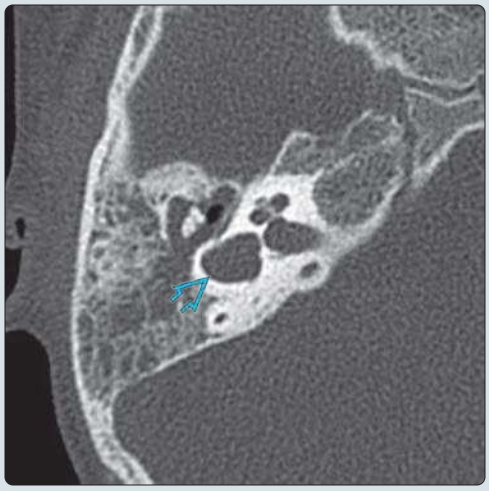
TOP DIFFERENTIAL DIAGNOSES



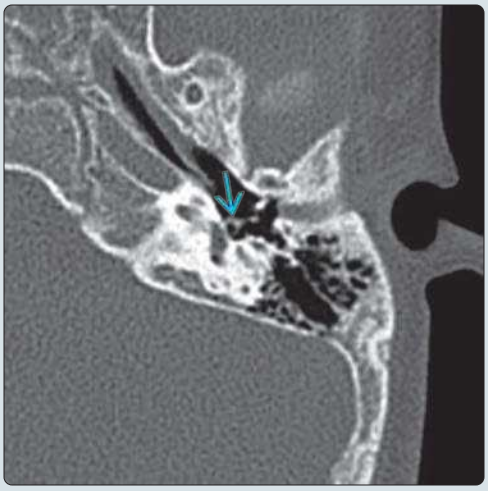
- Stickler & related syndromes (18% of PRS)
- VCFS (~ 7% of PRS)
- TCS (~ 5% of PRS)

PATHOLOGY

- Primary micrognathia → glossoptosis → failure of palatal shelf elevation & fusion
- Collagen (*COL*) gene mutations: Stickler syndrome
- 22q11.2 deletion: VCFS



CLINICAL ISSUES



- Feeding & breathing difficulties, failure to thrive
- Stickler: Progressive myopia, joint degeneration
- VCFS: Cardiac anomalies, adenoidal hypoplasia, velopharyngeal insufficiency, medial deviation of cervical internal carotid arteries, learning difficulties
- TCS: Malar flattening, downslanting palpebral fissures, coloboma

(Left) *Lateral 3D surface-rendered CT in a 1-year-old with Pierre Robin sequence (PRS) shows significant symmetric micrognathia with a normal external auditory canal & zygomatic arch.* **(Right)** *Sagittal bone CT reconstruction in a 3-week-old with PRS reveals a shortened hard palate & glossoptosis (abnormal downward or backward displacement of tongue). The tongue, which protrudes above & behind the palate, obstructs the oropharynx, resulting in difficulty with breathing & feeding.*

(Left) *Axial bone CT in a 5-year-old with velocardiofacial syndrome (VCFS) shows an anlage anomaly where the lateral semicircular canal (SCC) & vestibule form a single globular space without a bone island. There is diffuse opacification of the middle ear space & mastoid air cells.* **(Right)** *Axial bone CT in a 7-year-old with VCFS & hearing loss shows mild thickening of anterior crus of the stapes & mildly reduced mastoid pneumatization. A more cephalad image (not shown) demonstrated a slightly small lateral SCC bone island.*

Thyroglossal Duct Cyst

KEY FACTS

TERMINOLOGY

- Thyroglossal duct cyst (TGDC): Cystic remnant of embryologic thyroglossal duct (TGD)

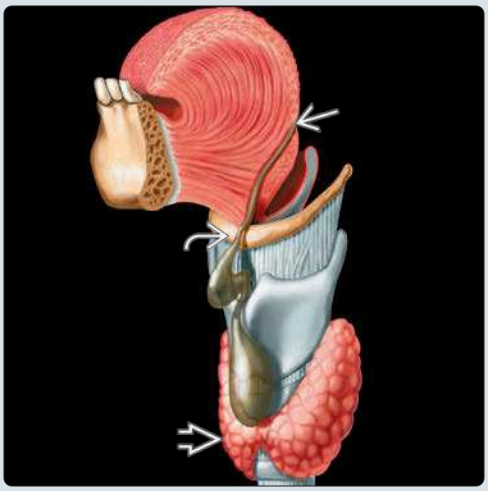
IMAGING

- Best diagnostic clue: Round or ovoid midline suprahyoid or midline/paramidline infrahyoid cystic neck mass
- Suprahyoid neck: ~ 20-25%, typically midline
- At hyoid bone: ~ 50%
- Infrahyoid neck: ~ 25%, midline or paramidline
  - Embedded in strap muscles: Claw sign
- ± wall enhancement, soft tissue stranding if infected

TOP DIFFERENTIAL DIAGNOSES

- Dermoid or epidermoid
- Lingual thyroid
- Lymphatic malformation
- 4th branchial apparatus anomaly
- Cervical thymic cyst

PATHOLOGY

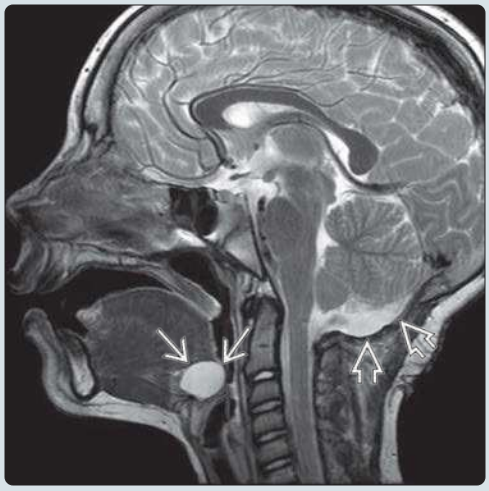


- Failure of involution of TGD + persistent secretion of epithelial cells lining duct → TGDC
- Lies anywhere along TGD route of thyroid anlage descent from foramen cecum at tongue base to thyroid bed in infrahyoid neck

CLINICAL ISSUES

- Most common congenital neck lesion
- Treatment: Sistrunk procedure (excision of cyst, tract, & midline hyoid bone) → ↓ recurrences

DIAGNOSTIC CHECKLIST



- Relationship to hyoid bone important to note: Suprahyoid, hyoid, or infrahyoid in location
- Nodularity or Ca^{2+} can suggest associated thyroid carcinoma
- Confirm normal thyroid by ultrasound prior to TGDC or lingual thyroid resection

(Left) *Sagittal oblique graphic shows the potential sites of a thyroglossal duct cyst (TGDC) from the foramen cecum ➡ to the thyroid bed ➡. Note the close relationship of the midportion of the hyoid bone ➡ to this pathway. A cyst can occur anywhere along this tract.* **(Right)** *Sagittal CECT in a young child shows a well-defined, cystic-appearing mass ➡ at the midline base of the tongue. This mass was incidentally found on a CT performed to evaluate the extent of a deep neck infection (not shown). A TGDC was proven upon resection.*

(Left) *Sagittal CECT in a child with sore throat & difficulty swallowing shows a lobulated, rim-enhancing, fluid-attenuation mass ➡ in the midline sublingual space with a small, posterior extension at the tongue base ➡. Histologically, this proved to be an inflamed TGDC.* **(Right)** *Sagittal T2 MR incidentally shows a well-defined, hyperintense TGDC ➡ in the midline base of the tongue (at the level of the foramen cecum) in a patient imaged after posterior fossa decompression ➡ for treatment of Chiari 1.*

TERMINOLOGY

Synonyms

- Thyroglossal duct cyst (TGDC)
- Thyroglossal duct (TGD) remnant

Definitions

- Remnant of embryologic TGD found between foramen cecum at tongue base & thyroid bed in infrahyoid neck

IMAGING

General Features

- Best diagnostic clue
  - Anterior midline suprahyoid or midline/paramidline infrahyoid cystic neck mass
- Location
  - Suprahyoid neck: ~ 20-25%, typically midline
    - Base of tongue or within posterior floor of mouth
  - At hyoid bone: ~ 50%
    - Usually abutting anterior hyoid bone
    - May project into preepiglottic space
  - Infrahyoid neck: ~ 25%, midline or paramidline, embedded in strap muscles
    - Further inferior TGDC is more likely to be off midline
- Size
  - Variable, usually 2-4 cm
- Morphology
  - Round or ovoid cyst
  - More likely to be irregular in shape, elongated toward tongue base, & have ill-defined margins vs. dermoid

Ultrasonographic Findings

- Anechoic or hypoechoic midline neck mass
- Internal heterogeneity, septations, & solid components are more likely in TGDC than dermoid
  - SIST score (favors TGDC over dermoid): Septations + irregular walls + solid components = TGDC
- Synchronous movement with hyoid bone
- Elongation toward tongue base
- Must image lower neck to prove presence of normal-appearing bilobed thyroid

CT Findings

- CECT
  - Low-attenuation, cystic midline neck mass with thin rim of peripheral enhancement
    - ± wall enhancement, soft tissue stranding if infected
    - Occasional septations
  - Paramidline infrahyoid TGDC embedded in strap muscles may show claw sign
  - < 1% contain associated thyroid carcinoma (usually papillary carcinoma)
    - Solid eccentric mass, often with Ca^{2+}, within cyst
    - May only be microscopic & not identifiable prospectively with imaging
    - Majority occur in adults but may occur in teenagers
      - Youngest reported: 10 years old

MR Findings

- T1WI
  - Usually hypointense; hyperintense if proteinaceous fluid
- T2WI
  - Hyperintense, often homogeneous
- DWI
  - Mean ADC values of ~ 2.2×10^{-3} mm²/s
- T1WI C+
  - Nonenhancing cyst
    - Rim enhancement if infected

Imaging Recommendations

- Ultrasound can suggest TGDC vs. other lesions & confirm normal thyroid
- Nuclear scintigraphy is helpful if ectopic thyroid is suspected

DIFFERENTIAL DIAGNOSIS

Dermoid or Epidermoid

- Dermoid: Fat, fluid, or mixed
  - ADC ~ 1.54×10^{-3} mm²/s
- Epidermoid: Fluid
- More likely to be in subcutaneous fat
- Floor of mouth & suprasternal notch are classic locations

Lingual Thyroid

- Most common location of ectopic thyroid
- In 75% of patients, lingual thyroid is only functioning thyroid tissue
- May expand rapidly during puberty
- Solid, round, hyperattenuating mass in base of tongue on NECT; avid enhancement on CECT
- Variable T1 & T2 signal, variable contrast enhancement on MR

Lymphatic Malformation

- Classic appearance: Multilocular & transspatial
- Microcystic or macrocystic
- Fluid-fluid levels are common secondary to hemorrhage
- Thin rim & septal enhancement unless infected, microcystic, or part of combined venolymphatic malformation

4th Branchial Apparatus Anomaly

- May present with recurrent thyroiditis
- Majority are sinus tracts from apex of left pyriform sinus to lower neck → abscess in or adjacent to left thyroid lobe
- May be 4th (or 3rd) pharyngeal pouch remnant

Cervical Thymic Cyst

- Congenital cyst, anywhere along thymopharyngeal duct from pyriform sinus to anterior mediastinum
  - May be bilobed with waist at thoracic inlet
- L> R
- Close association with carotid sheath
  - May splay carotid artery & jugular vein, particularly near skull base
- May be combined solid thymic tissue & cyst

Mixed Laryngocele

- Off-midline, fluid- or air- & fluid-containing mass
- Traces back to laryngeal origin
- Not embedded within strap muscles

Delphian Chain Necrotic Node

- Can be difficult to differentiate from infected TGDC

- Rare in children

PATHOLOGY

General Features

- Genetics
  - Thyroid developmental anomalies often occur in same family
- Associated abnormalities
  - Thyroid agenesis, ectopia, or pyramidal lobe
  - Occasionally associated with carcinoma
    - Most common: Papillary carcinoma within TGDC
- Embryology/anatomy
  - TGD originates near foramen cecum at posterior 3rd of tongue
  - Thyroid anlage arises at base of tongue → descends around or through hyoid bone → descends along strap muscles → final position in thyroid bed, anterior to thyroid cartilage or cricoid cartilage
  - At 5- to 6-gestational weeks, TGD usually involutes
    - Foramen cecum & pyramidal thyroid lobe may be left as normal remnants
  - Failure of TGD involution with persistent secretory activity of epithelial cells lining duct → TGDC
  - TGDC or ectopic thyroid tissue may occur anywhere along TGD

Gross Pathologic & Surgical Features

- Smooth, benign-appearing cyst with tract to hyoid bone ± foramen cecum

Microscopic Features

- Cyst is lined by respiratory or squamous epithelium
- Small deposits of thyroid tissue with colloid are commonly associated
- ± thyroid carcinoma (papillary carcinoma is most common)

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Midline or paramidline doughy, compressible, painless neck mass in child or young adult
  - Cyst elevates when tongue protrudes if TGDC is located around hyoid bone
- Other signs/symptoms
  - Recurrent midline neck mass with upper respiratory tract infections or trauma
  - ± multiple prior incision & drainage procedures for neck abscess
  - Rarely, lingual TGDC may lead to airway obstruction in infants
  - Small lesion may be recognized as incidental finding on brain MR
    - Majority are at base of tongue

Demographics

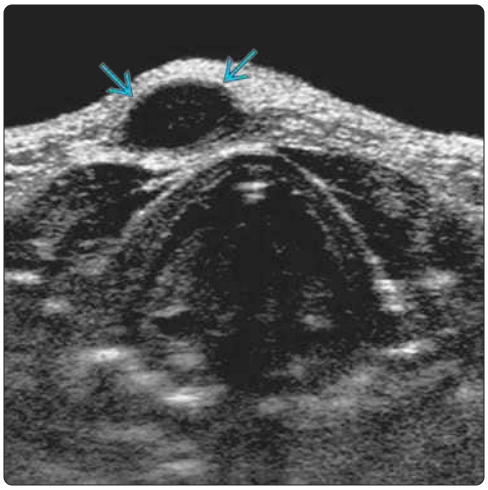
- Age
  - < 10 years at presentation (up to 90%)
- Epidemiology
  - Most common congenital neck lesion
    - Up to 90% of nonodontogenic congenital cysts
  - At autopsy > 7% of population will have TGD remnant somewhere along course of tract

Natural History & Prognosis

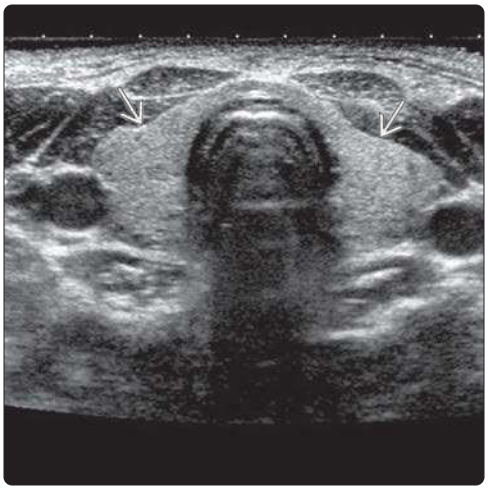
- Recurrent, intermittent swelling of mass, usually following minor upper respiratory infection
- Rapidly enlarging mass suggests either infection or differentiated thyroid carcinoma (< 1%)
  - 85% papillary carcinoma

Treatment

- Complete surgical resection: Sistrunk procedure ↓ recurrence rate from 50% to < 4%
  - Tract to foramen cecum is dissected free
  - Entire cyst & midline portion of hyoid bone are resected
    - Even if imaging shows no obvious connection to hyoid bone
    - Exception: Low infrahyoid neck TGDC
  - Prognosis is excellent with complete surgical resection
- Isolated lingual TGDC may be treated endoscopically
- Recurrences (from incomplete resection) are often complicated & lateral
  - ↑ risk of recurrence in patients with postoperative infection
- Increasing reports of successful sclerotherapy



DIAGNOSTIC CHECKLIST



Consider

- Relationship to hyoid bone is important to note
  - Suprahyoid, hyoid, or infrahyoid in location
- Nodularity or Ca^{2+} can suggest associated thyroid carcinoma
- Image thyroid bed with ultrasound to confirm presence of normal thyroid gland prior to TGDC or lingual thyroid excision

(Left) *Transverse US of the anterior neck shows a well-defined, subcutaneous, right paramidline, hypoechoic mass ⇨ ventral to the strap muscles. This lesion was surgically removed & confirmed to be a TGDC.* **(Right)** *Transverse US in a child with a suspected TGDC (not shown) demonstrates a normal-appearing, bilobed thyroid ➡ at the expected location in the lower anterior midline neck. It is important to document the presence of normal thyroid tissue in all patients imaged for the work-up of a TGDC.*

(Left) *Sagittal CECT in a child with a proven recurrence of a TGDC demonstrates a lobulated, heterogeneous mass ➡ in the midline suprahyoid neck. By imaging, this is indistinguishable from a postsurgical collection. Note the absence of a midline hyoid bone ➡, consistent with a prior Sistrunk procedure.* **(Right)** *Sagittal T2 MR in a child undergoing brain imaging for the work-up of seizures shows an incidental, well-defined, hyperintense mass ➡ at the midline tongue base, subsequently proven to be a TGDC.*

(Left) *Transverse color Doppler US in a child with the new onset of a paramidline anterior left neck mass shows a heterogeneously hypoechoic lesion ➡ with internal echoes. No internal vascularity is seen. Histologically, the lesion proved to be an uncomplicated TGDC.* **(Right)** *Axial CECT of the neck in a teenager with the new onset of a neck mass demonstrates a low-attenuation infrahyoid mass ➡ embedded within the left strap muscle, typical of a TGDC.*

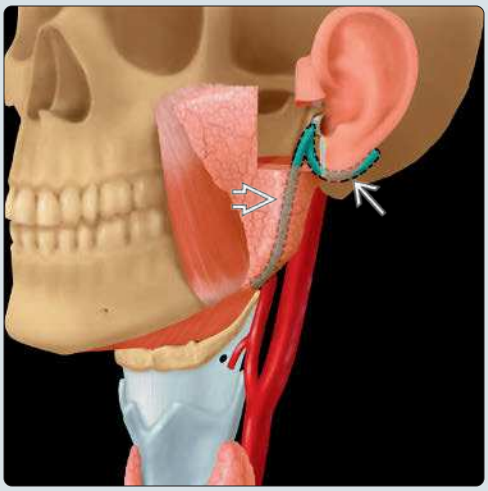
Branchial Cleft Anomalies

KEY FACTS

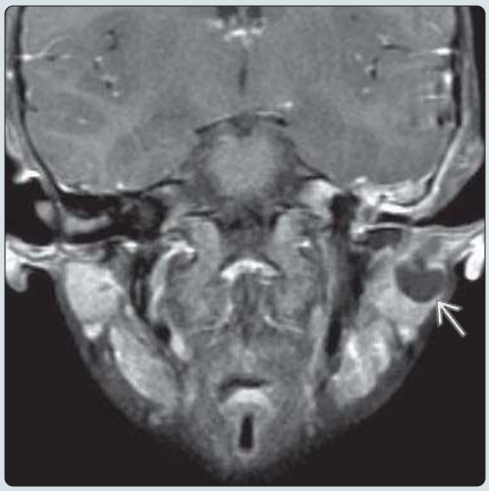
TERMINOLOGY

- Branchial cleft cyst, branchial apparatus cyst (BAC), branchial apparatus anomaly (BAA)
- Anomaly/remnant of embryologic endodermal pouch, mesodermal arch, or ectodermal cleft
  - May be cyst, fistula, or sinus tract

IMAGING

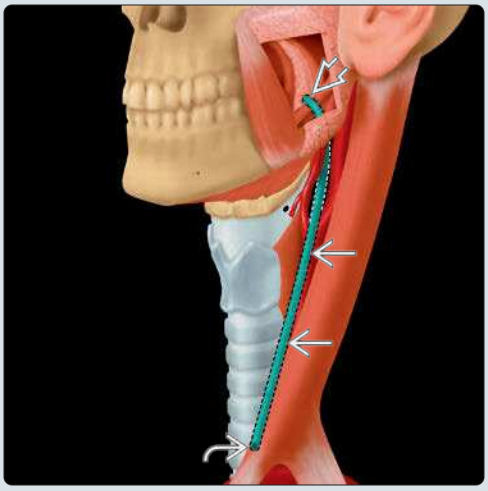


- Well-defined, smooth-walled unilocular cyst of face/neck
  - ± wall thickening, enhancement, & septation with surrounding edema if infected
- Location
  - 1st BAC: Periauricular, in or adjacent to parotid
  - 2nd BAC (most common): Anterior to sternocleidomastoid muscle, posterior to submandibular gland, lateral to carotid sheath
  - 3rd BAC: Posterior triangle in upper neck or anterior triangle in lower neck
  - Cervical thymic cyst: Anywhere along thymopharyngeal duct from lateral hypopharynx to location of normal lobes of thymus in superior mediastinum
  - 4th BAA: Typically sinus tract or fistula extending from apex of pyriform sinus to anterior lower neck, usually in or adjacent to left thyroid lobe

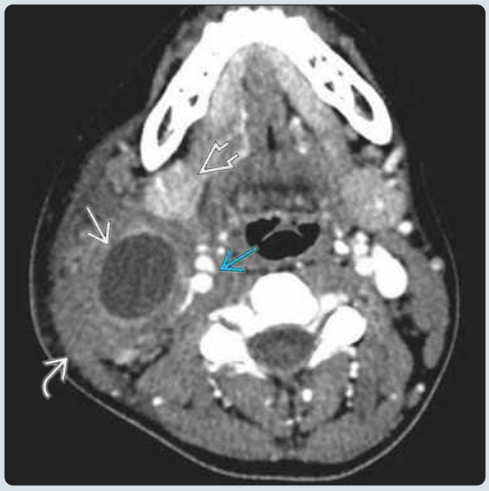


TOP DIFFERENTIAL DIAGNOSES

- Suppurative lymph node or abscess
- Thyroglossal duct cyst
- Lymphatic malformation
- Dermoid & epidermoid



CLINICAL ISSUES



- Typical presentations include soft, painless mass vs. recurrent infections or drainage
  - 1st BAC: ± otorrhea or recurrent parotid abscess
  - 4th BAA: ± left thyroid lobe abscess
- Treatment requires complete surgical excision of cyst & associated fistula or sinus tract, if present

(Left) *Oblique graphic shows the 2 forms of a 1st branchial apparatus cyst (BAC). A type 1 1st BAC ➪ courses from the medial bony external auditory canal (EAC) toward the retroauricular area. The tract of a type 2 first BAC ➪ connects the EAC to the angle of the mandible.* **(Right)** *Coronal T1 C+ FS MR in a 3-year-old patient with a 1st BAC shows a lobulated, nonenhancing periparotid cyst ➪ extending toward the junction of the cartilaginous & bony EAC.*

(Left) *Oblique graphic of the tract of a 2nd BAC ➪ shows a proximal opening ➪ in the faucial tonsil & a distal opening in the anterior supraclavicular neck ➪.* **(Right)** *Axial CECT in a teenager with an enlarging mass shows a cystic-appearing lesion ➪ in the typical location of a 2nd BAC (dorsal to the submandibular gland ➪, anterior to the SCM ➪, & lateral to the carotid sheath vessels ⇨). Note the thick, irregular rim & adjacent soft tissue edema, consistent with superimposed infection & cellulitis/myositis.*

TERMINOLOGY

Synonyms

- Branchial cleft cyst, branchial apparatus cyst (BAC), branchial apparatus anomaly (BAA)

Definitions

- Anomaly/remnant of embryologic endodermal pouch, mesodermal arch, or ectodermal cleft
- May be cyst, fistula, or sinus tract

IMAGING

General Features

- Best diagnostic clue
  - Well-defined, smooth-walled cyst (types 1-3)
    - ± surrounding edema/enhancement if infected
  - Left thyroid lobe abscess: Suspect pyriform sinus fistula or sinus tract (type 4)
    - CT after barium swallow best identifies sinus tract or fistula
- Location
  - 1st BAC
    - Periauricular (type 1)
    - Periparotid (type 2): May extend to angle of mandible
  - 2nd BAC (95%): 4 locations based on Bailey classification
    - Deep to platysma (type 1): Rare
    - Anterior to sternocleidomastoid (SCM) muscle, posterior to submandibular gland, lateral to carotid sheath (type 2): Most common
    - Protrude between internal carotid artery & external carotid artery (type 3)
    - Adjacent to lateral pharyngeal wall (type 4, probably remnant of 2nd pharyngeal pouch)
  - 3rd BAC
    - Posterior triangle in upper neck, anterior triangle in lower neck
  - Cervical thymic cyst
    - 3rd pharyngeal pouch remnant: Thymopharyngeal duct remnant from lateral hypopharynx to location of normal lobes of thymus in superior mediastinum
    - ± solid ectopic thymus along same tract
    - Remnants may be mixed cystic & solid
  - 4th BAA
    - Sinus tract or fistula extending from apex of pyriform sinus to anterior lower neck, usually adjacent to left thyroid lobe
    - 4th pharyngeal pouch remnant (or recent literature suggests 3rd pouch remnant)
- Size
  - Variable from small to several cm
- Morphology
  - Most BACs are well defined, unilocular, & round or ovoid

CT Findings

- CECT
  - Low-density cyst with nonenhancing wall in typical location
    - If infected: Thickened, enhancing wall with surrounding cellulitis
  - Pyriform sinus fistula (extends to skin surface) or sinus tract (does not extend to skin surface)
    - Abscess in or adjacent to left thyroid lobe
    - May only show subtle inflammation around apex of pyriform sinus
    - Sinus tract or fistula is best demonstrated on neck CT obtained immediately after swallowing oral contrast

MR Findings

- Without infection: Thin-walled, fluid-filled cyst
- If infected: Thick wall with variable signal intensity of fluid + surrounding cellulitis
- Ideal to demonstrate small sinus tract or fistula associated with type 1 BAC

Ultrasonographic Findings

- Thin-walled, hypoechoic cyst ± mobile internal echoes
- Remnant ectopic thymus shows characteristic "dot & dash" echoes in otherwise hypoechoic thymic tissue

Imaging Recommendations

- Best imaging tool
  - Ultrasound is helpful to confirm cystic nature & location
    - May not show total extent of lesion
  - MR is best to evaluate suspected 1st BAC
  - CECT in acute setting (typically infected cyst)
- Protocol advice
  - Suspected 1st BAC: Cover periauricular tissues through angle of mandible
    - MR best identifies associated fistula or sinus tract
    - Coronal images help evaluate relationship to external auditory canal (EAC)
  - Suspected 2nd or 3rd BACs: Image entire neck to upper mediastinum
  - Suspected pyriform sinus fistula or sinus tract: Helpful to image after swallowing oral contrast

DIFFERENTIAL DIAGNOSIS

Suppurative Lymph Nodes

- Thick, enhancing nodal wall with central hypoattenuation/hypoechogenicity = nodal necrosis/intranodal abscess
- Edema in surrounding fat (cellulitis)
- ± thickening of muscles (myositis)
- Associated nonsuppurative adenopathy
- Nontuberculous mycobacterial adenitis lacks surrounding inflammatory change

Abscess

- Conglomeration of suppurative nodes or rupture of node → extranodal abscess
- Superficial: Anterior or posterior cervical or submandibular spaces (SMSs)
- Deep: Retropharyngeal, parapharyngeal, or tonsillar; may grow rapidly → airway compromise ± mediastinal extension
- If anterior to left thyroid lobe, think of 4th BAA
- Exclude dental infection & salivary gland calculus as cause of head & neck infection

Thyroglossal Duct Cyst

- Remnant of thyroglossal duct, anywhere from foramen cecum/base of tongue to thyroid bed in infrahyoid neck
- Cyst with minimal rim enhancement

- Location: 50% at hyoid, up to 25% suprahyoid, up to 25% infrahyoid
  - Suprahyoid lesions are usually midline
  - Infrahyoid may be off midline, embedded in strap muscles
- ± nodularity or Ca^{2+} if associated thyroid carcinoma (usually adults)

Lymphatic Malformation

- Congenital slow-flow vascular malformation composed of variably-sized abnormal lymphatic channels
- Often multilocular transspatial mass
  - Thin rim/septal enhancement; ↑ enhancement if infected, microcystic, or combined with venous malformation
- Present at birth, grows commensurate with child; rapid growth from hemorrhage or hormonal stimulation
  - Hemorrhage → internal debris or fluid-fluid levels

Ranula

- Simple: Postinflammatory retention cyst with epithelial lining; arises in sublingual gland (or minor salivary gland) in sublingual space (SLS)
  - Well-defined, elongated cyst in SLS
- Diving: Ruptures out of SLS into SMS
  - Cyst in both SLS & SMS
  - May see "tail" if SLS component is collapsed

Dermoid & Epidermoid

- Dermoid: Epithelial & dermal elements
- Epidermoid: Epithelial elements only
- Well-defined cyst filled with fluid = dermoid or epidermoid
- Well-defined cyst with fatty material, mixed fluid ± Ca^{2+} = dermoid
- Diffusion restriction on DWI = dermoid or epidermoid

PATHOLOGY

General Features

- Associated abnormalities
  - Bilateral branchial apparatus fistulas/cysts & preauricular tag or pit are associated with branchiootorenal syndrome
    - Autosomal dominant inheritance
    - Profound mixed hearing loss: Cochlear & semicircular canal malformations, stapes fixation
    - Renal anomalies: Cysts, dysplasia, agenesis
    - Patulous eustachian tubes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Soft, painless, compressible mass
  - Fever & cellulitis with superimposed infection or pyriform sinus fistula (or sinus tract)
  - Drainage at skin opening if fistula is present
- Other signs/symptoms
  - Large thymic cysts may lead to airway compromise in neonates

Natural History & Prognosis

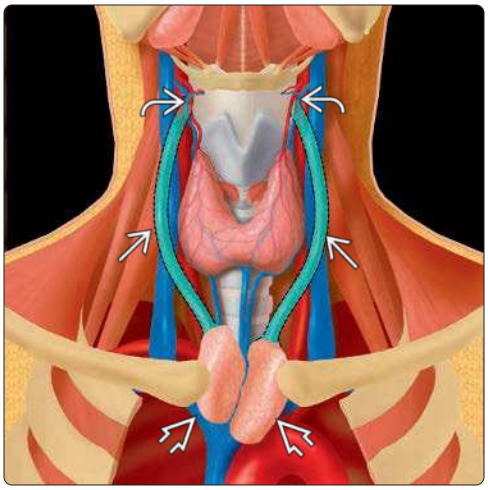
- If not recognized & treated, 1st BAC may present with recurrent otorrhea or parotid abscess
- If not recognized & completely excised, 4th BAA/BAC anomalies may present with recurrent thyroiditis

Treatment

- Complete surgical excision of cyst & associated fistula or sinus tract, if present
  - Proximity of facial nerve to cyst puts nerve at risk during surgical excision of 1st BACs
  - Large cervical thymic cysts may require otolaryngology & thoracic surgery

DIAGNOSTIC CHECKLIST

Consider



- 1st BAC if cyst is in or around EAC or parotid gland
  - May present with otorrhea or recurrent parotid gland abscess
- 2nd BAC if cyst is anterior to SCM, posterior to submandibular gland, & lateral to carotid sheath
- Thymic cyst if cystic mass extends from neck to superior mediastinum &/or associated with anterior carotid sheath
- Pyriform sinus fistula or sinus tract if abscess is identified in or adjacent to left thyroid lobe

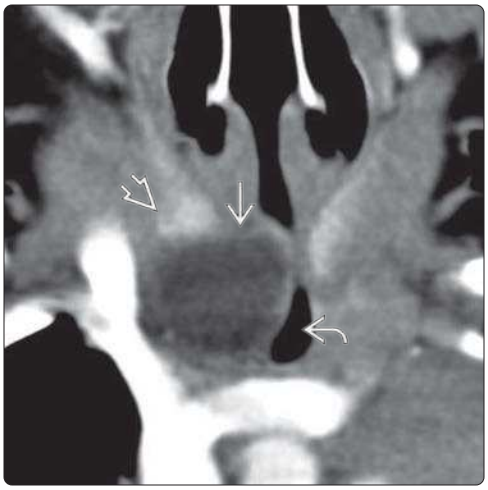


Image Interpretation Pearls

- If "abscess" is seen in typical location, think of infected preexisting BAC/BAA
- If patient is > 30 years of age, consider cystic nodal metastasis in differential diagnoses of 2nd or 3rd BAC

(Left) *Coronal graphic shows both thymopharyngeal duct tracts extending from the lateral hypopharyngeal area to the location of the normal lobes of the thymus in the superior mediastinum. The thymopharyngeal tracts are remnants of the 3rd branchial pouch.* **(Right)** *Coronal CECT in an infant with respiratory distress shows a thymic cyst inferior to the right thyroid lobe, deviating & compressing the trachea.*

(Left) *Transverse ultrasound in a 7-year-old demonstrates a mixed cystic & solid thymic remnant splaying the carotid sheath vessels. The lateral component demonstrates the "dot & dash" echogenicity typical of thymus while the medial component is cystic (showing mobile intraluminal echoes on real-time imaging).* **(Right)** *Coronal T2 FS MR in the same patient shows a mixed solid & cystic thymic remnant, the solid portion of which was isointense to intrathoracic thymus on all sequences (not shown).*

(Left) *Oblique graphic of the neck shows the tract of a 4th BAA extending from the hypopharynx to the location of the left thyroid lobe. This explains why this lesion often presents with thyroiditis/abscess.* **(Right)** *Axial CECT in a child with a recurrent draining 4th BAA fistula was obtained after a barium swallow study. Air is in the proximal fistulous tract just below the left pyriform sinus. Barium is in the tract extending anteriorly through the strap muscles. Barium was also noted at a skin opening (not shown).*

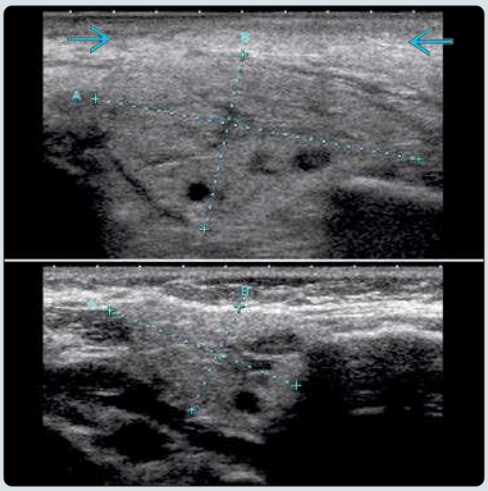
Acute Parotitis

KEY FACTS

TERMINOLOGY

- Acute inflammation of parotid gland
  - Bacterial: Localized bacterial infection ± abscess
  - Viral: Usually from systemic viral infection
  - Calculus-induced: Ductal obstruction by sialolith
  - Autoimmune: Acute episode of chronic disease
  - Juvenile recurrent parotitis (JRP): Intermittent idiopathic episodes of parotid inflammation

IMAGING



- Typical appearance: ↑ size & enhancement of parotid ± stranding of surrounding fat; parotid retains normal shape
- Bacterial parotitis: Typically unilateral
  - Periparotid cellulitis/stranding is common
  - Intra- or periparotid abscess may occur
- Viral parotitis: Typically bilateral
  - Clinical diagnosis; imaging rarely required
- Calculus-induced parotitis: Typically unilateral
  - Large duct with intraluminal stone
- Autoimmune parotitis: Typically bilateral
  - Diagnosed with serum markers
  - Sialography for chronic complications
- JRP: Often unilateral clinically with bilateral imaging abnormalities
  - Normal main duct with dilated intraglandular branches (sialectasis)

TOP DIFFERENTIAL DIAGNOSES

- Infected 1st branchial cleft anomaly
- Parotid infantile hemangioma
- Salivary gland neoplasms
- Parotid sialosis
- Benign lymphoepithelial lesions of HIV

DIAGNOSTIC CHECKLIST

- Reimage if mass persists after resolution of infection (to exclude underlying branchial cleft cyst or malignancy)
- Sialography for recurrent disease to assess complications

(Left) *Transverse US of the right (upper) & left (lower) parotid glands (denoted by calipers) in a toddler with right facial swelling shows normal size & echogenicity of the left parotid gland & overlying soft tissues. The right parotid gland is enlarged & mildly heterogeneous with induration of the overlying soft tissues, typical of parotitis.* **(Right)** *Axial CECT shows diffuse, asymmetric enlargement & enhancement of the right parotid gland with associated facial cellulitis & myositis due to acute bacterial parotitis.*

(Left) *Axial CECT shows a low-density, rim-enhancing collection replacing the left parotid gland. There is substantial surrounding fat stranding. These findings are consistent with an abscess complicating acute bacterial parotitis.* **(Right)** *Axial T1 C+ FS MR in a child with recurrent parotitis shows an enlarged, asymmetrically enhancing left parotid gland without significant cellulitis. Note the moderate enhancement in the ipsilateral accessory glandular tissue as well.*

TERMINOLOGY

Synonyms

- Acute sialadenitis

Definitions

- Acute inflammation of parotid gland
  - Bacterial: Localized infection ± abscess
  - Viral: Usually from systemic viral infection
  - Calculus-induced: Ductal obstruction by sialolith
  - Autoimmune: Acute episodes of chronic disease
  - Juvenile recurrent parotitis (JRP) or chronic recurrent parotitis of childhood: Intermittent idiopathic episodes of parotid inflammation

IMAGING

General Features

- Best diagnostic clue
  - Enlarged parotid(s) with surrounding fat stranding
- Location
  - Bacterial: Usually unilateral
  - Viral: 75% bilateral; ± submandibular &/or sublingual gland involvement
    - Rare cases of COVID-19 parotitis, often unilateral
  - Calculus-induced: Unilateral
  - Autoimmune: Usually bilateral
  - Juvenile recurrent: Unilateral or asymmetric clinical presentations with bilateral imaging findings
- Morphology
  - Entire gland is usually involved (but can be focal); parotid retains normal triangular configuration

CT Findings

- CECT
  - Bacterial: Enlarged, diffusely enhancing parotid
    - Inflammatory stranding of surrounding fat
    - Rim enhancement of low-density abscess (if present)
  - Viral: Enlarged parotids with mild enhancement
  - Calculus-induced: Calcified stone; dilated parotid duct with enhancing walls; otherwise like bacterial
  - Autoimmune: Less stranding of surrounding fat; may have ductal dilation if longstanding disease

MR Findings

- T2WI
  - Diffuse moderately high signal ± focal areas of fluid signal (microabscesses or dilated ducts)
- T1WI C+
  - Enlarged parotid gland with diffuse, moderate enhancement; abscesses: Rim-enhancing fluid collections
- MR sialography (3D SSFP)
  - Exquisite for demonstrating cysts or dilated ducts
  - JRP: Normal main duct with dilated intraglandular branches (sialectasis)

Ultrasonographic Findings

- Enlarged, hypoechoic, heterogeneous gland
- Numerous small, hypoechoic lesions bilaterally in JRP
- Echogenic calculi with posterior acoustic shadowing ± dilated, hypoechoic duct
- Focal hypoechoic collection suggests abscess formation

Other Modality Findings

- Sialography is contraindicated in acute suppurative parotitis
  - Useful in evaluating recurrent disease & complications

Imaging Recommendations

- Best imaging tool
  - Bacterial & calculus-induced inflammation: CECT is best for detection of stone or abscess
  - Viral: Typically diagnosed clinically; imaging rarely required
  - Autoimmune disease: Diagnosed with serum markers
    - Sialography for chronic complications
  - JRP: MR sialography or conventional sialogram

DIFFERENTIAL DIAGNOSIS

Infected 1st Branchial Cleft Anomaly

- 1st branchial cleft cyst lies in or adjacent to parotid gland
- Superinfection presents as parotid abscess

Parotid Infantile Hemangioma

- Diffusely expanded, hypervascular, & homogeneously hyperenhancing parotid; normal surrounding soft tissues
- Presents with swelling in 1st few weeks to months of life

Salivary Gland Neoplasms

- Firm focal or infiltrative mass without hyperenhancement

Parotid Sialosis

- Bilateral prolonged, painless, soft parotid (& occasionally submandibular) gland enlargement

Benign Lymphoepithelial Lesions of HIV

- Bilateral, heterogeneous parotids, ± cystic & solid lesions
- Prominent Waldeyer ring & cervical nodes

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Bacterial: Sudden onset of parotid pain & swelling
  - Viral: Prodromal symptoms of headaches, malaise, myalgia followed by parotid pain, earache, trismus
  - Calculus-induced: Recurrent episodes of swollen, painful gland, usually related to eating
  - Autoimmune: Recurrent episodes of swollen, painful gland + dry mouth; JRP: Recurrent episodes ± fever, malaise

Demographics

- Age
  - Viral: Most < 15 years; peak age: 5-9 years
  - JRP: Usually begins by 5 years; resolves by ages 10-15
  - Bacterial: > 50 years or neonates

Infantile Hemangioma, Cervicofacial

KEY FACTS

TERMINOLOGY

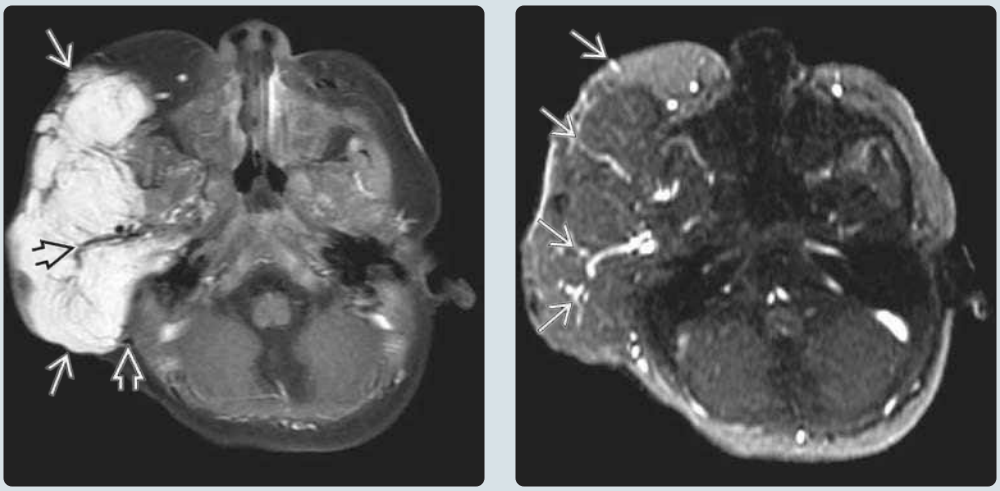
- Benign vascular neoplasm of proliferating endothelial cells; **not** vascular malformation

IMAGING

- Ultrasound + Doppler
  - Soft subcutaneous mass with patchy ↑ echogenicity
  - High vessel density (> 5/cm²) with low resistance arterial waveforms but no arteriovenous shunting
- Contrast-enhanced CT/MR
  - Well-defined mass with diffuse & intense enhancement during proliferative phase
  - High-flow vessels in/adjacent to mass during proliferation
  - ↓ size with ↑ fatty replacement during involuting phase

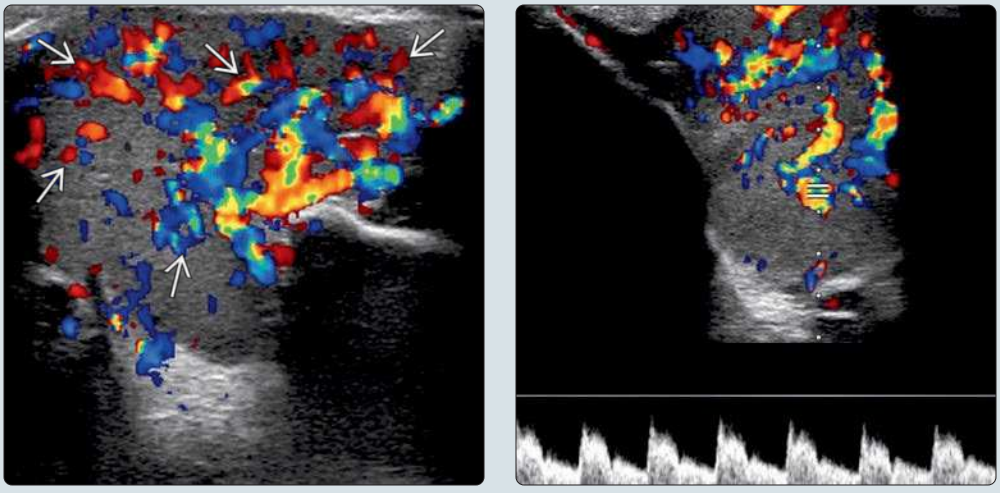
TOP DIFFERENTIAL DIAGNOSES

- Congenital hemangioma
- Venous malformation
- Arteriovenous malformation
- Soft tissue sarcoma
- Plexiform neurofibroma



PATHOLOGY

- GLUT-1(+) in all phases of growth & regression
- In contrast to GLUT-1(-) congenital hemangioma



CLINICAL ISSUES

- Typically inapparent at birth → appears in 1st few weeks of life → grows rapidly for months → spontaneously involutes over years
  - Typically warm, soft, raised reddish or strawberry-like cutaneous lesion
- Majority do not require treatment; propranolol is 1st-line therapy in setting of ulceration or vital structure compromise (e.g., airway or orbit)
- If age, clinical/imaging appearance, or growth history are atypical for infantile hemangioma, biopsy is recommended

(Left) *Axial T1 C+ FS MR in a 5-month-old shows a large, lobulated, intensely enhancing lesion ➡ infiltrating the massively enlarged right parotid gland. Note the prominent intralesional ⇨ & perilesional ➡ flow voids typical of an infantile hemangioma (IH).* **(Right)** *Axial 2D SPGR flow-sensitive MR sequence in the same patient shows the typical appearance of multiple high-flow vessels ➡ within & adjacent to the primary parotid IH.*

(Left) *Transverse color Doppler ultrasound in a 1-month-old child shows a lobular lesion replacing & expanding the parotid gland. Note the high vessel density ➡, typical of a proliferating IH.* **(Right)** *Transverse color Doppler spectral tracing through the lesion in the same patient demonstrates low-resistance arterial waveforms, typical of a proliferating IH. The waveforms will develop a high-resistance pattern during involution, & there will be a ↓ in vessel density.*

TERMINOLOGY

Synonyms

- Capillary hemangioma
- Widespread misuse of term "hemangioma" in literature; infantile hemangioma (IH) is different entity from
  - Congenital hemangioma, spindle cell hemangioma, epithelioid hemangioma, lobular capillary hemangioma (pyogenic granuloma): All benign but different vascular neoplasms
  - Hemangioendothelioma: Higher grade vascular neoplasm
  - Cavernous hemangioma, vertebral body hemangioma, & synovial hemangioma: Venous malformations

Definitions

- IH: Benign vascular neoplasm (not malformation) of proliferating endothelial cells
  - Most common soft tissue tumor of infancy
- **Not** vascular malformation
- 2018 revised classification by International Society for Study of Vascular Anomalies (ISSVA) retains 2 main categories
  - Vascular tumors: True neoplasms with cellular proliferation; generally grow out of proportion to patient
  - Vascular malformation: Congenital errors of vessel development; generally grow commensurate with patient

IMAGING

General Features

- Best diagnostic clue
  - During proliferative phase: Lobular, well-defined mass with intense, diffuse enhancement + high-flow vessels in/adjacent to mass
  - During involuting phase: ↓ size, vascularity, & enhancement with progressive fatty replacement
- Location
  - 60% occur in head & neck
    - Any space: Parotid space, orbit, nasal cavity, subglottic airway, face, neck, rarely intracranial
      - When intracranial &/or multiple, consider PHACE(S) association
      - Typically not deep/intramuscular (in absence of syndrome)
- Size
  - Depends on phase of growth & regression; predictable clinical course
    - Proliferative phase: Rapid growth beginning days-weeks after birth & continuing 6-24 months
    - Involuting phase: Gradual regression over next several years
    - Involuted phase: Relatively small, residual lesion
- Morphology
  - Majority: Isolated, focal, well-circumscribed, lobulated lesions in subcutaneous tissues
    - Tend to displace/efface rather than encase normal structures
  - Occasionally multiple, transspatial, or deep
    - May be part of PHACE(S) association
      - **P**osterior fossa malformations (cerebellar hypoplasia is most common)
      - **H**emangioma (infantile) of face & neck, typically segmental or midline; can involve deep tissues
      - **A**rterial stenosis, occlusion, aneurysm, hypoplasia, agenesis, aberrant origin
      - **C**ardiovascular defects (aortic coarctation/aneurysm/dysplasia, aberrant subclavian artery ± vascular ring)
      - **E**ye abnormalities (coloboma, morning glory disc anomaly, optic nerve hypoplasia, peripapillary staphyloma, microphthalmia, cataract, sclerocornea)
      - **S**upraumbilical raphe & sternal clefts/defects
- Ultrasonographic findings
  - Grayscale
    - Soft lobular mass with variable echogenicity & few macroscopic vessels; ↑ echogenicity during involution
  - Color/spectral Doppler
    - High vessel density (> 5 vessels/cm²); high systolic Doppler shift (> 2 kHz) & low resistive indices in arteries without arterialized veins (to suggest shunting) during proliferation
    - Mean venous peak velocities are not elevated
  - ↓ vessel density, ↑ resistive indices during involution
- CECT
  - Well-circumscribed lobulated mass with diffuse & intense contrast enhancement during proliferation
    - Prominent vessels in/adjacent to mass
    - No internal Ca^{2+} or surrounding edema
  - Progressive fatty infiltration of mass + ↓ size during involution
- MR
  - T1: Isointense to muscle in proliferation; hyperintense from fatty replacement during involution
  - T2: Mildly hyperintense relative to muscle
  - T2 FS/STIR: At least moderately hyperintense relative to muscle (but not fluid signal intensity) during proliferation; hypointense to muscle (follows fat) during involution
  - GRE: High-flow vessels in/adjacent to mass in proliferation
    - Corresponding serpiginous flow voids in/adjacent to mass on SE/FSE sequences
  - DWI: ADC values are higher in IHs vs. pediatric soft tissue malignancies
    - IH: ~ 1.3-1.6 x 10^{-3} mm²/sec
    - Sarcomas: ~ 0.7-1.2 x 10^{-3} mm²/sec
  - Perfusion/ASL: Markedly hyperintense during proliferation
  - T1 C+ FS: Intense uniform contrast enhancement in proliferation
  - MRA: Stenosis, occlusion, agenesis, or aneurysm of craniocervical vessels in PHACE(S) association

Imaging Recommendations

- No imaging is necessary in majority of patients due to characteristic cutaneous appearance & timeframe
- Best imaging tool depends on indications

- To establish diagnosis with atypical history, appearance, or clinical behavior of lesion: US with spectral Doppler if relatively superficial
  - Deeper lesions may not have classic cutaneous appearance
- To define deep extension of lesion with implications for compromise of vital structures (e.g., orbit & airway): MR
- To evaluate for suspected PHACE(S) association (e.g., large segmental facial IH): MR

DIFFERENTIAL DIAGNOSIS

Congenital Hemangioma (RICH/NICH/PICH)

- Present at birth or on prenatal imaging; does not proliferate after birth
  - Rapidly involuting congenital hemangioma (RICH): Involutes by 3-14 months
  - Noninvoluting congenital hemangioma (NICH)
  - Partially involuting congenital hemangioma (PICH)
- Solid, heterogeneous, less well-defined mass ± Ca^{2+}, hemorrhage, necrosis
- Glucose transporter 1 (GLUT-1) negative on histology

Venous Malformation

- Congenital vascular malformation composed of large venous lakes
- Fluid signal intensity throughout mass; ± fluid-fluid levels, phleboliths
- Gradual patchy fill-in with contrast

Arteriovenous Malformation

- Congenital high-flow vascular malformation
- Arteriovenous shunting through tangle of feeding arteries & large draining veins
  - ± other soft tissue components

Soft Tissue Sarcoma

- Solid or mixed cystic/solid mass, typically firm
- Variable enhancement ± osseous erosion
- Variable internal vascularity but typically << IH
- Typically restricts diffusion (lower ADC values)
- Fat is highly unlikely

Plexiform Neurofibroma

- Infiltrative lobulated masses with target appearance in cross section
- Transspatial involvement ± poorly defined margins
- Additional stigmata of neurofibromatosis type 1

PATHOLOGY

Microscopic Features

- Prominent endothelial cells forming small vascular channels during proliferation; flat endothelial cells + fibrofatty replacement during involution

Immunohistochemical Features

- GLUT-1 positive during all phases of proliferation & regression

CLINICAL ISSUES

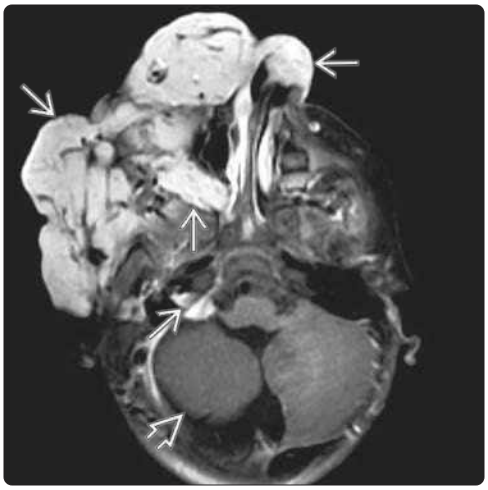
Presentation

- Most common signs/symptoms
  - Growing superficial soft tissue mass in young infant, typically with warm, soft, raised reddish or strawberry-like cutaneous discoloration
  - Deeper lesions may show bluish skin discoloration secondary to prominent draining veins
- Other signs/symptoms
  - Ulceration of overlying skin
  - Airway obstruction from airway involvement
  - Proptosis from orbital lesion
  - Associated abnormalities in PHACE(S) association

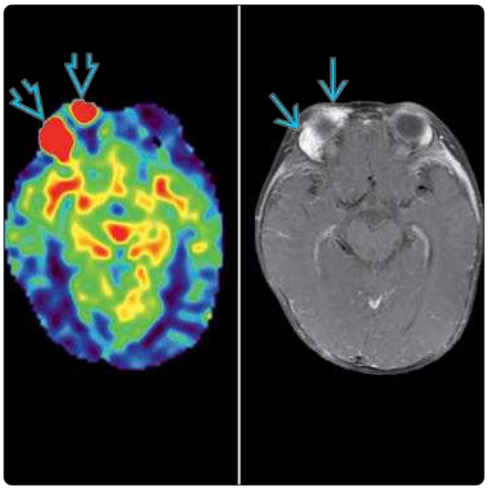
Demographics

- Age
  - Median at presentation: 2 weeks; majority by 1-3 months
    - Typically inapparent at birth
    - Up to 1/3 are nascent at birth (i.e., pale or erythematous macule, telangiectasia, pseudoecchymotic patch or red spot)
- Epidemiology
  - Most common head & neck tumor in infants
  - 1-2% of neonates; 12% by 1 year of age
  - ↑ in preterm infants & low birth weight infants
    - Up to 30% of infants weighing < 1 kg
- Ethnicity
  - Most frequent in White patients
- Sex: F > M (1.5-4:1)

Natural History & Prognosis



- Gradual spontaneous regression
  - 90% resolve by 9 years of age
- Large & segmental facial hemangiomas have ↑ incidence of complications if not treated



Treatment

- Majority do not require treatment
- Treatment indications
  - Compromise of vital structures (e.g., optic nerve compression or airway obstruction)
  - Significant skin ulceration
- Treatment options
  - Oral propranolol (β-blocker) is now primary therapy (instead of oral steroids) due to low side effect profile
  - Less common: Intralesional steroids, laser, rarely surgical excision

(Left) *Axial T1 C+ FS MR in a 4-month-old girl with PHACE(S) association demonstrates multiple enhancing hemangiomas in the right parotid space, right posterior-inferior orbit, right cheek, nose, & right internal auditory canal (IAC)/cerebellopontine angle (CPA). Also note the ipsilateral right cerebellar hemisphere hypoplasia.* **(Right)** *Axial arterial spin-labeled (ASL) (left) & T1 C+ FS (right) MR images in a 6-week-old show markedly ↑ perfusion & uniform enhancement of a periorbital & intraorbital IH.*

(Left) *Coronal T1 C+ FS MR in a 2-month-old shows a large, intensely enhancing IH involving the right intraconal & extraconal orbit. There is a 2nd lesion involving the right palate.* **(Right)** *Coronal T1 C+ FS MR in the same patient after 6 months of propranolol therapy (which was instituted to prevent orbital complications) shows interval regression of the orbital & palatal lesions. In a patient with multiple IHs, consider PHACE(S) association.*

(Left) *Axial CECT in a 1-year-old girl demonstrates intense homogeneous enhancement of a very large IH replacing the entire superficial & deep lobes of the left parotid gland.* **(Right)** *Axial T1 MR in the same child 8 years later shows interval size ↓ & diffuse fatty replacement of the left parotid IH. Note the thin sliver of overlying normal-appearing, superficial parotid gland tissue.*

Rhabdomyosarcoma, Head and Neck

KEY FACTS

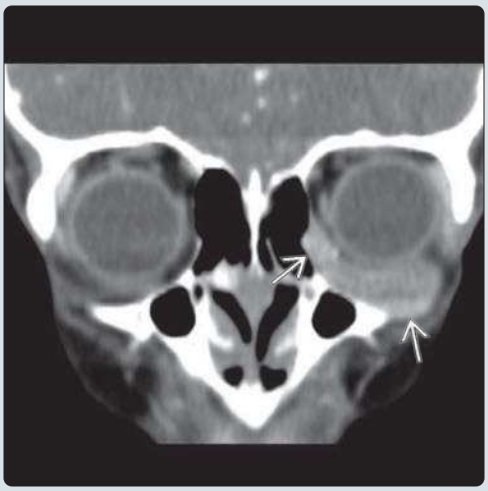
TERMINOLOGY

- Rhabdomyosarcoma (RMS): Most common childhood soft tissue sarcoma

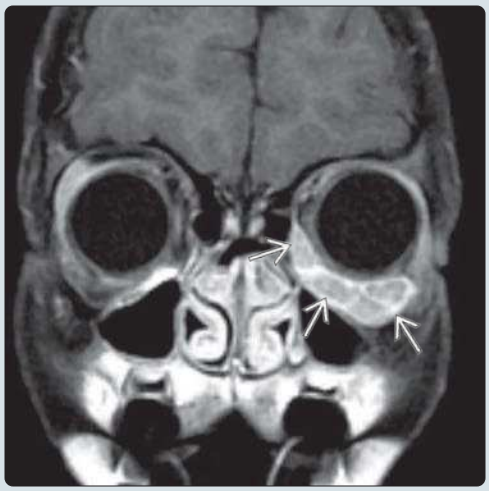
IMAGING

- Up to 40% occur in H&N
  - Orbital, parameningeal, other sites
- MR is best to
  - Characterize solid soft tissue mass
    - Often intermediate signal on T2 FS or STIR
    - Variable contrast enhancement
    - Typically restrict diffusion
  - Evaluate intracranial spread (requires contrast)
- CT is best to look for bone destruction or remodeling
- Neck imaging for cervical metastatic adenopathy
  - PET/CT may improve staging & treatment evaluation

TOP DIFFERENTIAL DIAGNOSES

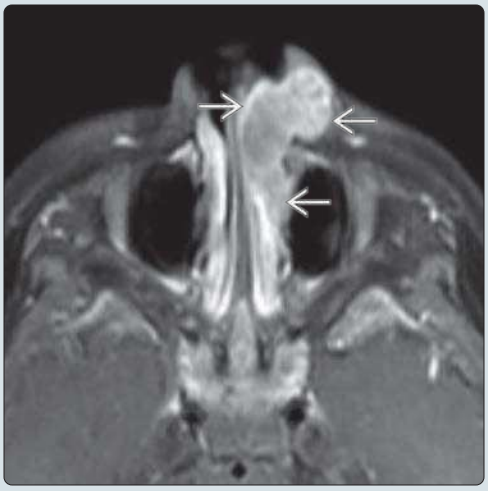


- Infantile hemangioma
- Slow-flow vascular malformations
- Fibromatosis colli
- Metastatic neuroblastoma
- Langerhans cell histiocytosis
- Juvenile angiofibroma
- Nasopharyngeal carcinoma
- Non-Hodgkin & Hodgkin lymphoma
- Plexiform neurofibroma

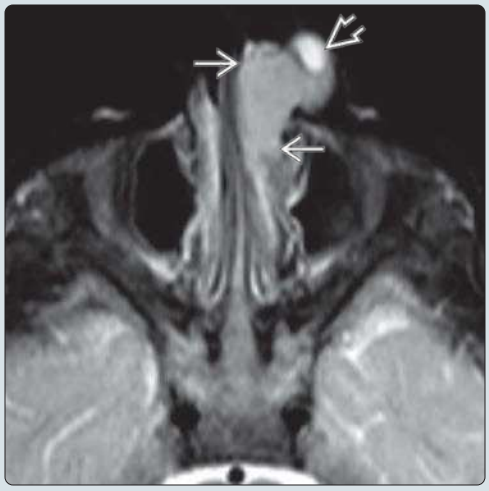


PATHOLOGY

- 3 histologic subtypes
  - Embryonal RMS: Most common; young children
  - Alveolar RMS: 2nd most common; 15-25 years of age
  - Pleomorphic RMS: Least common; 40-60 years of age



CLINICAL ISSUES



- Presentation: 70% < 12 years of age, 40% < 5 years
- Treatment: Surgery, chemotherapy, ± radiation therapy

(Left) *Coronal CECT in an 8-year-old shows a nonspecific, mildly heterogeneous extraconal mass ⇒ in the inferior & inferomedial left orbit without bone destruction.* **(Right)** *Coronal T1 C+ FS MR in the same child shows a heterogeneously enhancing mass ⇒ with an atypical appearance for a hematoma, hemangioma, or vascular malformation. Biopsy confirmed an embryonal rhabdomyosarcoma. The absence of bone destruction does not exclude rhabdomyosarcoma (RMS).*

(Left) *Axial T1 C+ FS MR in a 15-month-old boy with intermittent epistaxis & swelling of the left nasal ala demonstrates a heterogeneously enhancing left intranasal/nasal alar mass ⇒ obstructing the left nasal cavity.* **(Right)** *Axial STIR MR in the same patient demonstrates primarily intermediate signal intensity throughout the mass ⇒ with the exception of a small cystic/necrotic region anteriorly ⇒. Subsequent biopsy revealed an alveolar RMS.*

TERMINOLOGY

Definitions

- Rhabdomyosarcoma (RMS): Malignant neoplasm of rhabdomyoblasts
  - Most common childhood soft tissue sarcoma

IMAGING

General Features

- Best diagnostic clue
  - Solid soft tissue mass with variable enhancement
- Location
  - Up to 40% occur in head & neck, including orbit, parameningeal sites, neck/face soft tissues, nasal cavity
    - Parameningeal sites: Middle ear, paranasal sinus, nasal cavity, nasopharynx, masticator space, pterygopalatine fossa, parapharyngeal space
      - Intracranial extension in up to 55%
      - Temporal bone involvement: Petrous apex & middle ear > mastoid
    - Orbit
    - All other head & neck sites: Scalp, cheek, parotid, oral cavity, larynx, oropharynx, hypopharynx, thyroid/parathyroid
- Size
  - Variable; may present earlier in orbit due to confined space → early proptosis

Ultrasonographic Findings

- Solid, firm mass with variable internal vascularity
- May show bone destruction in superficial masses

CT Findings

- Invasive soft tissue mass with variable enhancement
- Osseous erosion is common but not seen in all cases

MR Findings

- Isointense T1, hyperintense T2 signal relative to muscle
  - Not "fluid bright" unless necrotic/cystic components
- Variable contrast enhancement, often mild to moderate
  - Diffuse, intense enhancement is atypical
- Often restricts diffusion
  - ADC values range from ~ 0.5-1.3 x 10^{-3}/mm²
- ASL: Variable, but ↑ perfusion argues against benign low-flow vascular malformations

Nuclear Medicine Findings

- PET/CT
  - Hypermetabolic
    - May improve staging & posttreatment evaluation

Imaging Recommendations

- Best imaging tool
  - CT to evaluate osseous erosion
  - MR is best for soft tissue mass characterization
  - MR to evaluate perineural & intracranial spread of parameningeal RMS
    - Thickening & enhancement of nerves, leptomeninges
  - MR to distinguish between sinonasal tumor & obstructive/inflammatory disease
- Protocol advice
  - T2 FS or STIR MR: ↑ tumor conspicuity
  - Coronal T1 C+ FS MR: Detect intracranial extension
  - DWI MR: ADC values can help separate cellular tumor from benign vascular anomaly
  - Axial & coronal thin-section bone CT: Osseous erosion
  - Image neck: Rule out cervical metastatic adenopathy

DIFFERENTIAL DIAGNOSIS

Infantile Hemangioma

- Benign vascular neoplasm in infants, often with characteristic cutaneous involvement
- Intensely enhancing round or lobulated mass with high-flow vessels during proliferative phase
- ASL MR shows markedly ↑ perfusion
- ADC MR values typically range from ~ 1.3-1.6 x 10^{-3}/mm²
- No bone destruction
- Fatty infiltration during involuting phase

Slow-Flow Vascular Malformation

- May be well defined or extensive/infiltrative
- Fluid signal contents ± layering blood products, retracted clots, or phleboliths (in venous type)
- Venous type shows gradual patchy enhancement; lymphatic macrocystic type shows thin septal enhancement
- ADC values typically range from ~ 2.0-2.6 x 10^{-3}/mm²
- ASL MR will not show ↑ perfusion

Fibromatosis Colli

- Benign, self-limited, heterogeneous mass within & expanding midportion of sternocleidomastoid muscle in young infant with torticollis

Metastatic Neuroblastoma

- Most cervical disease is due to metastatic adenopathy rather than primary lesion
- Metastatic disease to skull/skull base is frequently bilateral: Enhancing masses surround aggressive osseous permeation/expansion with radiating spicules of new bone

Langerhans Cell Histiocytosis

- Enhancing soft tissue mass filling sharply marginated punched-out lytic bone lesion
- Temporal bone: Mastoid > petrous apex & middle ear

Juvenile Angiofibroma

- Highly vascular mass causing nasal obstruction &/or epistaxis in adolescent males
- Intensely enhancing lesion with bone destruction & internal high-flow vessels
- Originates at sphenopalatine foramen on lateral nasal wall
- Often involves nasal cavity, nasopharynx, skull base, masticator space ± orbit, sinus, intracranial extension

Nasopharyngeal Carcinoma

- Nasopharyngeal mass in 2nd decade of life
- Variable contrast enhancement
- Central skull base erosion, widening of petroclival fissure, extension to pterygopalatine fossa + masticator & parapharyngeal spaces
- Unilateral or bilateral cervical & lateral retropharyngeal adenopathy

Non-Hodgkin Lymphoma

- Non-Hodgkin lymphoma & Hodgkin lymphoma imaging findings are similar; difficult to differentiate
- Large, nonnecrotic nodes are typical
- Sinonasal, orbital, or nasopharyngeal NHL may cause osseous erosion

Plexiform Neurofibroma

- Benign peripheral nerve sheath tumor in neurofibromatosis type 1
- Lobulated masses with peripherally ↑ T2 signal & centrally ↓ T2 signal (target sign)
- Bone remodeling, typically without destruction

PATHOLOGY

General Features

- Etiology
  - Originates from primitive mesenchymal cells committed to skeletal muscle differentiation (rhabdomyoblasts)
- Genetics
  - ↑ incidence in children with *TP53* tumor suppressor gene mutation
  - Most embryonal RMS has loss of heterozygosity at 11p15 locus
  - Alveolar RMS: 50% have *FOX01* to *PAX3* (or *PAX7*) gene fusion
    - *PAX3-FKHR* gene fusion has better prognosis
- Associated abnormalities
  - ↑ incidence of embryonal RMS in Noonan syndrome
    - Hematologic malignancies & neuroblastoma are also seen
  - Rarely associated with neurofibromatosis type 1, Li-Fraumeni, & Beckwith-Wiedemann syndromes
  - Rarely associated with hereditary retinoblastoma
  - May occur as radiation-induced 2nd primary neoplasm

Staging, Grading, & Classification

- Soft Tissue Sarcoma Committee of Children's Oncology Group
  - Group I: Localized tumor completely resected
  - Group II: Gross total resection with microscopic residual
  - Group III: Incomplete resection with gross residual
  - Group IV: Distant metastases
- TNM: Tumor site, size, local invasion, lymph nodes, distant metastases

Microscopic Features

- 3 histologic subtypes
  - Embryonal RMS: Most common (> 50% of all RMS)
    - Occurs in younger children
    - 70-90% occur in head & neck or GU tract
    - Botryoid RMS: Gross appearance like cluster of grapes, typically in patients 2-5 years of age
      - 75% arise in vagina, prostate, or bladder
      - 25% in head/neck or bile ducts
  - Alveolar RMS: 2nd most common
    - Usually occurs in patients 15-25 years of age
    - Most common in extremities & trunk
  - Anaplastic RMS (also called pleomorphic): Least common
    - Usually in adults 40-60 years of age; rarely < 15 years
    - Most arise in extremities; rarely in head & neck

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Symptoms are variable, depend on location
    - Orbit: Mass, proptosis, ↓ vision
    - Sinonasal: Nasal obstruction, epistaxis; may present late with soft tissue facial mass
    - Temporal bone: Postauricular or external auditory canal mass, otitis media, CNVII palsy
    - Neck: Mass, pain, rarely airway compromise

Demographics

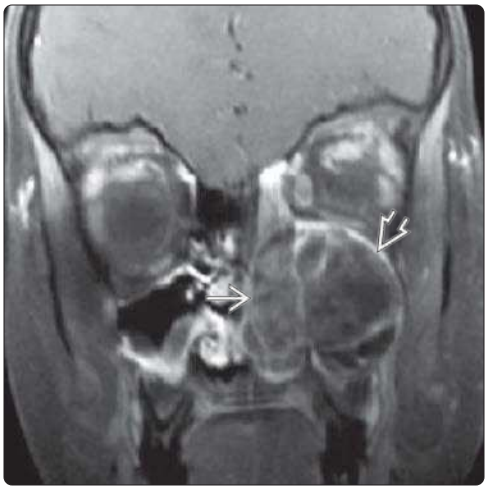
- Age
  - 70% < 12 years of age; 40% < 5 years of age
- Ethnicity
  - More common in White patients

Natural History & Prognosis

- Variable; depends on location & cell type
  - Orbit: Best prognosis (80-90% disease-free survival)
  - Parameningeal: Worst prognosis (40-50% disease-free survival)
  - Embryonal & pleomorphic: Better prognosis than alveolar RMS
    - Alveolar RMS without gene fusion: Prognosis is similar to embryonal RMS

Treatment

- Surgical debulking, chemotherapy, ± radiation therapy
- Research ongoing in proton therapy, immunotherapy, & vaccination
- Sentinel node biopsy may improve treatment stratification



DIAGNOSTIC CHECKLIST

Consider

- Not always associated with bone destruction
  - Beware of enhancing soft tissue mass without bone destruction; may simulate infantile hemangioma (IH)
    - IH is almost always found in 1st year of life; RMS is more common beyond 12 months
    - IH is typically soft/compressible while RMS is more likely firm
    - IH demonstrates high density of low-resistance arterial vessels on color Doppler
    - IH enhances more intensely & homogeneously
    - IH has higher ADC values on DWI MR

(Left) *Coronal T1 C+ FS MR shows a heterogeneously enhancing left nasal RMS with expansion of the left maxillary sinus. Some component of the disease in the left maxillary sinus could represent inflammation rather than tumor.* **(Right)** *Coronal STIR MR in the same patient better differentiates the tumor filling the expanded left maxillary sinus & nasal cavity from hyperintense, inflammatory mucosal disease in the left ethmoid & right maxillary sinuses.*

(Left) *Axial T1 C+ FS MR demonstrates a moderately enhancing RMS destroying the right petrous apex & otic capsule bone adjacent to the cochlea & extending along margins of the internal carotid artery into the clivus.* **(Right)** *Axial T2 MR in a 5-year-old with left proptosis & palpable cervical adenopathy demonstrates a mixed-intensity alveolar RMS as compared to the hyperintense sphenoid sinus inflammatory disease & incidental middle cranial fossa arachnoid cyst.*

(Left) *Axial T2 MR in a 21-year-old with an embryonal RMS shows anterior bowing of the left maxillary sinus posterior wall by a heterogeneous, mildly hypointense left infratemporal fossa mass, consistent with a highly cellular RMS. Although it is relatively hypointense without FS, it is hyperintense relative to skeletal muscle, typical of RMS.* **(Right)** *Coronal T1 C+ FS MR shows an extensive left skull base RMS with left middle cranial fossa extension (displacing the left temporal lobe) & invasion of the left cavernous sinus.*

Fibromatosis Colli

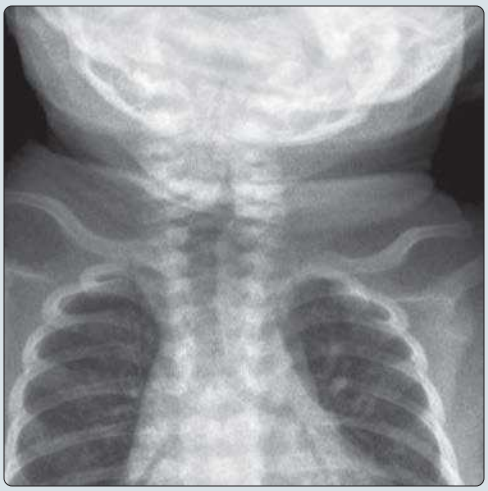
KEY FACTS

TERMINOLOGY

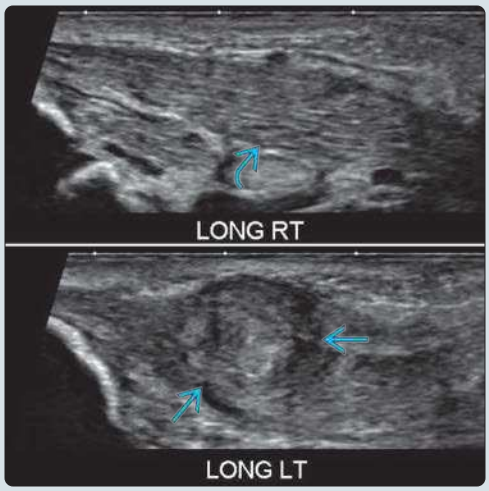
- Benign fibrosis of sternocleidomastoid (SCM) muscle
- Most common cervical "mass" of infancy
- Postulated to be due to birth trauma, peripartum injury, in utero compartment syndrome, or maldevelopment

IMAGING

- Often diagnosed clinically without imaging
- Ultrasound is modality of choice if imaging is required
- Process is entirely intramuscular (contained within SCM) without local invasion or inflammatory changes
- Fusiform expansion of central SCM muscle
  - Thick & short compared to contralateral SCM
- Variable heterogeneity of lesion
  - Ranges from nearly homogeneous to markedly heterogeneous on ultrasound/CECT/MR
- Variable internal vascularity within/about mass
- No associated adenopathy, Ca^{2+}, extramuscular edema, intrasubstance hemorrhage, or fluid collection
- Fascial planes around SCM are preserved

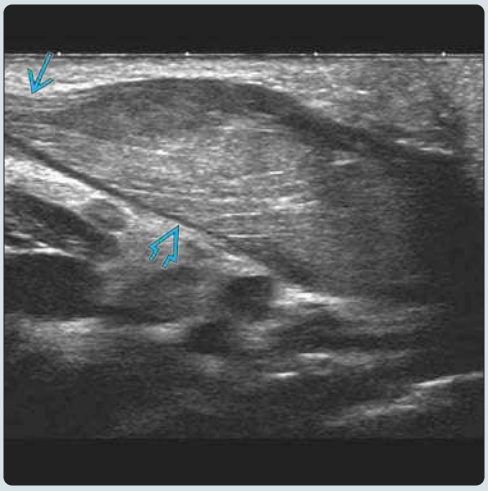


TOP DIFFERENTIAL DIAGNOSES

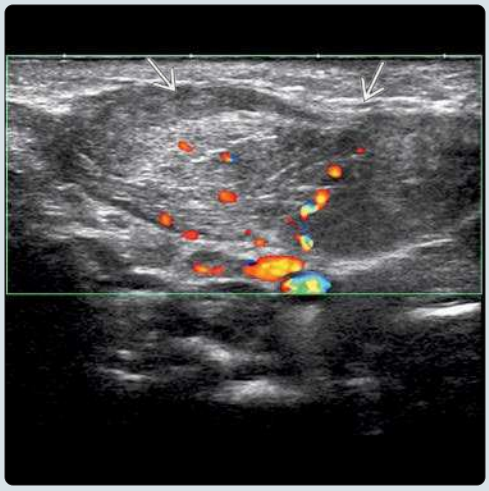


- Cervical lymphadenopathy
- Infantile hemangioma
- Cervical teratoma
- Congenital neuroblastoma
- Rhabdomyosarcoma
- Branchial cleft anomalies
- Lymphatic malformation
- Cervical extension of mediastinal thymus
- Spinal fusion anomalies

CLINICAL ISSUES



- Painless, palpable mass with torticollis
- Contralateral occipital flattening (plagiocephaly) is common
- Peak presentation at 24 days old
- Self-limited, usually resolves completely by 6 months of age with conservative treatment/physical therapy



(Left) *AP radiograph of the neck shows mild torticollis with the left ear closer to the left shoulder & the chin slightly turned away. No bony anomalies are seen to explain this neck positioning in this infant with fibromatosis colli. Mild buckling of the trachea at the thoracic inlet is normal in young infants.* **(Right)** *Split-screen longitudinal US images in a 24-day-old boy with torticollis show a focally enlarged left sternocleidomastoid (SCM) muscle ⇨ compared to the right ⇨, typical of fibromatosis colli.*

(Left) *Orienting the US transducer along the long axis of the SCM optimally shows the mildly heterogeneous enlargement/expansion of the muscle belly with normal SCM proximal tapering ⇨ & sharp, distinct borders ⇨ with adjacent tissues.* **(Right)** *Longitudinal US with color Doppler shows that the enlarged SCM muscle has mildly ↑ blood flow ➡ & slightly ↑ heterogeneous echotexture centrally.*

TERMINOLOGY

Synonyms

- Sternocleidomastoid (SCM) pseudotumor, SCM tumor of infancy, congenital muscular torticollis, neonatal torticollis, pseudotumor of infancy

Definitions

- Most common cervical "mass" of infancy
- Benign fibrosis of SCM muscle
- Postulated to be due to birth trauma, peripartum injury, in utero compartment syndrome, or maldevelopment
- Torticollis ("wryneck"): Persistent twisting of neck such that ear on affected side is positioned lower & more midline than normal
  - When bony causes of torticollis have been excluded, consider fibrosis of SCM muscle

IMAGING

General Features

- Best diagnostic clue
  - Focal thickening & fibrosis of sternal or clavicular head of SCM muscle
  - Process is entirely intramuscular without local invasion or inflammatory changes
- Location
  - Middle or lower 1/3 of SCM muscle belly
  - Sternal & clavicular muscle bundles are affected equally often
  - Unilateral: Equal frequency of right vs. left
- Size
  - 1-3 cm in length
  - May ↑ in size in first 2-3 months of life
- Morphology
  - Focal, heterogeneous to homogeneous expansion of SCM muscle, distorting normal muscle architecture
  - SCM tapers to normal thickness proximal & distal to lesion
  - Affected SCM is mildly shorter than contralateral side
  - No extramuscular extension, surrounding inflammatory changes, or adenopathy

Radiographic Findings

- Cervical spine radiographs may be obtained to exclude bony abnormality, causing torticollis
  - Hemivertebrae or omovertebral bones: Congenital bony anomalies not related to fibromatosis colli
- May see nonspecific, unilateral soft tissue fullness or "mass"
- Virtually never calcifies
  - If Ca^{2+} is seen, consider neuroblastoma & teratoma

Ultrasonographic Findings

- Grayscale ultrasound
  - Focal mass mildly or moderately expanding SCM muscle belly
  - Loss of normal muscle architecture
  - Variable echogenicity of mass; may be homogeneous or heterogeneous
  - Affected SCM is shorter & thicker than contralateral side
    - Comparison with asymptomatic side is useful
    - Extended field-of-view imaging is useful to show entire length of SCM
  - Fascial planes surrounding SCM are preserved
  - No associated adenopathy, Ca^{2+}, extramuscular edema, intrasubstance hemorrhage, or fluid collection
  - Lack of extramuscular involvement excludes other differential diagnoses
- Color Doppler
  - Variable hyperemia in acute phase
  - May see diminished blood flow in quiescent/fibrotic phase

CT Findings

- Focal thickening/expansion of unilateral SCM muscle
  - Variable enhancement & heterogeneity
- No associated adenopathy or regional inflammatory changes

MR Findings

- T1WI
  - Fusiform enlargement of affected SCM
  - Variable signal intensity
    - Usually isointense to hypointense compared to normal muscle
- T2WI FS/STIR
  - Heterogeneous intramuscular mass; affected SCM is overall hyperintense to other muscles
    - Hypointense zones are probably due to evolving fibrosis
- T1WI C+ FS
  - Affected muscle enhances heterogeneously

Imaging Recommendations

- Best imaging tool
  - Often diagnosed clinically without imaging
  - Ultrasound is modality of choice if imaging is required
    - No ionizing radiation or sedation
    - Clearly localizes mass within SCM muscle
  - MR is reserved for atypical cases
    - Best for determining extent of alternate malignant diagnoses
      - Intracranial extension (in rhabdomyosarcoma)
      - Intraspinal extension (in neuroblastoma)
  - CT is best modality for showing cortical bony abnormalities of alternate diagnoses
    - Erosion, destruction, remodeling, vertebral segmentation anomalies, or congenital scoliosis
- Protocol advice
  - Regardless of imaging modality, none of these findings should be seen with fibromatosis colli
    - Involvement of tissues outside SCM muscle
    - Ca^{2+} or cystic change
    - Lymphadenopathy
    - Airway compression
    - Vascular encasement
    - Bone involvement
    - Intracranial/intraspinal extension
    - Other neck masses

DIFFERENTIAL DIAGNOSIS

Cervical Lymphadenopathy

- Nodes are typically discrete & easily recognizable but may appear mass-like when enlarged & confluent
- Adenopathy is more likely to have lobulated contour than smooth, spindle shape of SCM

Infantile Hemangioma

- Rapidly growing, benign, vascular neoplasm presenting as soft mass weeks to months after birth, ultimately regressing over years
- Characteristic Doppler ultrasound appearance: > 5 vessels/cm², shows numerous low-resistance arterial waveforms

Cervical Teratoma

- Congenital mixed solid & cystic mass, often large
- Typically contains Ca^{2+}
- May present with airway or feeding difficulties

Congenital Neuroblastoma

- Arises from paraspinal sympathetic ganglia outside SCM
- May displace &/or encase vessels
- Look for Ca^{2+}, intraspinal extension, & bony erosion

Rhabdomyosarcoma

- Solid mass outside SCM, typically in older children
- Variable enhancement & vascularity

Branchial Cleft Anomalies

- Unilocular cyst adjacent to SCM

Lymphatic Malformation

- Compressible multicystic congenital mass, often with deep infiltration & extension across midline

Cervical Extension of Mediastinal Thymus

- Look for contiguity with mediastinal thymic tissue
- Characteristic dot & dash appearance on ultrasound

Spinal Fusion Anomalies

- Torticollis with cervical scoliosis due to hemivertebra, fused vertebra, bony bar, omovertebral body, etc.

PATHOLOGY

General Features

- Etiology
  - Uncertain: Probably response to perinatal injury, partial muscle tear, or intramuscular hematoma

Gross Pathologic & Surgical Features

- Seldom resected
- Fine-needle aspirates are more common than excisional specimens
- Firm, spindle-shaped thickening of muscle without transmuscular inflammation

Microscopic Features

- Bland-appearing fibroblasts & degenerative, atrophic skeletal muscle in clean background
- Collagen is always present
- Occasional giant cells & parallel clusters of fibroblasts

CLINICAL ISSUES

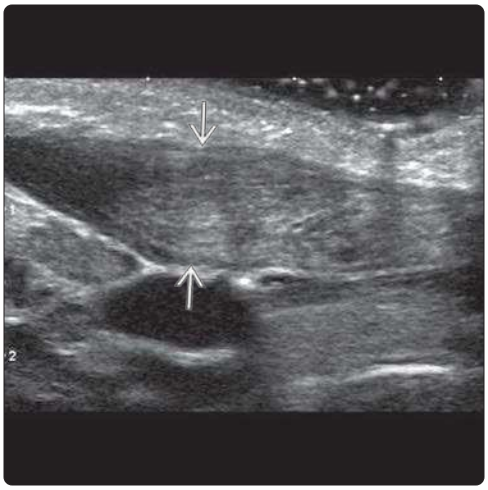
Presentation

- Most common signs/symptoms
  - Painless, palpable mass with torticollis
  - Contralateral occipital flattening (plagiocephaly) is common
  - History of breech presentation &/or "difficult" vaginal birth is common but not mandatory
- Other signs/symptoms
  - If severe or persistent, may result in limited range of motion at neck &/or facial asymmetry

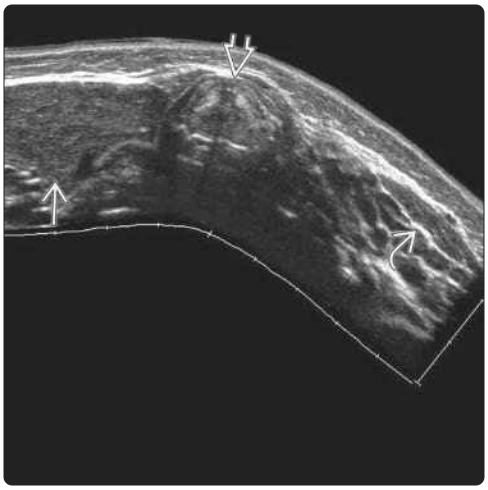
Demographics

- Age
  - Newborn infants
  - Peak presentation at 24 days old
  - Classically noticed < 8 weeks of age but may worsen in first 2-3 months of life
- Sex
  - Males affected slightly more often than females
- Epidemiology
  - Occurs with 0.4% of live births
  - Associated with breech presentation & birth dystocia

Natural History & Prognosis



- Self-limited, usually resolves completely by 6 months of age
- Occasional cases recur or flare during periods of rapid somatic growth



Treatment

- Physical therapy to encourage full range of motion → "stretch" SCM
- 90% have full recovery with conservative treatment &/or physiotherapy
- Surgery is only indicated in unusual cases when craniofacial asymmetry or refractory torticollis persists after 1 year

(Left) *Longitudinal US in a 1-month-old infant shows ↑ size & echotexture of the SCM ⇨, consistent with fibromatosis colli. Note that the fat & facial planes around the muscle are preserved.* **(Right)** *Transverse extended field-of-view US across the neck in an infant with torticollis illustrates the enlargement of the right SCM ⇨ as compared to the left ⇨. The trachea is seen in the midline at the level of the vocal cords ⇨.*

(Left) *Longitudinal US in a 28-day-old girl shows focal enlargement of both the sternal & clavicular bundles ⇨ of the SCM in this patient with fibromatosis colli. Note the normal proximal & distal tapering of the muscle ⇨.* **(Right)** *Longitudinal color Doppler US in the same patient shows normal to minimally ↑ blood flow ⇨ in affected portions of the muscle.*

(Left) *Coronal STIR MR in an infant with obvious torticollis shows heterogeneously ↑ signal intensity & thickness of the left SCM ⇨, consistent with fibromatosis colli. Note the normal right SCM ⇨.* **(Right)** *Coronal CECT in an infant with facial anomalies shows homogeneous thickening of the right SCM ⇨, which lies just superficial to the jugular & carotid vessels. Fibromatosis colli can appear much more heterogeneous than this.*

Suppurative Adenitis

KEY FACTS

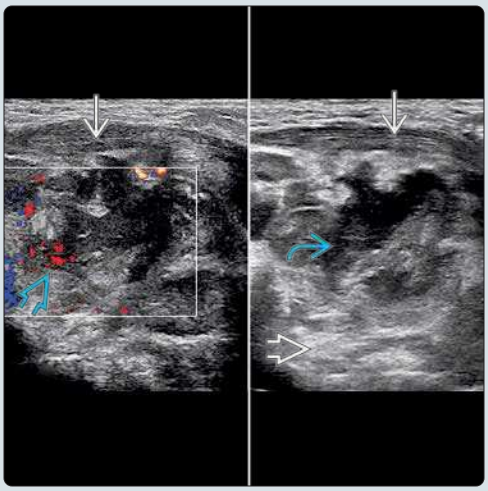
TERMINOLOGY

- Pus formation within nodes from bacterial infection
- Synonyms: Adenitis, lymphadenitis, intranodal abscess

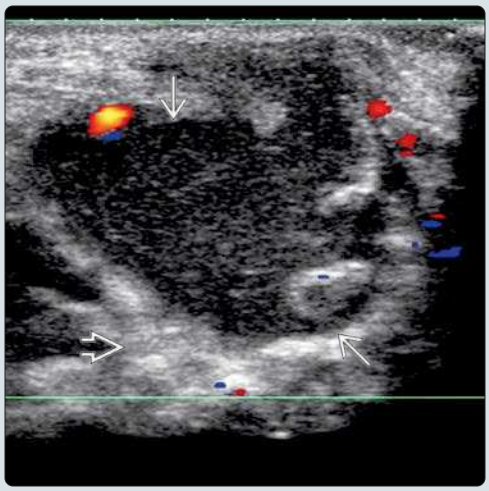
IMAGING

- Enlarged node(s) with internal fluid & surrounding inflammation (cellulitis)
  - Most often jugulodigastric, submandibular, or retropharyngeal
- Loss of normal nodal architecture & internal vascularity/enhancement
- Conglomeration of necrotic nodes progressing to abscess shows marked heterogeneity of irregular collection
  - Well-defined, enhancing/hyperemic wall
  - Complex hypoechoic/nonenhancing center
- US is useful to confirm true liquefaction with drainable pus
  - Swirling internal debris upon compression
- CECT best defines deep extent & complications
  - Lemierre syndrome (venous thrombophlebitis), internal carotid artery spasm or pseudoaneurysm, airway compression, mediastinal extension

TOP DIFFERENTIAL DIAGNOSES



- Nontuberculous *Mycobacterium* adenopathy
- Tuberculous adenopathy
- 2nd branchial cleft anomaly
- Rhabdomyosarcoma
- Lymphoma
- Lymphatic malformation
- Fibromatosis colli



PATHOLOGY

- *Staphylococcus* & *Streptococcus*: Most frequent organisms

DIAGNOSTIC CHECKLIST

- Look for primary infectious source on images
  - Pharyngitis, dental infection, salivary gland calculi

(Left) *Transverse (left) & long (right) Doppler & grayscale US images of an infant with suppurative adenitis show a heterogeneous conglomeration of level II nodes with internal debris, posterior acoustic enhancement, & peripheral hyperemia.* **(Right)** *Transverse Doppler US in a 6-year-old with fever & a tender neck mass shows an irregular hypoechoic abscess with posterior acoustic enhancement & no internal vascularity. Swirling of debris upon compression can help confirm drainability.*

(Left) *Coronal CECT in a 6-year-old with fever & a fluctuant neck mass shows an irregular, rim-enhancing abscess with overlying myositis/cellulitis & an adjacent nonsuppurative lymph node.* **(Right)** *More inferior axial CECT in the same child shows a round focus of nonenhancement, representing a segmental clot in the right internal jugular vein, consistent with Lemierre syndrome. Note the R > L nonsuppurative nodes as well as the overlying myositis/cellulitis.*

TERMINOLOGY

Synonyms

- Adenitis, acute lymphadenitis, intranodal abscess

Definitions

- Pus formation within nodes from bacterial infection

IMAGING

General Features

- Best diagnostic clue
  - Enlarged node(s) with internal fluid & surrounding inflammation (cellulitis)
- Location
  - Any nodal groups of head/neck
    - Most often: Jugulodigastric, submandibular, retropharyngeal
  - May be unilateral or bilateral
- Size
  - Enlarged single node or conglomeration of nodes
    - Often in 1- to 4-cm range
- Morphology
  - Ovoid to round, large node with central necrosis
  - Margins are often poorly defined
  - Additional adjacent solid or suppurative nodes are typically present

Ultrasonographic Findings

- Early adenitis may show enlarged ovoid foci with retained nodal architecture & hyperemia
- Loss of architecture & internal vascularity occurs with necrosis
  - Central ↓ echogenicity with ↑ through transmission
- Conglomeration of necrotic nodes progressing to abscess shows marked heterogeneity of irregular collection
  - Liquefied pus: Swirling internal debris with compression
  - ↑ peripheral vascularity
    - Very low-resistance & pulsatility indices

CT Findings

- CECT
  - Enhancing nodal wall with central hypoattenuation/lack of enhancement
  - Stranding/edema of surrounding tissues = cellulitis
  - With progression to abscess → irregular, ill-defined, peripherally enhancing, low-attenuation collection
    - Caveat: Well-defined, low-attenuation collection with rim enhancement is not necessarily pathognomonic for drainable pus → consider US
      - Represents nondrainable phlegmon in ~ 20%
  - ± myositis, Lemierre syndrome (venous thrombophlebitis), deviation of carotid sheath vessels, internal carotid artery spasm or pseudoaneurysm, retropharyngeal soft tissue edema, mass effect on airway, mediastinal extension

MR Findings

- T1WI
  - Node with central low signal intensity
  - Dampening of normal high signal intensity of surrounding fat
- STIR/T2WI FS
  - Node with diffuse or central high signal intensity
  - Edema of surrounding soft tissues
- DWI
  - Complimentary to routine pulse sequences
  - Suppurative, necrotic nodes have reduced diffusivity (bright DWI, dark ADC signal)
    - May show higher DWI & lower ADC signal relative to metastatic necrotic nodes
      - Optimal ADC thresholds remain undefined
- T1WI C+ FS
  - Marked peripheral enhancement with poorly defined margin
  - Absent central enhancement

Nuclear Medicine Findings

- PET
  - Nonspecific ↑ FDG uptake
  - Abscess shows central ↓ FDG uptake

Imaging Recommendations

- Best imaging tool
  - Ultrasound to determine phlegmon vs. abscess & guide aspiration
    - May be difficult to determine deep relationships
  - CECT is best for deep neck infections
    - Determines epicenter & total extent for aspiration or surgical planning

DIFFERENTIAL DIAGNOSIS

Nontuberculous *Mycobacterium* Adenopathy

- Asymmetric, enlarged nodes with adjacent necrotic, ring-enhancing masses
- Minimal or absent subcutaneous fat stranding
- Purified protein derivative (PPD) skin test is weakly reactive in ~ 55%
- Usually ≤ 5 years of age

Tuberculous Adenopathy

- Painless low jugular & posterior cervical low-density nodes
- Ca^{2+} may be present
- Strongly reactive PPD skin test, positive interferon gamma release assay
- Systemically unwell if active pulmonary infection

2nd Branchial Cleft Anomaly

- Solitary unilocular cyst, posterior to submandibular gland
  - Anterior to sternocleidomastoid (SCM), posterolateral to carotid sheath
- Mimics suppurative node, particularly if inflamed

Rhabdomyosarcoma

- Solid, firm soft tissue neoplasm of children (typically beyond infancy) occurring in many head/neck locations
- Typically lacks surrounding edema
- ± bone destruction

Lymphoma

- Multifocal, solid, enhancing nodes, often of bilateral neck & chest
- ± enlargement of tonsillar tissue

Lymphatic Malformation

- Congenital, multicystic mass with thin rim & septations
- Variable internal echogenicity due to internal hemorrhage
- No significant internal vascularity
- Often infiltrative & transspatial, may be bilateral

Fibromatosis Colli

- Self-limited, benign reactive mass within SCM muscle of young infants, likely due to birth trauma
  - Usually appears within 2 weeks of delivery, regresses by 8 months
  - Associated torticollis in up to 30%
- Expands SCM focally or diffusely
- Ranges from homogeneous to very heterogeneous on ultrasound, CECT, & MR
  - Heterogeneous contrast enhancement is common
  - SCM muscle may be edematous surrounding mass, but further soft tissue edema is not typical
  - No adenopathy

PATHOLOGY

General Features

- Etiology
  - Primary head/neck infection: Pharyngitis, salivary gland ductal calculus, dental decay ± mandibular osteomyelitis
    - Adjacent lymph nodes enlarge 2° to pathogen: Reactive nodes
    - Intranodal exudate forms, containing protein-rich fluid with dead neutrophils (pus): Suppurative nodes
    - If untreated or incorrectly treated, suppurative nodes rupture → interstitial pus walled-off by immune system → extranodal abscess in soft tissues
  - Reactive nodes from viral pathogen may have 2° bacterial superinfection, creating suppurative nodes

Microscopic Features

- Acute inflammatory cell infiltrate in necrotic background
  - Presence of neutrophils & macrophages
  - Negative staining for acid-fast bacilli
- *Staphylococcus* & *Streptococcus* are most frequent organisms
  - ↑ incidence of MRSA
- Pediatric infections show clustering of organisms by age
  - Infants < 1 year: *Staphylococcus aureus*, group B *Streptococcus*
  - Children 1-4 years: *S. aureus,* group A β-hemolytic *Streptococcus*, atypical mycobacteria
  - 5-15 years: Anaerobic bacteria, toxoplasmosis, cat-scratch disease, tuberculosis
- Dental infections: Typically polymicrobial, predominantly anaerobic

CLINICAL ISSUES

Presentation

- Most common signs/symptoms
  - Painful neck mass
    - Overlying skin is often warm, erythematous
  - Fever, poor oral intake
  - Elevated WBC & ESR
- Other signs/symptoms
  - Symptoms referable to primary source of infection
    - Pharyngeal/laryngeal infection: Drooling, respiratory distress
    - Peritonsillar infection: Trismus
    - Retropharyngeal or paravertebral infection: Neck stiffness, torticollis
- Clinical profile
  - Young patient presents with acute/subacute onset of tender neck mass & fever
- Clinical predictors of drainable suppurative adenitis in children
  - Absence of pharyngitis, WBC > 15,000/mm³, age ≤ 3 years, anterior cervical chain, largest palpable diameter > 3 cm, prior antibiotic treatment ≥ 24 hours

Demographics

- Age
  - Most commonly seen in pediatric & young adult population
  - Odontogenic neck infections: Adults > > children

Natural History & Prognosis

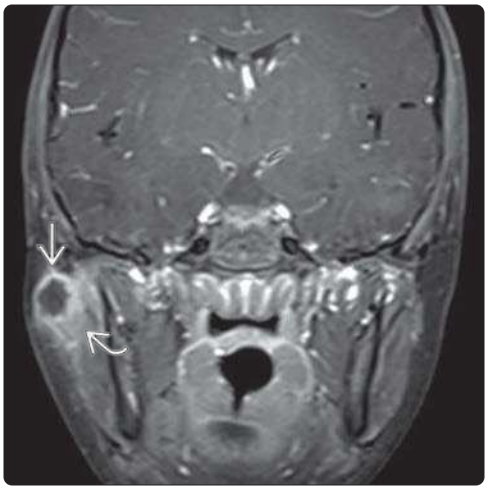
- Conglomeration of suppurative nodes or rupture of node → abscess formation
  - Superficial neck abscesses: Anterior or posterior cervical space, submandibular space
  - Deep neck abscesses: Retropharyngeal or parapharyngeal space
    - Deep space abscesses can rapidly progress with airway compromise

Treatment

- Small suppurative nodes & primary infection → antibiotics
- Large suppurative nodes, abscesses, or poor response to antibiotics → incision & drainage
  - CT & US-guided aspiration for minimally invasive management
- Nodes from atypical mycobacteria → excision to prevent recurrence or fistula/sinus tract

DIAGNOSTIC CHECKLIST

Consider



- Nontuberculous mycobacterial adenitis if no significant inflammatory changes

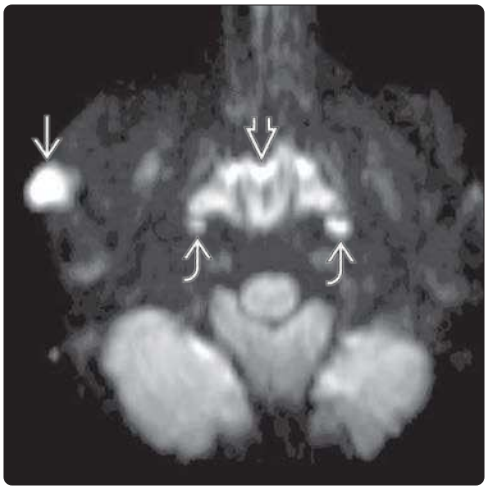


Image Interpretation Pearls

- Look for primary infectious source on images
  - Pharyngitis, dental infection, salivary gland calculi
- Evaluate airway for compromise with any neck infection
  - More problematic in deep infections
- Evaluate vascular structures for thrombophlebitis

  - pulmonary sling vs., **40**
- interrupted
  - aortic coarctation vs., **275**
  - hypoplastic left heart syndrome vs., **266**
- left, with aberrant left subclavian artery vs., **45**
- right, with mirror image branching, right arch with aberrant left subclavian artery vs., **45**

Aortic atresia. *See* Hypoplastic left heart syndrome.
Aortic coarctation, **274–277**
- aortic stenosis vs., **279**
- diagnostic checklist, **276**
- differential diagnosis, **275–276**
- genetics, **276**
- prognosis, **276**

INDEX

Aortic injury, **166–169**
- diagnostic checklist, **168**
- differential diagnosis, **167**
- prognosis, **168**
- staging, grading, & classification, **168**

Aortic stenosis, **278–281**. *See also* Hypoplastic left heart syndrome.
- associated abnormalities, **279–280**
- differential diagnosis, **279**
- genetics, **279**
- prognosis, **280**
- staging, grading, & classification, **280**

Aortic valvar stenosis. *See* Aortic stenosis.
Aortic valvular stenosis. *See* Aortic stenosis.
Aortopulmonary window, truncus arteriosus vs., **257**
Aphonia, congenital high airway obstruction syndrome, **16**
Apical petrositis, acute otomastoiditis with abscess vs., **1213**
Apicolateral bulge, arrhythmogenic right ventricular dysplasia vs., **312**
Apophyseal injuries, **798–801**
- diagnostic checklist, **799–800**
- differential diagnosis, **799–800**
- prognosis, **800**

Apophysis, **773**
Apophysitis. *See* Apophyseal injuries.
Appendage testis, torsion of, epididymoorchitis vs., **739**
Appendagitis, epiploic, omental infarction vs., **499**
Appendiceal torsion. *See* Testicular appendage, torsion of.
Appendicitis, **418–421**
- Crohn disease vs., **542**
- cystic fibrosis, **565**
- diagnostic checklist, **420**
- differential diagnosis, **420**
- ileocolic intussusception vs., **423**
- Meckel diverticulum vs., **428**
- MIS-C vs., **122**
- neutropenic colitis vs., **531**
- omental infarction vs., **499**
- ovarian torsion vs., **733**
- perforated
  - with appendicolith, ovarian teratoma vs., **725**
  - hydrometrocolpos vs., **713**
- primary mesenteric adenitis vs., **495**
- prognosis, **420**
- ruptured, small bowel intussusception vs., **559**

Appendicolith, perforated appendicitis with, ovarian teratoma vs., **725**
Appendicular skeleton
- osteopetrosis, **981**
- rickets, **985**

Aqueductal stenosis, **1046–1047**
- associated abnormalities, **1047**
- diagnostic checklist, **1047**
- differential diagnosis, **1047**
- genetics, **1047**
- holoprosencephalies vs., **1027**
- prognosis, **1047**

Arachnoid cyst, **1060–1061**. *See also* Cavum veli interpositi.
- colloid cyst vs., **1059**
- dermoid/epidermoid cysts vs., **1063**
- diagnostic checklist, **1061**
- differential diagnosis, **1061**
- neurenteric cyst vs., **1153**
- pineal cyst vs., **1064**
- posterior fossa, Dandy-Walker continuum vs., **1019–1020**

Arachnoid granulation, cerebral venous sinus thrombosis vs., **1109**
Arch, right, with aberrant left subclavian artery, **44–45**
- diagnostic checklist, **44**
- differential diagnosis, **45**
- double aortic arch vs., **35**
- prognosis, **45**
- pulmonary sling vs., **39**

Architectural distortion, widespread, alveolar growth abnormality vs., **179**
Arcuate uterus, müllerian duct anomalies, **717**
Arrhythmias, severe, hypoplastic left heart syndrome vs., **266**
Arrhythmogenic right ventricular dysplasia, **310–313**
- diagnostic checklist, **312**
- differential diagnosis, **311–312**
- Ebstein anomaly vs., **247**
- genetics, **312**
- prognosis, **312**

ARS. *See* Acute rhinosinusitis.
Arterial aneurysm, arteriovenous malformation vs., **1115**
Arterial feeders, **1115**
Arterial infundibulum, childhood aneurysms vs., **1111**
Arterial ischemic stroke, hypoxic-ischemic encephalopathy vs., **1103**
Arterial spin labeling (ASL), **1007**
Arterial stroke, causes of, **1105**
Arterial switch procedure, **292–293**
- differential diagnosis, **293**

Arterial tortuosity syndrome, pulmonary sling vs., **40**
Arteriopathy, moyamoya, **1107**
Arterioportal fistula, hepatic hemangiomas, infantile and congenital vs., **440**
Arteriovenous fistula
- arteriovenous malformation vs., **1115**
- childhood dural, vein of Galen aneurysmal malformation vs., **1113**
- musculoskeletal arteriovenous malformation vs., **901**

Arteriovenous malformation
- brain, **1114–1115**
  - associated abnormalities, **1115**
  - differential diagnosis, **1115**
  - staging, grading, & classification, **1115**
- infantile hemangioma
  - cervicofacial vs., **1232**
  - musculoskeletal vs., **888**
- lymphatic malformation, musculoskeletal vs., **897**
- musculoskeletal, **900–901**
  - differential diagnosis, **901**
  - prognosis, **901**
- pulmonary, **156–157**
  - associated abnormalities, **157**
  - differential diagnosis, **157**
  - prognosis, **157**

INDEX

- venous malformation, musculoskeletal vs., **893**

- atrioventricular septal defect vs., **232**
- differential diagnosis, **224**
- genetics, **224**
- large, Ebstein anomaly vs., **247**

Atrioventricular septal defect, **230–233**
- associated abnormalities, **232**
- differential diagnosis, **232**
- genetics, **232**
- prognosis, **232**
- ventricular septal defect vs., **227**

Attenuation, of corpus callosum, callosal anomalies vs., **1029**

Atypical teratoid/rhabdoid tumor, **1070–1071**
- choroid plexus tumors vs., **1089**
- desmoplastic infantile tumors vs., **1082**
- diagnostic checklist, **1071**
- differential diagnosis, **1071**
- embryonal tumor with multilayered rosettes vs., **1083**
- genetics, **1071**
- glioblastoma vs., **1075**
- medulloblastoma vs., **1069**
- posterior fossa ependymoma vs., **1073**
- staging, grading, & classification, **1071**
- supratentorial ependymoma vs., **1074**

Autoimmune disorders, hemophagocytic lymphohistiocytosis vs., **569**

Autoimmune hepatitis, cirrhosis, **461**

Autoimmune inflammation, brainstem tumors vs., **1078**

Autoimmune-mediated vasculitis, demyelinating diseases vs., **1133**

Autoinflammatory disorders, chronic recurrent multifocal osteomyelitis, **884**

Autosomal dominant dysplastic kidney disease, autosomal recessive polycystic kidney disease vs., **636**

Autosomal dominant polycystic kidney disease (ADPKD), **580**. *See also* Polycystic kidney disease, autosomal dominant.

Autosomal recessive disorder, congenital adrenal hyperplasia, **700**

Autosomal recessive multisystem disorder, **203**

Autosomal recessive polycystic kidney disease (ARPKD), **580**
- autosomal recessive polycystic kidney disease vs., **639**
- renal vein thrombosis vs., **679**

Avascular necrosis, normal developmental variants confused with disease vs., **773**

AVSD. *See* Atrioventricular septal defect.

Avulsion fracture. *See* Apophyseal injuries; Medial epicondyle avulsion.

Avulsive cortical irregularity or tug lesion. *See* Distal femoral avulsive irregularity.

Axial mesodermal dysplasia spectrum. *See* VACTERL association.

Axial skeleton
- osteopetrosis, **981**
- rickets, **985**

B

Bacterial infection, hemophagocytic lymphohistiocytosis vs., **569**

Bacterial osteomyelitis, syphilis vs., **869**

Bacterial pneumonia
- fungal pneumonia in immunocompromised children vs., **135**
- recurrent, chronic granulomatous disease vs., **536**
- sickle cell disease, acute chest syndrome vs., **209**
- viral chest infection vs., **117–118**

Bacterial tracheitis, **26–29**
- croup vs., **23**
- diagnostic checklist, **28**
- differential diagnosis, **27**
- epiglottitis vs., **19–20**
- prognosis, **28**

"Ball-&-socket" ankle joint, **997**

Balloon cells, focal cortical dysplasia, **1041**

Bartter syndrome, transient neonatal renal medullary hyperechogenicity vs., **677**

Battered child syndrome. *See* Child abuse.

Beam-hardening artifact, splenic trauma vs., **513**

Beckwith-Wiedemann syndrome
- adrenocortical carcinoma, **709**
- congenital adrenal hyperplasia vs., **700**
- genitourinary rhabdomyosarcoma, **692**
- neuroblastoma, **704**
- omphalocele, **410**
- pancreatoblastoma, **481**
- Wilms tumor, **642**

Behçet disease, abdominal aneurysms, **577**

Benign cortical irregularity of distal femur. *See* Distal femoral avulsive irregularity.

Benign fibrous tumors, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**

Benign lymphoepithelial lesions of HIV, acute parotitis vs., **1229**

Benign macrocrania of infancy, abusive head trauma vs., **1094**

Benign mixed glial-neuronal neoplasm, **1080**

Benign pneumatosis, in older children
- necrotizing enterocolitis vs., **385–386**
- neutropenic colitis vs., **531**
- pseudomembranous colitis vs., **529**

Benign rheumatoid nodule. *See* Granuloma annulare.

Benign soft tissue tumors, soft tissue foreign bodies vs., **829**

Bezoars, **550–553**
- diagnostic checklist, **552**
- differential diagnosis, **551**
- prognosis, **552**

Bicêtre neonatal evaluation score, **1113**

Bicornuate/didelphys uterus
- anorectal malformations, **378**
- müllerian duct anomalies, **717**

Bicuspid aortic valve, aortic coarctation, **276**

Bifid pelvis. *See* Ureteropelvic duplications.

INDEX

Bilateral agenesis, renal agenesis, **629**
Bilateral facial microsomia, Treacher Collins syndrome vs., **1218**
Bilateral multicystic dysplastic kidney, autosomal recessive polycystic kidney disease vs., **635**
Bilateral renal enlargement, autosomal recessive polycystic kidney disease vs., **639**
Bile-plug syndrome, biliary atresia vs., **450**

Bladder exstrophy, **622–623**
- cloacal exstrophy/OEIS vs., **416**
- differential diagnosis, **623**
- omphalocele vs., **409**
- prognosis, **623**

Bladder hematoma, genitourinary myosarcoma vs., **691**
Bladder Hutch diverticulum, ureterocele vs., **604**
Bladder mass, ureterocele vs., **604**
Blalock-Taussig shunt, **296–297**
- differential diagnosis, **297**
- modified, Sano shunt, **301**

Blastoma, pleuropulmonary
- bronchopulmonary sequestration vs., **68**
- congenital pulmonary airway malformation vs., **63**
- pulmonary interstitial emphysema vs., **99**

Bleeding disorders, abusive head trauma vs., **1094**
Blood flow to lung, anomalous systemic, bronchopulmonary sequestration vs., **67**
Bloom syndrome, Wilms tumor, **642**
Blue rubber bleb nevus syndrome, Sturge-Weber syndrome vs., **1055**
Blunt injury to spleen. *See* Splenic trauma.
Blunt trauma, **522**
Bolande tumor. *See* Nephroma, mesoblastic.
Bone, stress injury of, apophyseal injuries vs., **800**
Bone bowing, diseases that cause, osteogenesis imperfecta vs., **977**
Bone contusions, **851**
Bone cyst
- aneurysmal
  - nonossifying fibroma vs., **941–942**
  - osteosarcoma vs., **930**
- unicameral, nonossifying fibroma vs., **942**

Bone disease
- chylothorax, **105**
- metabolic, forearm fractures vs., **845**

Bone dysplasias, osteogenesis imperfecta vs., **977**
Bone infarction
- osteomyelitis vs., **863**
- osteosarcoma vs., **930**

Bone malignancy, stress injuries vs., **813**
Bone metastases, distal femoral avulsive irregularity vs., **779**
Bone sarcoma, palpable normal variants of chest wall vs., **61**
Bone scan, orthopedic hardware and complications, **825**
Bone tumor
- septic arthritis vs., **871**
- transient synovitis vs., **873**

Botryoid tumor. *See* Rhabdomyosarcoma, genitourinary.
Bourneville syndrome. *See* Tuberous sclerosis.
Bowel-containing inguinal hernia, ectopic ovary vs., **737**
Bowel injury, **504–507**
- associated abnormalities, **506**
- diagnostic checklist, **506**
- differential diagnosis, **505–506**
- prognosis, **506**
- staging, grading, & classification, **506**

Bowel ischemia, due to vascular occlusion, hypoperfusion complex vs., **502**
Bowel malrotation, colonic volvulus, **431**
Bowel obstruction
- differential diagnosis, **335**

INDEX

- necrotizing enterocolitis vs., **385**
- neonatal distal
  anorectal malformations vs., **377**
  meconium peritonitis vs., **382**
- pneumatosis intestinalis vs., **539**

Bowel obstruction, abnormalities
- appendicitis, **418–421**
  diagnostic checklist, **420**
  differential diagnosis, **420**
  prognosis, **420**
- colonic volvulus, **430–431**
  associated abnormalities, **431**
  diagnostic checklist, **431**
  differential diagnosis, **431**
- ileocolic intussusception, **422–425**
  diagnostic checklist, **424**
  differential diagnosis, **423**
  prognosis, **424**
- internal hernia, **432**
- Meckel diverticulum, **426–429**
  diagnostic checklist, **427–428**
  differential diagnosis, **427–428**
- segmental volvulus, **433**
  diagnostic checklist, **433**

Bowel trauma, hypoperfusion complex vs., **501**
Bowel wall thickening, other causes, Burkitt lymphoma vs., **573**
Bowing, due to underlying skeletal disease, incomplete fractures vs., **803**
BPD. *See* Bronchopulmonary dysplasia.
Brachial plexopathy, **1000–1001**
- differential diagnosis, **1001**
- prognosis, **1001**
- staging, grading, & classification, **1001**

Brachial plexus birth injury (BPBI). *See* Brachial plexopathy.
Brachial plexus neuropathies, brachial plexopathy, **1000–1001**
Brain
- abusive head trauma, **1092–1095**
- aqueductal stenosis, **1046–1047**
- arachnoid cyst, **1060–1061**
- arteriovenous malformation, **1114–1115**
- atypical teratoid/rhabdoid tumor, **1070–1071**
- birth injury, **1090–1091**
- brainstem tumors, **1076–1079**
- callosal anomalies, **1028–1029**
- cavum septum pellucidum, **1016**
  diagnostic checklist, **1016**
  differential diagnosis, **1016**
- cephalocele, **1024–1025**
- cerebral venous sinus thrombosis, **1108–1109**
- Chiari 1 malformation, **1042–1043**
- Chiari 2 malformation, **1044–1045**
- childhood aneurysms, **1110–1111**
- childhood stroke, **1104–1105**
- choroid plexus tumors, **1088–1089**
- colloid cyst, **1058–1059**
- craniopharyngioma, **1084–1085**
- Dandy-Walker continuum, **1018–1021**
- dermoid and epidermoid cysts, **1062–1063**
- desmoplastic infantile tumors, **1082**
- DNET, **1080**
- embryonal tumor with multilayered rosettes, **1083**
- enlarged perivascular spaces, **1065**
- enlarged subarachnoid spaces, **1014–1015**
- focal cortical dysplasia, **1040–1041**
- ganglioglioma, **1081**
- germinal matrix hemorrhage, **1096–1099**
- germinoma, **1086–1087**
- glioblastoma, **1075**
- hemimegalencephaly, **1030–1031**
- heterotopic gray matter, **1034–1035**
- holoprosencephalies, **1026–1027**
- hypoxic-ischemic encephalopathy, **1102–1103**
- lissencephaly, **1032–1033**
- medulloblastoma, **1068–1069**
- Moyamoya, **1106–1107**
- neurofibromatosis type 1, **1048–1051**
- normal myelination, **1010–1013**
- other cerebellar malformations, **1022–1023**
- pediatric, approach to, **1006–1009**
  cerebral edema, **1007**
  hydrocephalus, **1007**
  normal development, **1006**
  overview, **1006**
- PHACES syndrome, **1056**
- pilocytic astrocytoma, **1066–1067**
- pineal cyst, **1064**
- polymicrogyria, **1038–1039**
- posterior fossa ependymoma, **1072–1073**
- schizencephaly, **1036–1037**
- Sturge-Weber syndrome, **1054–1055**
- supratentorial ependymoma, **1074**
- tuberous sclerosis, **1052–1053**
- vein of Galen aneurysmal malformation, **1112–1113**
- white matter injury of prematurity, **1100–1101**

Brain abscess, **1128–1129**
- diagnostic checklist, **1129**
- differential diagnosis, **1129**
- orbital cellulitis, **1198**
- prognosis, **1129**
- staging, grading, & classification, **1129**

Brain volume loss, enlarged subarachnoid spaces vs., **1015**
Brainstem abscess, brainstem tumors vs., **1078**
Brainstem tumors, **1076–1079**
- associated abnormalities, **1078**
- diagnostic checklist, **1078**
- differential diagnosis, **1078**
- genetics, **1078**
- nuclear medicine findings, **1077**
- staging, grading, & classification, **1078**

Branchial apparatus anomalies, **1180**. *See also* Branchial cleft anomalies.
Branchial apparatus cyst. *See* Branchial cleft anomalies.
Branchial apparatus lesions, **1181**
- congenital cystic neck masses vs., **1181**

Branchial cleft anomalies, **1224–1227**
- associated abnormalities, **1226**
- diagnostic checklist, **1226**
- differential diagnosis, **1225–1226**
- fibromatosis colli vs., **1240**
- prognosis, **1226**

- 2nd, cervical lymphatic malformation vs., **15**

Branchial cleft cyst. *See* Branchial cleft anomalies.
Branchiootic syndrome, branchiootorenal syndrome vs., **1217**
Branchiootorenal syndrome, **1217**
- CHARGE syndrome vs., **1216**
- congenital auricle malformations vs., **1205**
- differential diagnosis, **1217**
- large vestibular aqueduct vs., **1207**
- Treacher Collins syndrome vs., **1218**

Brett syndrome. *See* Swyer-James syndrome (SJS).
Bronchial atresia, **52, 78–79**
- associated abnormalities, **79**
- congenital lobar overinflation vs., **75**
- differential diagnosis, **79**

Bronchial foreign body
- esophageal atresia and tracheoesophageal fistula vs., **82**
- viral chest infection vs., **118**

Bronchial malformation, primary, pulmonary sling vs., **39**
Bronchial obstruction, **53, 198–201**
- diagnostic checklist, **200**
- differential diagnosis, **199–200**
- mechanism, **200**
- prognosis, **200**

Bronchiectasis, cystic, Langerhans cell histiocytosis vs., **187**
Bronchiolitis, **117, 118**
Bronchiolitis, viral, asthma vs., **195**
Bronchiolitis obliterans (BO)
- neuroendocrine cell hyperplasia of infancy vs., **174**
- postinfectious. *See* Swyer-James syndrome (SJS).

Bronchogenic cyst, **52, 70–73**
- associated abnormalities, **72**
- bronchial atresia vs., **79**
- bronchopulmonary sequestration vs., **67**
- congenital pulmonary airway malformation vs., **63**
- differential diagnosis, **71–72**
- pneumonia with cavitary necrosis vs., **132**
- prognosis, **72**
- round pneumonia vs., **125**

Bronchopleural fistula, gastric volvulus vs., **397**
Bronchopulmonary aspergillosis, allergic, bronchial atresia vs., **79**
Bronchopulmonary dysplasia (BPD), **52, 106–109**
- developing, pulmonary interstitial emphysema vs., **99**
- differential diagnosis, **107**
- lymphangioleiomyomatosis vs., **185**
- new, **107**
- old, **107**
- prognosis, **108**

Bronchopulmonary sequestration (BPS), **52, 66–69**
- bronchial atresia vs., **79**
- bronchogenic cyst, **72**
- bronchogenic cyst vs., **72**
- congenital diaphragmatic hernia vs., **86**
- congenital lobar overinflation vs., **76**
- congenital pulmonary airway malformation vs., **63**
- diagnostic checklist, **68**
- differential diagnosis, **67–68**
- extralobar, neuroblastoma vs., **704**
- pneumonia with cavitary necrosis vs., **132**
- prognosis, **68**
- renal ectopia and fusion vs., **626**
- round pneumonia vs., **126**
- Scimitar syndrome vs., **287**

Bronchus intubation, right main, esophageal intubation vs., **112**
Bruck syndrome, osteogenesis imperfecta vs., **977**
Bucket-handle fracture. *See* Child abuse, metaphyseal fracture.
Bucket-handle tear, discoid meniscus vs., **791**
Buckle fracture, **803, 845**
Burkitt lymphoma, **572–573**
- differential diagnosis, **573**
- genitourinary myosarcoma vs., **691**
- hydrometrocolpos vs., **714**
- primary mesenteric adenitis vs., **495**
- prognosis, **573**
- staging, grading, & classification, **573**

Burns, fungal pneumonia in immunocompromised children, **135**
Burst fracture, chance fracture vs., **1175**
Butterfly apex, arrhythmogenic right ventricular dysplasia vs., **312**
Button battery ingestion
- ingested coins vs., **399**
- ingested multiple magnets vs., **403**

Buttress plating, orthopedic hardware and complications, **826**

C

C sign, **997**
CAH. *See* Congenital adrenal hyperplasia.
Calcified small spleen, wandering spleen vs., **473**
Calcified soft tissue mass, partially, of chest wall, **193**
Calcium, abdominal, anorectal malformations vs., **377**
Calcium stones, renal stones, **674**
Calculus, distal ureteral, ovarian torsion vs., **734**
Callosal agenesis, with interhemispheric cyst, holoprosencephalies vs., **1026**
Callosal anomalies, **1028–1029**
- associated abnormalities, **1029**
- diagnostic checklist, **1029**
- differential diagnosis, **1029**
- embryology, **1029**
- staging, grading, & classification, **1029**

Canal of Nuck, **405**
Cancellous screws, orthopedic hardware and complications, **826**
Cannulated screw, orthopedic hardware and, **826**
Capillary hemangioma. *See* Infantile hemangioma.
Capillary telangiectasia, cavernous malformation vs., **1117**
Capital femoral epiphysis, slipped, Legg-Calvé-Perthes disease vs., **962**
Capitellar osteochondritis dissecans, medial epicondyle avulsion vs., **843**
Carcinoma, renal cell, angiomyolipoma vs., **661**

INDEX

Cardiac complications, umbilical catheter positions and complications, **111**
Cardiac malformations, congenital diaphragmatic hernia, **86**
Cardiac malignancies, rhabdomyoma vs., **319**
Cardiac transplantation, primary, Norwood procedure vs., **295**
Cardiomyopathies
- arrhythmogenic right ventricular dysplasia, **310–313**
  - diagnostic checklist, **312**
  - differential diagnosis, **311–312**
  - genetics, **312**
  - prognosis, **312**
- dilated
  - left coronary artery anomalous origin vs., **269**
  - left ventricular noncompaction vs., **305**
- Duchenne muscular dystrophy-related, **308–309**
  - differential diagnosis, **309**
  - prognosis, **309**
- hypertrophic, **306–307**
  - differential diagnosis, **307**
  - Duchenne muscular dystrophy-related cardiomyopathy vs., **309**
  - left ventricular noncompaction vs., **305**
  - prognosis, **307**
  - staging, grading, & classification, **307**
- left ventricular noncompaction, **304–305**
  - differential diagnosis, **305**
  - prognosis, **305**
- myocarditis, **302–303**
- noncompaction, Duchenne muscular dystrophy-related cardiomyopathy vs., **309**
- of other causes, Duchenne muscular dystrophy-related cardiomyopathy vs., **309**

Cardiopulmonary resuscitation, trauma from, child abuse, rib fractures vs., **160**
Cardiosplenic syndromes. *See* Heterotaxy syndromes.
Cardiovascular shunts, left-to-right, viral chest infection vs., **118**
Carney complex, adrenocortical carcinoma, **709**
Carnitine palmitoyl transferase deficiencies, **1119**
Caroli disease, **458–459**
- choledochal cyst vs., **455**
- differential diagnosis, **459**
- staging, grading, & classification, **459**

Castleman disease, **574**
- inflammatory myofibroblastic tumor vs., **575**

Cat-scratch disease, **478–479**
- associated abnormalities, **479**
- diagnostic checklist, **479**
- differential diagnosis, **479**
- kaposiform lymphangiomatosis vs., **213**
- prognosis, **479**

Catheters, **52–53**
- extracorporeal membrane oxygenation, **113**
- peripherally inserted central, **114–115**
  - diagnostic checklist, **115**
  - malposition, **115**
- umbilical catheter positions and complications, **110–111**

Caudal appendage, achondroplasia vs., **970**
Caudal regression, **1150**
- diagnostic checklist, **1150**
- differential diagnosis, **1150**
- neurogenic bladder, **684**

Caustic strictures, esophageal strictures, **547, 548**
Cavernous hemangioma. *See* Infantile hemangioma, cervicofacial.
Cavernous malformation, **1116–1117**
- arteriovenous malformation vs., **1115**
- associated abnormalities, **1117**
- brainstem tumors vs., **1078**
- differential diagnosis, **1117**
- genetics, **1117**
- prognosis, **1117**
- spinal cord ependymoma vs., **1159**
- staging, grading, & classification, **1117**

Cavitary abscess, complicating pneumonia, congenital pulmonary airway malformation vs., **63–64**
Cavitary necrosis
- complicating pneumonia, congenital pulmonary airway malformation vs., **63–64**
- pneumonia with, **130–133**
  - differential diagnosis, **131–132**
  - prognosis, **132**

Cavopulmonary connection, total. *See* Fontan operation.
Cavum septum pellucidum, **1016**
- diagnostic checklist, **1016**
- differential diagnosis, **1016**

Cavum veli interpositi (CVI), **1017**
- diagnostic checklist, **1017**
- differential diagnosis, **1017**

Cavus, forefoot adductus, hindfoot varus, hindfoot equinus (CAVE). *See* Clubfoot.
CD. *See* Crohn disease.
Cecal position, normal variations of, **342–343**
- differential diagnosis, **343**
- prognosis, **343**

Cecal volvulus. *See* Colonic volvulus.
Cecoureterocele, **603**
Cell carcinoma, renal, renal medullary carcinoma vs., **659**
Cellulitis, **875**
- granuloma annulare vs., **921**
- kaposiform hemangioendothelioma vs., **891**
- lymphatic malformation, musculoskeletal vs., **897**
- retropharyngeal, pseudothickening of retropharyngeal tissues vs., **7**
- stromal, epididymoorchitis vs., **739**

Central conducting lymphatic anomaly, kaposiform lymphangiomatosis vs., **213**
Central echo complex, **585**
Central pattern, hypoxic-ischemic encephalopathy, **1103**
Cephalocele, **1024–1025**
- differential diagnosis, **1025**
- frontoethmoidal (nasoorbital), nasolacrimal duct mucocele vs., **11**

Cerebellar hypoplasia
- Dandy-Walker continuum vs., **1020**
- isolated, other cerebellar malformations vs., **1023**
- omphalocele, **410**

INDEX

Cerebellar malformations, other, **1022–1023**
- diagnostic checklist, **1023**
- differential diagnosis, **1023**

Cerebellar tonsil position, normal variation of, Chiari 1 malformation vs., **1043**
Cerebral edema
- pediatric brain, **1007**
- unilateral, hemimegalencephaly vs., **1031**

Cerebral palsy
- developmental hip dysplasia vs., **955–956**
- neurogenic bladder, **684**

Cerebral venous sinus thrombosis, **1108–1109**
- differential diagnosis, **1109**
- prognosis, **1109**

Cerebritis, orbital cellulitis, **1198**
Cervical extension of mediastinal thymus, fibromatosis colli vs., **1240**
Cervical lymphadenopathy, fibromatosis colli vs., **1240**
Cervical lymphatic malformation, **14–15**
- differential diagnosis, **15**
- genetics, **15**

Cervical spinal cord injury, brachial plexopathy vs., **1001**
Cervical spine, pathology, pseudothickening of retropharyngeal tissues vs., **7**
Cervical stenosis, müllerian duct anomalies vs., **718**
Cervical teratoma, fibromatosis colli vs., **1240**
Cervical thymic cyst, thyroglossal duct cyst vs., **1221**
CF. *See* Cystic fibrosis.
CFTR gene mutation, **566**
CGD. *See* Chronic granulomatous disease.
Chance fracture, **1174–1175**
- associated abnormalities, **1175**
- bowel injury, **506**
- diagnostic checklist, **1175**
- differential diagnosis, **1175**

CHARGE syndrome, **1216**
- choanal atresia, **13**
- congenital auricle malformations vs., **1205**
- differential diagnosis, **1216**
- large vestibular aqueduct vs., **1207**
- VACTERL association vs., **781**

Chest
- alveolar growth abnormality, **178–179**
  - diagnostic checklist, **179**
  - differential diagnosis, **179**
  - prognosis, **179**
- aortic injury, **166–169**
  - diagnostic checklist, **168**
  - differential diagnosis, **167**
  - prognosis, **168**
  - staging, grading, & classification, **168**

  - prognosis, **103**
- neuroblastoma, thoracic, **148–151**
  - associated abnormalities, **149**
  - diagnostic checklist, **150**
  - differential diagnosis, **149**
  - genetics, **149**
  - prognosis, **150**
  - staging, grading, & classification, **150**
- neuroendocrine cell hyperplasia of infancy, **174–175**
  - diagnostic checklist, **175**
  - differential diagnosis, **175**
  - prognosis, **175**
  - staging, grading, & classification, **175**
- normal thymus, **56–59**
  - diagnostic checklist, **58**
  - differential diagnosis, **58**
- palpable normal variants of chest wall, **60–61**
  - differential diagnosis, **61**
  - prognosis, **61**
- papillomatosis, **136–139**
  - diagnostic checklist, **138**
  - differential diagnosis, **137**
  - prognosis, **138**
  - staging, grading, & classification, **138**
- parapneumonic effusion and empyema, **128–129**
  - differential diagnosis, **129**
  - prognosis, **129**
  - stages, **129**
- pectus excavatum, **188–189**
  - associated abnormalities, **189**
  - differential diagnosis, **189**
- peripherally inserted central catheters, **114–115**
  - diagnostic checklist, **115**
  - malposition, **115**
- pleuropulmonary blastoma, **152–155**
  - associated abnormalities, **153–154**
  - associated syndromes, **153**
  - diagnostic checklist, **154**
  - differential diagnosis, **153**
  - genetics, **153**
  - prognosis, **154**
  - staging, grading, & classification, **154**
- pneumomediastinum, **170–173**
  - diagnostic checklist, **171**
  - differential diagnosis, **171**
  - prognosis, **171**
- pneumonia, with cavitary necrosis, **130–133**
  - differential diagnosis, **131–132**
  - prognosis, **132**
- pneumothorax, congenital lobar overinflation vs., **75**
- pulmonary arteriovenous malformation, **156–157**
  - associated abnormalities, **157**
  - differential diagnosis, **157**
  - prognosis, **157**

INDEX

- pulmonary interstitial emphysema, **98–101**
  - diagnostic checklist, **100**
  - differential diagnosis, **99**
  - prognosis, **100**
- pulmonary interstitial glycogenosis, **176–177**
  - diagnostic checklist, **177**
  - differential diagnosis, **177**
  - prognosis, **177**
- round pneumonia, **124–127**
  - diagnostic checklist, **126**
  - differential diagnosis, **125–126**
  - prognosis, **126**
- sickle cell disease, acute chest syndrome, **208–211**
  - diagnostic checklist, **209–210**
  - differential diagnosis, **209–210**
  - prognosis, **209–210**
- surfactant deficiency disease, **88–91**
  - differential diagnosis, **89–90**
  - genetics, **90**
  - prematurity-related, **89**
  - primary, **89**
  - prognosis, **90**
  - secondary, **89**
- surfactant dysfunction disorders, **180–181**
  - differential diagnosis, **181**
  - prognosis, **181**
- Swyer-James syndrome, **182–183**
  - bronchial obstruction vs., **200**
  - differential diagnosis, **183**
  - prognosis, **183**
- transient tachypnea of newborn, **96–97**
  - associated abnormalities, **97**
  - differential diagnosis, **97**
  - prognosis, **97**
- trauma, **53**
- umbilical catheter positions and complications, **110–111**
- viral infection, **116–119**
  - diagnostic checklist, **118**
  - differential diagnosis, **117–118**
  - prognosis, **118**

Chest infection, viral, sickle cell disease, acute chest syndrome vs., **209**

Chest wall
- aggressive lesions, pectus excavatum vs., **189**
- Ewing sarcoma of, **191**
  - diagnostic checklist, **191**
  - round pneumonia vs., **126**
- hamartoma, **192–193**
  - differential diagnosis, **193**
  - prognosis, **193**
- mesenchymal hamartoma, **193**
- palpable normal variants of, **60–61**
  - differential diagnosis, **61**
  - pectus excavatum vs., **189**
  - prognosis, **61**
- partially calcified soft tissue mass of, **193**
- vascular malformations, pectus excavatum vs., **189**

Chiari 1 malformation, **1042–1043**
- Chiari 2 malformation vs., **1045**
- diagnostic checklist, **1043**
- differential diagnosis, **1043**

Chiari 2 malformation, **1044–1045**
- Chiari 1 malformation vs., **1043**
- differential diagnosis, **1045**
- staging, grading, & classification, **1045**

Chiari 3 malformation, Chiari 2 malformation vs., **1045**

Child abuse
- clavicle injuries vs., **833**
- hemophagocytic lymphohistiocytosis vs., **569**
- Henoch-Schönlein purpura vs., **561**
- metaphyseal fracture, **804–807**
  - diagnostic checklist, **806**
  - differential diagnosis, **806**
  - prognosis, **806**
  - rickets vs., **986**
- normal developmental variants confused with disease vs., **773**
- osteogenesis imperfecta vs., **977**
- other fractures, **808–811**
  - dating fractures, **810**
  - diagnostic checklist, **810**
  - differential diagnosis, **810**
  - high-specificity fractures, **809**
  - low-specificity fractures, **810**
  - moderate-specificity fractures, **809–810**
  - prognosis, **810**
- rib fractures, **158–161**
  - diagnostic checklist, **160**
  - differential diagnosis, **159–160**
  - prognosis, **160**
- syphilis vs., **869**

Childhood accidental spiral tibial (CAST) fracture. *See* Toddler's fracture.

Childhood aneurysms, **1110–1111**
- differential diagnosis, **1111**
- staging, grading, & classification, **1111**

Childhood dural arteriovenous fistula, vein of Galen aneurysmal malformation vs., **1113**

Childhood nasopharyngeal carcinoma, juvenile angiofibroma vs., **1190**

Childhood stroke, **1104–1105**
- differential diagnosis, **1105**
- prognosis, **1105**

Choanal atresia, **12–13**
- associated abnormalities, **13**
- congenital nasal pyriform aperture stenosis vs., **9**
- diagnostic checklist, **13**
- differential diagnosis, **13**

Choanal stenosis
- choanal atresia vs., **13**
- congenital nasal pyriform aperture stenosis vs., **9**

Cholangiocarcinoma, biliary rhabdomyosarcoma vs., **449**

Cholangitis, primary sclerosing, cirrhosis, **461**

Choledochal cyst, **454–457**
- biliary atresia vs., **450**
- biliary rhabdomyosarcoma vs., **449**
- Caroli disease vs., **459**
- cirrhosis, **461**
- diagnostic checklist, **456**
- differential diagnosis, **455**
- duodenal atresia or stenosis, **356**

- gastrointestinal duplication cysts vs., **556**
- genetics, **455**
- mesenteric lymphatic malformation vs., **497**
- pancreaticobiliary maljunction vs., **487**
- prognosis, **456**
- staging, grading, & classification, **455–456**

Choledochal malformations. *See* Choledochal cyst.
Choledochocele. *See also* Choledochal cyst.
- hypertrophic pyloric stenosis vs., **394**

Chondroblastoma, **948–949**
- differential diagnosis, **949**
- prognosis, **949**

Chondrodysplasia, metaphyseal, child abuse, metaphyseal fracture vs., **806**
Chondrolysis, **821**
- idiopathic, slipped capital femoral epiphysis vs., **966**

Chondromatous hamartoma. *See* Chest wall, hamartoma.
Chondromyxoid fibroma, nonossifying fibroma vs., **942**
Choriocarcinoma, **729**
Choroid plexus carcinoma, embryonal tumor with multilayered rosettes vs., **1083**
Choroid plexus cysts, germinal matrix hemorrhage vs., **1097**
Choroid plexus papilloma
- medulloblastoma vs., **1069**
- posterior fossa ependymoma vs., **1073**

Choroid plexus tumor (CPT), **1088–1089**
- atypical teratoid/rhabdoid tumor vs., **1071**
- diagnostic checklist, **1089**
- differential diagnosis, **1089**
- genetics, **1089**
- prognosis, **1089**

Choroidal angioma, Sturge-Weber syndrome, **1055**
Choroidal type, vein of Galen aneurysmal malformation, **1113**
Christmas disease. *See* Hemophilia.
Chromosome 22 deletions, multicystic dysplastic kidney disease, **632**
Chronic ACL tears, **847**
Chronic back pain, pediatric spine, approach, **1144**
Chronic bronchial obstruction, bronchopulmonary sequestration vs., **67**
Chronic constipation, colonic volvulus, **431**
Chronic cough, croup, **24**
Chronic esophageal foreign body, **206–207**
- differential diagnosis, **207**
- prognosis, **207**

Chronic foreign body. *See also* Soft tissue foreign bodies.
- granuloma annulare vs., **921**

Chronic granulomatous disease (CGD), **534–537**
- Crohn disease vs., **542**
- diagnostic checklist, **536**
- differential diagnosis, **536**
- genetics, **536**
- prognosis, **536**

Chronic infection, diffuse leptomeningeal glioneuronal tumor vs., **1157**
Chronic lung disease (CLD) of prematurity. *See also* Bronchopulmonary dysplasia (BPD).
- pulmonary interstitial emphysema vs., **99**

Chronic lymphocytic leukemia (CLL). *See* Leukemia.
Chronic myelogenous leukemia (CML). *See* Leukemia.
Chronic nonbacterial osteomyelitis (CNO). *See* Chronic recurrent multifocal osteomyelitis.
Chronic otitis media, acquired cholesteatoma vs., **1211**
Chronic physeal stress injury, **813**
- physeal fractures vs., **795**

Chronic recurrent multifocal osteomyelitis (CRMO), **882–885**
- associated abnormalities, **884**
- associated syndromes, **883**
- diagnostic checklist, **884**
- differential diagnosis, **883**
- discitis/osteomyelitis vs., **1167**
- genetics, **884**
- osteomyelitis vs., **864**

Chronic renal disease, rickets, **985**
Chronic subdural hematoma, arachnoid cyst vs., **1061**
Chronic venous ischemia, TORCH infections vs., **1127**
Chylothorax, **52, 104–105**
- parapneumonic effusion and empyema vs., **129**
- prognosis, **105**

Ciliary dyskinesia
- asthma vs., **195**
- cystic fibrosis, pulmonary vs., **203**

Circle of Willis, severely attenuated, moyamoya, **1107**
Cirrhosis, **460–461**
- cystic fibrosis, **565**
- steatosis/steatohepatitis vs., **463**

Classic bladder exstrophy (CBE), **623**
Classic metaphyseal lesion (CML). *See* Child abuse, metaphyseal fracture.
Classic Morel-Lavallée lesion, **830**
Classic triplane fracture pattern, **859**
Clavicle injuries, **832–833**
- diagnostic checklist, **833**
- differential diagnosis, **833**

Clear cell sarcoma
- of kidney, **655**
  mesoblastic nephroma vs., **651**
- renal cell carcinoma vs., **657**
- Wilms tumor vs., **641**

Cleft
- laryngeal, croup, **24**
- laryngotracheal, esophageal atresia and tracheoesophageal fistula vs., **81**

Cleft cyst, Rathke, craniopharyngioma vs., **1085**
Cleft palate, VACTERL association, **782**
Cleidocranial dysplasia, osteogenesis imperfecta vs., **978**
Clinical profile, white matter injury of prematurity, **1101**
CLO. *See* Congenital lobar overinflation.
Cloaca, **620–621**
- differential diagnosis, **621**
- prognosis, **621**

Cloacal anomalies
- prune-belly syndrome vs., **611**
- urachal abnormalities, **614**

Cloacal exstrophy/OEIS, **416**
- bladder exstrophy vs., **623**
- covered, cloacal exstrophy/OEIS vs., **416**
- differential diagnosis, **416**

- gastroschisis vs., **413**
- omphalocele, **409**

Cloacal malformation. *See also* Cloaca.
- megacystis-microcolon-intestinal hypoperistalsis syndrome, **609**

Closed congenital spinal dysraphism, neurogenic bladder, **684**
"Closed-lip" schizencephaly, heterotopic gray matter vs., **1035**
Closed (occult) spinal dysraphism
- caudal regression vs., **1150**
- myelomeningocele vs., **1147**
- terminal myelocystocele vs., **1152**

Clubfoot, **788–789**
- differential diagnosis, **789**
- omphalocele, **410**
- prognosis, **789**

Coagulopathy
- birth injury vs., **1091**
- bowel injury vs., **506**

Coalescent (or confluent) otomastoiditis with abscess. *See* Acute otomastoiditis with abscess.
Coarctation, double aortic arch, **36**
Coats disease, retinoblastoma vs., **1201**
"Cobblestone" malformations, polymicrogyria vs., **1039**
Coccygeal pit, dorsal dermal sinus vs., **1149**
Cochlear hypoplasia, large vestibular aqueduct vs., **1207**
Coin ingestion
- ingested button batteries vs., **401**
- ingested multiple magnets vs., **403**

Cole-Carpenter syndrome, osteogenesis imperfecta vs., **977**
Colitis
- indeterminate, Crohn disease vs., **542**
- infectious
  - graft-vs.-host disease vs., **533**
  - Henoch-Schönlein purpura vs., **561**
  - ulcerative colitis vs., **545**
- inflammatory, Henoch-Schönlein purpura vs., **561**
- posttransplant lymphoproliferative disease vs., **525–526**
- pseudomembranous, ulcerative colitis vs., **545**
- ulcerative, **544–545**
  - Crohn disease vs., **542**
  - diagnostic checklist, **545**
  - differential diagnosis, **545**

Collateral ligament injury, ulnar/medial, medial epicondyle avulsion vs., **843**
Colloid cyst, **1058–1059**
- diagnostic checklist, **1059**
- differential diagnosis, **1059**

Colon, small left
- anorectal malformations vs., **377**
- jejunoileal atresia vs., **362**
- meconium ileus vs., **367**
- meconium peritonitis vs., **381**

Colonic aganglionosis. *See* Hirschsprung disease.
Colonic atresia, **364**
- cloaca vs., **621**
- differential diagnosis, **364**
- Hirschsprung disease vs., **373**
- jejunoileal atresia vs., **362**
- meconium ileus vs., **367**
- neonatal small left colon vs., **371**

Colonic pseudoobstruction, colonic volvulus vs., **431**
Colonic volvulus, **430–431**
- associated abnormalities, **431**
- diagnostic checklist, **431**
- differential diagnosis, **431**
- gastric volvulus vs., **397**

Column of Bertin, ureteropelvic duplications vs., **600**
Common atrioventricular canal, truncus arteriosus vs., **257**
Common bile duct (CBD) cyst. *See* Choledochal cyst.
Common bile duct (CBD) diverticulum. *See* Choledochal cyst.
Common venous malformation (VM). *See* Venous malformation, musculoskeletal.
Communicating hydrocele, **761**
Communicating hydrocephalus, enlarged subarachnoid spaces vs., **1015**
Community-acquired pneumonia, **118**
Complete ACL tears, **848**
Complete discoid meniscus, **792**
Complete duplication. *See* Ureteropelvic duplications.
Complete fracture, **845**
Complex hydrocele, **761**
Complex migraine, childhood stroke vs., **1105**
Complex skull fractures, **809**
Compression plating, orthopedic hardware and complications, **826**
Computed tomography
- musculoskeletal system, **764**
- pediatric genitourinary tract, **581**

Condylar fracture, lateral, supracondylar fracture vs., **835**
Congenital abnormalities, musculoskeletal system, **764**
Congenital abnormality of kidney & urinary tract (CAKUT). *See* Renal agenesis.
Congenital absence of ACL, ACL injuries vs., **847**
Congenital adrenal hyperplasia (CAH), **698–701**
- adrenocortical carcinoma, **709**
- differential diagnosis, **700**
- ectopic testicle vs., **759**
- genetics, **700**
- neonatal adrenal hemorrhage vs., **695**
- neuroblastoma vs., **704**
- normal neonatal adrenal gland vs., **587**
- prognosis, **700**

Congenital airway obstructions, approach to, **4**
Congenital aural dysplasia. *See* Congenital auricle malformations.
Congenital auricle malformations, **1204–1205**
- associated abnormalities, **1205**
- diagnostic checklist, **1205**
- differential diagnosis, **1205**
- staging, grading, & classification, **1205**

Congenital bands, meconium peritonitis vs., **381**
Congenital biliary dilation. *See* Choledochal cyst.
Congenital central hypoventilation, Hirschsprung disease, **373**
Congenital central hypoventilation syndrome, neuroblastoma, **704**

INDEX

Congenital cerebral aneurysmal arteriopathies, childhood aneurysms vs., **1111**
Congenital cholesteatoma, **1208–1209**
- acquired cholesteatoma vs., **1211**
- associated abnormalities, **1209**
- differential diagnosis, **1209**
- prognosis, **1209**
- staging, grading, & classification, **1209**

Congenital coxa valga, developmental hip dysplasia vs., **955–956**
Congenital cystic adenomatoid malformation (CCAM). *See* Congenital pulmonary airway malformation.
Congenital cystic neck masses, **1180–1183**
- differential diagnosis, **1181**
- embryology, **1180–1181**
- imaging anatomy, **1181**
- imaging techniques & indications, **1180**
- terminology, **1180**
- types, **1181**

Congenital cytomegalovirus, heterotopic gray matter vs., **1035**
Congenital dacryocystocele. *See* Nasolacrimal duct mucocele.
Congenital diaphragmatic hernia (CDH), **84–87**
- associated abnormalities, **86**
- congenital pulmonary airway malformation vs., **63**
- differential diagnosis, **85–86**
- neonatal pneumothorax vs., **103**
- prognosis, **86**

Congenital dislocation of hip (archaic). *See* Developmental hip dysplasia.
Congenital duodenal obstruction, spectrum of, midgut volvulus vs., **352**
Congenital external ear malformation. *See* Congenital auricle malformations.
Congenital extrahepatic portosystemic shunt. *See* Abernethy malformation.
Congenital fascial hernia, **831**
Congenital fibrosarcoma, chest wall hamartoma vs., **193**
Congenital fusion & segmentation anomalies, craniocervical junction injuries vs., **1172**
Congenital heart disease (CHD), **218**
- Abernethy malformation, **467**
- annular pancreas., **489**
- aortic coarctation, **274–277**
  - diagnostic checklist, **276**
  - differential diagnosis, **275–276**
  - genetics, **276**
  - prognosis, **276**
- aortic stenosis, **278–281**
  - associated abnormalities, **279–280**
  - differential diagnosis, **279**
  - genetics, **279**
  - prognosis, **280**
  - staging, grading, & classification, **280**
- atrial septal defect, **222–225**
  - associated abnormalities, **224**
  - differential diagnosis, **224**
  - genetics, **224**
- atrioventricular septal defect, **230–233**
  - associated abnormalities, **232**
  - differential diagnosis, **232**
  - genetics, **232**
  - prognosis, **232**
- bronchogenic cyst, **72**
- D-transposition of great arteries, **250–251**
  - prognosis, **251**
- double aortic arch, **36**
- double-outlet right ventricle, **272–273**
  - differential diagnosis, **273**
- Ebstein anomaly, **246–249**
  - associated abnormalities, **247**
  - differential diagnosis, **247**
  - genetics, **247**
  - prognosis, **248**
- hypoplastic left heart syndrome, **264–267**
  - aortic coarctation vs., **275**
  - differential diagnosis, **266**
  - prognosis, **266**
- L-transposition of great arteries, **252–253**
  - associated abnormalities, **253**
  - differential diagnosis, **253**
  - prognosis, **253**
- with large left-to-right shunt, pulmonary artery stenosis vs., **283**
- left coronary artery anomalous origin, **268–271**
  - associated abnormalities, **269–270**
  - diagnostic checklist, **270**
  - differential diagnosis, **269**
  - prognosis, **270**
- meconium aspiration syndrome vs., **95**
- necrotizing enterocolitis, **386**
- neonatal pneumonia vs., **93**
- omphalocele, **410**
- patent ductus arteriosus, **234–237**
  - differential diagnosis, **235**
  - genetics, **235**
  - prognosis, **236**
- pulmonary artery stenosis, **282–285**
  - associated abnormalities, **284**
  - diagnostic checklist, **284**
  - differential diagnosis, **283**
  - genetics, **283–284**
  - prognosis, **284**
  - staging, grading, & classification, **284**
- pulmonary atresia, **242–245**
  - differential diagnosis, **243–244**
  - prognosis, **244**
  - staging, grading, & classification, **244**
- pulmonary sling, **40**
- Scimitar syndrome, **286–287**
  - differential diagnosis, **287**
  - prognosis, **287**
- surfactant deficiency disease vs., **89**
- tetralogy of Fallot, **238–241**
  - associated abnormalities, **239–240**
  - differential diagnosis, **239**
  - genetics, **239**
  - prognosis, **240**

- total anomalous pulmonary venous return, **260–263**
  associated abnormalities, **262**
  differential diagnosis, **261–262**
  genetics, **262**
  prognosis, **262**
- transient tachypnea of newborn vs., **97**
- tricuspid atresia, **254–255**
  diagnostic checklist, **255**
  differential diagnosis, **255**
  genetics, **255**
- truncus arteriosus, **256–259**
  associated abnormalities, **257**
  differential diagnosis, **257**
  genetics, **257**
  prognosis, **258**
  staging, grading, & classification, **258**
- ventricular septal defect, **226–229**
  differential diagnosis, **227–228**
  genetics, **228**
  prognosis, **228**

Congenital hemangioma (CH). *See also* Infantile hemangioma, cervicofacial.
- anorectal malformations vs., **378**
- hepatic, hypoplastic left heart syndrome vs., **266**
- infantile hemangioma
  cervicofacial vs., **1232**
  musculoskeletal vs., **888**
- kaposiform hemangioendothelioma vs., **891**
- mesenchymal hamartoma vs., **448**

Congenital hepatic hemangioma, meconium peritonitis vs., **382**
Congenital high airway obstruction syndrome, **16**
Congenital infantile fibrosarcoma, fibromatosis vs., **903**
Congenital infections. *See* TORCH infections.
Congenital lobar emphysema. *See also* Congenital lobar overinflation.
- neonatal pneumothorax vs., **103**

Congenital lobar hyperinflation. *See* Congenital lobar overinflation.
Congenital lobar overinflation (CLO), **74–77**
- associated abnormalities, **76**
- bronchial atresia vs., **79**
- bronchopulmonary dysplasia vs., **108**
- congenital diaphragmatic hernia vs., **86**
- congenital pulmonary airway malformation vs., **64**
- differential diagnosis, **75–76**
- prognosis, **76**
- pulmonary interstitial emphysema vs., **99**
- staging, grading, & classification, **76**

Congenital lung anomalies, pulmonary sling, **40**
Congenital lung lesion
- infected, esophageal atresia and tracheoesophageal fistula vs., **82**
- pneumonia with cavitary necrosis vs., **131**

Congenital lymphangiectasia, transient tachypnea of newborn vs., **97**
Congenital lymphocytic choriomeningitis, TORCH infections vs., **1127**
Congenital megalourethra
- megacystis-microcolon-intestinal hypoperistalsis syndrome, **609**
- prune-belly syndrome vs., **611**

Congenital mesoblastic nephroma (CMN). *See also* Nephroma, mesoblastic.
- multicystic dysplastic kidney vs., **631**
- Wilms tumor vs., **641**

Congenital muscular dystrophy
- lissencephaly vs., **1033**
- other cerebellar malformations vs., **1023**

Congenital muscular torticollis. *See* Fibromatosis colli.
Congenital nasal pyriform aperture stenosis (CNPAS), **8–9**
- associated abnormalities, **9**
- diagnostic checklist, **9**
- differential diagnosis, **9**

Congenital neuroblastoma, fibromatosis colli vs., **1240**
Congenital nonsyndromic external ear & middle ear malformation, branchiootorenal syndrome vs., **1217**
Congenital obstructive uropathy, multicystic dysplastic kidney disease, **631**
Congenital pseudoarthrosis, clavicle injuries vs., **833**
Congenital pulmonary airway malformation (CPAM), **62–65**
- associated abnormalities, **64**
- bronchial atresia vs., **79**
- bronchogenic cyst vs., **72**
- bronchopulmonary sequestration vs., **67**
- congenital diaphragmatic hernia vs., **85–86**
- congenital lobar overinflation vs., **75**
- diagnostic checklist, **64**
- differential diagnosis, **63–64**
- gastric volvulus vs., **397**
- neonatal pneumonia vs., **93**
- neonatal pneumothorax vs., **103**
- normal thymus vs., **58**
- prognosis, **64**
- pulmonary interstitial emphysema vs., **99**
- staging, grading, & classification, **64**
- VACTERL association, **782**

Congenital pulmonary venolobar syndrome. *See* Scimitar syndrome.
Congenital soft tissue mass
- infantile myofibroma vs., **907**
- myofibromatosis vs., **907**

Congenital spinal malformations, pediatric spine, approach, **1144**
Congenital stenosis, esophageal strictures, **547**
Congenital syphilis, **869**
- Langerhans cell histiocytosis vs., **938**
- leukemia vs., **934**
- rickets vs., **986**

Congenital tibial bowing, **764**
Congenital tibial dysplasia, **764**
Congenital vertical talus, clubfoot vs., **789**
Congestive heart failure, increased pulmonary blood flow, L-transposition of great arteries vs., **253**
Conjunctivitis, cat-scratch disease, **479**
Connective tissue abnormalities, pectus excavatum, **189**
Connective tissue disorder, arthrogryposis, **787**

INDEX

Conservative treatment, orthopedic hardware and complications, **825**
Constipation, cystic fibrosis, **565**
Constitutional fascial hernia, **831**
Constrictive bronchiolitis, neuroendocrine cell hyperplasia of infancy vs., **174**
Contour, normal variant, renal injury vs., **669**
Contralateral renal abnormalities, renal agenesis, **629**
Contralateral renal dysplasia, renal ectopia and fusion, **626**
Contusion. *See also* Bowel injury.
- granuloma annulare vs., **921**
- mesenteric, omental infarction vs., **499**
- pancreatic trauma vs., **521**

Conventional radiographs, pediatric spine, approach, **1144**
Cor triatriatum, total anomalous pulmonary venous return vs., **261**
Cord contusion, spinal cord ependymoma vs., **1159**
Cord infarction
- spinal cord astrocytoma vs., **1161**
- spinal cord ependymoma vs., **1159**

Coronary arteries, imaging anatomy, **218**
Coronary artery fistula, left coronary artery anomalous origin vs., **269**
Corpus callosum
- attenuation of, callosal anomalies vs., **1029**
- destruction of, callosal anomalies vs., **1029**
- immaturity of, callosal anomalies vs., **1029**

Cortical desmoid. *See* Distal femoral avulsive irregularity.
Cortical disruption, incomplete fractures, **803**
Cortical dysplasia
- focal
  - DNET vs., **1080**
  - hemimegalencephaly, **1031**
- tuberous sclerosis vs., **1053**

Cortical neoplasms
- adrenal, neuroblastoma vs., **704**
- focal cortical dysplasia vs., **1041**

Cortical screws, orthopedic hardware and complications, **826**
Corticomedullary differentiation, **585**
COVID-19, **120–123**
- differential diagnosis, **121**
- prognosis, **122**

Cowden syndrome. *See* Lhermitte-Duclos disease (LDD).
Coxa valga, congenital, developmental hip dysplasia vs., **955–956**
CPAM. *See* Congenital pulmonary airway malformation.
CPT. *See* Choroid plexus tumor.
Craniocervical junction injuries, **1170–1173**
- differential diagnosis, **1172**
- prognosis, **1172**

Craniopharyngioma, **1084–1085**
- colloid cyst vs., **1059**
- dermoid/epidermoid cysts vs., **1063**
- diagnostic checklist, **1085**
- differential diagnosis, **1085**
- germinoma vs., **1087**

Craniostenosis. *See* Craniosynostoses.
Craniosynostoses, **1134–1137**
- associated abnormalities, **1136**
- diagnostic checklist, **1136**
- differential diagnosis, **1135**
- genetics, **1136**
- prognosis, **1136**

Craniosynostosis. *See* Craniosynostoses.
CRMO. *See* Chronic recurrent multifocal osteomyelitis.
Crohn disease (CD), **540–543**
- chronic granulomatous disease vs., **536**
- diagnostic checklist, **542**
- differential diagnosis, **542**
- duodenal trauma vs., **517**
- hypoperfusion complex vs., **501**
- Meckel diverticulum vs., **428**
- neutropenic colitis vs., **531**
- primary mesenteric adenitis vs., **495**
- prognosis, **542**
- pseudomembranous colitis vs., **529**
- ulcerative colitis vs., **545**

Crossed fused ectopia. *See* Renal ectopia and fusion.
Crossed fused renal ectopia, renal agenesis vs., **629**
Croup, **22–25**
- associated abnormalities, **24**
- asthma vs., **195**
- bacterial tracheitis vs., **27**
- differential diagnosis, **23–24**
- epiglottitis vs., **19**
- expiratory buckling of trachea vs., **6**
- prognosis, **24**
- staging, grading, & classification, **24**
- viral, airway infantile hemangioma vs., **47**

Cryptorchidism. *See also* Ectopic testicle.
- gastroschisis, **414**
- omphalocele, **409**
- renal ectopia and fusion, **626**

CSF flow artifact (MR pseudocyst), colloid cyst vs., **1059**
CSF shunts and complications, **1138–1141**
- diagnostic checklist, **1140**
- differential diagnosis, **1140**
- prognosis, **1140**

Cubitus valgus, lateral condylar fracture, **840**
Cubitus varus, lateral condylar fracture, **840**
Currarino syndrome, VACTERL association vs., **781**
Currarino triad, caudal regression vs., **1150**
Cutis aplasia congenita, cephalocele vs., **1025**
Cutis laxa
- bladder diverticula, **687**
- neurogenic bladder vs., **684**

CVI. *See* Cavum veli interpositi.
Cyanosis, decreased pulmonary blood flow, L-transposition of great arteries vs., **253**
Cyanotic heart disease, pulmonary arteriovenous malformation, **157**
Cyanotic heart lesions
- with component of (sub-) pulmonary stenosis, pulmonary atresia vs., **243**
- right-sided obstructive, with decreased pulmonary vascularity, Ebstein anomaly vs., **247**

Cyst
- adrenal
  - neonatal adrenal hemorrhage vs., **696**
  - normal neonatal adrenal gland vs., **587**

- bronchogenic, **70–73**
  - associated abnormalities, **72**
  - bronchial atresia vs., **79**
  - bronchopulmonary sequestration vs., **67**
  - congenital pulmonary airway malformation vs., **63**
  - differential diagnosis, **71–72**
  - pneumonia with cavitary necrosis vs., **132**
  - prognosis, **72**
- choledochal
  - cirrhosis, **461**
  - gastrointestinal duplication cysts vs., **556**
  - mesenteric lymphatic malformation vs., **497**
  - pancreaticobiliary maljunction vs., **487**
- of CSP, **1016**
- duplication, enteric, duodenal trauma vs., **517**
- esophageal duplication, bronchogenic cyst vs., **71**
- foregut duplication, normal thymus vs., **58**
- functional, ovarian malignancies of childhood vs., **730**
- gastrointestinal duplication, **554–557**
  - diagnostic checklist, **556**
  - differential diagnosis, **555–556**
  - mesenteric lymphatic malformation vs., **497**
  - prognosis, **556**
- hemorrhagic, ovarian malignancies of childhood vs., **730**
- hepatic, mesenteric lymphatic malformation vs., **497**
- mesothelial, mesenteric lymphatic malformation vs., **497**
- neurenteric, bronchogenic cyst vs., **71**
- orbital dermoid & epidermoid, nasolacrimal duct mucocele vs., **11**
- ovarian, **720–723**
  - bladder diverticula vs., **687**
  - diagnostic checklist, **722**
  - differential diagnosis, **721–722**
  - gastrointestinal duplication cysts vs., **556**
  - prognosis, **722**
  - ureterocele vs., **604**
- paraovarian
  - bladder diverticula vs., **687**
  - ovarian cyst vs., **722**
- peritoneal inclusion, mesenteric lymphatic malformation vs., **497**
- pulmonary, pleuropulmonary blastoma, **153**
- renal, angiomyolipoma vs., **661**
- splenic, **476–477**
  - diagnostic checklist, **477**
  - differential diagnosis, **477**
  - prognosis, **477**
- thymic
  - cervical lymphatic malformation vs., **14**
  - germ cell tumors vs., **145**
  - normal thymus vs., **58**
- thyroglossal duct, cervical lymphatic malformation vs., **15**

Cyst-forming parasites, enlarged perivascular spaces vs., **1065**
Cystadenomas, ovarian teratoma vs., **725**
Cystic biliary atresia, choledochal cyst vs., **455**
Cystic bronchiectasis, Langerhans cell histiocytosis vs., **187**
Cystic cochleovestibular malformation, large vestibular aqueduct vs., **1207**
Cystic encephalomalacia, enlarged perivascular spaces vs., **1065**
Cystic fibrosis (CF)
- appendicitis vs., **420**
- asthma vs., **195**
- cirrhosis, **461**
- esophageal atresia and tracheoesophageal fistula vs., **82**
- fungal pneumonia in immunocompromised children, **135**
- gastrointestinal tract, **564–567**
  - diagnostic checklist, **566**
  - differential diagnosis, **566**
  - genetics, **566**
  - prognosis, **566**
- Langerhans cell histiocytosis vs., **187**
- lymphangioleiomyomatosis vs., **185**
- pancreatitis vs., **492**
- pulmonary, **202–205**
  - diagnostic checklist, **204**
  - differential diagnosis, **203**
  - prognosis, **204**
- small bowel intussusception, **559**
- steatosis/steatohepatitis vs., **463**

Cystic malignancy, mesenteric lymphatic malformation vs., **497**
Cystic neoplasms, enlarged perivascular spaces vs., **1065**
Cystic nephroma, pediatric, multicystic dysplastic kidney vs., **631**
Cystic renal disease, normal neonatal kidney vs., **585**
Cystic renal dysplasia, autosomal recessive polycystic kidney disease vs., **636**
Cystic teratoma. *See* Ovarian teratoma.
Cystinuria, renal stones, **674**
Cytokine release syndrome (CRS). *See* Hemophagocytic lymphohistiocytosis (HLH).
Cytomegalovirus (CMV), congenital, heterotopic gray matter vs., **1035**
Cytotoxic edema, pediatric brain, **1007**

D

D-transposition of great arteries, **250–251**
- double-outlet right ventricle vs., **273**
- prognosis, **251**

DAA. *See* Double aortic arch.
Dacryocystocele, acquired, nasolacrimal duct mucocele vs., **11**
Dandy-Walker continuum, **1018–1021**
- associated abnormalities, **1020**
- diagnostic checklist, **1020**
- differential diagnosis, **1019–1020**
- embryology, **1020**
- genetics, **1020**
- other cerebellar malformations vs., **1023**
- prognosis, **1020**

Dating fractures, **810**
Deep granuloma annulare. *See* Granuloma annulare.

INDEX

Deep pattern, hypoxic-ischemic encephalopathy, **1103**
Degenerative changes
- discitis/osteomyelitis vs., **1167**
- fracture complications, **821**
Dehydration, retropharyngeal space abscess, **32**
Delayed union, fracture complications, **821**
Delphian chain necrotic node, thyroglossal duct cyst vs., **1221–1222**
Demyelinating diseases, **1132–1133**
- brain abscess vs., **1129**
- diagnostic checklist, **1132**
- differential diagnosis, **1133**
- prognosis, **1133**
Denys-Drash syndrome, Wilms tumor associated with, **642**
Dermal sinus, split cord malformation, **1151**
Dermatologic disorders, chronic recurrent multifocal osteomyelitis, **884**
Dermatomyositis, **880–881**
- staging, grading, & classification, **881**
Dermoid and epidermoid cysts, **1062–1063**. *See also* Ovarian teratoma.
- branchial cleft anomalies vs., **1226**
- cavum septum pellucidum vs., **1016**
- cephalocele vs., **1025**
- diagnostic checklist, **1063**
- differential diagnosis, **1063**
- neurenteric cyst vs., **1153**
- orbital, nasolacrimal duct mucocele vs., **11**
- prognosis, **1063**
- split cord malformation, **1151**
- thyroglossal duct cyst vs., **1221**
- without sinus tract, dorsal dermal sinus vs., **1149**
Dermoid/teratoma, ovarian cyst vs., **721**
Dermoid tumor. *See* Ovarian teratoma.
Desmoid-type fibromatosis, **903**. *See also* Fibromatosis.
- musculoskeletal system, **765**
Desmoplastic infantile ganglioglioma, embryonal tumor with multilayered rosettes vs., **1083**
Desmoplastic infantile tumors, **1082**
- atypical teratoid/rhabdoid tumor vs., **1071**
Desmoplastic small round cell tumor
- Burkitt lymphoma vs., **573**
- inflammatory myofibroblastic tumor vs., **575**
Destruction, of corpus callosum, callosal anomalies vs., **1029**
Detrusor sphincter dyssynergia, epididymoorchitis, **740**
Devascularization, **757**
Developmental hip dysplasia, **954–957**
- differential diagnosis, **955–956**
- prognosis, **956**
- staging, grading, & classification, **956**
Dextroversion of heart, heterotaxy syndromes vs., **315**
Diaphragmatic eventration, congenital diaphragmatic hernia vs., **86**
Diaphragmatic hernia
- bronchogenic cyst, **72**
- congenital, **52, 84–87**
  - associated abnormalities, **86**
  - congenital pulmonary airway malformation vs., **63**
  - differential diagnosis, **85–86**
  - neonatal pneumothorax vs., **103**
  - prognosis, **86**
- VACTERL association, **782**
- wandering spleen, **473**
DICER1 mutation, genitourinary rhabdomyosarcoma, **692**
Diffuse alveolar hemorrhage, EVALI vs., **215**
Diffuse astrocytoma
- grade II, ganglioglioma vs., **1081**
- spinal cord astrocytoma, **1161**
Diffuse axonal injury, cavernous malformation vs., **1117**
Diffuse cerebral edema, **1007**
Diffuse hypertrophy of cerebellar cortex. *See* Lhermitte-Duclos disease (LDD).
Diffuse intrinsic pontine glioma (DIPG), **1077**
Diffuse leptomeningeal glioneuronal tumor, **1157**
- diagnostic checklist, **1157**
- differential diagnosis, **1157**
Diffuse lung developmental disorders, pulmonary interstitial glycogenosis vs., **177**
Diffuse lung disease, air bronchograms in, pulmonary interstitial emphysema vs., **99**
Diffuse midline glioma, spinal cord astrocytoma, **1161**
Diffuse neurofibroma, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
Diffusion tensor imaging (DTI), **1007**
DiGeorge syndrome
- fungal pneumonia in immunocompromised children, **135**
- VACTERL association vs., **782**
Digital fractures, **809–810**
Dilated cardiomyopathy
- left coronary artery anomalous origin vs., **269**
- left ventricular noncompaction vs., **305**
Dilated rete testes, testicular tumors vs., **754**
Direct inguinal hernia, **405**
Discitis/osteomyelitis, **1166–1167**
- differential diagnosis, **1167**
Discoid meniscus, **790–793**
- complete, **792**
- diagnostic checklist, **792**
- differential diagnosis, **791–792**
- incomplete, **792**
- lateral, **791**
- staging, grading, & classification, **792**
- Wrisberg ligament-type, **792**
Disseminated infection
- infantile myofibroma vs., **907**
- myofibromatosis vs., **907**
Distal femoral avulsive irregularity, **778–789**
- diagnostic checklist, **778**
- differential diagnosis, **779**
Distal femoral epiphyseal ossification, normal irregular, osteochondritis dissecans vs., **817–818**
Distal femoral metaphyseal irregularity, nonossifying fibroma vs., **941**
Distal humeral epiphyseal separation, supracondylar fracture vs., **835**
Distal intestinal obstruction syndrome (DIOS), cystic fibrosis, **565**
Distal neonatal bowel obstructions, cloaca vs., **621**
Distal radius fracture, **822**

Distal ureteral calculus, ovarian torsion vs., **734**
Distraction injury, chance fracture vs., **1175**
Diverticulum
- ductus diverticulum, aortic injury vs., **167**
- multiple, neurogenic bladder vs., **683–684**
- urachal, bladder diverticula vs., **687**

DNA polymerase γ-related disorders, **1123**
DNET. *See* Dysembryoplastic neuroepithelial tumor.
Dorsal agenesis, of pancreas, pancreas divisum vs., **485**
Dorsal dermal sinus, **1149**
- differential diagnosis, **1149**
- lipomyelomeningocele vs., **1148**

Dorsal enteric cyst. *See* Gastrointestinal duplication cysts.
Dorsal patellar defect, patellar dislocation vs., **852**
DORV. *See* Double-outlet right ventricle.
Double aortic arch (DAA), **34–37**
- associated abnormalities, **36**
- with atretic left arch, right arch with aberrant left subclavian artery vs., **45**
- diagnostic checklist, **36**
- differential diagnosis, **35–36**
- esophageal strictures vs., **547**
- genetics, **36**
- pulmonary sling vs., **40**

Double-inlet ventricule, L-transposition of great arteries vs., **253**
Double-outlet right ventricle, **272–273**
- differential diagnosis, **273**
- with normally related great vessels, tetralogy of Fallot vs., **239**
- pulmonary atresia vs., **243**
- with pulmonary stenosis, Ebstein anomaly vs., **247**
- with subaortic VSD, L-transposition of great arteries vs., **253**
- ventricular septal defect vs., **228**

Down syndrome
- congenital diaphragmatic hernia, **86**
- duodenal atresia or stenosis, **356**
- duodenal web, **358**
- germ cell tumors, **145**
- Hirschsprung disease, **373**

Drash syndrome, nephroblastomatosis, **645**
Duchenne muscular dystrophy-related cardiomyopathy, **308–309**
- differential diagnosis, **309**
- prognosis, **309**

Duct occluder device, **299**
Ductus diverticulum, aortic injury vs., **167**
Dumbbell-shaped femurs, achondroplasia vs., **970**
Duodenal atresia or stenosis, **354–357**
- annular pancreas vs., **489**
- anorectal malformations, **378**
- associated abnormalities, **356**
- diagnostic checklist, **356**
- differential diagnosis, **355–356**
- duodenal web vs., **358**
- genetics, **356**
- midgut volvulus vs., **352**
- prognosis, **356**
- pyloric atresia vs., **359**
- staging, grading, & classification, **356**

Duodenal hematoma, bezoars vs., **551**
Duodenal obstruction
- congenital, spectrum of, midgut volvulus vs., **352**
- gastroesophageal reflux vs., **391**

Duodenal perforation, pancreatic trauma vs., **521**
Duodenal stenosis
- gastroesophageal reflux vs., **391**
- hypertrophic pyloric stenosis vs., **393**
- midgut volvulus vs., **352**

Duodenal trauma, **516–519**
- associated abnormalities, **518**
- diagnostic checklist, **518**
- differential diagnosis, **517–518**
- pancreatic trauma vs., **521–522**
- prognosis, **518**
- staging, grading, & classification, **518**

Duodenal ulcer/duodenitis, duodenal trauma vs., **517**
Duodenal web, **358**
- annular pancreas, **489**
- annular pancreas vs., **489**
- associated anomalies, **358**
- differential diagnosis, **358**
- duodenal atresia or stenosis vs., **355**
- gastroesophageal reflux vs., **391**
- midgut volvulus vs., **352**

Duodenojejunal junction
- artifactual displacement, normal variations of duodenojejunal junction position vs., **339**
- normal variations of, **338–341**
  differential diagnosis, **339**

Duodenum, redundant
- malrotation vs., **347**
- midgut volvulus vs., **352**

Duodenum inversum
- malrotation vs., **347**
- normal variations of duodenojejunal junction position vs., **339**

Duplex collecting system. *See* Ureteropelvic duplications.
Duplicated collecting system, müllerian duct anomalies, **718**
Duplicated kidney. *See* Ureteropelvic duplications.
Duplicated renal collecting system, annular pancreas, **489**
Duplication cyst
- enteric, duodenal trauma vs., **517**
- foregut
  neuroblastoma vs., **704**
  normal thymus vs., **58**
- gastrointestinal
  duodenal atresia or stenosis vs., **355**
  duodenal web vs., **358**
- small bowel intussusception, **559**

Dural arteriovenous fistula, childhood, vein of Galen aneurysmal malformation vs., **1113**
Dynamic compression plate, orthopedic hardware and complications, **826**
Dysembryoplastic neuroepithelial tumor, **1080**
- ganglioglioma vs., **1081**

Dysgerminoma, **729**
Dyskinesia, ciliary, cystic fibrosis, pulmonary vs., **203**
Dysmorphic neurons, focal cortical dysplasia, **1041**
Dysphagia, retropharyngeal space abscess, **32**

Dysplasia
- bronchopulmonary, **106–109**
  differential diagnosis, **107**
  prognosis, **108**
- metatropic, achondroplasia vs., **970**
- spondylometaphyseal, child abuse, metaphyseal fracture vs., **806**
- thanatophoric, achondroplasia vs., **970**

Dysplasia epiphysealis hemimelica, osteochondroma, **952**
Dysplastic cerebellar gangliocytoma. *See* Lhermitte-Duclos disease (LDD).
Dysplastic kidney
- involuted microcystic, renal agenesis vs., **629**
- multicystic, ureteropelvic junction obstruction vs., **592**

Dystroglycanopathies
- Dandy-Walker continuum vs., **1020**
- lissencephaly vs., **1033**

E

E-cigarette vaping-associated lung injury (EVALI), COVID-19 vs., **121**
Eagle-Barrett syndrome. *See* Prune-belly syndrome.
Early bolus artifact, splenic trauma vs., **513**
Ebstein anomaly, **246–249**
- associated abnormalities, **247**
- differential diagnosis, **247**
- genetics, **247**
- prognosis, **248**
- pulmonary atresia vs., **244**
- tricuspid atresia vs., **255**

ECMO. *See* Extracorporeal membrane oxygenation (ECMO) catheters.
Ectopia, omphalocele, **410**
Ectopic kidney
- müllerian duct anomalies, **718**
- renal agenesis vs., **629**
- vesicoureteral reflux, **596**

Ectopic ovary, **736–737**
- diagnostic checklist, **737**
- differential diagnosis, **737**
- normal prepubertal uterus and ovaries vs., **589**
- prognosis, **737**

Ectopic pregnancy
- ovarian cyst vs., **722**
- ovarian teratoma vs., **725**
- ovarian torsion vs., **734**

Ectopic retropharyngeal thymus, **58**
Ectopic testicle, **758–759**
- diagnostic checklist, **759**
- differential diagnosis, **759**
- prognosis, **759**
- staging, grading, & classification, **759**

Ectopic thyroid tissue, **1181**
Ectopic ureter, epididymoorchitis, **740**
Ectopic vas deferens, epididymoorchitis, **740**
Edema
- angioneurotic, epiglottitis, **20**
- pulmonary, bacterial tracheitis, **28**
- retropharyngeal space, retropharyngeal space abscess vs., **31**

Effusions
- orbital cellulitis, **1198**
- pleural, malignant, parapneumonic effusion and empyema vs., **129**

Ehlers-Danlos syndrome
- abdominal aneurysms, **577**
- bladder diverticula, **687**
- neurogenic bladder vs., **684**
- vascular, Loeys-Dietz syndrome vs., **331**

Elbow fractures, musculoskeletal system, **764–765**
Electronic cigarette (e-cigarette) or vaping product use-associated lung injury (EVALI), **214–215**
- diagnostic checklist, **215**
- differential diagnosis, **215**
- prognosis, **215**

Ellis van Creveld syndrome, achondroplasia vs., **970**
Emboli, septic, posttransplant lymphoproliferative disease vs., **526**
Embryonal rhabdomyosarcoma, **913**. *See also* Rhabdomyosarcoma, genitourinary.
Embryonal sarcoma, undifferentiated, hepatoblastoma vs., **435**
Embryonal tumor with multilayered rosettes, **1083**
- differential diagnoses, **1083**
- glioblastoma vs., **1075**
- supratentorial ependymoma vs., **1074**

Embryonal tumors, omphalocele, **410**
Emphysema, pulmonary interstitial, **98–101**
- diagnostic checklist, **100**
- differential diagnosis, **99**
- prognosis, **100**

Empyema, **53**
- orbital cellulitis, **1198**

Encephalitis
- acute, childhood stroke vs., **1105**
- mitochondrial encephalopathies vs., **1123**

Encephalocele, **1025**
- autosomal recessive polycystic kidney disease vs., **636**
- juvenile angiofibroma vs., **1190**
- omphalocele, **410**

Encephaloclastic lesion, focal cortical dysplasia, **1041**
Encephaloclastic porencephaly, schizencephaly vs., **1037**
Encephalomalacia, cystic, enlarged perivascular spaces vs., **1065**
Encephalomyelitis, acute disseminated, brainstem tumors vs., **1078**
Encephalopathy
- cat-scratch disease, **479**
- hypoxic-ischemic, **1102–1103**
  associated abnormalities, **1103**
  differential diagnosis, **1103**
  germinal matrix hemorrhage vs., **1097**
  staging, grading, & classification, **1103**
- mitochondrial
  abusive head trauma vs., **1094**
  childhood stroke vs., **1105**

Enchondroma, nonossifying fibroma vs., **942**

End-stage renal disease, multicystic dysplastic kidney vs., **632**
Endobronchial neoplasm, obstructive, Swyer-James syndrome vs., **183**
Endobronchial tumor, slow-growing, bronchial atresia vs., **79**
Endocardial fibroelastosis
- aortic coarctation, **276**
- hypoplastic left heart syndrome vs., **266**
Endocarditis
- aortic stenosis, **279**
- cat-scratch disease, **479**
Endochondral growth slowing, other conditions with, achondroplasia vs., **970**
Endochondral ossification, **769**
Endocrine symptoms, craniopharyngioma, **1085**
Endometrioma, ovarian teratoma vs., **726**
Enema, reduction of, intussusception, gastrointestinal tract, **335**
Enlarged lymph nodes, variations of hydroceles vs., **761**
Enlarged perivascular spaces, **1065**
Enlarged subarachnoid spaces, **1014–1015**
- diagnostic checklist, **1015**
- differential diagnosis, **1015**
- prognosis, **1015**
Enlarged vestibular aqueduct. *See* Large vestibular aqueduct.
Enteric cyst. *See* Gastrointestinal duplication cysts.
Enteric duplication, omphalocele, **409**
Enteric duplication cyst
- duodenal trauma vs., **517**
- ovarian cyst vs., **722**
Enteric tubes, small bowel intussusception, **559**
Enteritis, radiation, graft-vs.-host disease vs., **533**
Enterocolitis
- in infant, Hirschsprung disease vs., **374**
- infectious
  - Crohn disease vs., **542**
  - hypoperfusion complex vs., **501**
- infectious/inflammatory, MIS-C vs., **122**
- necrotizing, **384–387**
  - associated abnormalities, **386**
  - diagnostic checklist, **386**
  - differential diagnosis, **385**
  - Hirschsprung disease vs., **374**
  - jejunoileal atresia vs., **362**
  - prognosis, **386**
  - staging, grading, & classification, **386**
- severe, pneumatosis intestinalis vs., **539**
- of term infants, necrotizing enterocolitis vs., **385**
Enterocyst. *See* Gastrointestinal duplication cysts.
Enterocystoma. *See* Gastrointestinal duplication cysts.
Enterogenous cyst. *See* Gastrointestinal duplication cysts.
Enteroliths, meconium peritonitis vs., **381–382**
Enterotomy. *See* Bowel injury.
Enthesis-related arthritis, chronic recurrent multifocal osteomyelitis, **884**
Enthesitis-related arthritis, **877**
Environmental factors, genitourinary rhabdomyosarcoma, **692**
Eosinophilic cystitis, genitourinary rhabdomyosarcoma vs., **692**
Eosinophilic esophagitis, esophageal strictures, **547**
Eosinophilic gastritis, hypertrophic pyloric stenosis, **394**
Eosinophilic pneumonia, acute, EVALI vs., **215**
Ependymal spread, of tumor, heterotopic gray matter vs., **1035**
Ependymoma
- atypical teratoid/rhabdoid tumor vs., **1071**
- choroid plexus tumors vs., **1089**
- medulloblastoma vs., **1069**
- pilocytic astrocytoma vs., **1067**
- posterior fossa, **1072–1073**
  - differential diagnosis, **1073**
  - prognosis, **1073**
- spinal cord astrocytoma vs., **1161**
- supratentorial, **1074**
  - desmoplastic infantile tumors vs., **1082**
Epicondyle avulsion, medial
- lateral condylar fracture vs., **839**
- supracondylar fracture vs., **835**
Epidermoid. *See* Congenital cholesteatoma.
Epidermoid cyst. *See also* Cavum veli interpositi.
- arachnoid cyst vs., **1061**
- cavum septum pellucidum vs., **1016**
- pineal cyst vs., **1064**
- testicular tumors vs., **754**
Epidermolysis bullosa, esophageal strictures, **547, 548**
Epididymal appendage, torsion of, testicular torsion vs., **743**
Epididymitis. *See also* Epididymoorchitis.
- paratesticular rhabdomyosarcoma vs., **751**
Epididymoorchitis, **738–741**
- associated abnormalities, **740**
- differential diagnosis, **739**
- prognosis, **740**
- testicular torsion vs., **743**
- torsion of testicular appendage vs., **747**
Epidural abscess, arachnoid cyst vs., **1061**
Epigastric veins, inferior, PICCs, **115**
Ω epiglottis (normal variant), epiglottitis vs., **20**
Epiglottitis, **18–21**
- bacterial tracheitis vs., **27**
- croup vs., **23**
- diagnostic checklist, **20**
- differential diagnosis, **19–20**
- prognosis, **20**
Epiphyseal dysplasias, Legg-Calvé-Perthes disease vs., **962**
Epiphyseal ossification, normal irregular distal femoral, osteochondritis dissecans vs., **817–818**
Epiphyseal separations, **809**
- distal humeral, supracondylar fracture vs., **835**
Epiphysiodesis
- physeal fractures vs., **795–796**
- stress injuries vs., **813**
Epiploic appendagitis
- Meckel diverticulum vs., **428**
- omental infarction vs., **499**
Epispadias, **623**
Epistaxis, telangiectasias, family history, pulmonary arteriovenous malformation, **157**

Epithelial tumors
- ovarian malignancies of childhood, **729**
- ovarian teratoma vs., **725**
Erythema multiforme, Kawasaki disease vs., **323**
Esophageal atresia
- duodenal atresia or stenosis, **356**
- gastroesophageal reflux vs., **391**
- hypertrophic pyloric stenosis, **394**
- with tracheoesophageal fistula, **335**
Esophageal atresia and tracheoesophageal fistula, **80–83**
- associated abnormalities, **82**
- diagnostic checklist, **82**
- differential diagnosis, **81–82**
- genetics, **82**
- prognosis, **82**
- staging, grading, & classification, **82**
Esophageal duplication cyst, bronchogenic cyst vs., **71**
Esophageal foreign body, **547**
- chronic, **206–207**
  differential diagnosis, **207**
  prognosis, **207**
Esophageal intubation, **53, 112**
- diagnostic checklist, **112**
- differential diagnoses, **112**
Esophageal strictures, **546–549**
- associated abnormalities, **548**
- differential diagnosis, **547**
- esophageal atresia and tracheoesophageal fistula vs., **82**
- prognosis, **548**
Esophagitis, gastroesophageal reflux vs., **391**
Esophagus, extrinsic compression, esophageal atresia and tracheoesophageal fistula vs., **82**
Essential hypertension, renal artery stenosis vs., **680**
Esthesioneuroblastoma, juvenile angiofibroma vs., **1190**
EVALI. *See* Electronic cigarette (e-cigarette) or vaping product use-associated lung injury.
Everting ureterocele, bladder diverticula vs., **687**
Ewing sarcoma, **924–927**
- apophyseal injuries vs., **800**
- chest wall, round pneumonia vs., **126**
- chest wall hamartoma vs., **193**
- chronic recurrent multifocal osteomyelitis vs., **883**
- diagnostic checklist, **926**
- differential diagnosis, **925–926**
- extraosseous, rhabdomyosarcoma, musculoskeletal vs., **913**
- genetics, **926**
- Langerhans cell histiocytosis vs., **938**
- leukemia vs., **934**
- musculoskeletal system, **765**
- osteomyelitis vs., **863**
- osteosarcoma vs., **929**
- prognosis, **926**
- stress injuries vs., **813**
Exanthematous infections, Kawasaki disease vs., **323**
Excessive dynamic airway collapse. *See* Tracheobronchomalacia.
Exomphalos. *See* Omphalocele.
Exstrophy-epispadias complex. *See* Bladder exstrophy.
Exstrophy of cloaca, VACTERL association, **782**
External fixation, orthopedic hardware and complications, **825**
Extraabdominal desmoid tumor. *See* Fibromatosis.
Extracorporeal membrane oxygenation (ECMO) catheters, **113**
Extrahepatic fluid collection, **469**
Extralobar bronchopulmonary sequestration
- neonatal adrenal hemorrhage vs., **695–696**
- neuroblastoma vs., **149, 704**
- normal neonatal adrenal gland vs., **587**
Extraosseous Ewing. *See* Ewing sarcoma.
Extraosseous Ewing sarcoma, rhabdomyosarcoma, musculoskeletal vs., **913**
Extrinsic compression
- by mass, esophageal strictures vs., **547**
- tracheobronchomalacia vs., **49**
Extrinsic esophageal compression, esophageal atresia and tracheoesophageal fistula vs., **82**
Extrinsic mass, primary megaureter vs., **607**
Extrinsic obstructions, noninfectious, approach to, **4**
Exudative tracheitis. *See* Bacterial tracheitis.

F

Facial anomalies, holoprosencephalies, **1027**
Facial capillary malformation, Sturge-Weber syndrome, **1055**
Facial nerve schwannoma, congenital cholesteatoma vs., **1209**
Factor IX deficiency. *See* Hemophilia.
Factor VIII deficiency. *See* Hemophilia.
Failure of forebrain cleavage, callosal anomalies vs., **1029**
Fallopian tube torsion
- hydrometrocolpos vs., **713**
- isolated, ovarian torsion vs., **734**
Familial adenomatous polyposis, pancreatoblastoma, **481**
Fanconi anemia, VACTERL association vs., **781**
Fasciitis, kaposiform hemangioendothelioma vs., **891**
Fat-containing masses, omental infarction vs., **499**
Fat-containing neoplasms, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
Fat necrosis
- granuloma annulare vs., **921**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- posttraumatic, soft tissue foreign bodies vs., **829**
Fat trauma, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
Fatigue fracture, **813**
Fatty acid oxidation disorders, **1119**
Fatty liver disease, nonalcoholic, cirrhosis, **461**
FCD. *See* Focal cortical dysplasia.
Fecal impaction, appendicitis vs., **420**
Fecal material, renal stones vs., **673**
Feces, small bowel, bezoars vs., **551**
Feingold syndrome, duodenal atresia or stenosis, **356**
Femoral epiphysis, slipped capital, Legg-Calvé-Perthes disease vs., **962**
Femoral hernia, **405**

Femur, proximal focal femoral deficiency, **959**
Femur fracture, **822**
Fetal alcohol syndrome, aortic coarctation, **276**
Fetal renal hamartoma. *See* Nephroma, mesoblastic.
Fever, posttransplant lymphoproliferative disease, **526**
Fibroadipose vascular anomaly, venous malformation, musculoskeletal vs., **894**
Fibroelastoma, papillary, rhabdomyoma vs., **319**
Fibroelastosis, endocardial, hypoplastic left heart syndrome vs., **266**
Fibroepithelial polyp, ureteral, ureteropelvic junction obstruction vs., **592**
Fibrohistiocytic reaction. *See* Soft tissue foreign bodies.
Fibrohistiocytic tumors, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
Fibrolamellar hepatocellular carcinoma
- focal nodular hyperplasia vs., **443**
- hepatocellular carcinoma vs., **446**

Fibroma
- chondromyxoid, nonossifying fibroma vs., **942**
- nonossifying, **940–943**
  - diagnostic checklist, **942**
  - differential diagnosis, **941–942**
  - genetics, **942**
  - prognosis, **942**
- rhabdomyoma vs., **319**

Fibromatosis, **902–905**
- associated abnormalities, **904**
- diagnostic checklist, **904**
- differential diagnosis, **903–904**
- genetics, **904**
- granuloma annulare vs., **921**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- prognosis, **904**

Fibromatosis colli, **1238–1241**
- differential diagnosis, **1240**
- prognosis, **1240**
- rhabdomyosarcoma, head and neck vs., **1235**
- suppurative adenitis vs., **1244**

Fibromatous/angiofibromatous hamartoma. *See* Juvenile angiofibroma.
Fibromuscular dysplasia, aortic coarctation, **276**
Fibrosarcoma
- infantile myofibroma vs., **907**
- myofibromatosis vs., **907**
- rhabdomyosarcoma, musculoskeletal vs., **913**

Fibrosis, **460–461**
- cystic, pulmonary, **202–205**
  - diagnostic checklist, **204**
  - differential diagnosis, **203**
  - prognosis, **204**

Fibrous cortical defect (FCD). *See* Nonossifying fibroma (NOF).
Fibrous dysplasia
- nonossifying fibroma vs., **942**
- osteogenesis imperfecta vs., **977**

Fibrous hamartoma of infancy, **904**
- fibromatosis vs., **904**
- infantile myofibroma vs., **907**
- lipoblastoma vs., **910**
- myofibromatosis vs., **907**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**

Fibrovascular polyp, post-Deflux procedure appearance vs., **689**
Fibroxanthoma. *See also* Nonossifying fibroma (NOF).
- distal femoral avulsive irregularity vs., **779**

Fibular head avulsion fracture, **847**
Fibular hemimelia, **785**
- diagnostic checklist, **785**

1st branchial cleft anomaly, infected, acute parotitis vs., **1229**
1st branchial cleft cyst
- type I, **1181**
- type II, **1181**

Fishtail deformity, **821**
- lateral condylar fracture, **840**

Fissures, normal, hepatic trauma, **509**
Flexion-distraction injury. *See* Chance fracture.
Flipped meniscus, discoid meniscus vs., **791**
Fluoroscopic voiding cystourethrogram, genitourinary tract, **581**
Focal bacterial nephritis. *See* Pyelonephritis.
Focal biliary cirrhosis, cystic fibrosis, **565**
Focal bone lesions, musculoskeletal system, **765**
Focal chest mass, bronchopulmonary sequestration vs., **67–68**
Focal cortical dysplasia (FCD), **1040–1041**
- diagnostic checklist, **1041**
- differential diagnosis, **1041**
- DNET vs., **1080**
- ganglioglioma vs., **1081**
- hemimegalencephaly, **1031**
- staging, grading, & classification, **1041**
- tuberous sclerosis vs., **1053**

Focal cystitis, ureterocele vs., **604**
Focal femoral deficiency, proximal, developmental hip dysplasia vs., **956**
Focal intestinal perforation. *See* Spontaneous intestinal perforation.
Focal nodular hyperplasia, **442–443**
- Abernethy malformation, **467**
- diagnostic checklist, **443**
- differential diagnosis, **443**
- hepatic adenoma vs., **445**
- hepatocellular carcinoma vs., **446**
- prognosis, **443**

Focal orchitis, testicular tumors vs., **753**
Focal periosteal reaction, stress injuries vs., **813**
Fontan operation, **290–291**
- differential diagnosis, **291**

FOOSH injury, **835**
Forearm fractures, **822, 844–845**
- differential diagnosis, **845**
- prognosis, **845**

Forebrain cleavage, failure of, callosal anomalies vs., **1029**
Foregut duplication. *See* Gastrointestinal duplication cysts.
Foregut duplication cyst
- neuroblastoma vs., **704**
- normal thymus vs., **58**

Foregut malformation. *See* Gastrointestinal duplication cysts.

Foreign body
- aspirated, congenital lobar overinflation vs., **76**
- aspiration
  Swyer-James syndrome vs., **183**
  tracheobronchomalacia vs., **49**
- bronchial, esophageal atresia and tracheoesophageal fistula vs., **82**
- chronic, granuloma annulare vs., **921**
- chronic esophageal, **206–207**
  differential diagnosis, **207**
  prognosis, **207**
- croup vs., **23**
- inhalation or ingestion, asthma vs., **195**
- metallic, ingested coins vs., **399**
- small bowel intussusception, **559**
- upper airway, bacterial tracheitis vs., **27**

Foreign body granuloma. *See* Soft tissue foreign bodies.
4th branchial apparatus anomaly, thyroglossal duct cyst vs., **1221**
4th branchial pouch remnant, **1181**
Fracture complications, **820–823**
- diagnostic checklist, **822**
- malunion, **822**
- nonunion, **821–822**

Fracture fixation, orthopedic hardware and complications, **825**
Fractures
- child abuse, rib fractures, **158–161**
  diagnostic checklist, **160**
  differential diagnosis, **159–160**
  prognosis, **160**
- multiple, entities associated with, child abuse, rib fractures vs., **159–160**

Fragile bones, diseases with, osteogenesis imperfecta vs., **977**
Free intraperitoneal air from perforation, mimics of, bowel injury vs., **506**
Frontal osteomyelitis, orbital cellulitis, **1198**
Frontoethmoidal cephalocele
- nasal dermal sinus vs., **1185**
- nasolacrimal duct mucocele vs., **11**

Fructose intake, increased, steatosis/steatohepatitis, **463**
Functional bladder outlet obstruction, megaureter-megacystis vs., **608**
Functional cyst
- ovarian cyst, **722**
- ovarian malignancies of childhood vs., **730**

Fungal infection
- age-related appearance of spleen vs., **345**
- posttransplant lymphoproliferative disease vs., **526**

Fungal pneumonia
- in immunocompromised children, **134–135**
  associated syndromes, **135**
  differential diagnosis, **135**
- in immunocompromised patients, **53**

Fungus ball
- post-Deflux procedure appearance vs., **689**
- ureterocele vs., **604**

G

Galenic varix. *See* Vein of Galen aneurysmal malformation.
Gallbladder, absent
- omphalocele, **409**
- pulmonary sling, **40**

Gallstone ileus, bezoars vs., **551**
Ganglioglioma, **1081**
- DNET vs., **1080**
- glioblastoma vs., **1075**
- spinal cord astrocytoma vs., **1161**
- supratentorial ependymoma vs., **1074**

Ganglion, ACL, ACL injuries vs., **847**
Ganglion cyst
- musculoskeletal system, **765**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**

Ganglioneuroblastoma, neuroblastoma vs., **149**
Ganglioneuroma, neuroblastoma vs., **149**
Gardner fibroma, **903**
Gartland fracture. *See* Supracondylar fracture.
Gaseous distention, nonspecific, necrotizing enterocolitis vs., **385**
Gastric bezoar, hypertrophic pyloric stenosis vs., **393**
Gastric volvulus, **396–397**
- differential diagnosis, **397**
- prognosis, **397**
- wandering spleen, **473**

Gastritis, eosinophilic, hypertrophic pyloric stenosis, **394**
Gastroenteritis, ileocolic intussusception vs., **423**
Gastroesophageal reflux, **390–391**
- with aspiration, esophageal atresia and tracheoesophageal fistula vs., **82**
- croup, **24**
- diagnostic checklist, **391**
- differential diagnosis, **391**
- hypertrophic pyloric stenosis vs., **393**
- prognosis, **391**

Gastroesophageal reflux disease (GERD), cystic fibrosis, **565**
Gastrointestinal disorders, chronic recurrent multifocal osteomyelitis, **884**
Gastrointestinal duplication, gastroschisis, **414**
Gastrointestinal duplication cysts, **554–557**
- bladder diverticula vs., **687**
- choledochal cyst vs., **455**
- diagnostic checklist, **556**
- differential diagnosis, **555–556**
- duodenal atresia or stenosis vs., **355**
- duodenal web vs., **358**
- mesenteric lymphatic malformation vs., **497**
- prognosis, **556**

Gastrointestinal tract
- abdominal aneurysm, **576–577**
  associated abnormalities, **577**
  differential diagnosis, **577**
  prognosis, **577**
- Abernethy malformation, **466–467**
  associated abnormalities, **467**

differential diagnosis, **467**
prognosis, **467**
- annular pancreas, **488–489**
associated anomalies, **489**
differential diagnosis, **489**
- anorectal malformations, **376–379**
associated abnormalities, **378**
differential diagnosis, **377–378**
genetics, **378**
- appendicitis, **418–421**
diagnostic checklist, **420**
differential diagnosis, **420**
prognosis, **420**
- approach to, **334–337**
differential diagnoses, **335**
imaging techniques, **334–335**
- bezoars, **550–553**
diagnostic checklist, **552**
differential diagnosis, **551**
prognosis, **552**
- bowel injury, **504–507**
associated abnormalities, **506**
diagnostic checklist, **506**
differential diagnosis, **505–506**
prognosis, **506**
staging, grading, & classification, **506**
- Burkitt lymphoma, **572–573**
differential diagnosis, **573**
prognosis, **573**
staging, grading, & classification, **573**
- Castleman disease, **574**
- cat-scratch disease, **478–479**
associated abnormalities, **479**
diagnostic checklist, **479**
differential diagnosis, **479**
prognosis, **479**
- chronic granulomatous disease, **534–537**
diagnostic checklist, **536**
differential diagnosis, **536**
genetics, **536**
prognosis, **536**
- cloacal exstrophy/OEIS, **416**
differential diagnosis, **416**
- colonic atresia, **364**
differential diagnosis, **364**
- colonic volvulus, **430–431**
associated abnormalities, **431**
diagnostic checklist, **431**
differential diagnosis, **431**
- Crohn disease, **540–543**
diagnostic checklist, **542**
differential diagnosis, **542**
prognosis, **542**
- cystic fibrosis, **564–567**
diagnostic checklist, **566**
differential diagnosis, **566**
genetics, **566**
prognosis, **566**
- duodenal atresia or stenosis, **354–357**
associated abnormalities, **356**
diagnostic checklist, **356**
differential diagnosis, **355–356**
genetics, **356**
prognosis, **356**
staging, grading, & classification, **356**
- duodenal trauma, **516–519**
associated abnormalities, **518**
diagnostic checklist, **518**
differential diagnosis, **517–518**
prognosis, **518**
staging, grading, & classification, **518**
- duodenal web, **358**
associated anomalies, **358**
differential diagnosis, **358**
- esophageal strictures, **546–549**
associated abnormalities, **548**
differential diagnosis, **547**
prognosis, **548**
- fibrosis/cirrhosis, **461**
- focal nodular hyperplasia, **442–443**
diagnostic checklist, **443**
differential diagnosis, **443**
prognosis, **443**
- gastric volvulus, **396–397**
differential diagnosis, **397**
prognosis, **397**
- gastroesophageal reflux, **390–391**
diagnostic checklist, **391**
differential diagnosis, **391**
prognosis, **391**
- gastroschisis, **412–415**
associated abnormalities, **414**
diagnostic checklist, **414**
differential diagnosis, **413**
genetics, **413–414**
prognosis, **414**
- graft-vs.-host disease, **532–533**
differential diagnosis, **533**
prognosis, **533**
- hemophagocytic lymphohistiocytosis, **568–571**
differential diagnosis, **569**
prognosis, **570**
staging, grading, & classification, **569–570**
- hepatic adenoma, **444–445**
differential diagnosis, **445**
prognosis, **445**
- hepatic hemangiomas, infantile and congenital, **438–441**
diagnostic checklist, **440**
differential diagnosis, **440**
prognosis, **440**
- hepatic venooclusive disease, **464–465**
differential diagnosis, **465**
prognosis, **465**
- hepatoblastoma, **434–437**
diagnostic checklist, **436**
differential diagnosis, **435–436**
prognosis, **436**
staging, grading, & classification, **436**
- Hirschsprung disease, **372–375**
associated abnormalities, **374**
diagnostic checklist, **374**

differential diagnosis, **373–374**
genetics, **374**
prognosis, **374**
- hypertrophic pyloric stenosis, **392–395**
associated abnormalities, **394**
diagnostic checklist, **394**
differential diagnosis, **393–394**
genetics, **394**
prognosis, **394**
- hypoperfusion complex, **500–503**
associated abnormalities, **502**
diagnostic checklist, **502**
differential diagnosis, **501–502**
prognosis, **502**
- ileocolic intussusception, **422–425**
diagnostic checklist, **424**
differential diagnosis, **423**
prognosis, **424**
- inflammatory myofibroblastic tumor, **575**
differential diagnosis, **575**
- ingested button batteries, **400–401**
differential diagnosis, **401**
prognosis, **401**
- ingested coins, **398–399**
differential diagnosis, **399**
prognosis, **399**
- ingested multiple magnets, **402–403**
differential diagnosis, **403**
prognosis, **403**
- internal hernia, **432**
- jejunoileal atresia, **360–363**
associated abnormalities, **362**
diagnostic checklist, **362**
differential diagnosis, **362**
genetics, **362**
prognosis, **362**
staging, grading, & classification, **362**
- limb-body wall complex, **417**
differential diagnosis, **417**
- liver transplant complications, **468–471**
- malrotation, **346–349**
associated abnormalities, **347–348**
diagnostic checklist, **348**
differential diagnosis, **347**
prognosis, **348**

- Meckel diverticulum, **426–429**
diagnostic checklist, **427–428**
differential diagnosis, **427–428**
- meconium ileus, **366–369**
associated abnormalities, **368**
diagnostic checklist, **368**
differential diagnosis, **367–368**
genetics, **368**
prognosis, **368**
staging, grading, & classification, **368**
- meconium peritonitis, **380–383**
diagnostic checklist, **382**
differential diagnosis, **381–382**
prognosis, **382**
- mesenteric lymphatic malformation, **496–497**
diagnostic checklist, **496**
differential diagnosis, **497**
prognosis, **497**
- midgut volvulus, **350–353**
diagnostic checklist, **352**
differential diagnosis, **352**
prognosis, **352**
- multiple intestinal atresias, **365**
- necrotizing enterocolitis, **384–387**
associated abnormalities, **386**
diagnostic checklist, **386**
differential diagnosis, **385**
prognosis, **386**
staging, grading, & classification, **386**
- neonatal small left colon, **370–371**
differential diagnosis, **371**
prognosis, **371**
- neutropenic colitis, **530–531**
differential diagnosis, **531**
prognosis, **531**
- normal variations of cecal position, **342–343**
differential diagnosis, **343**
prognosis, **343**
- normal variations of duodenojejunal junction, **338–341**
differential diagnosis, **339**
- omental infarction, **498–499**
differential diagnosis, **499**
primary mesenteric adenitis vs., **495**
- omphalocele, **408–411**
associated abnormalities, **409**
diagnostic checklist, **410**
differential diagnosis, **409**
genetics, **409**
prognosis, **410**
- pancreas divisum, **484–485**
diagnostic checklist, **485**
differential diagnosis, **485**
types, **485**
- pancreatic trauma, **520–523**
differential diagnosis, **521–522**
prognosis, **522**
staging, grading, & classification, **522**
- pancreaticobiliary maljunction, **486–487**
differential diagnosis, **487**
prognosis, **487**
staging, grading, & classification, **487**
- pancreatitis, **490–493**
acute, **491**
acute recurrent, **491**
chronic, **491**
differential diagnosis, **492**
genetics, **492**
interstitial edematous, **491**
mortality rate, **492**
necrotizing, **491**
prognosis, **492**
- pancreatoblastoma, **480–481**
associated abnormalities, **481**
differential diagnosis, **481**
prognosis, **481**

- pneumatosis in older children, **538–539**
  differential diagnosis, **539**
- posttransplant lymphoproliferative disease, **524–527**
  differential diagnosis, **525–526**
  prognosis, **526**
  staging, grading, & classification, **526**
- primary mesenteric adenitis, **494–495**
  diagnostic checklist, **495**
  differential diagnosis, **495**
- pseudomembranous colitis, **528–529**
  differential diagnosis, **529**
  prognosis, **529**
- pyloric atresia, **359**
  differential diagnosis, **359**
- segmental volvulus, **433**
  diagnostic checklist, **433**
- small bowel intussusception, **558–559**
  differential diagnosis, **559**
  prognosis, **559**
- solid pseudopapillary neoplasm, **482–483**
  differential diagnosis, **483**
  prognosis, **483**
- splenic abnormalities, age-related appearance of spleen, **344–345**
- splenic cyst, **476–477**
  diagnostic checklist, **477**
  differential diagnosis, **477**
  prognosis, **477**
- splenic infarct, **474–475**
  differential diagnosis, **475**
  prognosis, **475**
  staging, grading, & classification, **475**
- splenic trauma, **512–515**
  diagnostic checklist, **514**
  differential diagnosis, **513**
  prognosis, **514**
  staging, grading, & classification, **514**
- spontaneous intestinal perforation in neonates, **388–389**
  differential diagnosis, **389**
  prognosis, **389**
- steatosis/steatohepatitis, **462–463**
  differential diagnosis, **463**
  prognosis, **463**
  staging, grading, & classification, **463**
- trauma
  hepatic, **508–511**
  pancreatic, duodenal trauma vs., **517**
- ulcerative colitis, **544–545**
  diagnostic checklist, **545**
  differential diagnosis, **545**
- wandering spleen, **472–473**
  associated abnormalities, **473**
  differential diagnosis, **473**
  prognosis, **473**

Gastroschisis, **412–415**
- associated abnormalities, **414**
- bladder exstrophy vs., **623**
- diagnostic checklist, **414**
- differential diagnosis, **413**
- genetics, **413–414**
- jejunoileal atresia, **362**
- limb-body wall complex vs., **417**
- omphalocele vs., **409**
- prognosis, **414**

Gaucher disease
- mucopolysaccharidoses vs., **974**
- red to yellow marrow conversion vs., **771**

Generalized lymphatic anomaly (GLA)
- chylothorax, **105**
- kaposiform lymphangiomatosis vs., **213**

Genetic conditions, pectus excavatum, **189**

Genital anomalies, ureteropelvic duplications, **600**

Genitalia, ambiguous, normal prepubertal uterus and ovaries vs., **589**

Genitourinary, angiomyolipoma, **660–663**
- associated abnormalities, **662**
- associated syndromes, **661**
- diagnostic checklist, **662**
- differential diagnosis, **661–662**
- genetics, **662**
- prognosis, **662**
- sporadic, **662**

Genitourinary abnormalities
- multicystic dysplastic kidney disease, **632**
- Wilms tumor, **642**

Genitourinary tract
- adrenocortical carcinoma, **708–709**
  associated abnormalities, **709**
  differential diagnosis, **709**
  pheochromocytoma vs., **711**
  prognosis, **709**
  staging, grading, & classification, **709**
- approach to, **580–583**
- bladder diverticula, **686–687**
  associated abnormalities, **687**
  differential diagnosis, **687**
  prognosis, **687**
- congenital abnormalities, primary megaureter, **606–607**
  differential diagnosis, **607**
- congenital abnormalities, urachal abnormalities, **616–619**
  associated abnormalities, **618**
  differential diagnosis, **617**
  prognosis, **618**
- congenital adrenal hyperplasia, **698–701**
  differential diagnosis, **700**
  ectopic testicle vs., **759**
  genetics, **700**
  neuroblastoma vs., **704**
  prognosis, **700**
- congenital anomalies, ureteropelvic duplications, **598–601**
  associated abnormalities, **600**
  differential diagnosis, **600**
  prognosis, **600**
- ectopic ovary, **736–737**
  diagnostic checklist, **737**
  differential diagnosis, **737**
  prognosis, **737**
- ectopic testicle, **758–759**
  diagnostic checklist, **759**

INDEX

differential diagnosis, **759**
prognosis, **759**
staging, grading, & classification, **759**
- epididymoorchitis, **738–741**
associated abnormalities, **740**
differential diagnosis, **739**
prognosis, **740**
- hemolytic uremic syndrome, **681**
- hydrometrocolpos, **712–715**
associated abnormalities, **714**
differential diagnosis, **713–714**
genetics, **714**
prognosis, **714**
- müllerian duct anomalies, **716–719**
associated abnormalities, **718**
diagnostic checklist, **718**
differential diagnosis, **718**
prognosis, **718**
- neonatal adrenal hemorrhage, **694–697**
diagnostic checklist, **696**
differential diagnosis, **695–696**
genetics, **696**
neuroblastoma vs., **703**
prognosis, **696**
- nephroblastomatosis, **644–647**
associated syndromes, **645**
diagnostic checklist, **646**
differential diagnosis, **645–646**
prognosis, **646**
staging, grading, & classification, **646**
- neuroblastoma, **702–707**
associated abnormalities, **704**
differential diagnosis, **703–704**
genetics, **704**
prognosis, **704**
staging, grading, & classification, **704**
- neurogenic bladder, **682–685**
associated abnormalities, **684**
diagnostic checklist, **684**
differential diagnosis, **683–684**
prognosis, **684**
staging, grading, & classification, **684**
- normal neonatal adrenal gland, **586–587**
differential diagnosis, **587**
- normal prepubertal uterus and ovaries, **588–589**
differential diagnosis, **589**
- ovarian cyst, **720–723**
diagnostic checklist, **722**
differential diagnosis, **721–722**
prognosis, **722**
- ovarian malignancies of childhood, **728–731**
diagnostic checklist, **730**
differential diagnosis, **730**
prognosis, **730**
tumor markers, **730**
- ovarian teratoma, **724–727**
associated abnormalities, **726**
differential diagnosis, **725–726**
prognosis, **726**
- ovarian torsion, **732–735**
diagnostic checklist, **734**
differential diagnosis, **733–734**
prognosis, **734**
- paratesticular rhabdomyosarcoma, **750–751**
associated abnormalities, **751**
differential diagnosis, **751**
prognosis, **751**
staging, grading, & classification, **751**
- pheochromocytoma, **710–711**
adrenocortical carcinoma vs., **709**
associated syndromes, **711**
differential diagnosis, **711**
neuroblastoma vs., **704**
prognosis, **711**
- post-Deflux procedure appearance, **688–689**
differential diagnosis, **689**
prognosis, **689**
- posterior urethral valves, **612–615**
associated abnormalities, **614**
differential diagnosis, **613–614**
prognosis, **614**
staging, grading, & classification, **614**
- pyelonephritis, **664–667**
differential diagnosis, **665–666**
prognosis, **666**
- renal artery stenosis, **680**
differential diagnosis, **680**
- renal injury, **668–671**
associated abnormalities, **670**
diagnostic checklist, **670**
differential diagnosis, **669–670**
prognosis, **670**
staging, grading, & classification, **670**
- renal stones, **672–675**
differential diagnosis, **673**
prognosis, **674**
- renal vein thrombosis, **678–679**
differential diagnosis, **679**
prognosis, **679**
- rhabdomyosarcoma, genitourinary, **690–693**
associated abnormalities, **692**
differential diagnosis, **691–692**
prognosis, **692**
staging, grading, & classification, **692**
- testicular torsion, **742–745**
diagnostic checklist, **744**
differential diagnosis, **743**
prognosis, **744**
staging, grading, & classification, **744**
- testicular trauma, **756–757**
diagnostic checklist, **757**
differential diagnosis, **757**
prognosis, **757**
- testicular tumors, **752–755**
diagnostic checklist, **752**
differential diagnosis, **753–754**
prognosis, **754**
staging, grading, & classification, **754**
- torsion of testicular appendage, **746–749**
associated abnormalities, **748**
diagnostic checklist, **748**
differential diagnosis, **747–748**

prognosis, **748**
- transient neonatal renal medullary hyperechogenicity, **676–677**
diagnostic checklist, **676**
differential diagnosis, **677**
prognosis, **677**
- ureterocele, **602–605**
associated abnormalities, **604**
differential diagnosis, **604**
prognosis, **604**
- variations of hydroceles, **760–761**
Genitourinary tract disorders, pediatric, **580–583**
- adrenal abnormalities, **581**
- bladder abnormalities, **581**
- congenital, **581**
- renal masses, **580**
- testicular abnormalities, **581**
- uterine & ovarian abnormalities, **581**
Germ cell tumor of coccyx. *See* Sacrococcygeal teratoma.
Germ cell tumors, **144–147**
- associated abnormalities, **145–146**
- diagnostic checklist, **146**
- differential diagnosis, **145**
- lymphoma vs., **142**
- normal thymus vs., **58**
- ovarian malignancies of childhood, **729**
- ovarian teratoma vs., **725**
- prognosis, **146**
Germinal matrix bleed, preterm caudothalamic hemorrhage, GMH-IVH. *See* Germinal matrix hemorrhage.
Germinal matrix hemorrhage (GMH), **1096–1099**
- differential diagnosis, **1097–1098**
- prognosis, **1098**
- staging, grading, & classification, **1098**
Germinal zone, physeal fractures, **796**
Germinoma
- brain, **1086–1087**
associated abnormalities, **1087**
diagnostic checklist, **1087**
differential diagnosis, **1087**
prognosis, **1087**
- craniopharyngioma vs., **1085**
Giant aneurysm, vein of Galen aneurysmal malformation vs., **1113**
Giant cavernoma, embryonal tumor with multilayered rosettes vs., **1083**
Giant cell granulomatous reaction. *See* Soft tissue foreign bodies.
Giant cell tumor, chondroblastoma vs., **949**
Giant parietal foramina, cephalocele vs., **1025**
Glenn shunt, **288–289**
- bidirectional, **289**
- Blalock-Taussig shunt vs., **297**
- differential diagnosis, **289**
Glenoid version angle, **1001**
Glenoscapular angle (GSA), **1001**
Glioblastoma, **1075**
- differential diagnosis, **1075**
- embryonal tumor with multilayered rosettes vs., **1083**
- spinal cord astrocytoma, **1161**
- supratentorial ependymoma vs., **1074**
Glioblastoma multiforme, infantile, desmoplastic infantile tumors vs., **1082**
Glioma
- hypothalamic-chiasmatic, craniopharyngioma vs., **1085**
- tectal plate, germinoma vs., **1087**
Gliomatosis cerebri
- acute encephalitis vs., **1131**
- hemimegalencephaly vs., **1031**
Glomerulonephritis, autosomal recessive polycystic kidney disease vs., **639**
Glomus tympanicum paraganglioma, congenital cholesteatoma vs., **1209**
Glutaric aciduria type 1, enlarged subarachnoid spaces vs., **1015**
GMH. *See* Germinal matrix hemorrhage.
Goldenhar syndrome, VACTERL association vs., **781**
Gonadoblastoma, ovarian teratoma vs., **725**
Gorham-Stout disease
- chylothorax, **105**
- kaposiform lymphangiomatosis vs., **213**
Graft-vs.-host disease (GVHD), **532–533**
- acute, neutropenic colitis vs., **531**
- differential diagnosis, **533**
- hepatic venooclusive disease vs., **465**
- hypoperfusion complex vs., **501**
- posttransplant lymphoproliferative disease vs., **525**
- prognosis, **533**
Granulation tissue of umbilical stump, urachal abnormalities vs., **617**
Granuloma, pulmonary arteriovenous malformation vs., **157**
Granuloma annulare, **920–921**
- differential diagnosis, **921**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- prognosis, **921**
Granulomatosis, with polyangiitis, papillomatosis vs., **137**
Granulomatous disease, chronic, **534–537**
- Crohn disease vs., **542**
- diagnostic checklist, **536**
- differential diagnosis, **536**
- fungal pneumonia in immunocompromised children, **135**
- genetics, **536**
- prognosis, **536**
Granulomatous infection, Castleman disease vs., **574**
Gray matter heterotopia, periventricular, germinal matrix hemorrhage vs., **1097**
Grayscale ultrasound, Chiari 2 malformation, **1045**
Great vessels, imaging anatomy, **218**
Greenstick fracture, **803**
Grisel syndrome, retropharyngeal space abscess, **32**
Group B streptococcal pneumonia, surfactant deficiency disease vs., **89**
Gut herniation, physiologic, gastroschisis vs., **413**
GVHD. *See* Graft-vs.-host disease.
Gyral-Sulcal pattern, delayed, lissencephaly vs., **1033**

H

Hamartin, **1053**
Hamartoma, mesenchymal
- chest wall, **193**
- hepatic hemangiomas, infantile and congenital vs., **440**
- hepatoblastoma vs., **435**

Hamartomatosis, **1053**
HCM. *See* Hypertrophic cardiomyopathy.
Head trauma, abusive, birth injury vs., **1091**
Heart, dextroversion of, heterotaxy syndromes vs., **315**
Heart disease
- congenital
  - Abernethy malformation, **467**
  - annular pancreas., **489**
  - bronchogenic cyst, **72**
  - double aortic arch, **36**
  - meconium aspiration syndrome vs., **95**
  - mimicking of neonatal lung disease, **52**
  - neonatal pneumonia vs., **93**
  - pulmonary sling, **40**
  - surfactant deficiency disease vs., **89**
  - transient tachypnea of newborn vs., **97**
- cyanotic, pulmonary arteriovenous malformation, **157**
- heterotaxy syndromes, **314–317**
  - differential diagnosis, **315**
  - prognosis, **316**
  - staging, grading, & classification, **315–316**
- Kawasaki disease, **322–325**
  - diagnostic checklist, **324**
  - differential diagnosis, **323**
  - prognosis, **324**
- Loeys-Dietz syndrome, **330–331**
  - differential diagnosis, **331**
  - prognosis, **331**
  - staging, grading, & classification, **331**
- Marfan syndrome, **328–329**
  - genetics, **329**
  - prognosis, **329**
  - staging, grading, & classification, **329**
- rhabdomyoma, **318–321**
  - associated abnormalities, **320**
  - diagnostic checklist, **320**
  - differential diagnosis, **319**
  - genetics, **320**
  - prognosis, **320**
- rheumatic, **326–327**
  - prognosis, **327**

Heart-hand syndrome, VACTERL association vs., **781**
Hemangioblastoma, spinal cord ependymoma vs., **1159**
Hemangioendothelioma. *See also* Infantile hemangioma, cervicofacial.
- kaposiform
  - infantile hemangioma, musculoskeletal vs., **888**
  - kaposiform lymphangiomatosis vs., **213**

Hemangioma
- congenital
  - anorectal malformations vs., **378**
  - infantile hemangioma, musculoskeletal vs., **888**
- infantile
  - croup vs., **23**
  - expiratory buckling of trachea vs., **6**
  - musculoskeletal, **886–889**

- fibrolamellar, focal nodular hyperplasia vs., **443**
- focal nodular hyperplasia vs., **443**
- hepatic adenoma vs., **445**
- hepatoblastoma vs., **435**
- undifferentiated embryonal sarcoma vs., **447**

Hepatomegaly, hepatic venoocclusive disease, **465**

Hereditary multiple exostoses, osteochondroma, **952**

Hernias, **404–407**
- associations, **405**
- congenital diaphragmatic, **84–87**
  - associated abnormalities, **86**
  - differential diagnosis, **85–86**
  - neonatal pneumothorax vs., **103**
  - prognosis, **86**
- diaphragmatic
  - bronchogenic cyst, **72**
  - wandering spleen, **473**
- differential diagnosis, **406**
- epididymoorchitis vs., **739**
- femoral, **405**
- incarcerated, **405**
- inguinal, **405**
  - jejunoileal atresia vs., **362**
  - Meckel diverticulum vs., **428**
  - paratesticular rhabdomyosarcoma vs., **751**
  - testicular torsion vs., **743**
  - torsion of testicular appendage vs., **748**
- internal, **432**
  - differential diagnosis, **432**
  - duodenal atresia or stenosis vs., **355**
  - normal variations of cecal position vs., **343**
- prognosis, **406**
- renal ectopia and fusion vs., **626**
- scrotal, epididymoorchitis vs., **739**
- of stomach, pneumomediastinum vs., **171**
- umbilical, **405**
  - omphalocele vs., **409**

urachal abnormalities vs., **617**
Heterogeneous spleen, wandering spleen vs., **473**
Heterotaxia syndromes, wandering spleen vs., **473**
Heterotaxy syndromes, **314–317**
- differential diagnosis, **315**
- prognosis, **316**
- staging, grading, & classification, **315–316**
Heterotopic gray matter, **1034–1035**
- associated abnormalities, **1035**
- diagnostic checklist, **1035**
- differential diagnosis, **1035**
- genetics, **1035**
- prognosis, **1035**
Heterotopic ossification, osteogenesis imperfecta vs., **977**
Hiatal hernia, paraesophageal, gastric volvulus vs., **397**
Hibernoma
- lipoblastoma vs., **910**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
High airway obstruction syndrome, congenital, **16**
High-grade surface osteosarcoma, **929**
High-riding jugular bulb, large vestibular aqueduct vs., **1207**
High-risk recreational activities, aortic injury, **168**
High-specificity fractures, **809**
Hilgenreiner line, developmental hip dysplasia, **955**
Hindbrain development, Dandy-Walker continuum, **1020**
Hindgut duplication. *See* Gastrointestinal duplication cysts.
Hindgut malformation. *See* Gastrointestinal duplication cysts.
Hippocampal sclerosis, focal cortical dysplasia and, **1041**
Hirschsprung disease, **372–375**
- anorectal malformations, **378**
- anorectal malformations vs., **377**
- associated abnormalities, **374**
- cloaca vs., **621**
- colonic atresia vs., **364**
- colonic volvulus, **431**
- cystic fibrosis vs., **566**
- diagnostic checklist, **374**
- differential diagnosis, **373–374**
- gastric volvulus vs., **397**
- genetics, **374**
- jejunoileal atresia vs., **362**
- meconium ileus vs., **367**
- meconium peritonitis vs., **381**

- neonatal small left colon vs., **371**
- neuroblastoma, **704**
- prognosis, **374**
- pulmonary sling, **40**
- spontaneous intestinal perforation in neonates vs., **389**
Histiocytosis
- brainstem tumors vs., **1078**
- Langerhans cell
  Ewing sarcoma vs., **926**
  normal thymus vs., **58**
  osteoid osteoma vs., **946**
  osteomyelitis vs., **863**
Histoplasmosis, cat-scratch disease vs., **479**
HL. *See* Hodgkin lymphoma.
HLH. *See* Hemophagocytic lymphohistiocytosis.
HLHS. *See* Hypoplastic left heart syndrome.
HMC. *See* Hydrometrocolpos.
H1N1, viral chest infection, **117**
HNF1B/TCF2 mutations, multicystic dysplastic kidney vs., **632**
Hodgkin disease. *See* Lymphoma.
Hodgkin lymphoma (HL), **141**
- Burkitt lymphoma vs., **573**
Holoprosencephalies (HPE), **1026–1027**
- associated abnormalities, **1027**
- congenital nasal pyriform aperture stenosis, **9**
- diagnostic checklist, **1027**
- differential diagnosis, **1027**
- genetics, **1027**
- staging, grading, & classification, **1027**
Holoprosencephaly, omphalocele, **410**
Holt-Oram syndrome, VACTERL association vs., **781**
Homozygous achondroplasia, achondroplasia vs., **970**
Horseshoe kidney. *See also* Renal ectopia and fusion.
- anorectal malformations, **378**
Horseshoe kidney, müllerian duct anomalies, **718**
HPE. *See* Holoprosencephalies.
Human immunodeficiency virus (HIV), fungal pneumonia in immunocompromised children, **135**
Humeral epiphyseal separation, distal, supracondylar fracture vs., **835**
Hunter syndrome, **1119**
Hurler syndrome, **1119**
Hyaline membrane disease. *See* Surfactant deficiency disease.
Hybrid procedure, Norwood procedure vs., **295**
Hydranencephaly
- holoprosencephalies vs., **1027**
- schizencephaly vs., **1037**
Hydrocele, **757**
- hernias vs., **406**
- variations of, **760–761**
  differential diagnosis, **761**
  prognosis, **761**
Hydrocephalus
- communicating
  aqueductal stenosis vs., **1047**
  enlarged subarachnoid spaces vs., **1015**
- pediatric brain, **1007**
- posthemorrhagic, aqueductal stenosis vs., **1047**
- severe chronically shunted, Chiari 2 malformation vs., **1045**
- shunted, white matter injury of prematurity vs., **1101**
Hydrocolpos, anorectal malformations, **378**
Hydrometra. *See* Hydrometrocolpos.
Hydrometrocolpos (HMC), **712–715**
- associated abnormalities, **714**
- differential diagnosis, **713–714**
- gastrointestinal duplication cysts vs., **556**
- genetics, **714**
- isolated, cloaca vs., **621**
- prognosis, **714**
Hydromyelia, **1155**
- split cord malformation, **1151**

Hydronephrosis, **580**
- gastroschisis, **414**
- multicystic dysplastic kidney vs., **631**
- ureteropelvic junction obstruction vs., **592**

Hygroma, subdural, arachnoid cyst vs., **1061**
Hypercalciuria, renal stones, **674**
Hyperemia, hemophilia, **1003**
Hyperferritinemic inflammation. *See* Hemophagocytic lymphohistiocytosis.
Hypergastrinemia, hypertrophic pyloric stenosis, **394**
Hyperinflammation, severe COVID-19 with, MIS-C vs., **122**
Hypernatremic dehydration, transient neonatal renal medullary hyperechogenicity vs., **677**
Hyperoxaluria
- primary, renal stones, **674**
- renal stones, **674**

Hyperparathyroidism, osteogenesis imperfecta vs., **977**
Hyperplasia
- congenital adrenal, **698–701**
  - differential diagnosis, **700**
  - genetics, **700**
  - neuroblastoma vs., **704**
  - prognosis, **700**
- focal nodular, Abernethy malformation, **467**
- nodular regenerative, Abernethy malformation, **467**

Hypersensitivity pneumonitis, EVALI vs., **215**
Hypersensitivity reactions, Kawasaki disease vs., **323**
Hypertension
- essential, renal artery stenosis vs., **680**
- pulmonary
  - atrial septal defect vs., **224**
  - pulmonary artery stenosis vs., **283**
- systemic, aortic stenosis vs., **279**

Hypertrophic cardiomyopathy, **306–307**
- differential diagnosis, **307**
- Duchenne muscular dystrophy-related cardiomyopathy vs., **309**
- left ventricular noncompaction vs., **305**
- prognosis, **307**
- staging, grading, & classification, **307**

Hypertrophic obstructive cardiomyopathy. *See* Hypertrophic cardiomyopathy.
Hypertrophic pyloric stenosis, **392–395**
- associated abnormalities, **394**
- diagnostic checklist, **394**
- differential diagnosis, **393–394**
- duodenal atresia or stenosis vs., **355**
- gastric volvulus vs., **397**
- genetics, **394**
- necrotizing enterocolitis vs., **385–386**
- prognosis, **394**
- pyloric atresia vs., **359**

Hypertrophic zone, physeal fractures, **796**
Hyperuricosuria, renal stones, **674**
Hypervascular metastasis, hepatic adenoma vs., **445**
Hypochondroplasia, achondroplasia vs., **969**
Hypocitruria, renal stones, **674**
Hypogenetic lung syndrome. *See also* Scimitar syndrome.
- bronchial atresia vs., **79**
- bronchopulmonary sequestration vs., **67**
- total anomalous pulmonary venous return vs., **262**

Hypoglycemia
- hypoxic-ischemic encephalopathy vs., **1103**
- omphalocele, **410**

Hypointense signal, **1011**
Hypoperfusion complex, **500–503**
- associated abnormalities, **502**
- bowel injury vs., **505**
- diagnostic checklist, **502**
- differential diagnosis, **501–502**
- graft-vs.-host disease vs., **533**
- prognosis, **502**
- splenic trauma vs., **513**

Hypopharyngeal intubation, esophageal intubation vs., **112**
Hypophosphatasia
- osteogenesis imperfecta vs., **978**
- rickets vs., **986**

Hypophosphatemic rickets, **985**
Hypoplasia
- cerebellar, Dandy-Walker continuum vs., **1020**
- pulmonary, meconium aspiration syndrome vs., **95**

Hypoplastic/dysplastic vermis, Dandy-Walker continuum vs., **1020**
Hypoplastic left heart syndrome, **264–267**
- aortic coarctation vs., **275**
- aortic stenosis, **280**
- differential diagnosis, **266**
- Norwood procedure alternatives for, **295**
- prognosis, **266**
- total anomalous pulmonary venous return vs., **261**

Hypoplastic optic nerve syndrome
- holoprosencephalies vs., **1027**
- schizencephaly, **1037**

Hypoplastic transverse sinus, cerebral venous sinus thrombosis vs., **1109**
Hypospadias, renal ectopia and fusion, **626**
Hypotension, intracranial
- Chiari 1 malformation vs., **1043**
- Chiari 2 malformation vs., **1045**

Hypotension complex. *See* Hypoperfusion complex.
Hypothalamic/chiasmatic astrocytoma, germinoma vs., **1087**
Hypothalamic-chiasmatic glioma, craniopharyngioma vs., **1085**
Hypothalamic pituitary abnormalities, normal prepubertal uterus and ovaries vs., **589**
Hypothyroidism, osteogenesis imperfecta vs., **978**
Hypovolemic shock complex. *See* Hypoperfusion complex.
Hypoxic-ischemic encephalopathy, **1102–1103**
- associated abnormalities, **1103**
- differential diagnosis, **1103**
- germinal matrix hemorrhage vs., **1097**
- metabolic brain disease vs., **1119**
- mitochondrial encephalopathies vs., **1123**
- staging, grading, & classification, **1103**

Hysterosalpingography, müllerian duct anomalies, **718**

INDEX

I

Iatrogenic perforation, spontaneous intestinal perforation in neonates vs., **389**
Iatrogenic subglottic stenosis, croup vs., **24**
Idiopathic arthritis, juvenile
- Legg-Calvé-Perthes disease vs., **962**
- osteochondroses vs., **983**
- septic arthritis vs., **871**
- slipped capital femoral epiphysis vs., **965**
- transient synovitis vs., **873**

Idiopathic chondrolysis
- juvenile, Legg-Calvé-Perthes disease vs., **962**
- slipped capital femoral epiphysis vs., **966**

Idiopathic hypertrophic subaortic stenosis. *See* Hypertrophic cardiomyopathy.
Idiopathic intracranial hypertension, cerebral venous sinus thrombosis vs., **1109**
Idiopathic juvenile osteoporosis, osteogenesis imperfecta vs., **977**
Idiopathic orbital inflammation, orbital cellulitis vs., **1197**
Idiopathic right ventricular outflow tachycardia, arrhythmogenic right ventricular dysplasia vs., **312**
Idiopathic thrombocytopenic purpura, Henoch-Schönlein purpura vs., **561**
Idiopathic transverse myelitis, spinal cord ependymoma vs., **1159**
IgA vasculitis. *See also* Henoch-Schönlein purpura.
- small bowel intussusception vs., **559**

Ileal atresia
- cloaca vs., **621**
- cystic fibrosis vs., **566**
- meconium ileus vs., **367**
- meconium peritonitis vs., **381**
- neonatal small left colon vs., **371**

Ileitis, Meckel diverticulum vs., **428**
Ileocolic intussusception, **422–425**
- appendicitis vs., **420**
- diagnostic checklist, **424**
- differential diagnosis, **423**
- prognosis, **424**
- small bowel intussusception vs., **559**

Ileosigmoid knot, colonic volvulus vs., **431**
Ileus
- gallstone, bezoars vs., **551**
- internal hernia vs., **432**
- meconium, **366–369**
  - anorectal malformations vs., **377**
  - associated abnormalities, **368**
  - colonic atresia vs., **364**
  - diagnostic checklist, **368**
  - differential diagnosis, **367–368**
  - genetics, **368**
  - jejunoileal atresia vs., **362**
  - meconium peritonitis vs., **381**
  - neonatal small left colon vs., **371**
  - prognosis, **368**
  - spontaneous intestinal perforation in neonates vs., **389**
  - staging, grading, & classification, **368**

Iliac/pelvic (ptotic/mobile) kidney. *See* Renal ectopia and fusion.
Immature ovarian teratoma, **729**
Immaturity, of corpus callosum, callosal anomalies vs., **1029**
Immune deficiencies, asthma vs., **195**
Immunodeficiency
- acquired, fungal pneumonia in immunocompromised children, **135**
- primary, fungal pneumonia in immunocompromised children, **135**
- severe combined, fungal pneumonia in immunocompromised children, **135**

Impaction fracture, osteochondral, osteochondritis, **818**
Impaired urine production (absent bladder), bladder exstrophy vs., **623**
Imperforate anus
- duodenal atresia or stenosis, **356**
- omphalocele, **409**
- pulmonary sling, **40**

Imperforate hymen, müllerian duct anomalies vs., **718**
Inborn errors of metabolism affecting brain, **1119**
Incarcerated hernia, **405**
Incidental bilateral subdural fluid collections, enlarged subarachnoid spaces vs., **1015**
Incomplete discoid meniscus, **792**
Incomplete duplication. *See* Ureteropelvic duplications.
Incomplete fractures, **802–803, 845**
- with cortical disruption, **803**
- diagnostic checklist, **803**
- differential diagnosis, **803**
- normal developmental variants confused with disease vs., **773**
- physeal fractures vs., **795**
- prognosis, **803**

Indeterminate colitis, Crohn disease vs., **542**
Indirect inguinal hernia, **405**
- variations of hydroceles vs., **761**

Infantile cellular interstitial pneumonitis. *See* Pulmonary interstitial glycogenosis (PIG).
Infantile fibrosarcoma
- chest wall hamartoma vs., **193**
- congenital, fibromatosis vs., **903**

Infantile glioblastoma multiforme, desmoplastic infantile tumors vs., **1082**
Infantile hemangioma, **886–889**
- airway, **46–47**
  - associated abnormalities, **47**
  - differential diagnosis, **47**
  - genetics, **47**
  - prognosis, **47**
  - staging, grading, & classification, **47**
- arteriovenous malformation, musculoskeletal vs., **901**
- cervicofacial, **1230–1233**
  - differential diagnosis, **1232**
  - prognosis, **1232**
- croup vs., **23**

- diagnostic checklist, **888**
- differential diagnosis, **887–888**
- expiratory buckling of trachea vs., **6**
- fibromatosis colli vs., **1240**
- immunohistochemical features, **888**
- kaposiform hemangioendothelioma vs., **891**
- lipoblastoma vs., **910**
- nasolacrimal duct mucocele vs., **11**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- palpable normal variants of chest wall vs., **61**
- prognosis, **888**
- rhabdomyosarcoma
  - head and neck vs., **1235**
  - musculoskeletal vs., **914**
- subglottic, papillomatosis vs., **137**
- venous malformation, musculoskeletal vs., **893**

Infantile myofibroma, **906–907**
- chest wall hamartoma vs., **193**
- differential diagnosis, **907**
- kaposiform hemangioendothelioma vs., **891**
- prognosis, **907**

Infantile myofibromatosis
- Langerhans cell histiocytosis vs., **938**
- syphilis vs., **869**

Infantile polycystic kidney disease. *See* Polycystic kidney disease, autosomal recessive.

Infantile Refsum disease, **1119**

Infarction
- age-related appearance of spleen vs., **345**
- bone, osteomyelitis vs., **863**
- liver, hepatic trauma vs., **509**
- omental, **498–499**
  - differential diagnosis, **499**
  - primary mesenteric adenitis vs., **495**
- pulmonary, sickle cell disease, acute chest syndrome vs., **209**
- renal, pyelonephritis vs., **665**
- splenic, **474–475**
  - differential diagnosis, **475**
  - prognosis, **475**
  - splenic cyst vs., **477**
  - staging, grading, & classification, **475**
  - wandering spleen vs., **473**
- stress injuries vs., **813**

Infections, **53**
- fungal, posttransplant lymphoproliferative disease vs., **526**
- fungal pneumonia in immunocompromised children, **134–135**
- hepatic venooclusive disease vs., **465**
- musculoskeletal system, **765**
- parapneumonic effusion and empyema, **128–129**
- scoliosis vs., **994**
- sickle cell disease, acute chest syndrome, **210**
- splenic, splenic cyst vs., **477**
- tuberous sclerosis vs., **1053**
- white matter injury of prematurity vs., **1101**

Infectious colitis
- Henoch-Schönlein purpura vs., **561**
- neutropenic colitis vs., **531**
- pseudomembranous colitis vs., **529**
- ulcerative colitis vs., **545**

Infectious colitis, graft-vs.-host disease vs., **533**

Infectious enterocolitis, hypoperfusion complex vs., **501**

Infectious epididymitis, testicular trauma vs., **757**

Infectious/inflammatory enterocolitis, MIS-C vs., **122**

Infectious masses, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**

Infectious pneumonias, other, COVID-19 vs., **121**

Infective esophagitis, **548**

Inferior epigastric veins, PICCs, **115**

Inferior vena cava obstruction, **470**

Inflammation
- chronic esophageal foreign body vs., **207**
- scoliosis vs., **994**

Inflammatory arteritides, abdominal aneurysms, **577**

Inflammatory bowel disease
- appendicitis vs., **420**
- bowel injury vs., **506**
- Meckel diverticulum vs., **428**

Inflammatory colitis, Henoch-Schönlein purpura vs., **561**

Inflammatory disease, pelvic
- genitourinary myosarcoma vs., **692**
- ovarian torsion vs., **734**

Inflammatory masses, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**

Inflammatory myelopathies, **1168–1169**
- diagnostic checklist, **1169**
- differential diagnosis, **1169**
- prognosis, **1169**

Inflammatory myofibroblastic pseudotumor, post-Deflux procedure appearance vs., **689**

Inflammatory myofibroblastic tumor, **575**
- Castleman disease vs., **574**
- differential diagnosis, **575**
- fibromatosis vs., **904**
- genitourinary rhabdomyosarcoma vs., **692**

Ingested button batteries, **400–401**
- differential diagnosis, **401**
- prognosis, **401**

Ingested coins, **398–399**
- differential diagnosis, **399**
- prognosis, **399**

Ingested material, bezoars vs., **551**

Ingested multiple magnets, **402–403**
- differential diagnosis, **403**
- prognosis, **403**

Ingestion, caustic, epiglottitis, **20**

Inguinal hernia, **405**
- indirect, variations of hydroceles vs., **761**
- internal hernia vs., **432**
- jejunoileal atresia vs., **362**
- Meckel diverticulum vs., **428**
- paratesticular rhabdomyosarcoma vs., **751**
- testicular torsion vs., **743**
- torsion of testicular appendage vs., **748**

Inguinal ovarian hernia, ectopic ovary, **737**

Injuries, major groupings of, **1093**

Innominate artery compression syndrome, **42–43**
- diagnostic checklist, **43**
- differential diagnosis, **43**
- double aortic arch vs., **36**

- prognosis, **43**
Insufficiency fracture, **813**
- osteochondritis dissecans vs., **818**
Interfragmentary screw, orthopedic hardware and complications, **826**
Interhemispheric cyst
- callosal agenesis with, holoprosencephalies vs., **1026**
- cavum septum pellucidum vs., **1016**
Interhemispheric lipoma, callosal anomalies, **1029**
Internal fixation, orthopedic hardware and complications, **825**
Internal hernia, **405, 432**
- differential diagnosis, **432**
- duodenal atresia or stenosis vs., **355**
- normal variations of cecal position vs., **343**
International League of Associations for Rheumatology (ILAR), **877**
Interrupted aortic arch
- aortic coarctation vs., **275**
- hypoplastic left heart syndrome vs., **266**
Intestinal atresias
- gastroschisis, **414**
- multiple, **365**
  meconium peritonitis vs., **382**
- omphalocele, **409**
- spontaneous intestinal perforation in neonates vs., **389**
Intestinal ischemia, pneumatosis intestinalis vs., **539**
Intestinal obstruction
- distal, spontaneous intestinal perforation in neonates vs., **389**
- neonatal distal
  with microcolon, Hirschsprung disease vs., **373**
  with normal colon, Hirschsprung disease vs., **373–374**
  with small distal colon, Hirschsprung disease vs., **373**
Intestinal obstructions, neonatal lower
- anorectal malformations, **376–379**
  associated abnormalities, **378**
  differential diagnosis, **377–378**
  genetics, **378**
- colonic atresia, **364**
  differential diagnosis, **364**
- Hirschsprung disease, **372–375**
  associated abnormalities, **374**
  diagnostic checklist, **374**
  differential diagnosis, **373–374**
  genetics, **374**
  prognosis, **374**
- jejunoileal atresia, **360–363**
  associated abnormalities, **362**
  diagnostic checklist, **362**
  differential diagnosis, **362**
  genetics, **362**
  prognosis, **362**
  staging, grading, & classification, **362**
- meconium ileus, **366–369**
  associated abnormalities, **368**
  diagnostic checklist, **368**
  differential diagnosis, **367–368**
  genetics, **368**
  prognosis, **368**
  staging, grading, & classification, **368**
- multiple intestinal atresias, **365**
- neonatal small left colon, **370–371**
  differential diagnosis, **371**
  prognosis, **371**
Intestinal obstructions, neonatal upper
- duodenal atresia or stenosis, **354–357**
  associated abnormalities, **356**
  diagnostic checklist, **356**
  differential diagnosis, **355–356**
  genetics, **356**
  prognosis, **356**
  staging, grading, & classification, **356**
- duodenal web, **358**
  associated anomalies, **358**
  differential diagnosis, **358**
- malrotation, **346–349**
  associated abnormalities, **347–348**
  diagnostic checklist, **348**
  differential diagnosis, **347**
  prognosis, **348**
  staging, grading, & classification, **348**
- midgut volvulus, **350–353**
  diagnostic checklist, **352**
  differential diagnosis, **352**
  prognosis, **352**
- pyloric atresia, **359**
  differential diagnosis, **359**
Intraabdominal ectopia, ectopic ovary, **737**
Intracerebral hematoma, cavernous malformation vs., **1117**
Intracranial hemorrhage
- abusive head trauma, **1093**
- birth injury, **1091**
- necrotizing enterocolitis, **386**
Intracranial hypotension
- Chiari 1 malformation vs., **1043**
- Chiari 2 malformation vs., **1045**
Intracranial pressure, increased, tonsillar herniation from, Chiari 1 malformation vs., **1043**
Intradural lipoma, lipomyelomeningocele vs., **1148**
Intrahepatic cholestasis, cirrhosis, **461**
Intrahepatic portosystemic shunt, Abernethy malformation vs., **467**
Intraluminal calcifications, Hirschsprung disease vs., **374**
Intraluminal secretions, bacterial tracheitis vs., **27**
Intramedullary nails or rods, orthopedic hardware and complications, **826**
Intramural hematoma, small bowel intussusception, **559**
Intranodal abscess. *See* Suppurative adenitis.
Intraparenchymal hemorrhage, germinal matrix hemorrhage, **1098**
Intrapelvic masses, sacrococcygeal teratoma vs., **1163**
Intrasplenic pancreatic pseudocyst, splenic cyst vs., **477**
Intrauterine compression, arthrogryposis, **787**
Intrauterine infection. *See* TORCH infections.
Intravenous bisphosphonates, osteogenesis imperfecta, **978**
Intraventricular hemorrhage (IVH), **1097**
- choroid plexus tumors vs., **1089**
Intrinsic obstructions, noninfectious, approach to, **4**

Intubation, failed, congenital high airway obstruction syndrome, **16**
Intussusception
- cystic fibrosis, **565**
- enema reduction of, gastrointestinal tract, **335**
- ileocolic, **422–425**
  diagnostic checklist, **424**
  differential diagnosis, **423**
  prognosis, **424**
- internal hernia vs., **432**
- Meckel diverticulum vs., **428**
- pseudokidney of, renal ectopia and fusion vs., **626**

Invasive aspergillosis, papillomatosis vs., **137**
Involuted microcystic dsyplastic kidney, renal agenesis vs., **629**
Iron deposition disease, red to yellow marrow conversion vs., **771**
Irregular distal femoral epiphyseal ossification, normal, osteochondritis dissecans vs., **817–818**
Irregular physes/metaphyses, stress injuries vs., **813**
Ischemia
- perinatal, transient neonatal renal medullary hyperechogenicity vs., **677**
- subacute, glioblastoma vs., **1075**

Ischemic colitis, neutropenic colitis vs., **531**
Ischemic stroke, arterial, hypoxic-ischemic encephalopathy vs., **1103**
Isolated cerebellar hypoplasia, other cerebellar malformations vs., **1023**
Isolated fallopian tube torsion, ovarian torsion vs., **734**
Isolated hydrometrocolpos, cloaca vs., **621**
Isolated right pulmonary hypoplasia, Scimitar syndrome vs., **287**
Isolated scrotal wall edema, torsion of testicular appendage vs., **747**
Isolated simple cysts, autosomal recessive polycystic kidney disease vs., **639**
Isolated subcutaneous granuloma. *See* Granuloma annulare.
Isolated subcutaneous nodule. *See* Granuloma annulare.
Isolated tendon rupture, patellar sleeve avulsion vs., **854**
Isthmic spondylolysis. *See* Spondylolisthesis.
Ivemark syndrome. *See* Heterotaxy syndromes.
IVH. *See* Intraventricular hemorrhage.
Ivy sign, moyamoya vs., **1107**

J

JAF. *See* Juvenile angiofibroma.
Jakob classification, lateral condylar fracture, **839–840**
Jatene arterial switch. *See* Arterial switch procedure.
Jaundice, hepatic venooclusive disease, **465**
Jejunal atresia, duodenal atresia or stenosis vs., **355**
Jejunoileal atresia, **360–363**
- anorectal malformations vs., **377**
- associated abnormalities, **362**
- colonic atresia vs., **364**
- diagnostic checklist, **362**
- differential diagnosis, **362**
- genetics, **362**
- prognosis, **362**
- staging, grading, & classification, **362**

Job syndrome, fungal pneumonia in immunocompromised children, **134**
Joubert syndrome, Dandy-Walker continuum vs., **1020**
Joubert syndrome & related disorders (JSRD), **1023**
JSRD. *See* Joubert syndrome & related disorders.
Juvenile angiofibroma, **1188–1191**
- diagnostic checklist, **1190**
- differential diagnosis, **1190**
- prognosis, **1190**
- rhabdomyosarcoma, head and neck vs., **1235**
- staging, grading, & classification, **1190**

Juvenile chronic myeloid leukemia (JCML). *See* Leukemia.
Juvenile dermatomyositis (JDM), **881**
Juvenile granulosa-theca cell tumor, **729**
Juvenile idiopathic arthritis, **876–879**
- diagnostic checklist, **878**
- differential diagnosis, **878**
- hemophilia vs., **1003**
- Henoch-Schönlein purpura vs., **561**
- Legg-Calvé-Perthes disease vs., **962**
- osteochondroses vs., **983**
- septic arthritis vs., **871**
- slipped capital femoral epiphysis vs., **965**
- tarsal coalition vs., **998**
- transient synovitis vs., **873**

Juvenile idiopathic osteonecrosis. *See* Legg-Calvé-Perthes (LCP) disease.
Juvenile nasopharyngeal angiofibroma. *See* Juvenile angiofibroma.
Juvenile osteochondritis dissecans. *See* Osteochondritis dissecans.
Juvenile osteonecrosis, Legg-Calvé-Perthes disease vs., **962**
Juvenile polyp, bezoars vs., **551**
Juvenile Tillaux fracture, **860–861**
- diagnostic checklist, **861**
- musculoskeletal system, **765**
- prognosis, **861**

Juxtacortical chondroma
- distal femoral avulsive irregularity vs., **779**
- osteochondroma vs., **951**

K

Kallmann syndrome, CHARGE syndrome vs., **1216**
Kaposiform hemangioendothelioma, **890–891**
- diagnostic checklist, **890**
- differential diagnosis, **891**
- infantile hemangioma, musculoskeletal vs., **888**
- infantile myofibroma vs., **907**
- kaposiform lymphangiomatosis vs., **213**
- myofibromatosis vs., **907**
- prognosis, **891**

Kaposiform lymphangiomatosis, **212–213**
- differential diagnosis, **213**
- prognosis, **213**

Kawasaki disease (KD), **322–325**
- abdominal aneurysms, **577**
- diagnostic checklist, **324**
- differential diagnosis, **323**
- left coronary artery anomalous origin vs., **269**
- MIS-C vs., **121–122**
- prognosis, **324**

Kawashima procedure, Fontan operation vs., **291**
Kearns-Sayre syndrome, **1123**
Kidney
- ectopic, renal agenesis vs., **629**
- involuted microcystic dsyplastic, renal agenesis vs., **629**
- normal neonatal, **584–585**
  differential diagnosis, **585**
- unilateral, urachal abnormalities, **618**

Kidney stone. *See* Renal stones.
Kirschner wires, orthopedic hardware and complications, **825**
Klinefelter syndrome, germ cell tumors, **145**
Klippel-Trenaunay syndrome
- lymphatic malformation, musculoskeletal, **898**
- Sturge-Weber syndrome vs., **1055**

Kyphoscoliosis
- achondroplasia vs., **970**
- severe, simulated ectopia related to, renal ectopia and fusion vs., **626**
- split cord malformation, **1151**

L

L-transposition of great arteries, **252–253**
- associated abnormalities, **253**
- differential diagnosis, **253**
- prognosis, **253**

Labeled leukocyte scintigraphy, orthopedic hardware and complications, **825**
Laceration. *See also* Bowel injury.
- age-related appearance of spleen vs., **345**
- splenic infarct vs., **475**

Lactobezoar, **551, 552**
Lacunar infarcts, enlarged perivascular spaces vs., **1065**
Ladd bands, obstructing, malrotation with, midgut volvulus vs., **352**
LAM. *See* Lymphangioleiomyomatosis.
Lambdoid defect, neurofibromatosis type 1, **1049**
Langerhans cell histiocytosis (LCH), **936–939**
- acquired cholesteatoma vs., **1211**
- acute otomastoiditis with abscess vs., **1213–1214**
- brainstem tumors vs., **1078**
- chondroblastoma vs., **949**
- chronic recurrent multifocal osteomyelitis vs., **883**
- congenital cholesteatoma vs., **1209**
- diagnostic checklist, **938**
- differential diagnosis, **937–938**
- discitis/osteomyelitis vs., **1167**
- distal femoral avulsive irregularity vs., **779**
- Ewing sarcoma vs., **926**
- germinoma vs., **1087**
- hemophagocytic lymphohistiocytosis vs., **569**
- infantile myofibroma vs., **907**
- kaposiform lymphangiomatosis vs., **213**
- leukemia vs., **934**
- lymphangioleiomyomatosis vs., **185**
- musculoskeletal sickle cell disease vs., **990**
- musculoskeletal system, **765**
- myofibromatosis vs., **907**
- normal thymus vs., **58**
- orbital cellulitis vs., **1197**
- osteoid osteoma vs., **946**
- osteomyelitis vs., **863**
- papillomatosis vs., **137**
- prognosis, **938**
- pulmonary, **186–187**
  diagnostic checklist, **187**
  differential diagnosis, **187**
  prognosis, **187**
  staging, grading, & classification, **187**
- rhabdomyosarcoma, head and neck vs., **1235**

Large endolymphatic sac anomaly. *See* Large vestibular aqueduct.
Large polycystic kidneys, autosomal recessive polycystic kidney disease vs., **636**
Large vessel inflammatory vasculitis, moyamoya vs., **1107**
Large vestibular aqueduct, **1206–1207**
- differential diagnosis, **1207**
- genetics, **1207**

Laryngeal ulcer, laryngeal, croup, **24**
Laryngeal web, croup, **24**
Laryngomalacia, laryngeal, croup, **24**
Laryngotracheal cleft, esophageal atresia and tracheoesophageal fistula vs., **81**
Late or "missed" torsion. *See* Testicular torsion.
Late postoperative complications, minimally invasive pectus repair appearance, **190**
Lateral condylar fracture, **838–841**
- differential diagnosis, **839**
- musculoskeletal system, **764**
- prognosis, **840**
- staging, grading, & classification, **839–840**
- supracondylar fracture vs., **835**

LDD. *See* Lhermitte-Duclos disease.
Left coronary artery anomalous origin, **268–271**
- associated abnormalities, **269–270**
- diagnostic checklist, **270**
- differential diagnosis, **269**
- prognosis, **270**

Left heart syndrome, hypoplastic, **264–267**
- aortic coarctation vs., **275**
- differential diagnosis, **266**
- Norwood procedure alternatives for, **295**
- prognosis, **266**

Left-to-right cardiovascular, shunts, viral chest infection vs., **118**
Left-to-right shunting, other causes of, patent ductus arteriosus vs., **235**

Left-to-right shunts
- large, congenital heart disease with, pulmonary artery stenosis vs., **283**
- pretricuspid, arrhythmogenic right ventricular dysplasia vs., **311**

Left ventricular hypertrabeculation. *See* Left ventricular noncompaction.
Left ventricular hypertrophy, secondary, hypertrophic cardiomyopathy vs., **307**
Left ventricular noncompaction, **304–305**
- differential diagnosis, **305**
- hypertrophic cardiomyopathy vs., **307**
- prognosis, **305**

Left ventricular noncompaction cardiomyopathy (LVNC). *See* Left ventricular noncompaction.
Legg-Calvé-Perthes (LCP) disease, **960–963**
- diagnostic checklist, **962**
- differential diagnosis, **961–962**
- mucopolysaccharidoses vs., **974**
- prognosis, **962**
- septic arthritis vs., **871**
- slipped capital femoral epiphysis vs., **965**
- staging, grading, & classification, **962**
- transient synovitis vs., **873**

Legg-Perthes disease. *See* Legg-Calvé-Perthes (LCP) disease.
LEGO asthma. *See* Bronchial obstruction.
Leigh syndrome, **1123**
Leptomeningeal melanoma (LM), **1057**
Leptomeningeal melanosis (LMs), **1057**
Leptomeningeal metastatic disease, diffuse leptomeningeal glioneuronal tumor vs., **1157**
Leukemia, **932–935**
- associated abnormalities, **934**
- autosomal recessive polycystic kidney disease vs., **639**
- child abuse
  - metaphyseal fracture vs., **806**
  - rib fractures vs., **160**
- chronic recurrent multifocal osteomyelitis vs., **883**
- differential diagnosis, **933–934**
- epididymoorchitis vs., **739**
- genetics, **934**
- hemophagocytic lymphohistiocytosis vs., **569**
- Henoch-Schönlein purpura vs., **561**
- Langerhans cell histiocytosis vs., **937**
- musculoskeletal sickle cell disease vs., **990**
- normal thymus vs., **58**
- osteomyelitis vs., **864**
- prognosis, **934**
- rickets vs., **986**
- stress injuries vs., **813**
- syphilis vs., **869**

Leukocoria, retinoblastoma vs., **1201**
Leukocyte scintigraphy, labeled, orthopedic hardware and complications, **825**
Leukodystrophies, **1124–1125**
- demyelinating diseases vs., **1133**
- differential diagnosis, **1125**
- metabolic brain disease vs., **1119**

Leydig cell tumor. *See* Testicular tumors.
Lhermitte-Duclos disease (LDD), **1023**
Li-Fraumeni syndrome
- adrenocortical carcinoma, **709**
- genitourinary rhabdomyosarcoma, **692**
- germ cell tumors, **145**

Ligament of Treitz (LOT), **339, 351**
Ligamentous disruption, normal developmental variants confused with disease vs., **773**
Limb-body wall complex, **417**
- cloacal exstrophy/OEIS vs., **416**
- differential diagnosis, **417**
- gastroschisis vs., **413**
- omphalocele vs., **409**

Limb deficiency, omphalocele, **410**
Limb hypoplasia, gastroschisis, **414**
Limb length discrepancy, scoliosis vs., **994**
Limited dorsal myeloschisis, dorsal dermal sinus vs., **1149**
Linear sclerosis, within bone, stress injuries vs., **813**
Lingual thyroid, thyroglossal duct cyst vs., **1221**
Lingual tonsils, enlarged, epiglottitis vs., **19**
Lipoblastoma, **910**
- differential diagnosis, **910**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**

Lipoma
- dermoid/epidermoid cysts vs., **1063**
- lipoblastoma vs., **910**
- muscle hernia vs., **831**
- musculoskeletal system, **765**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- paratesticular rhabdomyosarcoma vs., **751**
- rhabdomyoma vs., **319**
- small bowel intussusception, **559**
- split cord malformation, **1151**

Lipomyelomeningocele, **1148**
- diagnostic checklist, **1148**
- differential diagnosis, **1148**
- dorsal dermal sinus vs., **1149**
- terminal myelocystocele vs., **1152**

Liposarcoma, lipoblastoma vs., **910**
Lissencephaly, **1032–1033**
- diagnostic checklist, **1033**
- differential diagnosis, **1033**
- genetics, **1033**

Little Leaguer's elbow. *See* Medial epicondyle avulsion.
Littre hernia, **405**
Liver abnormalities
- focal nodular hyperplasia, **442–443**
  - diagnostic checklist, **443**
  - differential diagnosis, **443**
  - prognosis, **443**
- hepatic adenoma, **444–445**
  - differential diagnosis, **445**
  - prognosis, **445**
- hepatic hemangiomas, infantile and congenital, **438–441**
  - diagnostic checklist, **440**
  - differential diagnosis, **440**
  - prognosis, **440**
- hepatoblastoma, **434–437**
  - diagnostic checklist, **436**
  - differential diagnosis, **435–436**

prognosis, **436**
staging, grading, & classification, **436**
- mesenchymal hamartoma, chest wall, **193**
pleuropulmonary blastoma vs., **153**
Liver disease
- end-stage, pulmonary arteriovenous malformation, **157**
- rickets, **985**
Liver fracture. *See* Hepatic trauma.
Liver infarction, hepatic trauma vs., **509**
Liver injury. *See* Hepatic trauma.
Liver laceration. *See* Hepatic trauma.
Liver parenchyma, meconium peritonitis vs., **382**
Liver transplant complications, **468–471**
Lobar emphysema, congenital, neonatal pneumothorax vs., **103**
Lobar overinflation
- bronchogenic cyst, **72**
- congenital, **52, 74–77**
associated abnormalities, **76**
bronchial atresia vs., **79**
bronchial obstruction vs., **200**
bronchopulmonary dysplasia vs., **108**
congenital diaphragmatic hernia vs., **86**
congenital pulmonary airway malformation vs., **64**
differential diagnosis, **75–76**
pleuropulmonary blastoma vs., **153**
prognosis, **76**
pulmonary interstitial emphysema vs., **99**
staging, grading, & classification, **76**
Swyer-James syndrome vs., **183**
Localized neurofibroma, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
Loculated ascites, mesenteric lymphatic malformation vs., **497**
Loeys-Dietz syndrome, **330–331**
- differential diagnosis, **331**
- PHACES syndrome vs., **1056**
- prognosis, **331**
- staging, grading, & classification, **331**
Long-chain acyl-CoA dehydrogenase deficiency, **1119**
Long common channel. *See* Pancreaticobiliary maljunction.
Low-lying conus medullaris, tethered spinal cord, **1156**
Low-specificity fractures, **810**
Lower airways disease, **117**
Lower extremity weakness, tethered spinal cord, **1156**
Lower respiratory tract, **117**
LPA sling. *See* Pulmonary artery sling.
Lucent physes/metaphyses, stress injuries vs., **813**
Lumbar veins, ascending, PICCs, **115**
Lung, chronic opacity, bronchopulmonary sequestration vs., **67**
Lung abscess
- parapneumonic effusion and empyema vs., **129**
- pneumonia with cavitary necrosis vs., **131–132**
- round pneumonia vs., **126**
Lung anomalies, congenital, pulmonary sling, **40**
Lung contusion and laceration, **162–165**
- associated abnormalities, **164**
- differential diagnosis, **163**
- mechanism of, **164**
- prognosis, **164**
Lung disease, diffuse, **53**
Lung disease of prematurity. *See also* Surfactant deficiency disease.
- necrotizing enterocolitis, **386**
Lung lesion, congenital
- infected, esophageal atresia and tracheoesophageal fistula vs., **82**
- pneumonia with cavitary necrosis vs., **131**
Lung metastases, **53**
Lungs, imaging anatomy, **218**
LVA. *See* Large vestibular aqueduct.
Lyme disease, **1132**
Lymph nodes, enlarged, variations of hydroceles vs., **761**
Lymphadenitis, mesenteric, omental infarction vs., **499**
Lymphadenopathy
- bronchogenic cyst vs., **72**
- cat-scratch disease, **479**
- ectopic ovary vs., **737**
- ectopic testicle vs., **759**
- posttransplant lymphoproliferative disease, **526**
Lymphangiectasia
- chylothorax, **105**
- congenital, transient tachypnea of newborn vs., **97**
- mesenteric, mesenteric lymphatic malformation vs., **497**
Lymphangiogram, of chylothorax, **105**
Lymphangioleiomyomatosis (LAM), **53, 184–185**
- differential diagnosis, **185**
- genetics, **185**
- Langerhans cell histiocytosis vs., **187**
- papillomatosis vs., **137**
- prognosis, **185**
Lymphangiomatosis, kaposiform, **212–213**
- differential diagnosis, **213**
- prognosis, **213**
Lymphatic anomalies, cat-scratch disease vs., **479**
Lymphatic malformation, **1181**
- branchial cleft anomalies vs., **1226**
- bronchogenic cyst vs., **72**
- bronchopulmonary sequestration vs., **68**
- cervical, **14–15**
differential diagnosis, **15**
genetics, **15**
- fibromatosis colli vs., **1240**
- germ cell tumors vs., **145**
- hydrometrocolpos vs., **713**
- infantile hemangioma, musculoskeletal vs., **888**
- innominate artery compression syndrome vs., **43**
- lymphoma vs., **142**
- mesenteric, **496–497**
diagnostic checklist, **496**
differential diagnosis, **497**
gastrointestinal duplication cysts vs., **555**
prognosis, **497**
- microcystic, kaposiform hemangioendothelioma vs., **891**
- musculoskeletal, **896–899**
associated abnormalities, **898**
differential diagnosis, **897**
prognosis, **898**
staging, grading, & classification, **898**
- neonatal adrenal hemorrhage vs., **696**

- neuroblastoma vs., **704**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- normal thymus vs., **58**
- omphalocele, **410**
- ovarian cyst vs., **722**
- retropharyngeal space abscess vs., **31**
- soft tissue abscess vs., **875**
- suppurative adenitis vs., **1244**
- thyroglossal duct cyst vs., **1221**
- variations of hydroceles vs., **761**
- venous malformation, musculoskeletal vs., **893**

Lymphoid hyperplasia
- of appendix, appendicitis vs., **420**
- small bowel intussusception, **559**

Lymphoma, **53, 140–143**
- age-related appearance of spleen vs., **345**
- associated abnormalities, **142**
- autosomal recessive polycystic kidney disease vs., **639**
- bezoars vs., **551**
- Burkitt, **572–573**
  - differential diagnosis, **573**
  - genitourinary myosarcoma vs., **691**
  - primary mesenteric adenitis vs., **495**
  - prognosis, **573**
  - staging, grading, & classification, **573**
- Castleman disease vs., **574**
- differential diagnosis, **142**
- germ cell tumors vs., **145**
- hemophagocytic lymphohistiocytosis vs., **569**
- inflammatory myofibroblastic tumor vs., **575**
- kaposiform lymphangiomatosis vs., **213**
- leukemia vs., **934**
- non-Hodgkin, pancreatoblastoma vs., **481**
- normal thymus vs., **58**
- pancreatic, pancreatitis vs., **492**
- prognosis, **142**
- renal, nephroblastomatosis vs., **646**
- renal ectopia and fusion vs., **626**
- splenic
  - cat-scratch disease vs., **479**
  - splenic cyst vs., **477**
- splenic infarct vs., **475**
- staging, grading, & classification, **142**
- suppurative adenitis vs., **1243**
- wandering spleen vs., **473**
- Wilms tumor vs., **642**

Lymphoproliferative disease, posttransplant, **524–527**
- differential diagnosis, **525–526**
- prognosis, **526**
- staging, grading, & classification, **526**

Lymphoproliferative disorder, age-related appearance of spleen vs., **345**

Lysis. *See* Spondylolisthesis.

Lysosomal storage disease, **1119**

M

Macrocrania of infancy, benign, abusive head trauma vs., **1094**

Macroglossia, omphalocele, **410**

Macrophage activation syndrome (MAS). *See* Hemophagocytic lymphohistiocytosis.

Magnet ingestion
- ingested button batteries vs., **401**
- ingested coins vs., **399**

Magnetic resonance imaging
- musculoskeletal system, **764**
- pediatric genitourinary tract, **581**

Majeed syndrome, chronic recurrent multifocal osteomyelitis, **884**

Malabsorption, rickets, **985**

Malabsorption syndromes, small bowel intussusception, **559**

Malfixation. *See* Malrotation.

Malignancy
- cystic fibrosis, **565**
- hemophagocytic lymphohistiocytosis vs., **569**

Malignant melanoma (MM), primary CNS, **1057**

Malignant primary bone tumor. *See* Ewing sarcoma.

Malignant teratomas, ovarian teratoma vs., **725**

Malone appendicostomy, postoperative appearance of, normal variations of cecal position vs., **343**

Malposition, umbilical catheter positions and complications, **111**

Malrotation, **346–349, 351**
- annular pancreas, **489**
- associated abnormalities, **347–348**
- diagnostic checklist, **348**
- differential diagnosis, **347**
- duodenal atresia or stenosis, **356**
- duodenal web, **358**
- gastroesophageal reflux vs., **391**
- hypertrophic pyloric stenosis vs., **393**
- internal hernia vs., **432**
- Meckel diverticulum vs., **428**
- meconium peritonitis vs., **381**
- with midgut volvulus, annular pancreas vs., **489**
- normal variations of cecal position vs., **343**
- prognosis, **348**
- staging, grading, & classification, **348**
- true, normal variations of duodenojejunal junction position vs., **339**

Malunion
- fracture complications, **822**
- lateral condylar fracture, **840**

Maple syrup urine disease (MSUD), **1119**
- hypoxic-ischemic encephalopathy vs., **1103**

Marfan disease, aortic stenosis vs., **279**

Marfan syndrome, **328–329**
- abdominal aneurysms, **577**
- genetics, **329**
- Loeys-Dietz syndrome vs., **331**
- prognosis, **329**

- staging, grading, & classification, **329**
Maroteaux-Lamy syndrome, **1119**
Marrow deposition diseases, red to yellow marrow conversion vs., **771**
Marrow edema, stress injuries vs., **813**
Mass
- compression of trachea, innominate artery compression syndrome vs., **43**
- extrinsic mass compression, expiratory buckling of trachea vs., **6**
- middle mediastinal, pulmonary sling vs., **39**
- nonvascular, double aortic arch vs., **36**
- vallecular, epiglottitis vs., **19**

Massively dilated abdominal viscus, gastric volvulus vs., **397**
Mature ovarian teratoma, **729**
McCune-Albright syndrome, adrenocortical carcinoma, **709**
MDA. *See* Müllerian duct anomalies.
Mechanical bladder outlet obstruction, megaureter-megacystis vs., **608**
Mechanical obstruction, primary megaureter vs., **607**
Meckel diverticulum, **426–429**
- annular pancreas., **489**
- appendicitis vs., **420**
- diagnostic checklist, **427–428**
- differential diagnosis, **427–428**
- gastroschisis, **414**
- ileocolic intussusception vs., **423**
- internal hernia vs., **432**
- omental infarction vs., **499**
- omphalocele, **409**
- pulmonary sling, **40**
- small bowel intussusception vs., **559**

Meckel-Gruber syndrome, autosomal recessive polycystic kidney disease vs., **636**
Meconium aspiration
- bronchopulmonary dysplasia vs., **107–108**
- pulmonary interstitial emphysema vs., **99**

Meconium aspiration syndrome, **52, 94–95**
- bronchopulmonary dysplasia vs., **108**
- diagnostic checklist, **95**
- differential diagnosis, **95**
- neonatal pneumonia vs., **93**
- prognosis, **95**
- surfactant deficiency disease vs., **90**
- transient tachypnea of newborn vs., **97**

Meconium cyst, **381**
Meconium ileus, **366–369**
- anorectal malformations vs., **377**
- associated abnormalities, **368**
- cloaca vs., **621**
- colonic atresia vs., **364**
- cystic fibrosis, **565**
- diagnostic checklist, **368**
- differential diagnosis, **367–368**
- genetics, **368**
- jejunoileal atresia vs., **362**
- meconium peritonitis vs., **381**
- neonatal small left colon vs., **371**
- prognosis, **368**
- spontaneous intestinal perforation in neonates vs., **389**
- staging, grading, & classification, **368**

Meconium peritonitis, **380–383**
- anorectal malformations vs., **378**
- diagnostic checklist, **382**
- differential diagnosis, **381–382**
- prognosis, **382**

Meconium plug syndrome (MPS)
- anorectal malformations vs., **377**
- cloaca vs., **621**
- colonic atresia vs., **364**
- cystic fibrosis vs., **566**
- Hirschsprung disease vs., **373**
- jejunoileal atresia vs., **362**
- meconium ileus vs., **367**
- meconium peritonitis vs., **381**

Meconium pseudocyst, **381**
- gastrointestinal duplication cysts vs., **556**
- hydrometrocolpos vs., **713**
- mesenteric lymphatic malformation vs., **497**

Medial collateral ligament injury, medial epicondyle avulsion vs., **843**
Medial epicondyle avulsion, **842–843**
- associated abnormalities, **843**
- differential diagnosis, **843**
- lateral condylar fracture vs., **839**
- musculoskeletal system, **764**
- supracondylar fracture vs., **835**

Medial epicondylitis. *See* Medial epicondyle avulsion.
Mediastinal germ cell tumors, **53**
Mediastinal masses, **53**
- in child less than 3 years of age, neuroblastoma vs., **149**
- esophageal atresia and tracheoesophageal fistula vs., **82**
- middle, pulmonary sling vs., **39**

Mediastinum, widened, aortic injury, **167**
Medical renal disease, normal neonatal kidney vs., **585**
Medium-chain acyl-CoA dehydrogenase deficiency, **1119**
Medullary carcinoma, renal, **658–659**
- differential diagnosis, **659**
- prognosis, **659**

Medullary nephrocalcinosis, transient neonatal renal medullary hyperechogenicity vs., **677**
Medullary pyramids, **585**
Medullary tumors, **1077**
Medulloblastoma (MB), **1068–1069**
- atypical teratoid/rhabdoid tumor vs., **1071**
- choroid plexus tumors vs., **1089**
- diagnostic checklist, **1069**
- differential diagnosis, **1069**
- pilocytic astrocytoma vs., **1067**
- posterior fossa ependymoma vs., **1073**
- staging, grading, & classification, **1069**

Mega cisterna magna, arachnoid cyst vs., **1061**
Megacalycosis or congenital megacalyces, ureteropelvic junction obstruction vs., **592**
Megacolon, toxic, colonic volvulus vs., **431**
Megacyst-microcolon-intestinal hypoperistalsis syndrome, prune-belly syndrome vs., **611**
Megacystis, megaureter-megacystis vs., **608**

Megacystis-megaureter, primary megaureter vs., **607**
Megacystis-megaureter association, posterior urethral valves vs., **614**
Megacystis-microcolon-intestinal hypoperistalsis
- jejunoileal atresia vs., **362**
- meconium ileus vs., **367**
Megacystis-microcolon-intestinal hypoperistalsis syndrome, **609**
- isolated, cloaca vs., **621**
- megaureter-megacystis vs., **608**
- posterior urethral valves vs., **614**
Megalencephalic leukoencephalopathy with subcortical cysts, TORCH infections vs., **1127**
Megalourethra
- congenital
  megacystis-microcolon-intestinal hypoperistalsis syndrome, **609**
  prune-belly syndrome vs., **611**
- megaureter-megacystis vs., **608**
- posterior urethral valves vs., **614**
- primary, primary megaureter vs., **607**
Megaureter
- nonrefluxing nonobstructive, primary megaureter vs., **607**
- primary, **606–607**
  differential diagnosis, **607**
  prognosis, **607**
  prune-belly syndrome vs., **611**
- refluxing nonobstructive, primary megaureter vs., **607**
- ureteropelvic junction obstruction vs., **592**
Megaureter-megacystis, **608**
- differential diagnosis, **608**
Membranous croup. *See* Bacterial tracheitis.
Membranous laryngotracheobronchitis. *See* Bacterial tracheitis.
Meningeal processes, acquired, Sturge-Weber syndrome vs., **1055**
Meningioangiomatosis, Sturge-Weber syndrome vs., **1055**
Meningitis, orbital cellulitis, **1198**
Meningocele, **1025**
- lipomyelomeningocele vs., **1148**
- terminal myelocystocele vs., **1152**
Menkes syndrome
- bladder diverticula, **687**
- child abuse
  metaphyseal fracture vs., **806**
  rib fractures vs., **160**
- neurogenic bladder vs., **683**
- osteogenesis imperfecta vs., **978**
MERS, viral chest infection, **117**
MEs. *See* Mitochondrial encephalopathies.
Mesenchymal hamartoma, **448**
- chest wall, pleuropulmonary blastoma vs., **153**
- diagnostic checklist, **448**
- differential diagnosis, **448**
- hepatic hemangiomas, infantile and congenital vs., **440**
- hepatoblastoma vs., **435**
- undifferentiated embryonal sarcoma vs., **447**
Mesenchymal hamartoma of chest wall (MHCW), **193**
Mesenchymal sarcoma, **913**
Mesenchymoma. *See* Chest wall, hamartoma.
Mesenteric adenitis, Meckel diverticulum vs., **428**
Mesenteric contusion, omental infarction vs., **499**
Mesenteric cyst. *See* Mesenteric lymphatic malformation.
Mesenteric lymphadenitis, omental infarction vs., **499**
Mesenteric lymphangiectasia, mesenteric lymphatic malformation vs., **497**
Mesenteric lymphatic malformation, **496–497**
- diagnostic checklist, **496**
- differential diagnosis, **497**
- gastrointestinal duplication cysts vs., **555**
- prognosis, **497**
Mesoblastic nephroma, **580, 650–653**
- diagnostic checklist, **652**
- differential diagnosis, **651–652**
- genetics, **652**
- multilocular cystic nephroma vs., **649**
- prognosis, **652**
- staging, grading, & classification, **652**
Mesothelial cyst
- mesenteric lymphatic malformation vs., **497**
- of round ligament, ectopic ovary vs., **737**
Metabolic bone diseases, forearm fractures vs., **845**
Metabolic brain disease, **1118–1121**
- diagnostic checklist, **1120**
- differential diagnosis, **1119**
Metabolic disorder-related bone changes, child abuse, other fractures vs., **810**
Metallic foreign bodies, ingested coins vs., **399**
Metaphyseal chondrodysplasia
- child abuse, metaphyseal fracture vs., **806**
- rickets vs., **986**
Metaphyseal corner fracture. *See* Child abuse, metaphyseal fracture.
Metaphyseal fibrous defect. *See* Nonossifying fibroma (NOF).
Metaphyseal fracture, child abuse, **804–807**
- diagnostic checklist, **806**
- differential diagnosis, **806**
- prognosis, **806**
- rickets vs., **986**
Metaphyseal spur, child abuse, metaphyseal fracture vs., **806**
Metastases
- colloid cyst vs., **1059**
- papillomatosis vs., **137**
- pulmonary
  fungal pneumonia in immunocompromised children vs., **135**
  pulmonary arteriovenous malformation vs., **157**
Metastatic disease
- chondroblastoma vs., **949**
- hepatic trauma vs., **509**
- round pneumonia vs., **126**
Metastatic neuroblastoma
- Ewing sarcoma vs., **926**
- infantile myofibroma vs., **907**
- Langerhans cell histiocytosis vs., **937**
- leukemia vs., **933–934**
- myofibromatosis vs., **907**
- rhabdomyosarcoma, head and neck vs., **1235**

- rickets vs., **986**
- stress injuries vs., **813**

Metatarsus adductus, clubfoot vs., **789**
Metatropic dysplasia, achondroplasia vs., **970**
Microabscess
- posttransplant lymphoproliferative disease vs., **526**
- splenic, cat-scratch disease vs., **479**

Microcephaly with simplified gyral pattern
- lissencephaly vs., **1033**
- polymicrogyria vs., **1039**

Microcystic lymphatic malformation
- granuloma annulare vs., **921**
- kaposiform hemangioendothelioma vs., **891**

Microgallbladder, cystic fibrosis, **565**
Midbrain or mesencephalic tumors, **1077**
Middle ear cholesterol granuloma, congenital cholesteatoma vs., **1209**
Midgut duplication. *See* Gastrointestinal duplication cysts.
Midgut malformation. *See* Gastrointestinal duplication cysts.
Midgut volvulus, **350–353**
- diagnostic checklist, **352**
- differential diagnosis, **352**
- duodenal atresia or stenosis vs., **355**
- duodenal web vs., **358**
- Hirschsprung disease vs., **373**
- hypertrophic pyloric stenosis vs., **393**
- meconium ileus vs., **367**
- meconium peritonitis vs., **381**
- neonatal small left colon vs., **371**
- prognosis, **352**

Midline descending aorta-carina compression syndrome, pulmonary sling vs., **39**
Midsubstance ACL tears, **847**
Milch classification, lateral condylar fracture, **840**
Mild hip dysplasia, **956**
Miliary tuberculosis, viral chest infection vs., **118**
Minimally invasive Nuss procedure, **190**
Minimally invasive pectus repair appearance, **190**
- diagnostic checklist, **190**

MIS-C. *See* Multisystem inflammatory syndrome in children.
Mitochondrial aminoacyl tRNA synthetase deficiencies, **1123**
Mitochondrial dysfunction, **1123**
Mitochondrial encephalopathies, **1122–1123**
- abusive head trauma vs., **1094**
- acute encephalitis vs., **1131**
- associated abnormalities, **1123**
- childhood stroke vs., **1105**
- diagnostic checklist, **1123**
- differential diagnosis, **1123**
- genetics, **1123**
- metabolic brain disease vs., **1119**

Mitral atresia. *See* Hypoplastic left heart syndrome.
Mitral stenosis. *See* Hypoplastic left heart syndrome.
Mixed germ cell tumor (MGCT). *See* Testicular tumors.
Mixed laryngocele, thyroglossal duct cyst vs., **1221**
MO. *See* Myositis ossificans.
Moderate hip dysplasia, **956**
Moderate-specificity fractures, **809–810**
Molar tooth malformation. *See* Joubert syndrome & related disorders (JSRD).
Molar tooth sign, **1023**
Molybdenum cofactor deficiency, **1119**
Mondini deformity. *See* Large vestibular aqueduct.
Mononucleosis
- Kawasaki disease vs., **323**
- wandering spleen vs., **473**

Morel-Lavallée lesion, **830**
- soft tissue abscess vs., **875**

Morquio disease, achondroplasia vs., **970**
Morquio syndrome, **1119**
Motion artifact, splenic trauma vs., **513**
Mounier-Kuhn syndrome, cystic fibrosis, pulmonary vs., **203**
Moyamoya arteriopathy, neurofibromatosis type 1, **1049**
Moyamoya disease, **1106–1107**
- differential diagnosis, **1107**
- prognosis, **1107**
- staging, grading, & classification, **1107**

MPFL injury, **851**
MPFL reconstruction, patellar dislocation, **852**
Mucinous tumor, **729**
Mucocele
- appendicitis vs., **420**
- nasolacrimal duct, **10–11**
  - choanal atresia vs., **13**
  - congenital nasal pyriform aperture stenosis vs., **9**
  - diagnostic checklist, **11**
  - differential diagnosis, **11**
  - prognosis, **11**

Mucocutaneous lymph node syndrome. *See* Kawasaki disease.
Mucopolysaccharidoses (MPS), **972–975, 1119**
- aortic coarctation, **276**
- differential diagnosis, **974**
- enlarged perivascular spaces vs., **1065**
- genetics, **974**
- prognosis, **974**

Mucositis, epiglottitis, **20**
Müllerian agenesis, **717**
Müllerian duct anomalies (MDA), **716–719**
- associated abnormalities, **718**
- diagnostic checklist, **718**
- differential diagnosis, **718**
- normal prepubertal uterus and ovaries vs., **589**
- prognosis, **718**

Müllerian hypoplasia, **717**
Multicentric osteosarcoma, **929**
Multicystic dysplastic kidney, **580, 630–633**
- associated abnormalities, **632**
- bladder exstrophy vs., **623**
- differential diagnosis, **631–632**
- genetics, **632**
- mesoblastic nephroma vs., **651**
- multilocular cystic nephroma vs., **649**
- prognosis, **632**
- segmental, ureteropelvic duplications vs., **600**
- ureteropelvic junction obstruction vs., **592**
- vesicoureteral reflux, **596**

Multifocal infantile lesions
- infantile myofibroma vs., **907**
- myofibromatosis vs., **907**
Multifocal osteomyelitis, chronic recurrent, osteomyelitis vs., **864**
Multifocal vascular anomalies
- infantile myofibroma vs., **907**
- myofibromatosis vs., **907**
Multilocular cystic nephroma, **580, 648–649**
- diagnostic checklist, **649**
- differential diagnosis, **649**
- genetics, **649**
- mesoblastic nephroma vs., **652**
- prognosis, **649**
Multipartite patella, patellar dislocation vs., **852**
Multiplanar reconstructions, heterotopic gray matter, **1035**
Multiple adjacent ribs, bizarre remodeling/distortion and erosion of, **193**
Multiple diverticula, neurogenic bladder vs., **683–684**
Multiple endocrine neoplasia syndrome type 2, pheochromocytoma, **711**
Multiple endocrine neoplasia type 1, adrenocortical carcinoma, **709**
Multiple epiphyseal dysplasia, mucopolysaccharidoses vs., **974**
Multiple intestinal atresias, **365**
- meconium peritonitis vs., **382**
Multiple sclerosis, **1132**
- inflammatory myelopathies vs., **1169**
- leukodystrophies vs., **1125**
- spinal cord astrocytoma vs., **1161**
- spinal cord ependymoma vs., **1159**
Multisystem disorder, autosomal recessive, **203**
Multisystem inflammatory syndrome in children (MIS-C), **120–123**
- differential diagnosis, **121–122**
- primary mesenteric adenitis vs., **495**
- prognosis, **122**
Mumps. *See* Epididymoorchitis.
Mural type, vein of Galen aneurysmal malformation, **1113**
Muscle hernia, **831**
- differential diagnosis, **831**
- granuloma annulare vs., **921**
Muscle injury, apophyseal injuries vs., **800**
Muscular dystrophies (MD), congenital
- lissencephaly vs., **1033**
- other cerebellar malformations vs., **1023**
Muscular VSD occluder, **299**
Musculoaponeurotic fibromatosis. *See* Fibromatosis.
Musculoskeletal system
- achondroplasia, **968–971**
- ACL injuries, **846–849**
  diagnostic checklist, **848**
  differential diagnosis, **847–848**
  prognosis, **848**
- apophyseal injuries, **798–801**
  diagnostic checklist, **799–800**
  differential diagnosis, **799–800**
  prognosis, **800**
- approach to, **764–767**
  congenital abnormalities, **764**
  focal bone lesions, **765**
  imaging modalities, **764**
  infection, **765**
  soft tissue masses, **765**
  trauma, **764–765**
- arteriovenous malformation, **900–901**
  differential diagnosis, **901**
  prognosis, **901**
- arthrogryposis, **787**
- brachial plexopathy, **1000–1001**
- child abuse
  metaphyseal fracture, **804–807**
  other fractures, **808–811**
- chondroblastoma, **948–949**
- chronic recurrent multifocal osteomyelitis, **882–885**
  associated abnormalities, **884**
  associated syndromes, **883**
  diagnostic checklist, **884**
  differential diagnosis, **883**
  genetics, **884**
- clubfoot, **788–789**
  differential diagnosis, **789**
  prognosis, **789**
- dermatomyositis, **880–881**
  staging, grading, & classification, **881**
- developmental hip dysplasia, **954–957**
- discoid meniscus, **790–793**
  diagnostic checklist, **792**
  differential diagnosis, **791–792**
  lateral, **791**
  staging, grading, & classification, **792**
- distal femoral avulsive irregularity, **778–789**
  diagnostic checklist, **778**
  differential diagnosis, **779**
- Ewing sarcoma, **924–927**
- fibromatosis, **902–905**
- forearm fractures, **844–845**
  differential diagnosis, **845**
  prognosis, **845**
- fracture complications, **820–823**
  diagnostic checklist, **822**
  malunion, **822**
  nonunion, **821–822**
- granuloma annulare, **920–921**
- hemophilia, **1002–1003**
- incomplete fractures, **802–803**
  diagnostic checklist, **803**
  differential diagnosis, **803**
  prognosis, **803**
- infantile hemangioma, **886–889**
  diagnostic checklist, **888**
  differential diagnosis, **887–888**
  immunohistochemical features, **888**
  prognosis, **888**
- infantile myofibroma, **906–907**
- juvenile idiopathic arthritis, **876–879**
  diagnostic checklist, **878**
  differential diagnosis, **878**

- juvenile tillaux fracture, **860–861**
  - diagnostic checklist, **861**
  - prognosis, **861**
- kaposiform hemangioendothelioma, **890–891**
  - diagnostic checklist, **890**
  - differential diagnosis, **891**
  - prognosis, **891**
- Langerhans cell histiocytosis, **936–939**
- lateral condylar fracture, **838–841**
  - differential diagnosis, **839**
  - prognosis, **840**
  - staging, grading, & classification, **839–840**
- Legg-Calvé-Perthes disease, **960–963**
- leukemia, **932–935**
- lipoblastoma, **910**
- lymphatic malformation, **896–899**
  - associated abnormalities, **898**
  - differential diagnosis, **897**
  - prognosis, **898**
  - staging, grading, & classification, **898**
- medial epicondyle avulsion, **842–843**
  - associated abnormalities, **843**
  - differential diagnosis, **843**
- Morel-Lavallée lesion, **830**
- mucopolysaccharidoses, **972–975**
- muscle hernia, **831**
  - differential diagnosis, **831**
- myofibromatosis, **906–907**
- myositis ossificans, **922–923**
- nonossifying fibroma, **940–943**
- nonrhabdomyosarcoma soft tissue sarcomas, **916–919**
- normal developmental variants confused with disease, **772–777**
  - diagnostic checklist, **773**
  - differential diagnosis, **773**
- orthopedic hardware and complications, **824–827**
- osteochondritis dissecans, **816–819**
  - diagnostic checklist, **818**
  - differential diagnosis, **817–818**
  - prognosis, **818**
  - staging, grading, & classification, **818**
- osteochondroma, **950–953**
- osteochondroses, **982–983**

Musculoskeletal tract
- clavicle injuries, **832–833**
  diagnostic checklist, **833**
  differential diagnosis, **833**
- toddler's fracture, **856**
- trampoline fracture, **856**

Mustard/Senning procedure, arterial switch procedure vs., **293**
Myelin & oligodendrocytes, leukodystrophies, **1125**
Myelin maturation. *See* Myelination, normal.
Myelination
- incomplete or delayed, focal cortical dysplasia vs., **1041**
- normal, **1010–1013**
  detection of, **1011**
  diagnostic checklist, **1012**
  genetics, **1012**
  staging, grading, & classification, **1012**

Myeloblastoma. *See* Leukemia.
Myelocele, **1147**
- lipomyelomeningocele vs., **1148**

Myelocystocele, sacrococcygeal teratoma vs., **1163**
Myelodysplasia
- neurogenic bladder, **684**
- vertical calcaneus in, clubfoot vs., **789**

Myelomeningocele, **1146–1147**
- anorectal malformations, **378**
- diagnostic checklist, **1147**
- differential diagnosis, **1147**
- lipomyelomeningocele vs., **1148**
- neurogenic bladder, **684**
- omphalocele, **410**
- prognosis, **1147**
- urachal abnormalities associated with, **618**

Myocarditis, **302–303**
- acute viral, Duchenne muscular dystrophy-related cardiomyopathy vs., **309**
- arrhythmogenic right ventricular dysplasia vs., **311**
- of other etiologies, MIS-C vs., **122**

Myofibroma
- infantile, kaposiform hemangioendothelioma vs., **891**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**

Myofibromatosis, **906–907**
- differential diagnosis, **907**
- infantile
  fibromatosis vs., **903**
  Langerhans cell histiocytosis vs., **938**
  syphilis vs., **869**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- prognosis, **907**

Myopathy, encephalopathy, lactic acidosis, & stroke-like episodes, **1123**
Myositis, kaposiform hemangioendothelioma vs., **891**
Myositis ossificans (MO), **922–923**
- diagnostic checklist, **923**
- differential diagnosis, **923**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- osteochondroma vs., **951**
- osteogenesis imperfecta vs., **977**
- osteosarcoma vs., **930**
- rhabdomyosarcoma, musculoskeletal vs., **914**
- soft tissue abscess vs., **875**

Myxoma, rhabdomyoma vs., **319**

N

Nasal dermal cyst. *See* Nasal dermal sinus.
Nasal dermal sinus, **1184–1187**
- associated abnormalities, **1186**
- diagnostic checklist, **1186**
- differential diagnosis, **1185**
- prognosis, **1186**

Nasal dermoid. *See* Nasal dermal sinus.
Nasal glial heterotopia, cephalocele vs., **1025**
Nasal glioma, nasal dermal sinus vs., **1185**
Nasal pyriform aperture stenosis, congenital, **8–9**
- associated abnormalities, **9**
- diagnostic checklist, **9**
- differential diagnosis, **9**

Nasoenteric tubes, hypertrophic pyloric stenosis, **394**
Nasogastric tube malposition, esophageal atresia and tracheoesophageal fistula vs., **81**
Nasolacrimal duct mucocele, **10–11**
- choanal atresia vs., **13**
- congenital nasal pyriform aperture stenosis vs., **9**
- diagnostic checklist, **11**
- differential diagnosis, **11**
- prognosis, **11**

Nasopharyngeal carcinoma, rhabdomyosarcoma, head and neck vs., **1235**
NAT. *See* Nonaccidental trauma.
Natowicz syndrome, **1119**
NBL. *See* Neuroblastoma.
NDS. *See* Nasal dermal sinus.
Near drowning, mitochondrial encephalopathies vs., **1123**
Necrobiotic granuloma. *See* Granuloma annulare.
Necrosis, cavitary, pneumonia with, **130–133**
- differential diagnosis, **131–132**
- prognosis, **132**

Necrotizing enterocolitis, **335, 384–387**
- associated abnormalities, **386**
- diagnostic checklist, **386**
- differential diagnosis, **385**
- Hirschsprung disease vs., **374**
- jejunoileal atresia vs., **362**

- prognosis, **386**
- spontaneous intestinal perforation in neonates vs., **389**
- staging, grading, & classification, **386**

Necrotizing pneumonia. *See also* Pneumonia, with cavitary necrosis.
- pleuropulmonary blastoma vs., **153**

NEHI. *See* Neuroendocrine cell hyperplasia of infancy.
Neonatal adrenal hemorrhage, **694–697**
- diagnostic checklist, **696**
- differential diagnosis, **695–696**
- genetics, **696**
- neuroblastoma vs., **703**
- normal neonatal adrenal gland vs., **587**
- prognosis, **696**

Neonatal adrenoleukodystrophy, **1119**
Neonatal bowel obstruction, differential diagnoses, **335**
Neonatal brachial plexus palsy. *See* Brachial plexopathy.
Neonatal distal bowel obstruction, anorectal malformations vs., **377**
Neonatal hepatitis, biliary atresia vs., **450**
Neonatal pneumonia, **92–93**
- diagnostic checklist, **93**
- differential diagnosis, **93**
- meconium aspiration syndrome vs., **95**
- prognosis, **93**

Neonatal pneumothorax, **102–103**
- diagnostic checklist, **103**
- differential diagnosis, **103**
- prognosis, **103**

Neonatal primary hyperparathyroidism, transient neonatal renal medullary hyperechogenicity vs., **677**
Neonatal pulmonary interstitial glycogen accumulation disorder. *See* Pulmonary interstitial glycogenosis (PIG).
Neonatal renal vein thrombus, transient neonatal renal medullary hyperechogenicity vs., **677**
Neonatal small left colon, **370–371**
- differential diagnosis, **371**
- Hirschsprung disease vs., **373**
- prognosis, **371**

Neonatal soft tissue mass
- infantile myofibroma vs., **907**
- myofibromatosis vs., **907**

Neonatal torticollis. *See* Fibromatosis colli.
Neoplasms
- adrenal cortical, neuroblastoma vs., **704**
- bezoars vs., **551**
- cavernous malformation vs., **1117**
- clear cell sarcoma, Wilms tumor vs., **641**
- clear cell sarcoma of kidney, **655**
  - mesoblastic nephroma vs., **651**
- renal, renal injury vs., **670**
- renal rhabdoid tumor, Wilms tumor vs., **641**
- small bowel, duodenal trauma vs., **517**
- solid pseudopapillary, **482–483**
  - differential diagnosis, **483**
  - prognosis, **483**
- testicular trauma vs., **757**
- tuberous sclerosis vs., **1053**

Nephrectomy, renal agenesis vs., **629**
Nephroblastoma. *See* Wilms tumor.
Nephroblastomatosis, **580, 644–647**
- associated syndromes, **645**
- autosomal recessive polycystic kidney disease vs., **639**
- diagnostic checklist, **646**
- differential diagnosis, **645–646**
- prognosis, **646**
- staging, grading, & classification, **646**
- Wilms tumor vs., **641**

Nephrocalcinosis
- medullary, transient neonatal renal medullary hyperechogenicity vs., **677**
- renal stones vs., **673**

Nephrolith. *See* Renal stones.
Nephrolithiasis. *See* Renal stones.
Nephroma
- congenital mesoblastic, multicystic dysplastic kidney vs., **631**
- mesoblastic, **580, 650–653**
  - congenital, Wilms tumor vs., **641**
  - diagnostic checklist, **652**
  - differential diagnosis, **651–652**
  - genetics, **652**
  - multilocular cystic nephroma vs., **649**
  - prognosis, **652**
  - staging, grading, & classification, **652**
  - Wilms tumor vs., **641**
- multilocular cystic, **580, 648–649**
  - diagnostic checklist, **649**
  - differential diagnosis, **649**
  - genetics, **649**
  - mesoblastic nephroma vs., **651**
  - pleuropulmonary blastoma, **153**
  - prognosis, **649**
  - Wilms tumor vs., **641**

Neural tube defect, VACTERL association, **782**
Neurenteric cyst, **1153**
- bronchogenic cyst vs., **71**
- diagnostic checklist, **1153**
- differential diagnosis, **1153**

Neuroblastoma metastasis, hepatic hemangiomas, infantile and congenital vs., **440**
Neuroblastoma (NBL), **53, 335, 702–707**
- adrenocortical carcinoma vs., **709**
- anorectal malformations vs., **378**
- associated abnormalities, **704**
- bezoars vs., **551**
- bronchogenic cyst vs., **72**
- bronchopulmonary sequestration vs., **68**
- congenital adrenal hyperplasia vs., **700**
- differential diagnosis, **703–704**
- genetics, **704**
- infantile myofibroma vs., **907**
- lymphoma vs., **142**
- meconium peritonitis vs., **382**
- mesoblastic nephroma vs., **651**
- metastatic
  - Ewing sarcoma vs., **926**
  - Langerhans cell histiocytosis vs., **937**
  - osteomyelitis vs., **863**
  - rickets vs., **986**
- myofibromatosis vs., **907**

- neonatal adrenal hemorrhage vs., **695**
- normal neonatal adrenal gland vs., **587**
- normal thymus vs., **58**
- pelvic
  - genitourinary myosarcoma vs., **691**
  - hydrometrocolpos vs., **714**
- pheochromocytoma vs., **711**
- prognosis, **704**
- renal ectopia and fusion vs., **626**
- round pneumonia vs., **125**
- sacrococcygeal teratoma vs., **1163**
- staging, grading, & classification, **704**
- syphilis vs., **869**
- thoracic, **148–151**
  - associated abnormalities, **149**
  - diagnostic checklist, **150**
  - differential diagnosis, **149**
  - genetics, **149**
  - prognosis, **150**
  - staging, grading, & classification, **150**
- Wilms tumor vs., **641**

Neurocristopathy syndromes, Hirschsprung disease, **373**
Neurocutaneous melanosis, **1057**
- diagnostic checklist, **1057**
- diffuse leptomeningeal glioneuronal tumor vs., **1157**

Neurocutaneous syndrome, **1053**
- neurofibromatosis type 1 vs., **1050**

Neurocysticercosis
- cavernous malformation vs., **1117**
- colloid cyst vs., **1059**
- diffuse leptomeningeal glioneuronal tumor vs., **1157**
- enlarged perivascular spaces vs., **1065**
- TORCH infections vs., **1127**

Neuroendocrine cell hyperplasia of infancy (NEHI), **53, 174–175**
- diagnostic checklist, **175**
- differential diagnosis, **175**
- prognosis, **175**
- staging, grading, & classification, **175**

Neuroendocrine tumor, pancreatic, pancreatoblastoma vs., **481**
Neuroepithelial cyst
- arachnoid cyst vs., **1061**
- DNET vs., **1080**

Neuroepithelial tumor, dysembryoplastic, ganglioglioma vs., **1081**
Neurofibroma
- cervical lymphatic malformation vs., **14**
- plexiform
  - musculoskeletal vs., **913**
  - venous malformation, musculoskeletal vs., **894**
- ureterocele vs., **604**

Neurofibromatosis
- aortic coarctation, **276**
- scoliosis, **993**

Neurofibromatosis type 1, **1048–1051**
- abdominal aneurysms, **577**
- associated abnormalities, **1050**
- brainstem tumors vs., **1078**
- diagnostic checklist, **1050**
- differential diagnosis, **1050**
- genetics, **1050**
- genitourinary rhabdomyosarcoma, **692**
- mitochondrial encephalopathies vs., **1123**
- neuroblastoma, **704**
- osteogenesis imperfecta vs., **977**
- pheochromocytoma, **711**
- prognosis, **1050**
- staging, grading, & classification, **1050**

Neurofibromatosis type 2 (NF2), neurofibromatosis type 1 vs., **1050**
Neurogenic bladder, **581, 682–685**
- associated abnormalities, **684**
- diagnostic checklist, **684**
- differential diagnosis, **683–684**
- epididymoorchitis, **740**
- primary megaureter vs., **607**
- prognosis, **684**
- staging, grading, & classification, **684**

Neurogenic pulmonary edema, lung contusion and laceration vs., **163**
Neurogenic tumor
- Castleman disease vs., **574**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**

Neuromuscular disease
- developmental hip dysplasia vs., **955–956**
- pectus excavatum, **189**

Neuromyelitis optica, inflammatory myelopathies vs., **1169**
Neuromyelitis optica spectrum disorders, **1132**
Neurons & axons, leukodystrophies, **1125**
Neurosarcoidosis, diffuse leptomeningeal glioneuronal tumor vs., **1157**
Neutralization plating, orthopedic hardware and complications, **826**
Neutropenic colitis, **530–531**
- differential diagnosis, **531**
- prognosis, **531**
- pseudomembranous colitis vs., **529**

Newborn stress demineralization, rickets vs., **986**
NF1. *See* Neurofibromatosis type 1.
NHL. *See* Non-Hodgkin lymphoma.
Nidus, arteriovenous malformation, **1115**
Nodular fasciitis
- granuloma annulare vs., **921**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**

Nodular regenerative hyperplasia, Abernethy malformation, **467**
NOF. *See* Nonossifying fibroma.
Non-Hodgkin lymphoma (NHL), **141**
- pancreatoblastoma vs., **481**
- rhabdomyosarcoma, head and neck vs., **1236**

Nonaccidental trauma (NAT), **159**. *See also* Child abuse.
Nonalcoholic fatty liver disease (NAFLD), **463**
- cirrhosis, **461**

Nonalcoholic steatohepatitis (NASH), **463**
Noncommunicating hydrocele, **761**
Noncompacted left ventricle. *See* Left ventricular noncompaction.
Noncompaction cardiomyopathy, Duchenne muscular dystrophy-related cardiomyopathy vs., **309**

Noninfectious extrinsic obstructions, approach, **4**
Noninfectious intrinsic obstructions, approach, **4**
Nonketotic hyperglycinemia, **1119**
Nonmalignant lymphoproliferative disorder, **574**
Nonossifying fibroma (NOF), **940–943**
- diagnostic checklist, **942**
- differential diagnosis, **941–942**
- distal femoral avulsive irregularity vs., **779**
- genetics, **942**
- prognosis, **942**

Nonrefluxing nonobstructive megaureter, primary megaureter vs., **607**
Nonrhabdomyosarcoma soft tissue sarcomas (NRSTS), **916–919**
- diagnostic checklist, **917**
- differential diagnosis, **917**
- prognosis, **917**

Nonseminomatous germ cell tumor (NSGCT). *See* Germ cell tumors.
Nonsyndromic congenital external & middle ear malformation, Treacher Collins syndrome vs., **1218**
Nontraumatic ligamentous instability, craniocervical junction injuries vs., **1172**
Nontuberculous *Mycobacterium* adenopathy, suppurative adenitis vs., **1243**
Nonunion
- fracture complications, **821–822**
- lateral condylar fracture, **840**

Nonvascular masses, double aortic arch vs., **36**
Noonan syndrome
- chylothorax, **105**
- pulmonary artery stenosis vs., **284**

Nora lesion, osteochondroma, **952**
Normal chest radiograph
- adolescent, pulmonary artery stenosis vs., **283**
- atrial septal defect vs., **224**

Normal development, pediatric brain, **1006**
Normal developmental variants
- confused with disease, **772–777**
  diagnostic checklist, **773**
  differential diagnosis, **773**
- forearm fractures vs., **845**
- incomplete fractures vs., **803**
- osteochondroses vs., **983**

Normal irregular distal femoral epiphyseal ossification, osteochondritis dissecans vs., **817–818**
Normal myelination, **1010–1013**
- detection of, **1011**
- diagnostic checklist, **1012**
- genetics, **1012**
- staging, grading, & classification, **1012**

Normal ossification variant, tibial tubercle avulsion vs., **855**
Normal periventricular halo, white matter injury of prematurity vs., **1101**
Normal unossified cartilage, clavicle injuries vs., **833**
Normal variant ossification, patellar sleeve avulsion vs., **854**
Normal variants confused with fractures, child abuse, other fractures vs., **810**
Normal with prominent trabeculations, left ventricular noncompaction vs., **305**
Norwood procedure, **294–295**
- differential diagnosis, **295**
- prognosis, **295**

NRSTS. *See* Nonrhabdomyosarcoma soft tissue sarcomas.
Nuclear cystograms, pediatric genitourinary tract, **581**
Nuclear medicine
- musculoskeletal system, **764**
- pediatric genitourinary tract, **581**

Nutritional vitamin D deficiency, **985**

O

Obesity, steatosis/steatohepatitis, **463**
Obstructed hemivagina, ipsilateral renal agenesis (OVHIRA syndrome), renal agenesis, **629**
Obstructing choledocholithiasis, choledochal cyst vs., **455**
Obstructing Ladd bands, malrotation with, midgut volvulus vs., **352**
Obstructive hydrocephalus, secondary, aqueductal stenosis vs., **1047**
Obstructive sleep apnea (OSA), approach, **4**
OC. *See* Osteochondroma.
Occult intrasacral meningocele, caudal regression vs., **1150**
OCD. *See* Osteochondritis dissecans.
Oculoauriculovertebral syndrome, VACTERL association vs., **781**
OEIS complex, limb-body wall complex vs., **417**
Olecranon fracture, lateral condylar fracture vs., **839**
Olecranon stress injury, medial epicondyle avulsion vs., **843**
Oligoarticular arthritis, **877**
Oligodendroglioma, ganglioglioma vs., **1081**
Oligohydramnios, autosomal recessive polycystic kidney disease, **636**
Omental cyst. *See* Mesenteric lymphatic malformation.
Omental infarction, **498–499**
- appendicitis vs., **420**
- differential diagnosis, **499**
- Meckel diverticulum vs., **428**
- primary mesenteric adenitis vs., **495**

Omphalitis, urachal abnormalities vs., **617**
Omphalocele, **408–411**
- associated abnormalities, **409**
- bladder exstrophy vs., **623**
- diagnostic checklist, **410**
- differential diagnosis, **409**
- gastroschisis vs., **413**
- genetics, **409**
- hernias vs., **406**
- limb-body wall complex vs., **417**
- prognosis, **410**
- urachal abnormalities, **614**
- VACTERL association, **782**

Omphalomesenteric abnormalities, colonic volvulus, **431**

Omphalomesenteric duct remnant
- Hirschsprung disease vs., **373**
- urachal abnormalities, **618**
Oncogenic rickets, **985**
Ondine curse, Hirschsprung disease, **373**
OO. *See* Osteoid osteoma.
Open-lip schizencephaly, holoprosencephalies vs., **1026**
Open spinal dysraphisms, lipomyelomeningocele vs., **1148**
Optic pathway gliomas (OPG), **1049**
Oral intake, poor, retropharyngeal space abscess, **32**
Orbital cellulitis, **1196–1199**
- associated abnormalities, **1198**
- diagnostic checklist, **1198**
- differential diagnosis, **1197**
- prognosis, **1198**
- staging, grading, & classification, **1198**
Orbital dermoid & epidermoid cyst, nasolacrimal duct mucocele vs., **11**
Orbital neoplasm, orbital cellulitis vs., **1197**
Orbital septum, **1197**
Orbital vascular anomaly, orbital cellulitis vs., **1197**
Orchitis. *See also* Epididymoorchitis.
- focal, testicular tumors vs., **753**
- testicular torsion vs., **743**
- torsion of testicular appendage vs., **747**
Organic & aminoacidopathies, **1119**
Organizing pneumonias, EVALI vs., **215**
Orthopedic hardware and complications, **824–827**
- diagnostic checklist, **826**
Os odontoideum, craniocervical junction injuries vs., **1172**
Osgood-Schlatter disease, tibial tubercle avulsion vs., **855**
Osler-Weber-Rendu syndrome, pulmonary arteriovenous malformation, **157**
Osmotic demyelination syndrome, brainstem tumors vs., **1078**
Ossifying renal tumor of infancy, mesoblastic nephroma vs., **651**
Osteoblastoma, osteoid osteoma vs., **946**
Osteochondral impaction fracture, osteochondritis dissecans vs., **818**
Osteochondral lesion. *See also* Osteochondritis dissecans.
- discoid meniscus vs., **791–792**
Osteochondritis dissecans (OCD), **816–819**
- diagnostic checklist, **818**
- differential diagnosis, **817–818**
- discoid meniscus vs., **791–792**
- primary and secondary growth centers vs., **769**
- prognosis, **818**
- staging, grading, & classification, **818**
- tarsal coalition vs., **998**
Osteochondroma (OC), **950–953**
- associated abnormalities, **952**
- differential diagnosis, **951**
- palpable normal variants of chest wall vs., **61**
- prognosis, **952**
Osteochondroses, **982–983**
- diagnostic checklist, **983**
- differential diagnosis, **983**
- primary and secondary growth centers vs., **769**
Osteochondrosis. *See* Apophyseal injuries.
Osteodystrophy, renal, slipped capital femoral epiphysis vs., **965**
Osteogenesis imperfecta (OI), **976–979**
- associated abnormalities, **978**
- child abuse
  - metaphyseal fracture vs., **806**
  - other fractures vs., **810**
  - rib fractures vs., **159–160**
- diagnostic checklist, **978**
- differential diagnosis, **977–978**
- genetics, **978**
- staging, grading, & classification, **978**
Osteoid osteoma (OO), **944–947**
- chondroblastoma vs., **949**
- diagnostic checklist, **946**
- differential diagnosis, **945–946**
- distal femoral avulsive irregularity vs., **779**
- Legg-Calvé-Perthes disease vs., **962**
- prognosis, **946**
- scoliosis vs., **994**
- stress injuries vs., **813**
Osteomyelitis, **862–867**
- apophyseal injuries vs., **799–800**
- bacterial, syphilis vs., **869**
- cat-scratch disease, **479**
- chondroblastoma vs., **949**
- chronic, osteogenesis imperfecta vs., **978**
- chronic granulomatous disease, **536**
- chronic recurrent multifocal, **882–885**
  - associated abnormalities, **884**
  - associated syndromes, **883**
  - diagnostic checklist, **884**
  - differential diagnosis, **883**
  - genetics, **884**
- chronic recurrent multifocal osteomyelitis vs., **883**
- diagnostic checklist, **864**
- differential diagnosis, **863–864**
- distal femoral avulsive irregularity vs., **779**
- Ewing sarcoma vs., **925–926**
- Langerhans cell histiocytosis vs., **937**
- leukemia vs., **934**
- osteoid osteoma vs., **945–946**
- osteosarcoma vs., **930**
- physeal fractures vs., **796**
- primary and secondary growth centers vs., **769**
- prognosis, **864**
- septic arthritis vs., **871**
- stress injuries vs., **813**
- tarsal coalition vs., **998**
- transient synovitis vs., **873**
Osteonecrosis
- fracture complications, **821, 822**
- primary and secondary growth centers vs., **769**
- of systemic disorders, osteochondroses vs., **983**
Osteopetrosis, **980–981**
- autosomal dominant type 1 (ADO1), **981**
- autosomal dominant type 2 (ADO2), **981**
- autosomal recessive (ARO), **981**
- genetics, **981**
- prognosis, **981**
- X-linked recessive, **981**

Osteoporosis-pseudoglioma syndrome, osteogenesis imperfecta vs., **977**
Osteosarcoma, **928–931**
- diagnostic checklist, **930**
- differential diagnosis, **929–930**
- distal femoral avulsive irregularity vs., **779**
- Ewing sarcoma vs., **926**
- musculoskeletal system, **765**
- osteochondroma vs., **951**
- osteogenesis imperfecta vs., **977**
- osteoid osteoma vs., **946**
- prognosis, **930**
- surface, myositis ossificans vs., **923**

Ostium secundum, atrial septal defect, **224**
Otofaciocervical syndrome, branchiootorenal syndrome vs., **1217**
Ovarian cyst, **720–723**
- bladder diverticula vs., **687**
- diagnostic checklist, **722**
- differential diagnosis, **721–722**
- gastrointestinal duplication cysts vs., **556**
- mesenteric lymphatic malformation vs., **497**
- ovarian torsion vs., **733**
- prognosis, **722**
- ureterocele vs., **604**

Ovarian malignancies of childhood, **728–731**
- diagnostic checklist, **730**
- differential diagnosis, **730**
- prognosis, **730**

  - duodenal web vs., **358**
  - hypertrophic pyloric stenosis vs., **394**
  - pancreas divisum vs., **485**
- dorsal agenesis of, pancreas divisum vs., **485**
- shock
  - pancreatic trauma vs., **521**
  - pancreatitis vs., **492**

Pancreas divisum, **484–485**
- annular pancreas, **489**
- diagnostic checklist, **485**
- differential diagnosis, **485**
- pancreaticobiliary maljunction vs., **487**
- types, **485**

Pancreatic abnormalities, pancreatitis, cystic fibrosis, **565**
Pancreatic adenocarcinoma, solid pseudopapillary neoplasm vs., **483**
Pancreatic cystosis, cystic fibrosis, **565**
Pancreatic insufficiency, cystic fibrosis associated with, **565**
Pancreatic lymphoma, pancreatitis vs., **492**
Pancreatic neuroendocrine tumor, pancreatoblastoma vs., **481**
Pancreatic pseudocyst, **491**
- choledochal cyst vs., **455**
- intrasplenic, splenic cyst vs., **477**
- pancreatoblastoma vs., **481**
- solid pseudopapillary neoplasm vs., **483**

Pancreatic trauma, **520–523**
- differential diagnosis, **521–522**
- duodenal trauma vs., **517**
- pancreatitis vs., **492**
- prognosis, **522**
- staging, grading, & classification, **522**

Pancreaticobiliary maljunction, **486–487**
- differential diagnosis, **487**
- prognosis, **487**
- staging, grading, & classification, **487**

Pancreatitis, **490–493**
- acute, **491**
- acute recurrent, **491**
- chronic, **491**
- cystic fibrosis, **565**
- differential diagnosis, **492**
- duodenal trauma vs., **517**

- genetics, **492**
- interstitial edematous, **491**
- mortality rate, **492**
- necrotizing, **491**
- pancreatic trauma vs., **522**
- prognosis, **492**

Pancreatoblastoma, **480–481**
- associated abnormalities, **481**
- differential diagnosis, **481**
- prognosis, **481**

Pancreatoblastoma, solid pseudopapillary neoplasm vs., **483**
Papillary fibroelastoma, rhabdomyoma vs., **319**
Papillomatosis, **53, 136–139**
- airway, airway infantile hemangioma vs., **47**
- croup, **24**
- diagnostic checklist, **138**
- differential diagnosis, **137**
- Langerhans cell histiocytosis vs., **187**
- lymphangioleiomyomatosis vs., **185**
- prognosis, **138**
- staging, grading, & classification, **138**

Paraesophageal hiatal hernia, gastric volvulus vs., **397**
Paralysis, vocal cord, croup, **24**
Paramediastinal pneumatocele, pneumomediastinum vs., **171**
Parameniscal cysts, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
Paraovarian cyst
- bladder diverticula vs., **687**
- ovarian cyst vs., **722**

Parapneumonic effusion, **53**
- empyema and, **128–129**
  - differential diagnosis, **129**
  - prognosis, **129**
  - stages, **129**

Parasitic infection, hemophagocytic lymphohistiocytosis vs., **569**
Paratesticular rhabdomyosarcoma (PT-RMS), **750–751**
- associated abnormalities, **751**
- differential diagnosis, **751**
- prognosis, **751**
- staging, grading, & classification, **751**
- variations of hydroceles vs., **761**

Paratesticular tumor, torsion of testicular appendage vs., **748**
Paravertebral soft tissues, inferior, widening of, neuroblastoma vs., **149**
Parenchymal ischemic injury, in shaking injuries, **1093**
Parenchymal lung diseases, alveolar growth abnormality vs., **179**
Parenchymal melanosis, **1057**
Parinaud syndrome, pineal cyst, **1064**
Parosteal osteosarcoma, **929**
Parotid infantile hemangioma, acute parotitis vs., **1229**
Parotid sialosis, acute parotitis vs., **1229**
Paroxysmal supraventricular tachycardia, hypoplastic left heart syndrome vs., **266**
Partial anomalous pulmonary venous return (PAPVR)
- Scimitar syndrome vs., **287**
- total anomalous pulmonary venous return vs., **262**

Partial duplication. *See* Ureteropelvic duplications.
PAS. *See* Pulmonary artery sling.
Patella alta, **851**
Patellar defect, dorsal, patellar dislocation vs., **852**
Patellar dislocation, **850–853**
- diagnostic checklist, **850**
- differential diagnosis, **852**
- prognosis, **852**

Patellar sleeve avulsion, **854**
- differential diagnoses, **854**
- tibial tubercle avulsion vs., **855**

Patellar tendon rupture, tibial tubercle avulsion vs., **855**
Patellar tendon to trochlear groove distance, patellar dislocation, **852**
Patent ductus arteriosus (PDA), **234–237**
- aortic coarctation, **276**
- atrioventricular septal defect vs., **232**
- differential diagnosis, **235**
- double aortic arch, **36**
- genetics, **235**
- prognosis, **236**
- stent, Blalock-Taussig shunt vs., **297**
- ventricular septal defect vs., **227–228**

Patent urachus. *See* Urachal abnormalities.
PDA. *See* Patent ductus arteriosus.
Pectus carinatum
- palpable normal variants of chest wall vs., **61**
- pectus excavatum vs., **189**

Pectus excavatum, **188–189**
- arrhythmogenic right ventricular dysplasia vs., **312**
- associated abnormalities, **189**
- differential diagnosis, **189**
- palpable normal variants of chest wall vs., **61**

Pectus repair appearance, minimally invasive, **190**
- diagnostic checklist, **190**

Pediatric airway, approach to, **4–5**
Pediatric arthropathies, hemophilia vs., **1003**
Pediatric heart, approach, **216–221**
- anatomy-based imaging issues, **219**
- cardiac 3D models, **219**
- cardiac MR & cardiac CT, **219**
- imaging anatomy, **218**
- indications for cardiac MR & CT, **219**

Pediatric soft tissue malignancies, **918**
Pediatric spine, approach, **1144–1145**
- embryology, **1144**
- imaging protocols, **1144**
- pathology-based imaging issues, **1144**

Pelvic abscess
- genitourinary myosarcoma vs., **692**
- hydrometrocolpos vs., **713**

Pelvic fractures, **810**
Pelvic inflammatory disease
- genitourinary myosarcoma vs., **692**
- ovarian torsion vs., **734**

Pelvic kidney. *See* Renal ectopia and fusion.
Pelvic mass
- hydrometrocolpos vs., **714**
- neurogenic bladder vs., **683**

Pelvic neuroblastoma
- genitourinary myosarcoma vs., **691**
- hydrometrocolpos vs., **714**
Pelvic rhabdomyosarcoma
- hydrometrocolpos vs., **714**
- renal ectopia and fusion vs., **626**
- sacrococcygeal teratoma vs., **1163**
Pelvis, proximal focal femoral deficiency, **959**
Pelviureteric obstruction. *See* Ureteropelvic junction obstruction.
Penetrating trauma, **522**
Pentalogy of Cantrell
- limb-body wall complex vs., **417**
- omphalocele, **410**
Peptic stricture, esophageal strictures, **547, 548**
Perforated appendicitis
- with appendicolith, ovarian teratoma vs., **725**
- hydrometrocolpos vs., **713**
Periarticular cysts, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
Peribronchial pneumonia, **117**
Pericardial defect, bronchogenic cyst, **72**
Pericardial effusion, Ebstein anomaly vs., **247**
Perimembranous ventricular septal defect, tetralogy of Fallot vs., **239**
Perinatal brachial plexus palsy. *See* Brachial plexopathy.
Perinatal ischemia, transient neonatal renal medullary hyperechogenicity vs., **677**
Periosteal chondroma
- distal femoral avulsive irregularity vs., **779**
- osteochondroma vs., **951**
Periosteal osteosarcoma, **929**
Peripheral nerve sheath tumor, malignant, plexiform neurofibroma vs., **909**
Peripheral pattern, hypoxic-ischemic encephalopathy, **1103**
Peripherally inserted central catheters (PICCs), **114–115**
- diagnostic checklist, **115**
- malposition, **115**
Peritoneal inclusion cyst
- mesenteric lymphatic malformation vs., **497**
- ovarian cyst vs., **722**
- ovarian teratoma vs., **726**
Perivascular spaces, enlarged, **1065**
Periventricular calcifications, germinal matrix hemorrhage vs., **1097**
Periventricular gray matter heterotopia, germinal matrix hemorrhage vs., **1097**
Periventricular halo, normal, white matter injury of prematurity vs., **1101**
Periventricular leukomalacia, leukodystrophies vs., **1125**
Perkin line, developmental hip dysplasia, **955**
Perlman syndrome, nephroblastomatosis, **645**
Peroxisomal biogenesis disorders, **1119**
Persistent fetal circulation syndrome
- patent ductus arteriosus vs., **235**
- total anomalous pulmonary venous return vs., **261**
Persistent hyperplastic primary vitreous, retinoblastoma vs., **1201**
Persistent pulmonary interstitial emphysema, congenital lobar overinflation vs., **76**
Perthes disease. *See* Legg-Calvé-Perthes (LCP) disease.
PHACES syndrome, **1056**
- airway infantile hemangioma vs., **47**
- diagnostic checklist, **1056**
- differential diagnosis, **1056**
- neurofibromatosis type 1 vs., **1050**
- Sturge-Weber syndrome vs., **1055**
Phakomatosis, **1049**
- neurofibromatosis type 1 vs., **1050**
Phenylketonuria, **1119**
Pheochromocytoma, **710–711**
- adrenocortical carcinoma vs., **709**
- associated syndromes, **711**
- differential diagnosis, **711**
- neuroblastoma vs., **704**
- prognosis, **711**
- renal artery stenosis vs., **680**
Phleboliths, renal stones vs., **673**
Phlegmon, **875**
Physeal fractures, **794–797**
- associated abnormalities, **796**
- diagnostic checklist, **796**
- differential diagnosis, **795–796**
- germinal zone, **796**
- hypertrophic zone, **796**
- normal developmental variants confused with disease vs., **773**
- prognosis, **796**
- proliferative zone, **796**
- rickets vs., **986**
- staging, grading, & classification, **796**
- zone of provisional calcification, **796**
Physeal stress fracture. *See* Apophyseal injuries.
Physeal stress injury
- chronic, **813**
  physeal fractures vs., **795**
- leukemia vs., **934**
- rickets vs., **986**
Physiologic gut herniation, gastroschisis vs., **413**
Physiologic hypertrophy, hypertrophic cardiomyopathy vs., **307**
Physiologic periosteal reaction, **773**
- syphilis vs., **869**
Phytobezoar, **551, 552**
PICCs. *See* Peripherally inserted central catheters.
PIE. *See* Pulmonary interstitial emphysema.
Pierre Robin sequence, **1219**
- congenital auricle malformations vs., **1205**
- differential diagnosis, **1219**
PIG. *See* Pulmonary interstitial glycogenosis.
Pigmented villonodular synovitis
- hemophilia vs., **1003**
- juvenile idiopathic arthritis vs., **878**
Pilocytic astrocytoma (PA), **1066–1067**
- brain abscess vs., **1129**
- cavum septum pellucidum vs., **1016**
- desmoplastic infantile tumors vs., **1082**
- differential diagnosis, **1067**
- ganglioglioma vs., **1081**

- genetics, **1067**
- medulloblastoma vs., **1069**
- prognosis, **1067**
- spinal cord astrocytoma, **1161**

Pilomatrixoma, **911**
Pilomyxoid astrocytoma, pilocytic astrocytoma vs., **1067**
Pilonidal sinus/cyst, dorsal dermal sinus vs., **1149**
Pin, orthopedic hardware and complications, **825**
Pineal cyst, **1064**. *See also* Cavum veli interpositi.
Pineal region germinoma, **1087**
Pineal region masses, germinoma vs., **1087**
Pineoblastoma, germinoma vs., **1087**
Pineocytoma, pineal cyst vs., **1064**
Pitfalls, arrhythmogenic right ventricular dysplasia vs., **312**
Pituitary adenoma, craniopharyngioma vs., **1085**
Pituitary-adrenal axis, endocrine dysfunction of, congenital nasal pyriform aperture stenosis, **9**
Plastic deformation, **803**
Plates, orthopedic hardware and complications, **826**
Pleomorphic xanthoastrocytoma
- desmoplastic infantile tumors vs., **1082**
- DNET vs., **1080**
- ganglioglioma vs., **1081**

Pleural effusions, malignant, parapneumonic effusion and empyema vs., **129**
Pleural pseudocyst, round pneumonia vs., **126**
Pleuropulmonary blastoma (PPB), **152–155**
- associated abnormalities, **153–154**
- associated syndromes, **153**
- bronchopulmonary sequestration vs., **68**
- congenital pulmonary airway malformation vs., **63**
- diagnostic checklist, **154**
- differential diagnosis, **153**
- genetics, **153**
- prognosis, **154**
- pulmonary interstitial emphysema vs., **99**
- staging, grading, & classification, **154**

Plexiform, musculoskeletal system, **765**
Plexiform neurofibroma (PNF), **908–909,** 1049
- differential diagnosis, **909**
- fibromatosis vs., **904**
- genitourinary rhabdomyosarcoma vs., **692**
- infantile hemangioma, cervicofacial vs., **1232**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- prognosis, **909**
- rhabdomyosarcoma, head and neck vs., **1236**
- venous malformation, musculoskeletal vs., **894**

Plexopathy, brachial, **1000–1001**
- differential diagnosis, **1001**
- prognosis, **1001**
- staging, grading, & classification, **1001**

PMG. *See* Polymicrogyria.
Pneumatocele
- papillomatosis vs., **137**
- paramediastinal, pneumomediastinum vs., **171**

Pneumatosis coli. *See* Pneumatosis in older children.
Pneumatosis cystoides intestinalis. *See* Pneumatosis in older children.
Pneumatosis in older children, **538–539**
- benign
  neutropenic colitis vs., **531**
  pseudomembranous colitis vs., **529**
- differential diagnosis, **539**

Pneumatosis intestinalis. *See also* Pneumatosis in older children.
- benign causes of, pneumatosis in older children vs., **539**
- clinically worrisome causes of pneumatosis in older children vs., **539**

Pneumomediastinum, **170–173**
- diagnostic checklist, **171**
- differential diagnosis, **171**
- neonatal pneumothorax vs., **103**
- prognosis, **171**

Pneumonia
- bacterial, sickle cell disease, acute chest syndrome vs., **209**
- cat-scratch disease, **479**
- with cavitary necrosis, **130–133**
  differential diagnosis, **131–132**
  prognosis, **132**
- cavitary necrosis/abscess complicating, congenital pulmonary airway malformation vs., **63–64**
- chronic or recurrent, bronchopulmonary sequestration vs., **67**
- fungal, in immunocompromised children, **134–135**
- group B streptococcal, surfactant deficiency disease vs., **89**
- lung contusion and laceration vs., **163**
- neonatal, **52, 92–93**
  bronchopulmonary dysplasia vs., **108**
  diagnostic checklist, **93**
  differential diagnosis, **93**
  meconium aspiration syndrome vs., **95**
  prognosis, **93**
  pulmonary interstitial glycogenosis vs., **177**
  surfactant dysfunction disorders vs., **181**
- recurrent bacterial, chronic granulomatous disease vs., **536**
- round, **124–127**
  diagnostic checklist, **126**
  differential diagnosis, **125–126, 129–130**
  neuroblastoma vs., **149**
  prognosis, **126**
- round pneumonia
  bronchogenic cyst vs., **71**
  bronchopulmonary sequestration vs., **67–68**

Pneumopericardium, pneumomediastinum vs., **171**
Pneumothorax
- congenital lobar overinflation vs., **75**
- neonatal, **102–103**
  diagnostic checklist, **103**
  differential diagnosis, **103**
  prognosis, **103**
- pneumomediastinum vs., **171**

Poland syndrome
- palpable normal variants of chest wall vs., **61**
- Swyer-James syndrome vs., **183**

Polyarteritis nodosa
- abdominal aneurysms and, **577**
- Kawasaki disease vs., **323**

Polyarticular RF-negative arthritis, **877**

Polyarticular rheumatoid factor (RF)-positive arthritis, **877**
Polycystic kidney disease
- autosomal dominant, **638–639**
  - differential diagnosis, **639**
  - genetics, **639**
  - prognosis, **639**
- autosomal recessive, **634–637**
  - associated abnormalities, **636**
  - differential diagnosis, **635–636**
  - genetics, **636**
  - multicystic dysplastic kidney vs., **632**
  - prognosis, **636**

Polycystic ovary syndrome, congenital adrenal hyperplasia vs., **700**
Polycystic renal disease, recessive, bladder exstrophy vs., **623**
Polydactyly, **784**
- diagnostic checklist, **784**
- omphalocele, **410**

Polymicrogyria (PMG), **1038–1039**
- associated abnormalities, **1039**
- diagnostic checklist, **1039**
- differential diagnosis, **1039**
- genetics, **1039**
- lissencephaly vs., **1033**

Polyneuropathy, plexiform neurofibroma vs., **909**
Polyorchidism, paratesticular rhabdomyosarcoma vs., **751**
Polyp
- juvenile, bezoars vs., **551**
- primary megaureter vs., **607**
- small bowel intussusception, **559**
- ureterocele vs., **604**

Polysplenia syndrome, heterotaxy syndromes vs., **316**
Polysyndactyly, **784**
Polyuria, primary megaureter vs., **607**
Pontocerebellar hypoplasia, other cerebellar malformations vs., **1023**
Porencephalic cyst, arachnoid cyst vs., **1061**
Porencephaly, encephaloclastic, schizencephaly vs., **1037**
"Port wine stain," **1055**
Portal vein, preduodenal, duodenal atresia or stenosis vs., **355**
Portal vein thrombosis, **470**
- Abernethy malformation vs., **467**

Portosystemic shunt, intrahepatic, Abernethy malformation vs., **467**
Positional plagiocephaly or molding, craniosynostoses vs., **1135**
Positive pertechnetate scan, GI bleeding with, Meckel diverticulum vs., **427–428**
Post-Deflux procedure appearance, **688–689**
- differential diagnosis, **689**
- prognosis, **689**

Post-Fontan physiology, cirrhosis, **461**
Posterior dislocation, supracondylar fracture vs., **835**
Posterior fossa arachnoid cyst, Dandy-Walker continuum vs., **1019–1020**
Posterior fossa ependymoma, **1072–1073**
- differential diagnosis, **1073**
- prognosis, **1073**

Posterior reversible encephalopathy syndrome
- childhood stroke vs., **1105**
- demyelinating diseases vs., **1133**

Posterior urethral valves (PUV), **612–615**
- associated abnormalities, **614**
- differential diagnosis, **613–614**
- epididymoorchitis, **740**
- megacystis-microcolon-intestinal hypoperistalsis syndrome, **609**
- primary megaureter vs., **607**
- prognosis, **614**
- prune-belly syndrome vs., **611**
- staging, grading, & classification, **614**
- urachal abnormalities, **618**

Posteromedial tibial bowing, **786**
Postgastric magnetopathy. *See* Ingested multiple magnets.
Posthemorrhagic hydrocephalus, aqueductal stenosis vs., **1047**
"Posthemorrhagic venous infarction," **1098**
Postobstructive secretions, acute rhinosinusitis vs., **1193**
Postoperative pseudomeningocele, myelomeningocele vs., **1147**
Postseptal cellulitis, **1197**
Posttransplant lymphoproliferative disease (PTLD), **469, 470, 524–527**
- differential diagnosis, **525–526**
- graft-vs.-host disease vs., **533**
- prognosis, **526**
- staging, grading, & classification, **526**

Posttraumatic blood level, acute rhinosinusitis vs., **1193**
Posttraumatic cerebral edema, **1007**
Posttraumatic fat necrosis, soft tissue foreign bodies vs., **829**
Posttraumatic lesions, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
Postviral autoimmune encephalitis of other etiologies, MIS-C vs., **122**
Pott puffy tumor, orbital cellulitis, **1198**
Potts shunt, Blalock-Taussig shunt vs., **297**
PPB. *See* Pleuropulmonary blastoma.
Precocious puberty, normal prepubertal uterus and ovaries vs., **589**
Preduodenal portal vein, duodenal atresia or stenosis vs., **355**
Pregnancy, ectopic
- ovarian cyst vs., **722**
- ovarian torsion vs., **734**

Premature physeal closure, fracture complications, **821, 822**
Premature sutural fusion. *See* Craniosynostoses.
Prematurity
- croup, **24**
- rickets, **985**
- white matter injury of, **1100–1101**
  - differential diagnosis, **1101**

Prematurity-related surfactant deficiency disease, **89**
Prenatal factors, rickets, **985**
Preseptal cellulitis, **1197**

Preserved splenic tissue in chronic infarction, splenic infarct vs., **475**
"Presyrinx" state, **1155**
Pretricuspid left-to-right shunts, arrhythmogenic right ventricular dysplasia vs., **311**
Primary bronchial malformation, pulmonary sling vs., **39**
Primary cholesteatoma. *See* Congenital cholesteatoma.
Primary growth centers, **768–769**
- diagnostic checklist, **769**
- differential diagnosis, **769**
Primary hyperoxaluria, renal stones, **674**
Primary megaureter, **606–607**
- differential diagnosis, **607**
- prune-belly syndrome vs., **611**
Primary mesenteric adenitis, **494–495**
- diagnostic checklist, **495**
- differential diagnosis, **495**
Primary myopathies, arthrogryposis, **787**
Primary osseous lesions, pediatric spine, approach, **1144**
Primary sclerosing cholangitis
- Caroli disease vs., **459**
- choledochal cyst vs., **455**
- cirrhosis, **461**
Primary surfactant deficiency disease, **89**
Primary tumor, hepatic trauma vs., **509**
Primitive neuroectodermal tumor (PNET). *See also* Ewing sarcoma.
- atypical teratoid/rhabdoid tumor vs., **1071**
- desmoplastic infantile tumors vs., **1082**
Pringle disease. *See* Tuberous sclerosis.
Progressive cerebral volume loss in presence of shunt, CSF shunts and complications vs., **1140**
Progressive familial intrahepatic cholestasis, cirrhosis, **461**
Proliferative zone, physeal fractures, **796**
Prominent trabeculations, normal with, left ventricular noncompaction vs., **305**
Prostaglandin-induced antral mucosal hyperplasia, hypertrophic pyloric stenosis, **394**
Prostatic utricle, epididymoorchitis, **740**
Proteolipid protein (PLP), **1011**
Proximal ACL tears, **847**
Proximal focal femoral deficiency (PFFD), **764, 958–959**
- associated abnormalities, **959**
- developmental hip dysplasia vs., **956**
- diagnostic checklist, **959**
- staging, grading, & classification, **959**
Proximal obstruction, other causes of, hypertrophic pyloric stenosis vs., **393–394**
Prune-belly syndrome, **610–611**
- colonic volvulus, **431**
- differential diagnosis, **611**
- megacystis-microcolon-intestinal hypoperistalsis syndrome, **609**
- megaureter-megacystis vs., **608**
- omphalocele, **409**
- posterior urethral valves vs., **613**
- primary megaureter vs., **607**
- prognosis, **611**
- wandering spleen, **473**
Pseudo-TORCH syndromes, TORCH infections vs., **1127**
Pseudoachondroplasia, achondroplasia vs., **970**
Pseudoarthroses
- congenital, clavicle injuries vs., **833**
- rib fractures vs., **160**
Pseudocoarctation, aortic coarctation vs., **276**
Pseudocyst, pancreatic
- pancreatoblastoma vs., **481**
- solid pseudopapillary neoplasm vs., **483**
Pseudoepiphysis, **773**
Pseudofluid level, acute rhinosinusitis vs., **1193**
Pseudokidney of intussusception, renal ectopia and fusion vs., **626**
Pseudomembranous colitis, **528–529**
- differential diagnosis, **529**
- hypoperfusion complex vs., **501**
- neutropenic colitis vs., **531**
- prognosis, **529**
- ulcerative colitis vs., **545**
Pseudomembranous croup. *See* Bacterial tracheitis.
Pseudoparesis, of upper extremity, brachial plexopathy vs., **1001**
Pseudorheumatoid nodule. *See* Granuloma annulare.
Pseudothickening of retropharyngeal tissues, **7**
- differential diagnoses, **7**
- retropharyngeal space abscess vs., **31**
Pseudotumor of infancy. *See* Fibromatosis colli.
Psoriatic arthritis, **877**
PT-RMS. *See* Paratesticular rhabdomyosarcoma.
PTEN hamartoma
- lipoblastoma vs., **910**
- soft tissue, arteriovenous malformation, musculoskeletal vs., **901**
PTLD. *See* Posttransplant lymphoproliferative disease.
Pulmonary airway malformation, congenital, **52, 62–65**
- associated abnormalities, **64**
- bronchial atresia vs., **79**
- bronchogenic cyst vs., **72**
- bronchopulmonary dysplasia vs., **108**
- bronchopulmonary sequestration vs., **67**
- congenital diaphragmatic hernia vs., **85–86**
- congenital lobar overinflation vs., **75**
- diagnostic checklist, **64**
- differential diagnosis, **63–64**
- neonatal pneumonia vs., **93**
- neonatal pneumothorax vs., **103**
- normal thymus vs., **58**
- pleuropulmonary blastoma vs., **153**
- pneumonia with cavitary necrosis vs., **131**
- prognosis, **64**
- pulmonary interstitial emphysema vs., **99**
- round pneumonia vs., **126**
- staging, grading, & classification, **64**
Pulmonary arteriovenous malformation, **156–157**
- associated abnormalities, **157**
- differential diagnosis, **157**
- prognosis, **157**
Pulmonary artery
- atresia, bronchopulmonary sequestration vs., **67**
- unilateral absence of, Swyer-James syndrome vs., **183**
Pulmonary artery sling (PAS), **38–41**
- associated abnormalities, **40**

- diagnostic checklist, **40**
- differential diagnosis, **39–40**
- genetics, **40**
- left, double aortic arch vs., **36**
- prognosis, **40**

Pulmonary artery stenosis, **282–285**
- associated abnormalities, **284**
- diagnostic checklist, **284**
- differential diagnosis, **283**
- genetics, **283–284**
- prognosis, **284**
- staging, grading, & classification, **284**

Pulmonary atresia, **242–245**
- differential diagnosis, **243–244**
- Ebstein anomaly vs., **247**
- with intact ventricular septum, tetralogy of Fallot vs., **239**
- prognosis, **244**
- staging, grading, & classification, **244**

Pulmonary compromise, autosomal recessive polycystic kidney disease, **636**
Pulmonary conditions, pectus excavatum, **189**
Pulmonary contusion, **53**
Pulmonary cystic fibrosis, **202–205**
- diagnostic checklist, **204**
- differential diagnosis, **203**
- prognosis, **204**

Pulmonary cysts, pleuropulmonary blastoma, **153**
Pulmonary edema, bacterial tracheitis, **28**
Pulmonary fat embolism, sickle cell disease, acute chest syndrome, **210**
Pulmonary gangrene. *See* Pneumonia, with cavitary necrosis.
Pulmonary hypertension
- atrial septal defect vs., **224**
- bronchopulmonary dysplasia, **107**
- primary, total anomalous pulmonary venous return vs., **261**
- pulmonary artery stenosis vs., **283**

Pulmonary hypoplasia, meconium aspiration syndrome vs., **95**
Pulmonary infarction, sickle cell disease, acute chest syndrome vs., **209**
Pulmonary interstitial emphysema (PIE), **52, 98–101**
- bronchopulmonary dysplasia vs., **107**
- diagnostic checklist, **100**
- differential diagnosis, **99**
- persistent, congenital lobar overinflation vs., **76**
- prognosis, **100**

Pulmonary interstitial glycogenosis (PIG), **176–177**
- diagnostic checklist, **177**
- differential diagnosis, **177**
- prognosis, **177**

Pulmonary metastases
- fungal pneumonia in immunocompromised children vs., **135**
- pulmonary arteriovenous malformation vs., **157**

Pulmonary sling
- bronchial obstruction vs., **199**
- esophageal strictures vs., **547**

Pulmonary stenosis
- complex cyanotic heart lesions with component of (sub-) pulmonary stenosis, pulmonary atresia vs., **243**
- double-outlet RV with, Ebstein anomaly vs., **247**
- tetralogy of Fallot vs., **239**
- transposition of great arteries (TGA) with, Ebstein anomaly vs., **247**

Pulmonary valve sinuses, arrhythmogenic right ventricular dysplasia vs., **312**
Pulmonary valve stenosis, tetralogy of Fallot vs., **239**
Pulmonary varix, pulmonary arteriovenous malformation vs., **157**
Pulmonary vascular disease (PVD), bronchopulmonary dysplasia, **107**
PUV. *See* Posterior urethral valves.
Pyelonephritis, **580, 664–667**
- differential diagnosis, **665–666**
- nephroblastomatosis vs., **646**
- prognosis, **666**
- renal injury vs., **669–670**
- renal vein thrombosis vs., **679**
- Wilms tumor vs., **641**

Pyknodysostosis, osteogenesis imperfecta vs., **978**
Pyloric atresia, **359**
- differential diagnosis, **359**
- duodenal atresia or stenosis vs., **355**
- hypertrophic pyloric stenosis vs., **394**

Pyloric stenosis
- gastroesophageal reflux vs., **391**
- hypertrophic, **392–395**
  - associated abnormalities, **394**
  - diagnostic checklist, **394**
  - differential diagnosis, **393–394**
  - duodenal atresia or stenosis vs., **355**
  - gastric volvulus vs., **397**
  - genetics, **394**
  - necrotizing enterocolitis vs., **385–386**
  - prognosis, **394**
  - pyloric atresia vs., **359**

Pylorospasm, hypertrophic pyloric stenosis vs., **393**
Pyriform aperture stenosis, choanal atresia vs., **13**
Pyruvate dehydrogenase (PDH) deficiency, **1123**

R

Radial neck fracture
- lateral condylar fracture vs., **839**
- musculoskeletal system, **765**

Radiation enteritis, graft-vs.-host disease vs., **533**
Radiocapitellar (RC) line, **835**
Radiography
- Chiari 2 malformation, **1045**
- musculoskeletal system, **764**

Ranula, branchial cleft anomalies vs., **1226**
Rapariz triplane fracture classification, **859**
Rapunzel syndrome, **551**
Rasmussen encephalitis, hemimegalencephaly vs., **1031**
Rastelli procedure, arterial switch procedure vs., **293**

Rathke cleft cyst, craniopharyngioma vs., **1085**
RB. *See* Retinoblastoma.
RCC. *See* Renal cell carcinoma.
Reactive airways disease. *See* Asthma.
Reactive effusion, due to adjacent bone pathology
- septic arthritis vs., **871**
- transient synovitis vs., **873**

Recurrent bacterial pneumonia, chronic granulomatous disease vs., **536**
Recurrent multifocal osteomyelitis, chronic, osteomyelitis vs., **864**
Recurrent respiratory papillomatosis (RRP), **137**
Red marrow, **770–771**
- differential diagnosis, **771**
- reconversion, red to yellow marrow conversion vs., **771**

Redundant duodenum
- malrotation vs., **347**
- midgut volvulus vs., **352**
- normal variations of duodenojejunal junction position vs., **339**

Reflux nephropathy, renal artery stenosis vs., **680**
Refluxing nonobstructive megaureter, primary megaureter vs., **607**
Remote trauma, normal developmental variants confused with disease vs., **773**
Renal agenesis, **628–629**
- associated abnormalities, **629**
- bladder exstrophy vs., **623**
- differential diagnosis, **629**
- müllerian duct anomalies, **718**
- prognosis, **629**

Renal artery stenosis, **680**
- differential diagnosis, **680**

Renal calculi. *See* Renal stones.
Renal cell carcinoma (RCC), **656–657**
- angiomyolipoma vs., **661**
- diagnostic checklist, **657**
- differential diagnosis, **657**
- prognosis, **657**
- renal medullary carcinoma vs., **659**
- Wilms tumor vs., **641**

Renal contusion/laceration, pyelonephritis vs., **666**
Renal cortex, echogenicity, **585**
Renal cyst
- angiomyolipoma vs., **661**
- autosomal recessive polycystic kidney disease vs., **636**
- multilocular cystic nephroma vs., **649**

Renal cystic disease, **580**
Renal disease, chronic, rickets, **985**
Renal dysplasia
- cystic, autosomal recessive polycystic kidney disease vs., **636**
- müllerian duct anomalies, **718**

Renal ectopia and fusion, **624–627**
- associated abnormalities, **626**
- crossed fused, renal agenesis vs., **629**
- differential diagnosis, **626**
- genetics, **626**
- omphalocele, **409**
- prognosis, **626**

Renal infarction, pyelonephritis vs., **665**
Renal injury, **668–671**
- associated abnormalities, **670**
- diagnostic checklist, **670**
- differential diagnosis, **669–670**
- prognosis, **670**
- staging, grading, & classification, **670**

Renal lymphoma, nephroblastomatosis vs., **646**
Renal masses, **580**
- pyelonephritis vs., **665–666**
- renal tumor of infancy, ossifying, mesoblastic nephroma vs., **651**

Renal medullary carcinoma, **580, 658–659**
- differential diagnosis, **659**
- prognosis, **659**
- renal cell carcinoma vs., **657**
- Wilms tumor vs., **641**

Renal neoplasm, renal injury vs., **670**
Renal osteodystrophy, slipped capital femoral epiphysis vs., **965**
Renal rhabdoid tumor, Wilms tumor vs., **641**
Renal scar
- normal neonatal kidney vs., **585**
- pyelonephritis vs., **666**

Renal scarring, pyelonephritis vs., **665**
Renal stones, **580, 672–675**
- differential diagnosis, **673**
- prognosis, **674**

Renal tumor of infancy, ossifying, mesoblastic nephroma vs., **651**
Renal vein thrombosis, **580, 678–679**
- autosomal recessive polycystic kidney disease vs., **639**
- differential diagnosis, **679**
- prognosis, **679**

Residual red marrow, red to yellow marrow conversion vs., **771**
Resolving hematoma, brain abscess vs., **1129**
Respiratory distress, congenital high airway obstruction syndrome, **16**
Respiratory distress syndrome. *See* Surfactant deficiency disease.
Respiratory insufficiency, omphalocele, **409–410**
Respiratory issues, chronic, esophageal atresia and tracheoesophageal fistula vs., **82**
Respiratory tract, viral infection, lower respiratory tract, bronchial obstruction vs., **199**
Rete testes, dilated, testicular tumors vs., **754**
Retinal astrocytic hamartoma, retinoblastoma vs., **1201**
Retinal hemorrhage, abusive head trauma, **1093**
Retinitis, cat-scratch disease, **479**
Retinoblastoma, **1200–1203**
- associated abnormalities, **1202**
- diagnostic checklist, **1202**
- differential diagnosis, **1201**
- genetics, **1202**
- prognosis, **1202**
- staging, grading, & classification, **1202**

Retinopathy of prematurity, retinoblastoma vs., **1201**
Retrocaval ureter, primary megaureter vs., **607**
Retroperitoneal teratoma, angiomyolipoma vs., **662**

Retropharyngeal abscess
- bacterial tracheitis vs., **27**
- epiglottitis vs., **20**
- pseudothickening of retropharyngeal tissues vs., **7**

Retropharyngeal cellulitis, pseudothickening of retropharyngeal tissues vs., **7**
Retropharyngeal soft tissue, **4**
- pseudothickening of, retropharyngeal space abscess vs., **31**

Retropharyngeal space
- edema in, retropharyngeal space abscess vs., **31**
- suppurative adenopathy in, retropharyngeal space abscess vs., **31**

Retropharyngeal space abscess, **30–33**
- diagnostic checklist, **32**
- differential diagnosis, **31**
- prognosis, **32**

Rhabdoid tumor, **654**
- desmoplastic infantile tumors vs., **1082**
- diagnostic checklist, **654**
- malignant, renal cell carcinoma vs., **657**
- mesoblastic nephroma vs., **651**

Rhabdomyoma, **318–321**
- associated abnormalities, **320**
- autosomal recessive polycystic kidney disease vs., **636**
- diagnostic checklist, **320**
- differential diagnosis, **319**
- genetics, **320**
- prognosis, **320**

Rhabdomyosarcoma
- acquired cholesteatoma vs., **1211**
- acute otomastoiditis with abscess vs., **1214**
- Burkitt lymphoma vs., **573**
- congenital cholesteatoma vs., **1209**
- fibromatosis colli vs., **1240**
- fibromatosis vs., **903**
- genitourinary, **690–693**
  - associated abnormalities, **692**
  - differential diagnosis, **691–692**
  - prognosis, **692**
  - staging, grading, & classification, **692**
- head and neck, **1234–1237**
  - associated abnormalities, **1236**
  - diagnostic checklist, **1236**
  - differential diagnosis, **1235–1236**
  - genetics, **1236**
  - prognosis, **1236**
  - staging, grading, & classification, **1236**
- juvenile angiofibroma vs., **1190**
- kaposiform hemangioendothelioma vs., **891**
- musculoskeletal, **912–915**
  - associated abnormalities, **914**
  - differential diagnosis, **913–914**
  - genetics, **914**
  - prognosis, **914**
  - staging, grading, & classification, **914**
- musculoskeletal system, **765**
- pelvic
  - hydrometrocolpos vs., **714**
  - renal ectopia and fusion vs., **626**
- post-Deflux procedure appearance vs., **689**
- suppurative adenitis vs., **1243**
- ureterocele vs., **604**

Rheumatic fever, Kawasaki disease vs., **323**
Rheumatic heart disease, **326–327**
- aortic stenosis vs., **279**
- prognosis, **327**

Rhombencephalic vesicle, **1020**
Rhombencephalosynapsis (RS), **1023**
Rib anomalies, omphalocele, **410**
Rib fractures, **53**
- child abuse, **158–161**
  - chest wall hamartoma vs., **193**
  - diagnostic checklist, **160**
  - differential diagnosis, **159–160**
  - prognosis, **160**

Rib infarction, with hypoventilation from pain &/or analgesics, sickle cell disease, acute chest syndrome, **210**
Rickets, **984–987**
- associated abnormalities, **986**
- child abuse
  - metaphyseal fracture vs., **806**
  - other fractures vs., **810**
  - rib fractures vs., **160**
- diagnostic checklist, **986**
- differential diagnosis, **986**
- leukemia vs., **934**
- oncogenic, **985**
- osteogenesis imperfecta vs., **977**
- physeal fractures vs., **796**
- stress injuries vs., **813**
- syphilis vs., **869**

Right/left isomerism. *See* Heterotaxy syndromes.
Right lower quadrant inflammation, Meckel diverticulum vs., **428**
Right ventricle-pulmonary artery (RV-PA) conduit. *See* Sano shunt.
Right ventricular dilatation, in endurance athletes, arrhythmogenic right ventricular dysplasia vs., **311**
Right ventricular dysplasia, arrhythmogenic, **310–313**
- diagnostic checklist, **312**
- differential diagnosis, **311–312**
- genetics, **312**
- prognosis, **312**

Right ventricular infarction, arrhythmogenic right ventricular dysplasia vs., **312**
Right ventricular outflow tachycardia, idiopathic, arrhythmogenic right ventricular dysplasia vs., **312**
Right ventricular volume overload, arrhythmogenic right ventricular dysplasia vs., **311**
Rocker-bottom foot, clubfoot vs., **789**
Round pneumonia, **53, 124–127**
- bronchogenic cyst vs., **71**
- bronchopulmonary sequestration vs., **67–68**
- diagnostic checklist, **126**
- differential diagnosis, **125–126**
- neuroblastoma vs., **149**
- prognosis, **126**

RRP. *See* Recurrent respiratory papillomatosis.
RS. *See* Rhombencephalosynapsis.

Rubinstein-Taybi syndrome, genitourinary rhabdomyosarcoma, **692**
RUQ mass, hypertrophic pyloric stenosis vs., **394**

S

Sacral agenesis, neurogenic bladder, **684**
Sacral anomalies, anorectal malformations, **378**
Sacrococcygeal teratoma, **1162–1165**
- associated abnormalities, **1163–1164**
- differential diagnosis, **1163**
- genetics, **1163**
- genitourinary myosarcoma vs., **691**
- hydrometrocolpos vs., **714**
- lipomyelomeningocele vs., **1148**
- meconium peritonitis vs., **382**
- prognosis, **1164**
- renal ectopia and fusion vs., **626**
- staging, grading, & classification, **1164**
- terminal myelocystocele vs., **1152**

Salivary gland neoplasms, acute parotitis vs., **1229**
Salter-Harris classification, trauma, musculoskeletal system, **764**
Salter-Harris I fracture, traumatic, slipped capital femoral epiphysis vs., **965**
Salter-Harris II (SHII) fractures, incomplete fractures vs., **803**
Salter-Harris (SH) fractures 1-5 (I-V). *See* Physeal fractures.
Sanfilippo syndrome, **1119**
Sano shunt, **300–301**
- Blalock-Taussig shunt vs., **297**
- differential diagnosis, **301**

SAPHO syndrome, chronic recurrent multifocal osteomyelitis, **884**
Sarcoid, cat-scratch disease vs., **479**
Sarcoidosis, Langerhans cell histiocytosis vs., **187**
Sarcoma
- clear cell
  - of kidney, mesoblastic nephroma vs., **651**
  - Wilms tumor vs., **641**
- pleuropulmonary blastoma vs., **153**
- soft tissue
  - arteriovenous malformation, musculoskeletal vs., **901**
  - cervical lymphatic malformation vs., **15**
  - infantile hemangioma, musculoskeletal vs., **888**
  - lymphatic malformation, musculoskeletal vs., **897**
  - myositis ossificans vs., **923**
  - soft tissue abscess vs., **875**
- undifferentiated, pleuropulmonary blastoma vs., **153**

Sarcoma botryoides. *See* Rhabdomyosarcoma, genitourinary.
Sarnat stage, hypoxic-ischemic encephalopathy, **1103**
SARS-CoV, viral chest infection, **117**
SARS-CoV-2 (COVID-19)
- MIS-C from, Kawasaki disease vs., **323**
- viral chest infection, **117**

Scalp hematomas, birth injury, **1091**
Scaphoid nonunion, **821**
Scapular fractures, **809**
SCD. *See* Sickle cell disease.
SCFE. *See* Slipped capital femoral epiphysis.
Schizencephaly, **1036–1037**
- associated abnormalities, **1037**
- "closed-lip," heterotopic gray matter vs., **1035**
- differential diagnosis, **1037**
- genetics, **1037**

Schwannoma
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- vestibular, PHACES syndrome vs., **1056**

Scimitar syndrome, **286–287**
- bronchial atresia vs., **79**
- differential diagnosis, **287**
- prognosis, **287**
- total anomalous pulmonary venous return vs., **262**

Sclerosis, tuberous
- autosomal recessive polycystic kidney disease vs., **639**
- multicystic dysplastic kidney vs., **632**

SCM tumor of infancy. *See* Fibromatosis colli.
Scoliosis, **992–995**
- aortic coarctation, **276**
- congenital, **993**
- developmental, **993**
- diagnostic checklist, **994**
- differential diagnosis, **994**
- idiopathic, **993**
- neuromuscular, **993**
- omphalocele, **410**
- other causes, scoliosis vs., **994**
- palpable normal variants of chest wall vs., **61**
- prognosis, **994**
- tumor associated, **993**

Screws, orthopedic hardware and complications, **825**
Scrotal cellulitis
- epididymoorchitis vs., **739**
- Henoch-Schönlein purpura vs., **561**

Scrotal hernia, epididymoorchitis vs., **739**
Scrotal wall edema, isolated, torsion of testicular appendage vs., **747**
SCT. *See* Sacrococcygeal teratoma.
SDD. *See* Surfactant deficiency disease.
Seasonal allergies, croup, **24**
Seat belt contusions, **335**
Seat belt fracture. *See* Chance fracture.
Secondary growth centers, **768–769**
- diagnostic checklist, **769**
- differential diagnosis, **769**

Secondary osteosarcoma, **929**
Secondary physis, **773**
Secondary surfactant deficiency disease, **89**
Secondary vein of Galen aneurysmal dilation, vein of Galen aneurysmal malformation vs., **1113**
2nd branchial cleft anomaly
- cervical lymphatic malformation vs., **15**
- suppurative adenitis vs., **1243**

2nd branchial cleft cyst, **1181**
Segmental infarction, testicular tumors vs., **754**
Segmental liver transplant, **469**. *See also* Liver transplant complications.

Segmental multicystic dysplastic kidney, ureteropelvic duplications vs., **600**
Segmental volvulus, **433**
- diagnostic checklist, **433**
Segmentation anomalies, split cord malformation, **1151**
Segond fracture, **847**
Seizure-related injury, childhood stroke vs., **1105**
Sellar/suprasellar masses, germinoma vs., **1087**
Seminoma. *See* Germ cell tumors.
Septal defect
- atrial, **222–225**
  - associated abnormalities, **224**
  - atrioventricular septal defect vs., **232**
  - differential diagnosis, **224**
  - genetics, **224**
- atrioventricular, **230–233**
  - associated abnormalities, **232**
  - differential diagnosis, **232**
  - genetics, **232**
  - prognosis, **232**
- omphalocele, **410**
- ventricular, **226–229**
  - atrioventricular septal defect vs., **232**
  - differential diagnosis, **227–228**
  - double-outlet right ventricle vs., **273**
  - genetics, **228**
  - prognosis, **228**

Septal occluder device, **299**
Septate uterus, müllerian duct anomalies, **717**
Septic arthritis, **870–871**
- developmental hip dysplasia vs., **956**
- diagnostic checklist, **870**
- differential diagnosis, **871**
- juvenile idiopathic arthritis vs., **878**
- Legg-Calvé-Perthes disease vs., **961**
- osteochondroses vs., **983**
- osteomyelitis vs., **863–864**
- prognosis, **871**
- slipped capital femoral epiphysis vs., **965**
- transient synovitis vs., **873**

Septic emboli
- papillomatosis vs., **137**
- posttransplant lymphoproliferative disease vs., **526**

Septic shock, bacterial tracheitis, **28**
Septooptic dysplasia (SOD)
- holoprosencephalies vs., **1027**
- schizencephaly, **1037**

Serous tumor, **729**
Sertoli cell tumor. *See* Testicular tumors.
Sertoli-Leydig cell tumor, **729**
Severe chronically shunted hydrocephalus, Chiari 2 malformation vs., **1045**
Severe combined immunodeficiency
- chronic granulomatous disease vs., **536**
- fungal pneumonia in immunocompromised children, **135**

Severe COVID-19 with hyperinflammation, MIS-C vs., **122**
Severe hip dysplasia, **956**
Severely attenuated circle of Willis, moyamoya, **1107**
Sex cord-stromal tumors
- ovarian malignancies of childhood, **729**
- ovarian teratoma vs., **725**

SGA. *See* Subcutaneous granuloma annulare.
Shenton line, developmental hip dysplasia, **955**
Shock, **502**
- septic, bacterial tracheitis, **28**
- stages, **502**

Shock abdomen. *See* Hypoperfusion complex.
Shock bowel. *See also* Hypoperfusion complex.
- graft-vs.-host disease vs., **533**

Shock bowel, bowel injury vs., **505**
Shock pancreas
- pancreatic trauma vs., **521**
- pancreatitis vs., **492**

Short-chain acyl-CoA dehydrogenase deficiency, **1119**
Shoulder contracture. *See* Brachial plexopathy.
Shunt
- Blalock-Taussig, **296–297**
  - differential diagnosis, **297**
- Glenn, **288–289**
  - bidirectional, **289**
  - differential diagnosis, **289**

Shunt failure with normal or stable ventricle size, CSF shunts and complications vs., **1140**
Shunted hydrocephalus, white matter injury of prematurity vs., **1101**
Sickle cell disease (SCD)
- acute chest syndrome, **208–211**
  - diagnostic checklist, **209–210**
  - differential diagnosis, **209–210**
  - prognosis, **209–210**
- age-related appearance of spleen vs., **345**
- mucopolysaccharidoses vs., **974**
- musculoskeletal, **988–991**
  - bony manifestations in, **990**
  - diagnostic checklist, **990**
  - differential diagnosis, **990**
  - genetics, **990**
  - nuclear medicine findings, **989**
  - prognosis, **990**
- wandering spleen vs., **473**

Sigmoid colon, mass effect, ureterocele vs., **604**
Sigmoid volvulus. *See* Colonic volvulus.
Sillence classification, osteogenesis imperfecta, **978**
Simple/follicular cysts, ovarian teratoma vs., **725**
Simplified gyral pattern, microcephaly with
- lissencephaly vs., **1033**
- polymicrogyria vs., **1039**

Sinding-Larsen-Johansson syndrome, patellar sleeve avulsion vs., **854**
Single coronary artery origin, left coronary artery anomalous origin vs., **269**
Single ventricle, pulmonary atresia vs., **243**
Sinus pericranii, cephalocele vs., **1025**
Sinus thrombosis, cerebral venous, **1108–1109**
- differential diagnosis, **1109**
- prognosis, **1109**

Sinus venosus, atrial septal defect, **224**
Sinusoidal obstruction syndrome. *See* Hepatic venooclusive disease.
Sirenomelia, VACTERL association, **782**
Situs, imaging anatomy, **218**

Situs ambiguous. *See* Heterotaxy syndromes.
Situs anomalies, duodenal atresia or stenosis, **356**
Situs inversus, abdominal, heterotaxy syndromes vs., **315**
Situs inversus totalis, heterotaxy syndromes vs., **315**
Situs solitus, abdominal, heterotaxy syndromes vs., **315**
SJS. *See* Swyer-James syndrome.
Skeletal disease, bowing due to, incomplete fractures vs., **803**
Skeletal dysplasia
- forearm fractures vs., **845**
- MPS, **1120**
Skin fold, neonatal pneumothorax vs., **103**
Skull fractures, abusive head trauma, **1093**
Sleep apnea, steatosis/steatohepatitis, **463**
Sleep-disordered breathing, croup, **24**
Slipped capital femoral epiphysis (SCFE), **964–967**
- associated abnormalities, **966**
- diagnostic checklist, **966**
- differential diagnosis, **965–966**
- Legg-Calvé-Perthes disease vs., **962**
- prognosis, **966**
Slomann view, **997**
Slow-flow vascular malformation
- chest wall hamartoma vs., **193**
- omental infarction vs., **499**
- rhabdomyosarcoma, head and neck vs., **1235**
Sly syndrome, **1119**
Small bowel feces, bezoars vs., **551**
Small bowel intussusception, **558–559**
- differential diagnosis, **559**
- prognosis, **559**
- transient, hypoperfusion complex vs., **501**
Small bowel neoplasm, duodenal trauma vs., **517**
Small bowel obstruction, Meckel diverticulum vs., **428**
Small bowel-small bowel intussusception, ileocolic intussusception vs., **423**
Small left colon
- anorectal malformations vs., **377**
- cloaca vs., **621**
- colonic atresia vs., **364**
- cystic fibrosis vs., **566**
- jejunoileal atresia vs., **362**
- meconium ileus vs., **367**
- meconium peritonitis vs., **381**
- neonatal, **370–371**
  differential diagnosis, **371**
  Hirschsprung disease vs., **373**
  prognosis, **371**
Small non-cleaved-cell lymphoma. *See* Burkitt lymphoma.
SMMCI syndrome, congenital nasal pyriform aperture stenosis, **9**
Soft tissue abscess, **874–875**
- diagnostic checklist, **875**
- differential diagnosis, **875**
- myositis ossificans vs., **923**
Soft tissue foreign bodies, **828–829**
- diagnostic checklist, **828**
- differential diagnosis, **829**
Soft tissue infection
- kaposiform hemangioendothelioma vs., **891**
- lymphatic malformation, musculoskeletal vs., **897**
Soft tissue malignancy, muscle hernia vs., **831**
Soft tissue mass, musculoskeletal system, **765**
Soft tissue sarcomas
- arteriovenous malformation, musculoskeletal vs., **901**
- cervical lymphatic malformation vs., **15**
- diagnostic checklist, **893**
- infantile hemangioma
  cervicofacial vs., **1232**
  musculoskeletal vs., **888**
- inflammatory myofibroblastic tumor vs., **575**
- lymphatic malformation, musculoskeletal vs., **897**
- myositis ossificans vs., **923**
- palpable normal variants of chest wall vs., **61**
- plexiform neurofibroma vs., **909**
- prognosis, **893**
- rhabdomyosarcoma, musculoskeletal vs., **913**
- soft tissue abscess vs., **875**
- soft tissue foreign bodies vs., **829**
- venous malformation, musculoskeletal vs., **894**
Solid abdominal mass, abdominal aneurysms vs., **577**
Solid pseudopapillary neoplasm, **482–483**
- differential diagnosis, **483**
- pancreatoblastoma vs., **481**
- prognosis, **483**
Solid suprarenal mass, bronchopulmonary sequestration vs., **68**
Solid tumors, hemophagocytic lymphohistiocytosis vs., **569**
Solitary kidney. *See also* Renal agenesis.
- omphalocele, **409**
Solitary soft tissue mass
- infantile myofibroma vs., **907**
- myofibromatosis vs., **907**
Sore throat, retropharyngeal space abscess, **32**
Sotos syndrome, Wilms tumor, **642**
Spasticity, tethered spinal cord, **1156**
Spermatic cord hydrocele, **761**
Spetzler-Martin scale, arteriovenous malformation, **1115**
Sphenoid wing dysplasia, neurofibromatosis type 1, **1049**
Spinal cord astrocytoma, **1160–1161**
- associated abnormalities, **1161**
- diagnostic checklist, **1161**
- differential diagnosis, **1161**
- inflammatory myelopathies vs., **1169**
- prognosis, **1161**
- staging, grading, & classification, **1161**
Spinal cord ependymoma, **1158–1159**
- differential diagnosis, **1159**
- genetics, **1159**
- staging, grading, & classification, **1159**
Spinal cord tethering, neurogenic bladder, **684**
Spinal fusion, complications, **994**
Spinal fusion anomalies, fibromatosis colli vs., **1240**
Spinal metastases, discitis/osteomyelitis vs., **1167**
Spindle cell hemangioma, venous malformation, musculoskeletal, **894**
Spine injury, bowel injury, **506**
Spinous process fractures, **809**
Spleen
- abnormal low T2 MR signal intensity, age-related appearance of spleen vs., **345**

- age-related appearance of, **344–345**
  differential diagnosis, **345**
- postchemotherapy appearance, age-related appearance of spleen vs., **345**
- wandering, **472–473**
  associated abnormalities, **473**
  differential diagnosis, **473**
  prognosis, **473**

Splenic abnormalities, age-related appearance of spleen, **344–345**
- differential diagnosis, **345**

Splenic abscess, splenic trauma vs., **513**
Splenic cleft, splenic trauma vs., **513**
Splenic cyst, **476–477**
- diagnostic checklist, **477**
- differential diagnosis, **477**
- prognosis, **477**

Splenic fracture. *See* Splenic trauma.
Splenic infarct, **474–475**
- differential diagnosis, **475**
- prognosis, **475**
- splenic cyst vs., **477**
- splenic trauma vs., **513**
- staging, grading, & classification, **475**
- wandering spleen vs., **473**

Splenic infection, splenic cyst vs., **477**
Splenic injury. *See* Splenic trauma.
Splenic laceration. *See* Splenic trauma.
Splenic lymphoma
- cat-scratch disease vs., **479**
- splenic cyst vs., **477**

Splenic microabscesses, cat-scratch disease vs., **479**
Splenic perfusion artifact, splenic cyst vs., **477**
Splenic sequestration, wandering spleen vs., **473**
Splenic trauma, **512–515**
- diagnostic checklist, **514**
- differential diagnosis, **513**
- prognosis, **514**
- staging, grading, & classification, **514**
- wandering spleen vs., **473**

Splenogonadal fusion, paratesticular rhabdomyosarcoma vs., **751**
Splenomegaly, nephroblastomatosis vs., **646**
Split cord malformation, **1151**
Spondyloepiphyseal dysplasia
- mucopolysaccharidoses vs., **974**
- osteochondroses vs., **983**

Spondylolisthesis, **1176–1177**
- associated abnormalities, **1177**
- diagnostic checklist, **1177**

Spondylolysis, **1176–1177**
- associated abnormalities, **1177**
- diagnostic checklist, **1177**
- pediatric spine, approach, **1144**

Spondylometaphyseal dysplasia
- child abuse, metaphyseal fracture vs., **806**
- mucopolysaccharidoses vs., **974**

Spongy myocardium. *See* Left ventricular noncompaction.
Spontaneous intestinal perforation
- necrotizing enterocolitis vs., **385**
- neonates, **388–389**
  differential diagnosis, **389**
  prognosis, **389**

Spontaneous pneumothorax, pleuropulmonary blastoma vs., **153**
Sporadic aniridia
- nephroblastomatosis, **645**
- Wilms tumor associated with, **642**

Staghorn calculus, vesicoureteral reflux vs., **596**
Status epilepticus, acute encephalitis vs., **1131**
Steatosis/steatohepatitis, **462–463**
- cystic fibrosis, **565**
- differential diagnosis, **463**
- prognosis, **463**
- staging, grading, & classification, **463**

Steinman pins, orthopedic hardware and complications, **825**
Stenosis
- aortic, **278–281**
  associated abnormalities, **279–280**
  differential diagnosis, **279**
  genetics, **279**
  prognosis, **280**
  staging, grading, & classification, **280**
- aqueductal, **1046–1047**
  associated abnormalities, **1047**
  diagnostic checklist, **1047**
  differential diagnosis, **1047**
  genetics, **1047**
  holoprosencephalies vs., **1027**
  prognosis, **1047**
- choanal, choanal atresia vs., **13**
- congenital subglottic tracheal, airway infantile hemangioma vs., **47**
- croup, **24**
- duodenal, **354–357**
  associated abnormalities, **356**
  diagnostic checklist, **356**
  differential diagnosis, **355–356**
  genetics, **356**
  prognosis, **356**
  staging, grading, & classification, **356**
- hepatic vein, **469, 470**
- iatrogenic subglottic, croup vs., **24**
- iatrogenic subglottic tracheal, airway infantile hemangioma vs., **47**
- pyriform aperture, choanal atresia vs., **13**

Sternal fractures, **809**
Sternal ossification centers, rib fractures vs., **160**
Sternoclavicular dislocations, clavicle injuries vs., **833**
Sternocleidomastoid (SCM) pseudotumor. *See* Fibromatosis colli.
Stevens-Johnson syndrome
- epiglottitis, **20**
- Kawasaki disease vs., **323**

Stickler & related syndromes, Pierre Robin sequence vs., **1219**
Still disease, **877**
Stool impaction, ovarian teratoma vs., **725**
Strangulated hernia, **405**
Strawberry hemangioma. *See* Infantile hemangioma.

Stress, osteochondritis dissecans vs., **818**
Stress fracture, osteosarcoma vs., **929–930**
Stress injuries, **812–815**. *See also* Medial epicondyle avulsion.
- of bone, apophyseal injuries vs., **800**
- differential diagnosis, **813**
- osteogenesis imperfecta vs., **977**
- osteoid osteoma vs., **946**

Stress response, **813**
Stricture, primary megaureter vs., **607**
Stroke, childhood, **1104–1105**
- differential diagnosis, **1105**
- prognosis, **1105**

Struvite stones, renal stones, **674**
Sturge-Weber syndrome (SWS), **1054–1055**
- choroid plexus tumors vs., **1089**
- differential diagnosis, **1055**
- diffuse leptomeningeal glioneuronal tumor vs., **1157**
- neurofibromatosis type 1 vs., **1050**
- PHACES syndrome vs., **1056**
- prognosis, **1055**

Subaortic ventricular septal defect, tetralogy of Fallot vs., **239**
Subarachnoid spaces (SAS), enlarged, **1014–1015**
- diagnostic checklist, **1015**
- differential diagnosis, **1015**

Subcutaneous granuloma annulare (SGA), **921**
Subcutaneous palisading granuloma. *See* Granuloma annulare.
Subdural hematoma, chronic, arachnoid cyst vs., **1061**
Subdural hemorrhage, cerebral venous sinus thrombosis vs., **1109**
Subdural hygroma, arachnoid cyst vs., **1061**
Subependymal giant cell astrocytoma (SEGA), **1053**
- colloid cyst vs., **1059**

Subependymal nodules (SENs), **1053**
Subglottic hemangioma, croup, **24**
Subglottic infantile hemangioma, papillomatosis vs., **137**
Subglottic stenosis, iatrogenic, croup vs., **24**
Subpulmonary obstruction, tetralogy of Fallot vs., **239**
Subtalar fractures, tarsal coalition vs., **997**
Subungual exostosis, osteochondroma, **952**
Sulcation, **585**
Superimposed insult, white matter injury of prematurity, **1101**
Superior cavopulmonary shunt. *See* Glenn shunt.
Superior mesenteric artery syndrome, duodenal web vs., **358**
Superior ophthalmic vein &/or cavernous sinus thrombosis, orbital cellulitis, **1198**
Suppurative adenitis, **1242–1245**
- chronic granulomatous disease, **536**
- diagnostic checklist, **1244**
- differential diagnosis, **1243–1244**
- prognosis, **1244**

Suppurative adenopathy, in retropharyngeal space, retropharyngeal space abscess vs., **31**
Suppurative lymph nodes, branchial cleft anomalies vs., **1225**
Supracondylar fracture, **822, 834–837**
- associated abnormalities, **835–836**
- diagnostic checklist, **836**
- differential diagnosis, **835**
- lateral condylar fracture vs., **839**
- musculoskeletal system, **764**
- prognosis, **836**
- staging, grading, & classification, **836**

Supraglottitis. *See* Epiglottitis.
Suprarenal gland. *See* Adrenal gland, normal.
Suprasellar germinoma, **1087**
Supratentorial ependymoma, **1074**
- desmoplastic infantile tumors vs., **1082**
- differential diagnosis, **1074**
- embryonal tumor with multilayered rosettes vs., **1083**
- glioblastoma vs., **1075**

Supraventricular tachycardia, paroxysmal, hypoplastic left heart syndrome vs., **266**
Surface osteosarcoma, myositis ossificans vs., **923**
Surfactant deficiency
- related to prematurity, surfactant dysfunction disorders vs., **181**
- transient tachypnea of newborn vs., **97**

Surfactant deficiency disease (SDD), **52, 88–91**
- bronchopulmonary dysplasia, **107**
- differential diagnosis, **89–90**
- genetics, **90**
- meconium aspiration syndrome vs., **95**
- neonatal pneumonia vs., **93**
- prematurity-related, **89**
- primary, **89**
- prognosis, **90**
- pulmonary interstitial emphysema vs., **99**
- secondary, **89**

Surfactant dysfunction disorders, **180–181**
- differential diagnosis, **181**
- neuroendocrine cell hyperplasia of infancy vs., **175**
- prognosis, **181**
- pulmonary interstitial glycogenosis vs., **177**

Surgical procedures for congenital heart disease
- Amplatzer occluder device, **298–299**
- arterial switch procedure, **292–293**
  differential diagnosis, **293**
- Blalock-Taussig shunt, **296–297**
  differential diagnosis, **297**
- Fontan operation, **290–291**
  differential diagnosis, **291**
- Glenn shunt, **288–289**
  bidirectional, **289**
  differential diagnosis, **289**
- Norwood procedure, **294–295**
  differential diagnosis, **295**
  prognosis, **295**
- Sano shunt, **300–301**
  differential diagnosis, **301**

Susceptibility weighted imaging (SWI), **1007**
Sutural synostosis. *See* Craniosynostoses.
Suture anchor, orthopedic hardware and complications, **826**
Swyer-James-MacLeod syndrome. *See* Swyer-James syndrome.

Swyer-James syndrome (SJS), **182–183**
- bronchial obstruction vs., **200**
- congenital lobar overinflation vs., **76**
- differential diagnosis, **183**
- prognosis, **183**

Symptomatic patients, colloid cyst, **1059**
Syndactyly, **784**
Synovial cleft of ACL, ACL injuries vs., **848**
Synovial cysts, nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
Synovial hemangioma. *See* Infantile hemangioma, cervicofacial.
Synovial sarcoma
- fibromatosis vs., **903–904**
- musculoskeletal system, **765**
- rhabdomyosarcoma, musculoskeletal vs., **913**

Synovial venous malformation
- hemophilia vs., **1003**
- juvenile idiopathic arthritis vs., **878**

Synovitis, transient
- Legg-Calvé-Perthes disease vs., **961–962**
- septic arthritis vs., **871**
- slipped capital femoral epiphysis vs., **965–966**

Syphilis, **868–869**
- congenital
  - Langerhans cell histiocytosis vs., **938**
  - leukemia vs., **934**
  - rickets vs., **986**
- diagnostic checklist, **869**
- differential diagnosis, **869**
- prognosis, **869**

Syringobulbia, **1155**
Syringohydromyelia, **1155**
Syringomyelia, **1154–1155**
- associated abnormalities, **1155**
- diagnostic checklist, **1155**
- prognosis, **1155**

Systemic arthritis, **877**
Systemic disorders, osteonecrosis of, osteochondroses vs., **983**
Systemic hypertension, aortic stenosis vs., **279**
Systemic lupus erythematosus (SLE), Kawasaki disease vs., **323**
Systemic marrow infiltrating processes, red to yellow marrow conversion vs., **771**
Systemic stress, syphilis vs., **869**

T

Tachypnea, intrathoracic causes, transient tachypnea of newborn vs., **97**
Takayasu arteritis
- abdominal aneurysms, **577**
- aortic coarctation vs., **276**
- Kawasaki disease vs., **323**

Talar beak, **997**
Talipes equinovarus. *See* Clubfoot.
Tamm-Horsfall proteinuria (THP). *See* Transient neonatal renal medullary hyperechogenicity.
Tardy ulnar nerve palsy, lateral condylar fracture, **840**
Tarsal coalition, **764, 996–999**
- associated abnormalities, **98**
- diagnostic checklist, **998**
- differential diagnosis, **997–998**
- genetics, **998**
- prognosis, **998**
- staging, grading, & classification, **998**

Taussig-Bing anomaly, aortic coarctation, **276**
Tear. *See* Bowel injury.
Tectal gliomas, **1077**
Tectal plate glioma, germinoma vs., **1087**
Telangiectasia, hereditary hemorrhagic, pulmonary arteriovenous malformation, **157**
Telangiectatic osteosarcoma, **929**
Tendon rupture, isolated, patellar sleeve avulsion vs., **854**
Tension band plating, orthopedic hardware and complications, **826**
Teratogen exposure, holoprosencephalies, **1027**
Teratoma. *See also* Germ cell tumors; Sacrococcygeal teratoma; Testicular tumors.
- anorectal malformations vs., **378**
- atypical teratoid/rhabdoid tumor vs., **1071**
- cervical lymphatic malformation vs., **15**
- chest wall hamartoma vs., **193**
- dermoid/epidermoid cysts vs., **1063**
- infantile myofibroma vs., **907**
- lipoblastoma vs., **910**
- myofibromatosis vs., **907**
- normal thymus vs., **58**
- ovarian, **724–727**
  - associated abnormalities, **726**
  - differential diagnosis, **725–726**
  - prognosis, **726**
- retroperitoneal, angiomyolipoma vs., **662**
- rhabdomyoma vs., **319**
- sacrococcygeal
  - genitourinary myosarcoma vs., **691**
  - meconium peritonitis vs., **382**

Terminal myelocystocele, **1152**
- diagnostic checklist, **1152**
- differential diagnosis, **1152**
- lipomyelomeningocele vs., **1148**

Testicle, traumatic rupture of, epididymoorchitis vs., **739**
Testicular abnormalities, approach, **581**
Testicular adrenal rest tumor
- paratesticular rhabdomyosarcoma vs., **751**
- testicular tumors vs., **754**

Testicular appendage, torsion of, **746–749**
- associated abnormalities, **748**
- diagnostic checklist, **748**
- differential diagnosis, **747–748**
- prognosis, **748**
- testicular torsion vs., **743**
- testicular trauma vs., **757**

Testicular fracture, **757**
Testicular retraction, **759**
Testicular rupture, **757**

Testicular torsion, **742–745**
- diagnostic checklist, **744**
- differential diagnosis, **743**
- epididymoorchitis vs., **739**
- Henoch-Schönlein purpura vs., **561**
- prognosis, **744**
- staging, grading, & classification, **744**
- testicular trauma vs., **757**
- torsion of testicular appendage vs., **747**

Testicular trauma, **756–757**
- diagnostic checklist, **757**
- differential diagnosis, **757**
- prognosis, **757**
- testicular torsion vs., **743**
- torsion of testicular appendage vs., **748**

Testicular tumors, **752–755**
- diagnostic checklist, **752**
- differential diagnosis, **753–754**
- prognosis, **754**
- staging, grading, & classification, **754**
- testicular torsion vs., **743**
- torsion of testicular appendage vs., **748**

Tethered cord, anorectal malformations, **378**
Tethered cord syndrome, **1156**
Tethered spinal cord, **1156**
- caudal regression vs., **1150**

Tethering adhesions, split cord malformation, **1151**
Tetralogy of Fallot, **238–241**
- anorectal malformations, **378**
- associated abnormalities, **239–240**
- differential diagnosis, **239**
- double aortic arch, **36**
- double-outlet right ventricle vs., **273**
- Ebstein anomaly vs., **247**
- genetics, **239**
- L-transposition of great arteries vs., **253**
- left coronary artery anomalous origin, **270**
- omphalocele, **410**
- prognosis, **240**
- pulmonary atresia vs., **243**
- repaired, arrhythmogenic right ventricular dysplasia vs., **311**
- tricuspid atresia vs., **255**

TFE RCC. *See* Renal cell carcinoma (RCC).
TGDC. *See* Thyroglossal duct cyst.
Thalassemia, musculoskeletal sickle cell disease vs., **990**
Thanatophoric dysplasia, **969**
- achondroplasia vs., **970**

Thermal injury, croup vs., **23**
3rd branchial cleft cyst, **1181**
3rd branchial pouch remnant, **1181**
Thoracic cage injuries, aortic injury, **168**
Thoracic kidneys. *See* Renal ectopia and fusion.
Thrombocytopenia
- abusive head trauma vs., **1094**
- VACTERL association vs., **781–782**

Thrombocytopenic purpura, idiopathic, Henoch-Schönlein purpura vs., **561**
Thrombosis
- anorectal malformations vs., **378**
- hepatic arterial, **469, 470**
- portal vein, Abernethy malformation vs., **467**
- umbilical catheter positions and complications, **111**

Thrombus
- renal vein, neonatal, transient neonatal renal medullary hyperechogenicity vs., **677**
- tumor, renal vein thrombosis vs., **679**

Thymic cyst
- cervical lymphatic malformation vs., **14**
- germ cell tumors vs., **145**
- normal thymus vs., **58**

Thymic sail sign. *See* Thymus, normal.
Thymoma
- germ cell tumors vs., **145**
- lymphoma vs., **142**
- normal thymus vs., **58**

Thymus
- ectopic retropharyngeal, **58**
- normal, **53, 56–59**
  - aortic injury vs., **167**
  - diagnostic checklist, **58**
  - differential diagnosis, **58**
  - germ cell tumors vs., **145**
  - lymphoma vs., **142**

Thyroglossal duct cyst, **1181, 1220–1223**
- associated abnormalities, **1222**
- branchial cleft anomalies vs., **1225–1226**
- cervical lymphatic malformation vs., **15**
- diagnostic checklist, **1222**
- differential diagnosis, **1221–1222**
- genetics, **1222**
- prognosis, **1222**

Thyroglossal duct lesions, **1181**
- congenital cystic neck masses vs., **1181**

Tibial bowing, **786**
- diagnostic checklist, **786**

Tibial eminence fractures, **847, 848**
Tibial hemimelia, **785**
- diagnostic checklist, **785**

Tibial tubercle avulsion, **855**
- differential diagnoses, **855**
- patellar sleeve avulsion vs., **854**

Tibial tubercle to trochlear groove distance, patellar dislocation, **851**
Tillaux fracture. *See* Juvenile tillaux fracture.
Toddler's fracture, **856**
Tonsillar herniation, from increased intracranial pressure, Chiari 1 malformation vs., **1043**
Tonsillitis, posttransplant lymphoproliferative disease, **526**
TORCH infections, **1126–1127**
- anorectal malformations vs., **378**
- diagnostic checklist, **1127**
- differential diagnosis, **1127**
- hypoxic-ischemic encephalopathy vs., **1103**
- meconium peritonitis vs., **382**

TORCHES. *See* TORCH infections.
Torsed appendix testis. *See* Testicular appendage, torsion of.
Torsion. *See also* Testicular torsion.
- appendage testis, epididymoorchitis vs., **739**
- appendix epididymis. *See* Testicular appendage, torsion of.

- epididymal appendage, testicular torsion vs., **743**
- ovarian, **732–735**
  diagnostic checklist, **734**
  differential diagnosis, **733–734**
  prognosis, **734**
- testicular appendage, testicular torsion vs., **743**

Total anomalous pulmonary venous return, **260–263**
- associated abnormalities, **262**
- differential diagnosis, **261–262**
- genetics, **262**
- prognosis, **262**

Total cavopulmonary connection. *See* Fontan operation.
Total colonic Hirschsprung disease, meconium peritonitis vs., **382**
Total parenteral nutrition (TPN), cirrhosis, **461**
Toxic megacolon
- colonic volvulus vs., **431**
- gastric volvulus vs., **397**

Toxic shock syndrome
- Kawasaki disease vs., **323**
- MIS-C vs., **121–122**

Toxin-induced brain injury, demyelinating diseases vs., **1133**
Toxocariasis, retinoblastoma vs., **1201**
Trachea, expiratory buckling of, **6**
- differential diagnoses, **6**

Tracheal agenesis, **17**
- associated anomalies, **17**

Tracheal compression, by extrinsic mass, bronchial obstruction vs., **200**
Tracheal intubation
- esophageal intubation vs., **112**
- of tracheoesophageal fistula, esophageal intubation vs., **112**

Tracheal perforation, esophageal intubation vs., **112**
Tracheal rings, complete, tracheobronchomalacia vs., **49**
Tracheal stenosis, subglottic
- congenital, airway infantile hemangioma vs., **47**
- iatrogenic, airway infantile hemangioma vs., **47**

Tracheitis, bacterial, **26–29**
- croup vs., **23**
- diagnostic checklist, **28**
- differential diagnosis, **27**
- epiglottitis vs., **19–20**
- prognosis, **28**

Tracheobronchial anomalies, pulmonary sling, **40**
Tracheobronchomalacia, **48–49**
- diagnostic checklist, **48**
- differential diagnosis, **49**
- staging, grading, & classification, **49**

Tracheobronchomegaly, cystic fibrosis, pulmonary vs., **203**
Tracheoesophageal fistula
- duodenal atresia or stenosis, **356**
- esophageal atresia with, **335**
- omphalocele, **409**

Tracheomalacia
- airway infantile hemangioma vs., **47**
- double aortic arch, **36**
- expiratory buckling of trachea vs., **6**
- laryngeal, croup, **24**

Traction apophysitis. *See* Medial epicondyle avulsion.
Trampoline fracture, **856**
Transcatheter embolization, vein of Galen aneurysmal malformation, **1113**
Transection. *See* Bowel injury.
Transependymal edema, pediatric brain, **1007**
Transient heterogeneous enhancement pattern, splenic infarct vs., **475**
Transient heterogeneous splenic enhancement, age-related appearance of spleen vs., **345**
Transient neonatal renal medullary hyperechogenicity, **676–677**
- diagnostic checklist, **676**
- differential diagnosis, **677**
- prognosis, **677**
- renal stones vs., **673**
- renal vein thrombosis vs., **679**

Transient patellar dislocation (TPD). *See* Patellar dislocation.
Transient renal medullary hyperechogenicity. *See* Transient neonatal renal medullary hyperechogenicity.
Transient small bowel intussusception, hypoperfusion complex vs., **501**
Transient synovitis, **872–873**
- diagnostic checklist, **873**
- differential diagnosis, **873**
- juvenile idiopathic arthritis vs., **878**
- Legg-Calvé-Perthes disease vs., **961–962**
- prognosis, **873**
- septic arthritis vs., **871**
- slipped capital femoral epiphysis vs., **965–966**

Transient tachypnea of newborn (TTN), **52, 96–97**
- associated abnormalities, **97**
- differential diagnosis, **97**
- meconium aspiration syndrome vs., **95**
- neonatal pneumonia vs., **93**
- prognosis, **97**
- surfactant deficiency disease vs., **90**
- surfactant dysfunction disorders vs., **181**

Transitional injury. *See* Triplane fracture.
Transmantle heterotopia, schizencephaly vs., **1037**
Transphyseal fracture
- lateral condylar fracture vs., **839**
- supracondylar fracture vs., **835**

Transplant dysfunction, posttransplant lymphoproliferative disease, **526**
Transposition of great arteries (TGA)
- D-transposition, **250–251**
  double-outlet right ventricle vs., **273**
  prognosis, **251**
- double aortic arch, **36**
- L-transposition of great arteries, **252–253**
  associated abnormalities, **253**
  differential diagnosis, **253**
  prognosis, **253**
- left coronary artery anomalous origin, **270**
- with pulmonary stenosis, Ebstein anomaly vs., **247**
- truncus arteriosus vs., **257**
- with VSD, pulmonary atresia vs., **243**

Transverse colon volvulus. *See* Colonic volvulus.
Transverse myelitis, spinal cord astrocytoma vs., **1161**

Transverse sinus, asymmetric or hypoplastic, cerebral venous sinus thrombosis vs., **1109**
Trauma, **53**
- abdominal, differential diagnosis, **335**
- blunt, **522**
- child abuse, Henoch-Schönlein purpura vs., **561**
- duodenal, **516–519**
  - associated abnormalities, **518**
  - diagnostic checklist, **518**
  - differential diagnosis, **517–518**
  - pancreatic trauma vs., **521–522**
  - prognosis, **518**
  - staging, grading, & classification, **518**
- epiglottitis, **20**
- granuloma annulare vs., **921**
- hepatic, **508–511**
  - associated abnormalities, **510**
  - diagnostic checklist, **510**
  - differential diagnosis, **509**
  - prognosis, **510**
  - staging, grading, & classification, **510**
- musculoskeletal system, **764–765**
- nonaccidental, enlarged subarachnoid spaces vs., **1015**
- pancreatic, **520–523**
  - differential diagnosis, **521–522**
  - duodenal trauma vs., **517**
  - pancreatitis vs., **492**
  - prognosis, **522**
  - staging, grading, & classification, **522**
- penetrating, **522**
- pneumatosis intestinalis vs., **539**
- renal injury, **668–671**
  - associated abnormalities, **670**
  - diagnostic checklist, **670**
  - differential diagnosis, **669–670**
  - prognosis, **670**
  - staging, grading, & classification, **670**
- septic arthritis vs., **871**
- splenic, **512–515**
  - diagnostic checklist, **514**
  - differential diagnosis, **513**
  - prognosis, **514**
  - staging, grading, & classification, **514**
  - wandering spleen vs., **473**
- transient synovitis vs., **873**

Traumatic brain injury
- bowel injury, **506**
- metabolic brain disease vs., **1119**

Traumatic compression fracture, chance fracture vs., **1175**
Traumatic epididymitis, **757**
Traumatic fascial tear/rupture, **831**
Traumatic hernia, **405**
Traumatic rupture of testicle, epididymoorchitis vs., **739**
Traumatic Salter-Harris I fracture, slipped capital femoral epiphysis vs., **965**
Traumatic spinal cord lesions, neurogenic bladder, **684**
Traumatic testicular ectopia, **757**
tRCC. *See* Renal cell carcinoma (RCC).
Treacher Collins syndrome, **1218**
- congenital auricle malformations vs., **1205**
- differential diagnosis, **1218**
- Pierre Robin sequence vs., **1219**

TREACLE association. *See* VACTERL association.
Trevor disease, osteochondroma, **952**
Triad syndrome. *See* Prune-belly syndrome.
Trichobezoar, **551, 552**
Tricuspid atresia, **254–255**
- diagnostic checklist, **255**
- differential diagnosis, **255**
- Ebstein anomaly vs., **247**
- genetics, **255**
- with increased pulmonary blood flow, L-transposition of great arteries vs., **253**
- with normally related great vessels, tetralogy of Fallot vs., **239**
- pulmonary atresia vs., **243**

Tricuspid insufficiency, Ebstein anomaly vs., **247**
Triplane fracture, **858–859**
- musculoskeletal system, **765**
- staging, grading, & classification, **859**

Trisomy 18
- congenital diaphragmatic hernia, **86**
- esophageal atresia and tracheoesophageal fistula, **82**
- nephroblastomatosis, **645**
- Wilms tumor associated with, **642**

Trisomy 21
- congenital diaphragmatic hernia, **86**
- esophageal atresia and tracheoesophageal fistula, **82**
- multicystic dysplastic kidney disease, **632**

Trochlear dysplasia, **851**
True dextrocardia
- with abdominal situs solitus, Scimitar syndrome vs., **287**
- heterotaxy syndromes vs., **315**

True malrotation, normal variations of duodenojejunal junction position vs., **339**
Truncus arteriosus, **256–259**
- associated abnormalities, **257**
- differential diagnosis, **257**
- double aortic arch, **36**
- genetics, **257**
- prognosis, **258**
- staging, grading, & classification, **258**

TTN. *See* Transient tachypnea of newborn.
Tuberculosis
- diffuse leptomeningeal glioneuronal tumor vs., **1157**
- hyperechoic splenic lesions from, cat-scratch disease vs., **479**

Tuberculous adenopathy, suppurative adenitis vs., **1243**
Tuberculous vertebral osteomyelitis, discitis/osteomyelitis vs., **1167**
Tuberin, **1053**
Tuberous sclerosis, **1052–1053**
- abdominal aneurysms, **577**
- autosomal recessive polycystic kidney disease vs., **636, 639**
- differential diagnosis, **1053**
- focal cortical dysplasia vs., **1041**
- genetics, **1053**
- germinal matrix hemorrhage vs., **1097, 1098**
- heterotopic gray matter vs., **1035**
- multicystic dysplastic kidney vs., **632**
- staging, grading, & classification, **1053**

- TORCH infections vs., **1127**
Tuberous sclerosis complex (TSC). *See also* Tuberous sclerosis.
- angiomyolipoma, **661**
- hemimegalencephaly, **1031**
- neurofibromatosis type 1 vs., **1050**
Tubers, **1053**
Tuboovarian abscess
- ovarian cyst vs., **722**
- ovarian teratoma vs., **725**
Tubular necrosis, acute, renal vein thrombosis vs., **679**
Tumefactive demyelination, glioblastoma vs., **1075**
Tumors
- Askin, **191**
  - diagnostic checklist, **191**
- brainstem, **1076–1079**
- germ cell, **144–147**
  - associated abnormalities, **145–146**
  - diagnostic checklist, **146**
  - differential diagnosis, **145**
  - prognosis, **146**
- glial or glioneuronal, focal cortical dysplasia, **1041**
- thrombus, renal vein thrombosis vs., **679**
Turner syndrome
- aortic coarctation, **276**
- chylothorax, **105**
- multicystic dysplastic kidney disease, **632**
- neuroblastoma, **704**
- normal prepubertal uterus and ovaries vs., **589**
21-hydroxylase deficiency (21-OHD). *See* Congenital adrenal hyperplasia.
22q11.2 deletion syndrome, VACTERL association vs., **782**
Twisted appendage. *See* Testicular appendage, torsion of.
Twisted ovary. *See* Ovarian torsion.
Typhlitis
- graft-vs.-host disease vs., **533**
- pseudomembranous colitis vs., **529**

U

UAC. *See* Umbilical arterial catheter.
UC. *See* Ulcerative colitis.
Uhl anomaly, Ebstein anomaly vs., **247**
Ulcer, laryngeal, laryngeal, croup, **24**
Ulcerative colitis (UC), **544–545**
- Crohn disease vs., **542**
- diagnostic checklist, **545**
- differential diagnosis, **545**
- pseudomembranous colitis vs., **529**
Ulnar collateral ligament injury, medial epicondyle avulsion vs., **843**
Ultrasound
- musculoskeletal system, **764**
- pediatric genitourinary tract, **581**
Umbilical arterial catheter (UAC), **111**
- malposition, **111**
Umbilical catheter positions and complications, **110–111**
- hepatic hemangiomas, infantile and congenital vs., **440**
Umbilical cord hemangioma, urachal abnormalities vs., **617**
Umbilical hernia, **405**
- omphalocele vs., **409**
- urachal abnormalities vs., **617**
Umbilical venous catheter (UVC), **111**
- extravasation, mesenchymal hamartoma vs., **448**
- malposition, **111**
Undescended testis (UDT). *See* Ectopic testicle.
Undifferentiated arthritis, **877**
Undifferentiated embryonal sarcoma, **447**
- differential diagnosis, **447**
- hepatoblastoma vs., **435**
- hepatocellular carcinoma vs., **446**
- mesenchymal hamartoma vs., **448**
Undifferentiated rhabdomyosarcoma, **913**
Unicameral bone cyst, nonossifying fibroma vs., **942**
Unicornuate uterus, müllerian duct anomalies, **717**
Unilateral cerebral edema, hemimegalencephaly vs., **1031**
Unilateral kidney, urachal abnormalitie, **618**
Unossified foramen cecum, nasal dermal sinus vs., **1185**
Upper airway foreign body, bacterial tracheitis vs., **27**
Urachal abnormalities, **616–619**
- associated abnormalities, **618**
- differential diagnosis, **617**
- prognosis, **618**
Urachal cyst. *See also* Urachal abnormalities.
- gastrointestinal duplication cysts vs., **556**
Urachal diverticulum. *See also* Urachal abnormalities.
- bladder diverticula vs., **687**
Urachal fistula. *See* Urachal abnormalities.
Urachal remnant. *See* Urachal abnormalities.
Urachal sinus. *See* Urachal abnormalities.
Urea cycle disorders, **1119**
- hypoxic-ischemic encephalopathy vs., **1103**
Ureteral calculus, distal, ovarian torsion vs., **734**
Ureteral fibroepithelial polyp, ureteropelvic junction obstruction vs., **592**
Ureteral stump, bladder diverticula vs., **687**
Ureteral valve, **607**
Ureterocele, **602–605**
- associated abnormalities, **604**
- differential diagnosis, **604**
- everting, bladder diverticula vs., **687**
- genitourinary myosarcoma vs., **691**
- incised, primary megaureter vs., **607**
- post-Deflux procedure appearance vs., **689**
- posterior urethral valves vs., **613**
- primary megaureter vs., **607**
- prognosis, **604**
Ureteropelvic duplications, **598–601**
- associated abnormalities, **600**
- differential diagnosis, **600**
- prognosis, **600**
Ureteropelvic junction obstruction, **590–593**
- associated abnormalities, **592**
- bladder exstrophy vs., **623**
- differential diagnosis, **592**
- omphalocele, **409**
- prognosis, **592**
- renal stones vs., **673**
- staging, grading, & classification, **592**

- ureteropelvic duplications, **600**
Ureters, duplicated, primary megaureter vs., **607**
Urethra, duplications, ureteropelvic duplications, **600**
Urethral atresia
- prune-belly syndrome vs., **611**
- urachal abnormalities, **618**
Urethral duplication, epididymoorchitis, **740**
Urethral stricture, posterior urethral valves vs., **614**
Urethral valves
- anterior, posterior urethral valves vs., **613**
- posterior, **612–615**
  associated abnormalities, **614**
  differential diagnosis, **613–614**
  prognosis, **614**
  staging, grading, & classification, **614**
Urethrorectal fistula, epididymoorchitis, **740**
Uric acid stones, renal stones, **674**
Urinary stone. *See* Renal stones.
Urinary tract calculus, post-Deflux procedure appearance vs., **689**
Urinary tract obstruction, normal neonatal kidney vs., **585**
Urogenital sinus malformation, urachal abnormalities, **618**
Urolith. *See* Renal stones.
Urolithiasis. *See also* Renal stones.
- primary megaureter vs., **607**
- vesicoureteral reflux vs., **596**
Uterine and ovarian abnormalities
- approach to, **581**
- ectopic ovary, normal prepubertal uterus and ovaries vs., **589**
- hydrometrocolpos, isolated, cloaca vs., **621**
- müllerian duct anomalies, normal prepubertal uterus and ovaries vs., **589**
- ovarian cyst, ureterocele vs., **604**
Uterine fusion anomalies. *See* Müllerian duct anomalies.
Uterus, prepubertal, normal, **588–589**
- differential diagnosis, **589**
Uterus didelphys, müllerian duct anomalies, **717**
UVC. *See* Umbilical venous catheter.

V

VACTEL association. *See* VACTERL association.
VACTER association. *See* VACTERL association.
VACTERL + hydrocephalus, VACTERL association vs., **782**
VACTERL association, **780–783**
- associated abnormalities, **782**
- CHARGE syndrome vs., **1216**
- diagnostic checklist, **782**
- differential diagnosis, **781–782**
- duodenal atresia or stenosis, **356**
- genetics, **782**
- prognosis, **782**
- staging, grading, & classification, **782**
Vacuum phenomenon, discoid meniscus vs., **791–792**
Vaginal atresia, urachal abnormalities, **618**
Vaginal bleeding, prepubertal, normal prepubertal uterus and ovaries vs., **589**
Vaginal rhabdomyosarcoma, normal prepubertal uterus and ovaries vs., **589**
Vaginal septum, müllerian duct anomalies, **717**
Vallecular mass, epiglottitis vs., **19**
"Vanishing bone disease," chylothorax, **105**
Vaping, epiglottitis, **20**
Varix, pulmonary, pulmonary arteriovenous malformation vs., **157**
Vascular abnormalities, innominate artery compression syndrome vs., **43**
Vascular anomaly
- cephalocele vs., **1025**
- infantile myofibroma vs., **907**
- myofibromatosis vs., **907**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- palpable normal variants of chest wall vs., **61**
Vascular disease, diffuse leptomeningeal glioneuronal tumor vs., **1157**
Vascular dysplasia, neurofibromatosis type 1, **1049**
Vascular Ehler-Danlos syndrome, Loeys-Dietz syndrome vs., **331**
Vascular malformations, **1181**
- chest wall, pectus excavatum vs., **189**
- congenital cystic neck masses vs., **1181**
- focal cortical dysplasia, **1041**
- muscle hernia vs., **831**
- musculoskeletal system, **765**
Vascular occlusion, bowel ischemia due to, hypoperfusion complex vs., **502**
Vascular plug, **299**
Vascular rings
- croup vs., **23**
- esophageal atresia and tracheoesophageal fistula vs., **82**
- esophageal strictures vs., **547**
Vascular sling
- asthma vs., **195–196**
- esophageal strictures vs., **547**
Vasculitides, Kawasaki disease vs., **323**
Vasculitis, large vessel inflammatory, moyamoya vs., **1107**
Vasogenic edema, pediatric brain, **1007**
VATER association. *See* VACTERL association.
Vein of Galen aneurysmal malformation (VGAM), **1112–1113**
- angiographic findings, **1113**
- differential diagnosis, **1113**
- prognosis, **1113**
Veins, imaging anatomy, **218**
Velocardiofacial syndrome (VCFS)
- Pierre Robin sequence vs., **1219**
- VACTERL association vs., **782**
Velum interpositum cyst, pineal cyst vs., **1064**
Vena cava, inferior, obstruction, **470**
Venoarterial ECMO (VA-ECMO), **113**
Venolymphatic malformation, **1181**
Venous anomaly. *See* Venous malformation, musculoskeletal.
Venous drainage, arteriovenous malformation, **1115**
Venous infarction, cavernous malformation vs., **1117**
Venous injury, hypoxic-ischemic encephalopathy vs., **1103**

Venous malformation, **1181**
- arteriovenous malformation, musculoskeletal vs., **901**
- fibromatosis vs., **904**
- hepatic hemangiomas, infantile and congenital vs., **440**
- infantile hemangioma
  - cervicofacial vs., **1232**
  - musculoskeletal vs., **887–888**
- lymphatic malformation, musculoskeletal vs., **897**
- musculoskeletal, **892–895**
  - associated abnormalities, **894**
  - differential diagnosis, **893–894**
  - genetics, **894**
  - prognosis, **894**
  - staging, grading, & classification, **894**
- myositis ossificans vs., **923**
- nonrhabdomyosarcoma soft tissue sarcomas vs., **917**
- plexiform neurofibroma vs., **909**
- rhabdomyosarcoma, musculoskeletal vs., **913**
- soft tissue foreign bodies vs., **829**

Venous pressures, elevated, enlarged subarachnoid spaces vs., **1015**
Venous sinus thrombosis, birth injury vs., **1091**
Venous thrombosis, hemorrhage infarction from, germinal matrix hemorrhage vs., **1097**
Venovenous ECMO (VV-ECMO), **113**
Ventricles, imaging anatomy, **218**
Ventricular noncompaction, left, **304–305**
- differential diagnosis, **305**
- prognosis, **305**

Ventricular rupture, schizencephaly vs., **1037**
Ventricular septal defect (VSD), **226–229**
- anorectal malformations, **378**
- aortic coarctation, **276**
- atrial septal defect vs., **224**
- atrioventricular septal defect vs., **232**
- differential diagnosis, **227–228**
- double aortic arch, **36**
- double-outlet right ventricle vs., **273**
- genetics, **228**
- isolated, L-transposition of great arteries vs., **253**
- prognosis, **228**

Ventriculitis, germinal matrix hemorrhage vs., **1097**
Ventriculoperitoneal shunt pseudocyst, mesenteric lymphatic malformation vs., **497**
Vertebral abnormalities, omphalocele, **410**
Vertebral body fractures, **809**
Vertebral body hemangioma. *See* Infantile hemangioma, cervicofacial.
Vertebral fracture-dislocations, **809**
Vertebral injury, neuroblastoma vs., **149**
Vertical calcaneus, in myelodysplasia, clubfoot vs., **789**
Vertical talus, congenital, clubfoot vs., **789**
Vesicoureteral reflux (VUR), **594–597**
- anorectal malformations, **378**
- associated abnormalities, **596**
- differential diagnosis, **596**
- epididymoorchitis, **740**
- fluoroscopic mimics, **596**
- prognosis, **596**
- renal ectopia and fusion, **626**
- severe, prune-belly syndrome vs., **611**
- sonographic mimics, **596**
- staging, grading, & classification, **596**

Vestibular schwannoma, PHACES syndrome vs., **1056**
Viral bronchiolitis, asthma vs., **195**
Viral chest infection, **116–119**
- diagnostic checklist, **118**
- differential diagnosis, **117–118**
- prognosis, **118**
- sickle cell disease, acute chest syndrome vs., **209**

Viral croup, airway infantile hemangioma vs., **47**
Viral encephalitis, demyelinating diseases vs., **1133**
Viral infection, **53**
- hemophagocytic lymphohistiocytosis vs., **569**

Viral lower respiratory tract infection, bronchial obstruction vs., **199**
Viral pneumonia, **117**
- fungal pneumonia in immunocompromised children vs., **135**

Visceromegaly, omphalocele, **410**
Viscus, distended/obstructed, mesenteric lymphatic malformation vs., **497**
Vocal cord paralysis, croup, **24**
Voiding dysfunction, posterior urethral valves vs., **613**
Volume loss, supratentorial, aqueductal stenosis vs., **1047**
Volvulus
- colonic, **430–431**
  - associated abnormalities, **431**
  - diagnostic checklist, **431**
  - differential diagnosis, **431**
  - gastric volvulus vs., **397**
- gastric, **396–397**
  - differential diagnosis, **397**
  - prognosis, **397**
- midgut, **350–353**
  - diagnostic checklist, **352**
  - differential diagnosis, **352**
  - duodenal web vs., **358**
  - hypertrophic pyloric stenosis vs., **393**
  - with malrotation, annular pancreas vs., **489**
  - meconium ileus vs., **367**
  - meconium peritonitis vs., **381**
  - neonatal small left colon vs., **371**
  - prognosis, **352**
- segmental, **433**
  - diagnostic checklist, **433**

Vomiting infant, gastrointestinal tract, **335**
von Hippel-Lindau disease (VHL), neurofibromatosis type 1 vs., **1050**
von Hippel-Lindau syndrome, pheochromocytoma, **711**
von Recklinghausen disease. *See* Neurofibromatosis type 1.
von Willebrand, abusive head trauma vs., **1094**
VUR. *See* Vesicoureteral reflux.

W

Waardenburg syndrome, multicystic dysplastic kidney disease, **632**
WAGR syndrome
- nephroblastomatosis, **645**
- Wilms tumor associated with, **642**
Walled-off necrosis, **491**
Wandering duodenum
- malrotation vs., **347**
- normal variations of duodenojejunal junction position vs., **339**
Wandering spleen, **472–473**
- associated abnormalities, **473**
- differential diagnosis, **473**
- prognosis, **473**
Washer, orthopedic hardware and complications, **826**
Watanabe classification, discoid meniscus, **792**
Waterston shunt, Blalock-Taussig shunt vs., **297**
Wegener granulomatosis, cat-scratch disease vs., **479**
Weight loss, posttransplant lymphoproliferative disease, **526**
White matter injury
- necrotizing enterocolitis, **386**
- of prematurity, **1100–1101**
  differential diagnosis, **1101**
White matter (WM) development. *See* Myelination, normal.
Whole-body DWI with background body signal suppression (DWIBS), lymphoma, **141**
Williams-Campbell syndrome, cystic fibrosis, pulmonary vs., **203**
Williams syndrome
- aortic coarctation, **276**
- aortic stenosis, **279**
- bladder diverticula, **687**
- neurogenic bladder vs., **683**
- pulmonary artery stenosis vs., **284**
- transient neonatal renal medullary hyperechogenicity vs., **677**
Wilms tumor, **335, 580, 640–643**
